Abstract

Background—T NADPH oxidase, by generating reactive oxygen species, is involved in the pathophysiology of many cardiovascular diseases and represents a therapeutic target for the development of novel drugs. A single-nucleotide polymorphism (SNP) C242T of the p22phox subunit of NADPH oxidase has been reported to be negatively associated with coronary heart disease (CHD) and may predict disease prevalence. However, the underlying mechanisms remain unknown.

Methods and Results—Using computer molecular modelling we discovered that C242T SNP causes significant structural changes in the extracellular loop of p22phox and reduces its interaction stability with Nox2 subunit. Gene transfection of human pulmonary microvascular endothelial cells showed that C242T p22phox reduced significantly Nox2 expression but had no significant effect on basal endothelial O2− production or the expression of Nox1 and Nox4. When cells were stimulated with TNFα (or high glucose), C242T p22phox inhibited significantly TNFα-induced Nox2 maturation, O2− production, MAPK and NFκB activation and inflammation (all p<0.05). These C242T effects were further confirmed using p22phox shRNA engineered HeLa cells and Nox2−/− coronary microvascular endothelial cells. Clinical significance was investigated using saphenous vein segments from non CHD subjects after phlebectomies. TT (C242T) allele was common (prevalence of ~22%) and compared to CC, veins bearing TT allele had significantly lower levels of Nox2 expression and O2− generation in response to high glucose challenge.

Conclusions—C242T SNP causes p22phox structural changes that inhibit endothelial Nox2 activation and oxidative response to TNFα or high glucose stimulation. C242T SNP may represent a natural protective mechanism against inflammatory cardiovascular diseases.

Key words: genetics; endothelial dysfunction; NAD(P)H oxidase; oxidative stress; vessel
Introduction

Single-nucleotide polymorphisms (SNP) are one base variations in DNA sequences that occur in at least 1% of the population. Although most SNPs have little or no effect on human health, some can predispose individuals to disease or have a major impact on the physiological response to environmental challenges or to drugs. Vascular endothelial cells express constitutively a Nox2 (also called gp91phox) containing NADPH oxidase, which by generating superoxide (O$_2^-$) plays an important role in oxidative stress-related endothelial dysfunction and cardiovascular diseases (CVD). The Nox2 catalytic subunit requires p22phox in a 1:1 ratio to form the cytochrome b$_{558}$ complex to produce O$_2^-$, and structural changes of p22phox may affect its interaction with Nox2. In the context of Nox2-derived oxidative stress and CVD, SNPs of the p22phox have attracted significant attention recently.

The p22phox is encoded by the CYBA gene located on the long arm of chromosome 16 at position 24. It spans 8.5 kb and is composed of six exons and five introns encoding an open reading frame of approximately 600 bp. The p22phox has three structural domains: 1) a hydrophobic N-terminal domain consisting of three transmembrane helices; 2) a hydrophilic extracellular region; and 3) a cytosolic tail featuring a proline rich region (PRR). So far, seven SNPs of the p22phox gene have been reported i.e. C242T, A640G; C549T; A930G; A675T; C852G and C536T, and only two of them (C242T and C549T) are translated into the protein. The C549T SNP changes an Ala to Val without any reported significant functional effect. In contrast, the C242T SNP changes His to Tyr that is located in the extracellular loop of the putative Nox2 binding region and has been reported in several studies to be negatively associated with CVD, such as hypertension, atherosclerosis, and myocardial infarction and to reduce oxidative burst in neutrophils. However, others have found that the C242T variant...
had no effect on cardiovascular disease progression\textsuperscript{16} or even increased ROS production in CVD arteries\textsuperscript{17,18}. Given the contradictory evidence, it is important to elucidate the molecular mechanism responsible for the effects of p22\textsuperscript{phox} C242T SNP on inhibiting endothelial Nox2 activity and vascular oxidative stress in order to ascertain its effect on CVD.

In this study, we used computer structural modeling plus molecular and biochemical approaches to elucidate the mechanism of p22\textsuperscript{phox} C242T SNP inhibition of endothelial Nox2 activation and oxidative stress in response to TNF\(\alpha\) or high glucose stimulation. Results were further confirmed using engineered p22\textsuperscript{phox} depleted (p22\textsuperscript{phox-depl}) HeLa cells, primary coronary microvascular endothelial cells (CMEC) isolated from Nox2\(-/-\) mice and saphenous vein segments of patients without history of coronary heart diseases (CHD) after phlebectomies. We report for the first time that C242T SNP is linked to the p22\textsuperscript{phox} extracellular domain morphological change that interferes with Nox2 binding stability and inhibits endothelial oxidative stress and inflammatory response to TNF\(\alpha\) or high glucose challenges.

**Materials and methods**

The \textit{in silico} p22\textsuperscript{phox} model was generated as reported previously by incorporating data from online prediction servers with the molecular operating environment (MOE; Chemical Computing Group Inc., Canada) and subjected to energy minimization using the AMBER99 forcefield\textsuperscript{9,10}. The docking of p22\textsuperscript{phox} with Nox2 peptides was performed in the MOE\textsuperscript{10}. HapMap analysis of the CYBA gene was performed using the International HapMap Project (HapMap phase II+III; dbSNP b126) and six common \textit{CYBA} SNPs were chosen from the National Centre for Biotechnology Information (NCBI) SNP database (dbSNP). Haplotype association was calculated using the Haplo-view analysis program (version 4.2) in the northern and western
European population (CEU). Human pulmonary microvascular endothelial cells (HPMEC-ST1.6R) were a kind gift from Dr R. Unger (Johannes Gutenberg University, Germany)\(^1\). Mouse CMEC were isolated from the hearts of ~12 week old Nox2\(^{-/-}\) and WT mice and cultured as described previously\(^2\)\(^{-}\)\(^{21}\). The shRNA p22\(^{phox}\) (p22\(^{phox-depl}\)) and shRNA scrambled control HeLa cells were generated as described previously\(^2\)\(^2\)\(^2\)\(^2\) in the laboratory of Professor Krönke (University of Cologne, Germany). Segments of human saphenous vein were collected from 36 patients (without history of CHD) undergoing phlebectomies at a specialist vein unit. Informed consents were obtained from the patients and the project was approved by the local NHS and the university ethical committees according to UK regulation. The IRB approval was obtained according to the guidelines noted in the Circulation Instruction to Authors. The C to T substitution at position 242 in the CYBA coding sequence was examined as described previously\(^2\)\(^3\). ROS production was measured using four independent methods as described previously\(^2\)\(^4\): 1) Lucigenin-chemiluminescence; 2) DHE fluorescence HPLC assay with or without superoxide dismutase–polyethylene glycol (PEG-SOD)\(^4\)\(^,\)\(^2\)\(^5\); 3) DHE flow cytometry; and 4) DCF fluorescence.

See the online-only Data Supplement for a full description of materials and methods.

**Statistics**

Data were presented as means ± SD in figures. For cell culture experiments, results were taken from at least 3 independent cell cultures and gene transfections for each condition. In the case of CMEC isolation, 6 mice/per group were used for each isolation and the data presented were the means ± SD from at least 3 separate CMEC isolations. Comparisons were made by ANOVA with Bonferroni *post hoc* correction or as indicated in the figure legend. Values of *P*<0.05 were considered statistically significant.
Results

Structural changes in p22^{phox} associated with C242T SNP

Computer modeling was used to investigate potential protein structural changes linked to p22^{phox} C242T SNP. Our consensus p22^{phox} model showed that His^{72} (WT p22^{phox}) is located within the extra-cellular region of the p22^{phox} (Figure 1A), which has been identified to be essential for interaction with Nox2^{12,26}. The histidine residue contains a polar hydrophilic imidazole in comparison to the aromatic and hydrophobic tyrosine residue. The substitution of His^{72} to Tyr^{72} alters the conformation of the extracellular region as shown by the backbone side-view (Figure 1A, left panels) and top-view (Figure 1A, right panels). Root mean squared deviation (RMSD) calculations of extracellular structures of WT and C242T p22^{phox} following energy minimization revealed significant difference between two structures (Figure 1C).

We next performed protein/protein docking of p22^{phox} with a known Nox2 peptide (222-HGAERIVR-229) that corresponds to the Nox2 extracellular region involved in binding to p22^{phox} in a previous report^{27}. We found that the Nox2 peptide interacted successfully with the WT p22^{phox} extracellular domain and formed a hydrogen-bond between Arg^{226} of the Nox2 and Asn^{86} of the p22^{phox} (Figure 1B, upper panels). However, this interaction was lost in the C242T model (Figure 1B, lower panels). Further docking experiments were performed using two Nox2 peptides (peptide 1: 154-NFARKRIKNPEGGLY-168; peptide 2: 222-HGAERIVRG-230), which are located in the Nox2 extracellular domain and have been reported previously to be recognized by a Nox2 antibody (7D5)^{27} (Figure 2). We found several important hydrogen bonds (labeled by H) formed between the Nox2 peptides and the WT p22^{phox} configuration, which further illustrated the importance of Nox2 Arg^{226} in stabilizing the interaction with WT p22^{phox}. However, these links were disrupted by the C242T p22^{phox} configuration. We also performed
HapMap analysis of the CEU (European) population, and found that the C242T SNP is only in strong correlation ($r^2 = 0.99$) with one SNP located within a non-coding region of intron 4 (rs12933505; Figure 1D). Moreover, the genotyped allele frequency of the CC (WT) and the CT and TT variants is 53% and 47%, respectively. This confirms the functional effect of C242T SNP is independent of other known p22phox SNPs at the protein level.

**Effect of C242T SNP on endothelial Nox2 activity**

The functional effect of p22phox C242T SNP on human endothelial Nox2 activity was firstly investigated by site-directed mutagenesis followed by gene transfection of human pulmonary microvascular endothelial cells (HPMECs) with or without acute TNFα (100 unit/ml; 30 min) stimulation. HPMECs displayed low levels of O$_2^-$ production at basal conditions (without TNFα stimulation) whereas TNFα increased significantly the levels of O$_2^-$ production in cells either transfected with an empty vector or with WT p22phox, without significant differences between them (Figure 3A). However, compared to WT p22phox, C242T p22phox had no significant effect on endothelial basal O$_2^-$ production, but did significantly inhibit TNFα-induced O$_2^-$ production (Figure 3A; right panel). The enzymatic sources of TNFα-induced O$_2^-$ production in vector or WT p22phox transfected cells was confirmed using human Nox2ds-tat peptide (a specific inhibitor of Nox2) and different enzyme inhibitors (Figure 3B). TNFα-induced O$_2^-$ production was inhibited significantly by Nox2ds-tat but not by NoxA1ds peptide (a specific inhibitor of Nox1, see Supplemental Figure 1) and was completely abolished by an O$_2^-$ scavenger (Tiron; 10mmol/L) which confirmed the detection of O$_2^-$. It was significantly inhibited by apocynin (100μmol/L, a Nox2 inhibitor) and diphenyliodium (DPI 20μmol/L, a flavoprotein inhibitor), but not by L-Nitroarginine-methyl-ester (L-NAME 100μmol/L, an eNOS inhibitor), oxypurinol (100μmol/L, a xanthine oxidase inhibitor) or rotenone (50μmol/L, a mitochondrial electron
transport chain inhibitor) (Figure 3B). Compared to WT p22phox transfected cells, C242T p22phox had no significant effect on Nox4 activity (H2O2 production) as shown using HEK293 cells (no endogenous Nox4 expression) co-transfected with Nox4 plus p22phox (Supplemental Figure 2). These data further confirmed a crucial role of Nox2-containing NADPH oxidase in TNFα-induced endothelial O2•− production.

The inhibitory effect of p22phox C242T on TNFα-induced endothelial O2•− production was further confirmed by two independent methods: DHE high-performance liquid chromatography (HPLC) detection of 2-OH-E+ (Figure 3C) and the tiron-inhibitable DCF-fluorescence microscopy using intact adherent endothelial cells (Figure 3D).

**Effects of C242T p22phox on endothelial Nox subunit expression and binding to p22phox**

The effects of p22phox C242T SNP on the basal levels of NADPH oxidase subunit expression was examined by Western blot. Compared to vector-transfected cells, the levels of p22phox expression were significantly increased in cells transfected with WT or C242T p22phox, which confirmed the success of gene transfection (Figure 4A). Nox1 expression was nearly undetectable. We found that C242T p22phox reduced significantly Nox2 expression without significant effect on Nox4 or Nox2 regulatory subunits i.e. p47phox, p67phox, p40phox and Rac1/2 and Nox4 as compared to cells transfected with vector or WT p22phox (Figure 4A).

Nox2 antibody 7D5 recognizes specifically an extracellular domain of human Nox2 and the levels of antibody 7D5 binding have been successfully used previously to indicate the levels of Nox2 maturation (cell surface membrane expression and stable cytochrome b formation) in cells27,29,30. Using flow cytometry, we found that TNFα increased significantly antibody 7D5 binding to endothelial cells, and C242T p22phox reduced significantly the antibody 7D5 binding at both basal and in response to TNFα stimulation as compared to cells transfected with vector or
WT p22\textsuperscript{phox} (Figure 4B). We then examined the effects of C242T p22\textsuperscript{phox} on p22\textsuperscript{phox} binding to Nox1, Nox2 and Nox4 by immuno-pull-down assay using p22\textsuperscript{phox} antibody coated beads (Figure 4C). Supplemental Figure 3 showed the molecular weights on full gel presentation, and the protein levels detected in the whole cell homogenates were shown in Supplemental Figure 4. The levels of Nox1 pulled-down by p22\textsuperscript{phox} were barely detectable, and we could not see a significant effect of C242T p22\textsuperscript{phox} on Nox1. Under basal condition (vehicle stimulated), there was no significant difference in the levels of Nox2 or Nox4 pulled-down by p22\textsuperscript{phox} beads between cells transfected with vector or WT or C242T p22\textsuperscript{phox} (Figure 4C). TNF\textalpha stimulation (24 h) increased significantly the levels of Nox2 and reduced the levels of Nox4 pulled-down by p22\textsuperscript{phox} beads in vector or WT p22\textsuperscript{phox} transfected cells. However, in cells transfected with C242T p22\textsuperscript{phox}, TNF\textalpha-induced Nox2 binding to p22\textsuperscript{phox} was significantly reduced, while the levels of Nox4 binding to p22\textsuperscript{phox} remained at vehicle levels as compared to vector or WT p22\textsuperscript{phox} transfected cells. Taken together our results strongly suggested that p22\textsuperscript{phox} C242T morphology inhibits specifically the interaction stability between Nox2 and p22\textsuperscript{phox} and reduced TNF\textalpha-induced Nox2 activation in endothelial cells.

**Effects of C242T p22\textsuperscript{phox} on TNF\textalpha-induced p22\textsuperscript{phox}/p47\textsuperscript{phox} binding and redox signaling through MAPKs and NF-\textkappaB in endothelial cells**

p22\textsuperscript{phox}, through its intracellular C-terminal domain, anchors p47\textsuperscript{phox} to Nox2 in the membrane to activate NADPH oxidase. In our computer model, C242T SNP was predicted not to affect p47\textsuperscript{phox} membrane translocation and binding to p22\textsuperscript{phox}. To confirm this, we prepared endothelial cell membrane fraction and examined for the membrane expression of p47\textsuperscript{phox} by immunoblot (Figure 5A). Compared to vehicle control cells, TNF\textalpha stimulation significantly increased the levels of p47\textsuperscript{phox} membrane expression without significant difference between vector and WT or
C242T p22\textsuperscript{phox} transfected cells. We then immuno-precipitated p47\textsuperscript{phox} and examined the levels of p22\textsuperscript{phox} pulled down by p47\textsuperscript{phox} beads and the levels of p47\textsuperscript{phox} phosphorylation (Figure 5B). Compared to vehicle control cells, TNF\textalpha{} stimulation increased the levels of p22\textsuperscript{phox}/p47\textsuperscript{phox} complex formation and p47\textsuperscript{phox} phosphorylation without significant difference between cells transfected with vector and WT or C242T p22\textsuperscript{phox}. Membrane ROS production was shown in the Supplemental Figure 5. Once again, our data confirmed that the C242T p22\textsuperscript{phox} inhibition of TNF\textalpha{}-induced endothelial O$_2^-$ production is specific to the Nox2 catalytic subunit.

Next, we examined the effect of C242T p22\textsuperscript{phox} on TNF\textalpha{}-induced redox activation of extracellular regulated kinase-1/2 (ERK1/2), p38\textsuperscript{MAPK} and NF\textkappa{}B in endothelial cells (Figure 5C). Compared to vehicle treated cells, TNF\textalpha{} stimulation increased significantly the levels of ERK1/2, p38\textsuperscript{MAPK} and NF\textkappa{}B\textsuperscript{Ser311} phosphorylation in WT p22\textsuperscript{phox} transfected cells (Figure 5C), and these were accompanied by significant increases in endothelial apoptosis detected by annexin-V flow cytometry (Figure 5D). Interestingly, these TNF\textalpha{} effects were significantly inhibited in cells transfected with C242T p22\textsuperscript{phox}. The levels of JNK phosphorylation was very low with no significant changes being detected after TNF\textalpha{} stimulation (data not shown).

**p22\textsuperscript{phox} C242T inhibition of TNF\textalpha{}-induced endothelial vascular cell adhesion molecule-1 (VCAM-1) expression and inflammation**

TNF\textalpha{} plays a key role in the pathogenesis of atherosclerosis and many other cardiovascular disorders. In order to explore the clinical significance of C242T p22\textsuperscript{phox} in inhibiting inflammatory endothelial dysfunction, we examined TNF\textalpha{} (24 h)-induced endothelial expression of VCAM-1 and NF\textkappa{}B nuclear translocation by immunofluorescence (Figure 6A). Compared to vehicle treated cells, TNF\textalpha{} increased significantly the levels of NF\textkappa{}B (green) in the nuclei and VCAM-1 expression (red) mainly around the plasma membrane in cells transfected with vector.
or WT p22\textsuperscript{phox}, but not with C242T p22\textsuperscript{phox} (Figure 6A). The inhibitory effect of p22\textsuperscript{phox} C242T on TNF\textgreek{a}-induced endothelial VCAM-1 expression was further confirmed by flow cytometry (Figure 6B).

We examined also TNF\textgreek{a}-induced monocyte adhesion to endothelial cells using FITC-labelled U937 cells, and found that 24 h of TNF\textgreek{a} stimulation increased significantly the number of monocytes attached to the endothelial monolayer in vector or WT p22\textsuperscript{phox} transfected HPMEC but not in C242T p22\textsuperscript{phox} transfected cells (Figure 6C). The inhibitory effect of C242T p22\textsuperscript{phox} on endothelial Nox2 activation was further confirmed using cells stimulated with high level of glucose (25 mmol/L) (Supplemental Figure 6).

**Experiments using engineered p22\textsuperscript{phox-depl} HeLa cells**

In order to confirm that our results of C242T p22\textsuperscript{phox} would not be affected by the intrinsic p22\textsuperscript{phox} protein expressed in HPMECs, we used engineered HeLa cells after p22\textsuperscript{phox} depletion using a specific short-hairpin RNA (shRNA). A scrambled shRNA was used as controls in all experiments. The absence of p22\textsuperscript{phox} protein in p22\textsuperscript{phox-depl} cells was confirmed by immunoblotting (Figure 7A) and immunofluorescence (Figure 7B and Supplemental Figure 7). The p22\textsuperscript{phox} protein was detected in scrambled shRNA treated cells and in p22\textsuperscript{phox-depl} cells after gene transfection of WT or C242T p22\textsuperscript{phox} (Figure 7A and B). Compared to scrambled shRNA treated control cells, the levels of both Nox2 and Nox4 were low in p22\textsuperscript{phox-depl} cells, and increased to control levels after p22\textsuperscript{phox} gene transfection. However, compared to WT p22\textsuperscript{phox} transfected cells, the levels of Nox2 (but not Nox4) remained significantly lower in C242T p22\textsuperscript{phox} transfected cells (Figure 7A). The levels of Nox1 expression was unaffected by the absence of p22\textsuperscript{phox}. We then examined Nox2 maturation recognized by Nox2 antibody 7D5 and analyzed by flow cytometry (Figure 7C). Compared to scrambled shRNA control cells, p22\textsuperscript{phox}-
cells had significantly lower (19.5±2.8%) levels of Nox2 maturation, and this was restored to the control levels after WT p22phox transfection. However, the levels of Nox2 maturation remained significantly lower (58.7±2.3%) in C242T p22phox transfected cells.

The levels of O$_2^-$ production by these cells were examined by lucigenin chemiluminescence in cell homogenates (Figure 7D, left panel) and the tiron-inhibitable DHE fluorescence flow cytometry (Figure 7D, right panel). Compared to scrambled shRNA treated control cells, p22phox-depl cells had significantly lower levels of O$_2^-$ production under basal condition and lost completely the O$_2^-$ response to TNFα stimulation. TNFα-induced O$_2^-$ production was restored to the scrambled shRNA control levels after gene transfection of WT p22phox. However, gene transfection of C242T p22phox only restored the basal but not the TNFα-induced O$_2^-$ production (Figure 7D). Reduced interaction between C242T p22phox and Nox2 (but not Nox4) after TNFα stimulation was further confirmed in p22phox-depl cells (Supplemental Figure 8).

**Experiments using Nox2$^{-/-}$ coronary microvascular endothelial cells (CMEC)**

In order to further confirm if C242T p22phox affected only Nox2 (but not Nox4 and/or Nox1), we isolated primary CMEC from wild-type and Nox2 knockout mice. Cells were then subjected to gene transfection and examined for O$_2^-$ production with or without TNFα stimulation (Supplemental Figure 9). Under basal conditions, Nox2$^{-/-}$ cells produced less O$_2^-$ compared to WT cells without significant differences between cells transfected with vector or WT p22phox or C242T p22phox. TNFα stimulation greatly increased the levels of O$_2^-$ production in WT CMEC transfected with vector or WT p22phox. Compared to WT p22phox transfected cells, p22phox C242T inhibited significantly the levels of TNFα-induced O$_2^-$ production (40±14% reduction) (Supplemental Figure 9). In contrast, TNFα increased only slightly (but still statistically
significant) the levels of O$_2^-$ production by Nox2$^{-/-}$ CMEC and there was no significant difference between cells transfected with vector, WT or C242T p22$^{phox}$. It was clear that C242T p22$^{phox}$ had no significant effect on TNF$\alpha$-induced endothelial O$_2^-$ production in the absence of Nox2.

**C242T SNP frequency and inhibition of Nox2 expression and high-glucose induced ROS production in human saphenous veins**

In order to investigate the clinical significance, we genotyped 36 saphenous vein samples collected from patients after phlebectomies who had no history of coronary heart disease. We found that 50% samples were wild-type (CC), ~27.8% were heterozygotes (CT) and ~22.2% had p22$^{phox}$ C242T SNP (TT) with ~36.1% frequency of T allele appearance (Figure 8A). Dot-blot showed a significant reduction of Nox2 expression in TT vessels in comparison to CC vessels (Figure 8B). Immunofluorescence images revealed that the reduction of Nox2 was mainly in the endothelium (Figure 8D). It is well known that superoxide (O$_2^-$) reacts with nitric oxide (NO) to form peroxynitrite which modifies tyrosine residue to form 3-nitrotyrosine (3NT), a biomarker of tissue oxidative damage. We found significantly lower levels of 3-nitrotyrosine (3NT) detected in TT samples as compared to CC samples (Figure 8C). When the vessels were challenged ex vivo with high level of glucose (25 mmol/L) for 24 h, TT samples had significantly less ROS production in comparison to CC sample (Figure 8E). Superoxidase dismutase was used to confirm the detection of O$_2^-$.

**Discussion**

The NADPH oxidase, by generating O$_2^-$, plays a crucial role in the inflammatory response involved in the pathogenesis of many cardiovascular diseases. The p22$^{phox}$ is an integral
membrane-associated subunit of NADPH oxidase responsible for assembling and stabilising Nox subunits into an active enzyme complex for ROS production\textsuperscript{8}. A number of clinical studies have reported that individuals bearing a naturally-occurring p22\textsuperscript{phox} C242T SNP have diminished O$_2^-$ production and are less susceptible to inflammatory cardiovascular diseases\textsuperscript{11,23,31,32}. However, little progress has been made to clarify the underlying molecular mechanisms. For the first time, our study provides scientific evidence that p22\textsuperscript{phox} C242T SNP causes p22\textsuperscript{phox} structural changes in the extracellular domain that are unfavorable for Nox2 maturation and activation, and inhibits endothelial O$_2^-$ production in response to TNF\textgreek{a} or high glucose stimulation.

A number of findings have been made by the current study in understanding the mechanism of p22\textsuperscript{phox} C242T SNP inhibition of Nox2 activation: 1) There is a significant structural difference between WT and the C242T p22\textsuperscript{phox} protein extracellular region that is important for Nox2 maturation\textsuperscript{12,33}; 2) C242T p22\textsuperscript{phox} structure compromises its binding stability with Nox2. The complex formed between Nox2 and C242T p22\textsuperscript{phox} is less stable due to the lacking of crucial hydrogen bonds to bind them together. Unstable binding may led to Nox2 protein degradation and this may explain the low levels of Nox2 detected in C242T p22\textsuperscript{phox} transfected cells and in vein samples of TT individuals.

The C242T SNP does not affect Nox1 because the Arg\textsuperscript{226} (crucial for the hydrogen bond formation to stabilize the interaction between Nox2 and WT p22\textsuperscript{phox}) is replaced by Gly in Nox1. Furthermore, the putative epitope 1 (160-IKNP-163) that is required to interact with p22\textsuperscript{phox}\textsuperscript{27} is absent in Nox1 (Supplemental Table 1). Nevertheless, Nox1 expression is extremely low in endothelial cells and is not a major source of endothelial ROS production in inflammation. Nox4 is highly expressed in endothelial cells. Nox4 generates H$_2$O$_2$ and has been found to be involved mainly in cellular growth and normal function, and is protective to cardiovascular function\textsuperscript{34,35}. 

14
Using immunoblotting, real-time PCR (Supplemental Figure 10) and co-immunoprecipitation we have shown that C242T p22phox does not inhibit Nox4 expression or its complex formation with p22phox. Furthermore, using HEK293 cells that do not express endogenous Nox4, we have demonstrated that (after Nox4 gene transfection) C242T p22phox has no effect on Nox4 activity (Supplemental Figure 2). Under the basal condition (without TNFα), C242T p22phox has no effect on endothelial Nox2 mRNA expression (Supplemental Figure 10) but reduces the protein levels of Nox2 expression and Nox2 maturation. These results strongly suggest that the effect of C242T p22phox on Nox2 expression is post-translational. When the cells were challenged by TNFα, the inhibitory effect of C242T p22phox on TNFα-induced Nox2 mRNA expression (Supplemental Figure 10) is more likely due to reduced levels of oxidative stress and redox signaling (such as NFκB) that impair Nox2 transcription in C242T p22phox transfected cells. Nox2 has low basal activity in endothelial cells and generates a small quantity of O2•− mainly used for redox-signaling under physiological conditions. Another important finding by the current study is that C242T p22phox configuration can still allow Nox2 to bind and support a low basal level of O2•− production. However, when the cells face challenge by TNFα C242T p22phox could not support a full Nox2 activation and thereby inhibits endothelial oxidative response to TNFα and protects endothelial cells from inflammation and cell apoptosis. The inhibitory effect of C242T p22phox on TNFα-induced endothelial ROS production by Nox2 was examined using four independent complementary methods: lucigenin-chemiluminescence; DHE-HPLC; DHE-flow cytometry and DCF fluorescence microscopy and further confirmed by experiments using Nox2ds-tat, several enzyme inhibitors and Nox2−/− CMEC.

Previously, C242T SNP was reported to form a haplotype correlated with two other p22phox SNPs: namely the C521T (rs1049254) and A24G (rs1049255) that reduced Nox2-activity
in Epstein-Barr virus-transformed B-lymphocytes isolated from 50 healthy individuals of an Utah pedigree. However, our HapMap analysis could not identify a close correlation of C242T with any other SNPs of p22phox currently identified within the HapMap database. Our results strongly suggest that the functional effects of C242T SNP on NADPH oxidase are independent of any other known protein-translated p22phox SNPs.

Using engineered p22phox-depl HeLa cells we further demonstrated that in the absence of p22phox, both Nox2 and Nox4 expressions were reduced, and could be restored after gene transfection of WT p22phox. However, gene transfection of C242T p22phox into p22phox-depl cells only fully restored the expression of Nox4 (but not Nox2). When cells were subjected to TNFα challenge, C242T p22phox transfected cells failed to increase O2\(^{-}\) production. C242T p22phox had no significant effect on its interaction with p47phox or on TNFα-induced p47phox phosphorylation. However, due to the inhibitory effect of C242T p22phox on Nox2 activation, TNFα-induced ROS production and redox-signaling through MAPK and NFκB were compromised in endothelial cells, which protected endothelial cells from oxidative damage and inflammation.

Increased VCAM-1 expression and monocyte adherence to endothelial cells are crucial steps in the pathogenesis of inflammatory cardiovascular diseases. The clinical significance of C242T p22phox was demonstrated by showing that TNFα-induced endothelial VCAM-1 expression and monocyte adherence to endothelial cells were significantly inhibited in C242T p22phox transfected cells. Saphenous veins are commonly used as conduits for bypass surgery to treat coronary artery diseases. Information on the p22phox genetic variation can predict graft oxidative response to environment challenge and help clinical management of vein grafts. We found a genetic frequency of 22.2% for TT genotype (36.1% for T allele) in our samples, which is in accordance to those reported previously for control samples or for the general population.
Using both dot-blotting and immunofluorescence, we confirmed that p22\textsuperscript{phox} C242T SNP is indeed associated with reduced Nox2 expression mainly in the endothelium, and TT vessels had significantly less ROS generation in response to high glucose challenge as compared to CC vessels.

Limitations need to be considered in the interpretation of our p22\textsuperscript{phox} molecular models. Although our computer models are supported by extensive cell and molecular experimental data, the structural models still need to be confirmed by X-ray crystallography or nuclear magnetic resonance spectroscopy.

In summary, this is the first report to describe the mechanism of p22\textsuperscript{phox} C242T SNP in inhibiting Nox2 activity and protecting endothelial cells from TNF-\alpha-induced oxidative damage and inflammation. p22\textsuperscript{phox} C242T SNP represents a natural protective mechanism against inflammatory cardiovascular diseases. The molecular mechanism reported here can be further explored for novel drug development.

Clinical Perspective

NADPH oxidase, by generating reactive oxygen species, is involved in the pathophysiology of many cardiovascular diseases and represents a therapeutic target for the development of novel drugs. A number of clinic studies have reported that individuals bearing a naturally-occurring p22\textsuperscript{phox} C242T single-nucleotide polymorphism (SNP) have diminished ROS production in the cardiovascular system and are less susceptible to inflammatory cardiovascular diseases. However, little progress has been made to clarify the underlying molecular mechanisms. The current study using computer molecular modelling plus cell and molecular techniques provides scientific evidence that p22\textsuperscript{phox} C242T SNP causes p22\textsuperscript{phox} structural changes in the extracellular domain that compromises its binding stability with Nox2 (the catalytic subunit of the NADPH oxidase) and reduces the levels of Nox2 protein expression and maturation. In response to TNF\textalpha challenge, C242T p22\textsuperscript{phox} inhibits endothelial NADPH oxidase O\textsubscript{2}\textsuperscript{-} production, inflammatory VCAM-1 expression and monocyte adherence to endothelial cells. Clinical significance was investigated using saphenous vein segments from non-coronary heart disease subjects after phlebectomies. TT (C242T) allele was common (prevalence of ~22\%) and compared to CC, veins bearing TT allele had significantly lower levels of Nox2 expression and O\textsubscript{2}\textsuperscript{-} generation in response to high glucose challenge. C242T SNP may represent a natural protective mechanism against inflammatory cardiovascular diseases. The molecular mechanism reported in this study can be further explored for novel drug development.
Figure Legends:

Figure 1. Computer modelling of p22\textsuperscript{phox} structural changes associated with C242T SNP. (A) Morphological differences between WT and C242T p22\textsuperscript{phox} structures (ribbon presentation). (B) Docking of a Nox2-peptide (222-HGAERIVR-229) (skeleton in left panels and silver-space-fill in right panels) with p22\textsuperscript{phox} extracellular domain (ribbon). Nox2 peptide interacts and forms an H-bond with the N\textsuperscript{86} (ball and stick presentation) of WT p22\textsuperscript{phox} but not with the N\textsuperscript{86} of C242T p22\textsuperscript{phox}. (C) RMSD calculations of the extracellular domain structural differences between WT and C242T p22\textsuperscript{phox} following energy minimization. n=3 independent investigators. *\(p<0.05\) for C242T values versus WT values (Mann-Whitney U-test). (D) Linkage disequilibrium (LD) plot from Haplo-view of common genotyped SNPs within the CYBA (p22\textsuperscript{phox}) gene. The darker a diamond appears, the greater the correlation \((r^2 \times 100)\) between the respective genotyped CYBA polymorphisms. The C242T SNP (rs4673) is outlined.

Figure 2. Docking of two Nox2 peptides with p22\textsuperscript{phox} extracellular domain. Images are shown as a tiled 45 degrees side-view/top-view. Two Nox2 peptides (peptide 1: 154-NFARKRIKNPEGGLY-168; peptide 2: 222-HGAERIVRG-230) used for the docking have been reported previously to be the extracellular epitopes of Nox2 recognised by an antibody (7D5) to Nox2. WT p22\textsuperscript{phox} configuration forms several hydrogen bonds (short grey dashed lines labelled by H) with Nox2 peptides. The location of Nox2 Arg\textsuperscript{226} is indicated. However, these interactions were lost in the C242T p22\textsuperscript{phox} configuration. Red ribbons represent alpha helix.

Figure 3. The effect of p22\textsuperscript{phox} C242T SNP on HPMEC ROS production. (A) Kinetic measurement of O\textsubscript{2}\textsuperscript{-} production. Area under curve (AUC) was calculated for each sample.
*p<0.05 for TNFα AUC values verses vehicle AUC values analyzed by unpaired t-test with Welch’s correction. (B) Inhibition of O$_2^-$ production measured by lucigenin-chemiluminescence. Left panel: Nox2ds-tat peptide; Right panel: Effects of different enzyme inhibitors presented as percentages to TNFα values without inhibitor (filled bar). *p<0.05 for indicated values versus vehicle values under the same gene transfection. †p<0.05 for indicated values versus TNFα values (filled bar) under the same gene transfection. (C) O$_2^-$ production (2-OH-E) measured by DHE-HPLC. The amount of 2-OH-E was quantified against a standard curve and expressed as nmol/mg protein. (D) Intracellular ROS production examined by DCF fluorescence microscopy. Tiron was used to confirm the detection of O$_2^-$ (C-D) *p<0.05 for TNFα values verses vehicle values under the same gene transfection. †p<0.05 for indicated values versus WT Tp22 TNFα values. Sample size (A-C): n=4 independent experiments; (D): n=3 independent experiments.

Figure 4. NADPH oxidase subunit expression, Nox2 maturation and binding to p22$^{phox}$ in HPMEC. (A) Western blots. Optical densities (OD) of protein bands of p22$^{phox}$, Nox1, Nox2, Nox4, p47$^{phox}$, p67$^{phox}$, p40$^{phox}$ and Rac1/2 were quantified and normalized to the levels of α-tubulin (loading control) detected in the same samples. (B) Flow cytometry for the binding of Nox2 antibody (7D5). *p<0.05 for indicated values versus to vector values. †p<0.05 for indicated values versus WT values. (C) Left panel: p22$^{phox}$ was immunoprecipitated (IP) followed by immunoblotting (IB) of Nox1, Nox2 and Nox4. Right panels: Optical densities (OD) of protein bands were quantified and normalized to the levels of total p22$^{phox}$ detected in the same samples. *p<0.05 for indicated values versus vehicle values under the same gene transfection. †P<0.05 for indicated values versus WT TNFα values. n=4 independent experiments.
Figure 5. TNFα-induced p47phox membrane translocation and binding to p22phox, redox signaling and cell apoptosis in HMEC. (A) Western blot. The optical densities (OD) of protein bands were quantified and normalized to the levels of CD31 (an endothelial membrane marker) detected in the same samples. (B) p47phox was immunoprecipitated (IP) and detected by Western blot for the presence of p22phox and p47phox phosphorylation (P-p47). The optical densities (OD) of protein bands were quantified and normalized to the levels of total p47phox (T-p47) detected in the same samples. (C) Western blots. The phospho-bands were quantified and normalized to the total levels of the same protein detected in the same samples. (D) Right panels: Annexin-V/propidium iodide detection of cell apoptosis (upper right square) by flow cytometry. Apoptotic cells were presented as a percentage of total cells (20,000). *p<0.05 for indicated value versus vehicle values under the same gene transfection. †p<0.05 for indicated values versus WTp22 TNFα values. n=4 independent experiments.

Figure 6. TNFα-induced NFκB nuclear translocation, VCAM1 expression and monocyte adherence in HPMECs. (A) Immunofluorescence microscopy detection of NFκB (green) nuclear translocation and VCAM1 (red) expression. Nuclei were labelled with DAPI (blue) to visualize cells. The fluorescence intensity was quantified from 20 images/per group. n=3 independent experiments. (B) Flow cytometry detection of VCAM-1 expression. (C) U937 monocytes were labeled with FITC (green) and the number of monocytes adhering to the HPMEC monolayer was counted for quantification. *p<0.05 for indicated value versus vehicle values under the same gene transfection. †p<0.05 for indicated values versus WTp22 TNFα values. n=4 independent experiments (B-C).
Figure 7. Experiments using p22phoxdepl HeLa cells. (A) Western blots. Optical densities (OD) of protein bands were quantified and normalized to the levels of α-tubulin detected in the same sample. (B) Immunofluorescence detection of p22phox expression. The color images and quantification of p22phox fluorescence intensities are presented in the Supplemental Figure 7. (C) Flow cytometry detection of anti-Nox2 antibody (7D5) binding to HeLa cells. Shaded area represents control cells without Nox2 antibody labelling. (D) O$_2^-$ production. SCR: scrambled shRNA. *$p<0.05$ for indicated values versus SCR values under the same treatment. †$p<0.05$ for indicated values versus WTP22 values under the same treatment. n=4 independent experiment.

Figure 8. The effects of C242T p22phox SNP on Nox2 expression and high-glucose induced ROS production in human saphenous veins. (A) Genotyping of C242T p22phox SNP (left panel) and calculated frequency in a total of 36 samples. WT p22phox appeared as a single band of 348 bp and C242T SNP had two bands at 188 and 160 bp. B) Nox2 expression detected by dot-blotting. C) 3NT formation detected by dot-blotting. *$p<0.05$ for indicated values versus CC values. D) Nox2 (red color) expression detected by Immunofluorescence. Lumen was labeled for the location of the endothelium. Vessel structure was shown by H&E staining (right panel). E) Left panels: Representative images of vessel ROS production with or without high-glucose (H-glucose) challenge (24 h) detected by DHE fluorescence on vessel sections. Superoxide dismutase (SOD) was used to confirm the detection of O$_2^-$.*$p<0.05$ for indicated values versus control values in the same genetic group. †$p<0.05$ for indicated values versus CT values under H-glucose.

SUPPLEMENTAL MATERIAL

Materials and methods

Reagents

Human recombinant TNFα was from Roche Applied Sciences. Polyethyleneimine (linear MW=25,000) was from Polysciences Inc (UK). Rabbit and goat polyclonal antibodies to NADPH oxidase subunits Nox1, Nox2, Nox4, p22phox, p47phox, p67phox, rac1, total ERK1/2, p38 MAPK, total JNK, NFkB, phosphor-NFkBSer311, CD31 and α-tubulin were purchased from Santa Cruz (UK). Monoclonal antibody to p40phox was from Upstate Biotechnology. Antibodies to phospho-ERK1/2, phospho-p38 MAPK, phospho-JNK were from Cell Signalling Technology. Dihydroethidium (DHE) and 5-(and 6)-chloromethyl-2’,7’-dichlorodihydrofluorescein diacetate (DCF) were from Invitrogen. Other reagents were from Sigma except where specified.

In silico protein structural modelling and protein docking

The in silico model of p22phox was generated as reported previously by incorporating data from the online prediction servers with the molecular operating environment (MOE; Chemical Computing Group Inc., Canada) and subjected to energy minimization using the AMBER99 force field until all unfavorable residue contacts and atom clashes were repaired as described previously1,2. To calculate differences in the WT and C242T extracellular domains, the root-mean squared deviation (RMSD) was investigated by superimposing alpha-carbon backbone atoms in MOE, expressed in angstroms (Å) as described previously1,2. RMSD results were collected from three independent modeling experiments and expressed as Mean±SD of 3 sets of data. The docking of p22phox with Nox2 peptide was performed in the MOE program and refined by energy minimization using the AMBER99 forcefield as described previously2.

HapMap analysis of the CYBA gene

Using the International HapMap Project (HapMap phase II+III; dbSNP b126), 6 common CYBA SNPs were chosen from the National Centre for Biotechnology Information (NCBI) SNP database (dbSNP). Haplotype association was calculated using the Haplo-view analysis program (version 4.2) in the northern and western European population (CEU) and is expressed as r². CYBA SNPs in complete linkage disequilibrium have an r² correlation value of 100%.
Site-directed mutagenesis

The recombinant human p22phox cDNA sequence (GenBank:BC006465.1) subcloned into pcDNA3.1 (Invitrogen) at Xba I and Hind III sites was a kind gift from Prof. J.D. Lambeth (Emory University, USA). Primer design and the site-directed mutagenesis experiments were performed according to the manufacturer’s instruction using the QuikChange Multi Site-Directed Mutagenesis kit (Agilent Technologies) as described previously. The PCR products of these mutations were cloned into E.coli, DH5α (Invitrogen), and the C242T substitution of the p22phox was verified by molecular sequencing.

Cell culture, Gene transfection and TNFα stimulation

Human pulmonary microvascular endothelial cells (HPMEC-ST1.6R) were a kind gift from Dr R. Unger (Johannes Gutenberg University, Germany) and were cultured in M199 medium containing 10% (v/v) fetal bovine serum (FBS), 20µg/ml of endothelial cell growth supplement (ECGS) and 25µg/mL heparin. The monocytic cell line (U937) was obtained from ATCC and grown in RPMI medium supplemented with 10% (v/v) FBS, 2mmol/L L-glutamine, 100U/mL penicillin and 100µg/mL streptomycin. CMEC were isolated from the hearts of 10-12 week old Nox2 KO and WT mice and cultured as described previously and used at passage 2. The shRNA p22phox targeted sequence is: GGCCCTTTACCAGGAATTA, and the shRNA scrambled control sequence is GACAACGTATCCGTCAGTT. The shRNA p22phox (p22phox-depl) and shRNA scrambled control HeLa cells were generated using the techniques as described previously in the laboratory of Professor Krönke (University of Cologne, Germany). Gene transfection was performed exactly as described previously using polyethyleneimine. Transfection efficiency (65-70%) was verified with a reporter gene, β-galactosidase. After 48h of culture, cells were treated with either vehicle or TNFα (100 U/mL) for 30 min or 24 h according to the experimental design in 5% FCS/DMEM and harvested for further experiments.

Preparation of cell membrane fraction

Cellular membrane protein fraction was prepared as described previously. Briefly, cells were detached by mechanical scraping and then were re-suspended in MOPS-KOH buffer (MOPS-KOH 20mmol/L, sucrose 250mmol/L, pH 7.4). Cell homogenate was quickly centrifuged at 1,475g for 15 min. to remove any unbroken cells and the nuclei-enriched fraction. The resulting supernatant was then centrifuged for 15 min. at 29,000g to pellet mitochondria and subcellular organelles. The resulting supernatant was centrifuged for 60
min. at 100,000g to produce a membrane fraction. Pellets of the membrane fraction were re-suspended in homogenization buffer and washed once before using.

*Human saphenous vein sample collection, genotyping and glucose challenge.*

Segments of human saphenous vein were collected from 36 patients (without histories of coronary heart diseases) undergoing phlebectomies at a specialist vein unit. Informed consent was obtained from the patients and the project was approved by the local NHS and the University ethical committees. Vein segments (3-5 mm long) with normal morphological appearance were used for the experiments. The C to T substitution at 242 in the CYBA coding sequence was examined exactly as described previously using specific intron-spanning primers (forward: 5’CGCTGGCGTCCGGCCTGATCCTCA3’; reverse: 5’ACGCACAGCCGCCAGTAGGTAGAT3’). Expression of the T-allele produces two bands at 160- and 188-bp respectively, whereas the C-allele has one band at 348-bp. For the experiments of high-glucose challenge, vessel segments were then cultured in the 5% FCS/M199 medium with normal glucose (5 mmol/L) or high glucose (25 mmol/L) for 24 h before ROS measurement.

*Measurement of ROS production*

Endothelial (or vessel tissue) $\text{O}_2^-$ production was measured using four independent methods as described previously. 1) Lucigenin (5µmol/L)-chemiluminescence (BMG Lumistar, Germany). The assay specificity for $\text{O}_2^-$ detection was confirmed by adding tiron (10mM), a non-enzymatic scavenger of $\text{O}_2^-$. Potential enzymatic sources of $\text{O}_2^-$ production were also investigated by using the following inhibitors: Nox2 –ds-tat (10 µmol/L), apocynin (100µmol/L), N-ω-nitro-L-arginine methyl ester (L-NAME, 100µmol/L), rotenone (50µmol/L), oxypurinol (100µmol/L) or diphenyleneiodonium (DPI, 20µmol/L). 2) DHE fluorescence HPLC assay with or without superoxide dismutase–polyethylene glycol (PEG-SOD) was performed exactly as described previously. The amount of 2-OH-E generated was normalized to the protein concentration of the same sample. 3) The intracellular $\text{O}_2^-$ production was examined using DHE flow cytometry in the presence or absence of tiron. 4) The ROS production by adherent cells was measured using DCF fluorescence acquired under Olympus BX61 fluorescence microscopy. Fluorescence intensity was quantified from at least 3 random fields (269.7 x 269.2 µm) per chamber, >100 cells were assessed per cell culture experiment, and at least 3 separate cell cultures per condition.
Amplex Red assay for H₂O₂ measurement

Total cell homogenate H₂O₂ production was measured using the Amplex Red (Invitrogen Inc.) assay as described previously. Briefly, 50 µg/ml protein was added to the wells of a black 96-well plate containing the assay buffer (25 mmol/L HEPES, pH 7.4, containing 0.12 mol/L NaCl, 3 mmol/L KCl, 1 mmol/L MgCl₂, 0.1 mmol/L Amplex red, and 0.32 U/ml HRP). The reaction was initiated by the addition of 36 μmol/L NADPH and detected using a BMG Fluostar Galaxy multimode microplate reader. Catalase (300 U/ml) was added in the parallel wells. H₂O₂ production was quantified against a standard curve.

Quantitative real-time (RT)-PCR

These experiments were performed as described previously using human primers for Nox1 (F: CAGGGAGACAGGTGCTTTTCC; R: GAACCAGAGCAGTCCAAACTCG), Nox2 (F: CAAGATGCGTGGAAACTACCTAAGAT; R: TCCCTGCTCCACTAACATCA) and Nox4 (F: CTGCTGACGTTGATGTTTC; R: TTCTGAGAGCTGGTTCGTT), β-actin, (F: CTGGCACCCAGCACAATG; R: GCCGATCCACACGAGTACT). Each gene expression levels were normalized to β-actin, and expressed log₂ ratio of ΔCt values.

Immunoprecipitation and immunoblotting

Immunoblotting experiments were performed exactly as described previously. The α-tubulin detected in the same sample was used as a loading control. Co-immunoprecipitation (IP) was performed as described previously using anti-p22phox or anti-p47phox antibody coated protein G agarose beads. Normal rabbit IgG-coupled beads were used as negative controls. Samples were then examined for the presence of other Nox subunits pulled down by the beads using immunoblotting (IB). The levels of total p22phox or total p47phox in the same IP sample were used as loading controls.

Dot blotting

Human vessel Nox2 expression and protein nitration were detected by dot-blot analysis according to a previous publication using 5 µl (50 µg) of protein samples. Immuno-blotting was performed using specific antibodies to Nox2 or 3-nitrotyrosine (3NT). Positive labelling was detected by fluorescence (Cy5 or FITC)-conjugated secondary antibodies. Blots were scanned using a fluorescence imager (Typhoon Trio, Amersham) and quantified.
Flow cytometry

This was done exactly as described previously\textsuperscript{16}. Briefly, cells were trypsinized, washed in PBS supplemented with 1% BSA and 1% FCS. Cells were then incubated on ice for 30 min with primary antibodies (as indicated in the text) or buffer only as controls. After washing, cells were then incubated with FITC- or Cy3-labelled specific secondary antibodies. Fluorescence intensity of cells was measured using Accuri C6 flow cytometer (BD Bioscience). Data were analyzed with the Accuri C6 software.

Immunofluorescence microscopy

Cell preparation and immunofluorescence microscopy were performed as described previously\textsuperscript{8}. Cells were labelled with primary antibodies and detected using biotin-conjugated anti-rabbit or anti-goat IgG (1:1000 dilution) as the secondary antibodies. Specific antibody binding was detected by extravidin-FITC (green) or streptavidin-Cy3 (red). Normal rabbit or goat IgG (5µg/mL) was used in place of primary antibody as negative controls. Images were acquired with an Olympus BX61 fluorescence microscope system. Fluorescence intensities were quantified as described above.

Statistics

Data were presented as means ± SD of results taken from at least 3 independent cell cultures and gene transfections for each condition. In the case of CMEC, each isolation used 6 mice/per group, and the data presented were the means ± SD from at least 3 separate CMEC isolations. Comparisons were made by ANOVA with Bonferroni test analysis except where it was specified in the figure legend. P<0.05 was considered statistically significant.

</table>

Two epitopes (yellow colour shaded areas, epitope 1: 160-INKP-163 and epitope 2: 226-RIVRG-230) in the extracellular region of Nox2 are found to be involved in the interaction with p22\textsuperscript{phox} (details in Figure 2), and are recognised by antibody 7D5. Sequence homology matching table shows that Nox1 does not contain the sequence of epitope 1. In the sequence of epitope 2, the key positively charged amino acid (Arg\textsuperscript{226}) of Nox2 that forms the crucial hydrogen bond with Asn\textsuperscript{86} of p22\textsuperscript{phox} (see Figure 2) is substituted by the smallest and uncharged amino acid (Gly\textsuperscript{225}) in Nox1.
References:

Supplemental Figure I: Inhibition of TNFα-induced O$_2^-$ production by human coronary arterial endothelial cells (HCAEC) using specific peptide inhibitors to Nox1 and Nox2.

HCAEC were cultured in the complete culture medium. Peptides (10 μmol/L) were added into the culture medium 1 h before TNFα stimulation. Cells were then stimulated by TNFα (100 U/ml) for 30 min. NADPH-dependent O$_2^-$ production by cell homogenates was measured by lucigenin (5 μmol/L)-chemiluminescence. *p<0.05 for indicated values versus vehicle values in the same peptide treatment group. †p<0.05 for indicated values versus TNFα values in the scrambled peptide (SCR-tat) treatment group. n=4 separate experiments.

Supplemental Figure II: Nox4-derived H$_2$O$_2$ production by HEK293 cells co-transfected with Nox4 plus WT or C242T p22phox.

HEK293 cells were co-transfected with human Nox4 plus either WT or C242T p22phox plasmids. Cells were then stimulated with or without TNFα for 30 min. The H$_2$O$_2$ production was measured in cell homogenates by Amplex-red assay in the presence or absence of catalase (300 units/ml). *P<0.05 for indicated values versus vector values under the same treatment. †p<0.05 for catalase values versus vehicle or TNFα value in the same gene transfection group. n=4 separate gene transfection experiments.
Supplemental Figure III: Representative examples of Western blots of co-immunoprecipitation (used in Figure 3C).

p22phox was immunoprecipitated (IP) and detected by immunoblotting (IB) for the existence (pulled-down) of Nox2, Nox1 and Nox4 (in Figure 3C). The molecular weights are indicated on the left.
**Supplemental Figure IV.** The effect of C242T p22\textsubscript{phox} on TNF\textalpha-induced Nox2 and Nox4 protein expression in HPMEC (Input data for Figure 4C).

The whole cell homogenates were used for Western blots. Optical density of protein bands were quantified and normalized to \alpha-tubulin detected in the same sample. *\(p<0.05\) for TNF\textalpha values versus vehicle values in the same gene transfection group. †\(p<0.05\) for indicated values versus WT TNF\textalpha values. #\(p<0.05\) for indicated values versus vector vehicle values. n=4 separate gene transfection experiments.

**Supplemental Figure V.** Effects of p22\textsubscript{phox} C242T SNP on TNF\textalpha-induced O$_2^-$ production by endothelial membrane fractions

HPMEC membrane fraction was prepared as described in the method. NADPH-dependent O$_2^-$ production was measured by lucigenin (5 \textmu mol/L)-chemiluminescence. *\(p<0.05\) for indicated values versus vehicle values in the same gene transfection group. †\(p<0.05\) for indicated values versus WT TNF\textalpha values.
Supplemental Figure VI. Effects of p22^{phox} C242T SNP on high glucose (25 mmol/L)-induced \( \text{O}_2^\cdot \) production

HPMEC were cultured in the presence of normal glucose level (5 mmol/L) or high-glucose level (25 mmol/L) for 24 h. NADPH-dependent \( \text{O}_2^\cdot \) generation by cell homogenates was measured by lucigenin (5 \( \mu \)mol/L)-chemiluminescence. *\( p<0.05 \) for indicated values versus 5 mM glucose values in the same gene transfection group. †\( p<0.05 \) for indicated values versus vector or WT p22^{phox} transfected 25 mmol/L glucose values. n=4 separate gene transfection experiments.

Supplemental Figure VII. Colour presentation and quantification of the p22^{phox} fluorescence intensity in HeLa cells presented in Figure 7B

For quantification, results are means ± SD from 30 images of 3 independent experiments. *\( p<0.05 \) for indicated value versus SCR values.
Supplemental Figure VIII. p22\textsuperscript{phox} binding to Nox isoforms in p22\textsuperscript{phox} depleted HeLa cells.

A) Western blots of whole cell homogenates (Input of B). Optical densities (OD) of protein bands were quantified and normalised to α-tubulin detected in the same sample. *P<0.05 for TNFα values versus vehicle values in the same gene transfection group. †P<0.05 for indicated values versus WTp22 TNFα values. B) p22\textsuperscript{phox} was immunoprecipitated (IP) followed by immunoblot (IB). The results were normalized to the levels of total p22\textsuperscript{phox} detected in the same samples. *p<0.05 for indicated values versus vehicle values under the same gene transfection. †p<0.05 for indicated values versus WTp22 TNFα values. n=4 separate gene transfection experiments.
**Supplemental Figure IX.** TNFα-induced O$_2^-$ production by coronary microvascular endothelial cells (CMEC) isolated from WT and Nox2KO mice

WT and Nox2 knockout (KO) CMEC were transfected with an empty vector or WT p22$^{phox}$ or C242T p22$^{phox}$ plasmids. Cells were then stimulated with TNFα for 30 min. The O$_2^-$ production was measured by lucigenin (5 µmol/L)-chemiluminescence. n=3 separate cell isolations (6 mice/per isolation). *p<0.05 for indicated values versus vehicle values in the same gene transfection group. †p<0.05 for indicated values versus WTp22 TNFα values.

**Supplemental Figure X.** Real-time PCR detection of Nox mRNA expressions in HPMEC.

A) Basal Nox1, Nox2 and Nox4 mRNA expression (without TNFα). B) Fold changes of Nox1, Nox2 and Nox4 mRNA expression in response to TNFα (24 h) stimulation. The values of vector transfected control cells for each gene were expressed as 1. *p<0.05 for TNFα values versus vehicle values in the same gene transfection group. †p<0.05 for indicated values versus WT TNFα values. n=4 independent gene transfection experiments.
