4 **Abstract**

5 Project managers regularly allocate human resources to construction projects. This critical

6 task is usually executed by fulfilling the minimum project staffing requirements normally

7 based around the quantity and competence of project members. However, research has shown

8 that team performance can increase by up to 10% and 18%, respectively, as a consequence of

9 the group members' heterogeneity and social cohesion. Also, there is currently no practical

10 quantitative tool which incorporates these aspects to allow project managers to achieve this

11 task efficiently and objectively.

12 A new quantitative model for the effective allocation of human resources to multiple projects,

13 which takes into account group heterogeneity and social cohesion is proposed. This model is

14 easy to build, update and use in real project environments with the use of a spreadsheet and a

15 basic optimization engine (e.g. Excel Solver). A case study is proposed and solved with a

16 Genetic Algorithm to illustrate the model implementation. Finally, a validation example is

17 provided to exemplify how group heterogeneity and social cohesion condition academic

18 achievement in an academic setting.

Introduction

It is a well-known saying that 'people are the lifeblood of organizations'. Indeed,

despite living in an era of constant technological advancement, most of our tasks are still

done, handled or supervised by human beings. In organization life, the size and/or complexity

of many undertakings nowadays demand the involvement of many people (sometimes from

different organizations) working together to achieve a common goal. This goal can be

anything, but many times involves creating deliverables (products, services) to enhance a

company's internal performance, to make profit, or both. However, people (employees,

workers) who take part in these undertakings are normally subject to constraints. For

example, they are qualified to do certain jobs and not others; they have different levels of

competence in different domains; they cannot be present in multiple locations; and, certainly,

they have physical constraints in terms of how long they can work for (Hendriks et al. 1999).

Therefore, when there are several, sometimes concurrent projects that require the

participation of people to be completed, a project manager faces a practical dilemma: how to

best allocate his/her human resources on-hand to deliver his/her projects successfully.

'Successfully' can mean completing the projects on time, on budget and within an agreed (or

shared) quality threshold, or just meeting the key stakeholders' expectations (Xia et al. 2017).

In any case, as long as there are ongoing projects, the project manager will require competent

human resources to engage in certain tasks for a period of time before they are freed and able

43   to join other ongoing or upcoming projects. An essential part of the project manager's role in

44   the allocation of optimum human resources is to ensure, as much as possible, that the

45   individuals within the projects can work cooperatively with each other (Anvuur and

46   Kumaraswamy 2016).

47   However, collaboration between project members does not happen by chance. There

48   are indeed many factors that prevent this from happening. These factors can be

49   communication-related for instance, and/or have to do with the project member's

50   demographic attributes such as (differences in) nationality, education, religion, experience, to

51   cite a few (Al-Bayati et al. 2017). Sometimes, there are people who do not like working with

52   certain individuals, and this can also be really detrimental to the project progress and its

53   eventual success (Chen et al. 2017b). In this regard, Phua (2004) and Phua and Rowlinson

54   (2004) have found that cooperative behavior between project members is influenced, to a

55   certain extent by individual members' intrinsic social and psychological factors which have

56   to do with many more factors other than just their extrinsic demographic profile such as age,

57   sex, education, work experience and roles. For this reason, we will consider both cohesion

58   and heterogeneity factors later when aiming to build high-performing teams.

59   Given our existing understanding of the various factors that affect team performance,

60   there is however, a scarcity of quantitative and objective tools that enable the effective

61   allocation of human resources in terms of where and when they are to be allocated to projects

62   (Ahmadian Fard Fini et al. 2017). Conventionally, this type of allocation issues largely fall

63   within mainstream Human Resource Management (HRM) application which has its roots in

64   social sciences.

65   A different, maybe opposite, scenario can be found within Operational Research

66   (OR), which deals with the modeling and application of advanced analytical methods to make

67   better decisions. The problem of allocating multiple human resources to a single project is

68   relatively recent in OR, but it has been well studied and is known nowadays as the 'Team

69   Formation Problem' (TFP) (Tseng et al. 2004). When there are multiple simultaneous

70   projects, the TFP becomes the 'Multiple Team Formation Problem' (MTFP). Particularly, the

71   grouping of individuals to create teams have been made by attending to multiple factors: the

72   resources' temporal availability, current workload, individuals' skills, level of competence,

73   geographical distance, seniority, number of contacts, among many others (Gutiérrez et al.,

74   2016). In this line of research, it is not common to find theoretically-grounded sociological

75   considerations in the composition of teams. This means that, whereas it is relatively easy to

76   come across OR models that allocate resources that meet some functional (e.g. skills,

77   competence) project members' requirements, it is very rare to find models that try to optimize

78   other socially-based group traits like intra-group social preferences and group cohesion

79   (Ballesteros-Pérez et al. 2012). This piece of research proposes to take a step forward in

80   bridging this gap.

81   In this paper, a new human resource allocation model that takes into account, not just

82   basic project staff requirements and employees' profiles, but also group heterogeneity

83   (diversity) and social cohesion, is developed. This is a worthwhile contribution because, as

84   discussed earlier, team performance has been demonstrated to be significantly influenced by

85   these two factors. Hence, it seems logical to incorporate this knowledge when creating high-

86   functioning teams which comprise the 'right' individuals working together. To this end, the

87   rest of the paper will be structured as follows. The *literature review* section will go over the

88   major contributions published in the areas of the MTFP, group heterogeneity and social

89   cohesion. The *materials and methods* section will formulate the model, define its major

90   variables and explain how these are interrelated under mathematical expressions for

91   measuring team performance. A *case study* will exemplify the model implementation in a

92   fictitious company environment with twenty people and three simultaneous projects. A short

93   *validation* section will implement the model in a real academic setting where a cohort of 15

94   MSc students worked in groups to deliver three projects. The *discussions* will provide some

95   insight and further analysis on the implications and limitations of the model. Finally, the

96   *conclusions* will summarize the paper and convey why the proposed tool is relevant to the

97   wider project management community.

98

99   **Literature review**

100   The proposed model draws from research developed in two very different areas –

101   operational research (OR) and applied psychology (AP) –, but it is applied on a third one:

102   Human Resource Management (HRM). The amount of works published in connection with

103   HRM within both OR and AP is endless, so it is necessary to narrow down significantly the

104   works to be presented here. In this regard, only three very relevant topics will be reviewed:

105   the MTFP, group heterogeneity and faultlines, and group cohesion and sociometry.

106

107   *The Multiple Team Formation Problem (MTFP)*

108   The MTFP involves the distribution of people with different skillsets to a series of

109   teams (projects) that usually require more than a single area of expertise while optimizing

110   other criteria (e.g. profits, execution time, number of people). This problem is known to be

111   NP-hard (Non-deterministic Polynomial-time Hard) even for instances with a single project

112   (Gutiérrez et al., 2016). This means the MTFP belongs to the set of OR problems that are

113   harder to solve.

114   The first attempt to model and compute a solution to the TFP is relatively recent and

115   was developed by Lappas et al. (2009) when trying to create teams of experts from

116   professional profiles posted on social networks. Just a year later, Dorn and Dustdar (2010)

117   proposed solving the TFP with a first heuristic approach, whereas Li and Shan (2010)

118   improved the Enhanced-Steiner algorithm that was one of the two original algorithms used to

119   solve the TFP.

120   A year later, Yin et al., (2011) were the first to consider social influence among the

121   teams of experts. Additionally, Farhadi et al. (2011) allowed for the possibility of different

122   competence levels among the human resources, a generalization that will also be considered

123   in our model.

124   In 2012, the number of works published on the TFP grew exponentially. Among the

125   most relevant: Sorkhi et al. (2012) proposed a game theoretic approach to form and rank

126   project teams; Farhadi et al. (2012a, 2012b) extended the second original algorithm that had

127   proven to be very effective when dealing with the TFP – the Rarest First algorithm –;

128   whereas Gajewar and Sarma (2012) proposed three new optimization algorithms and

129   successfully applied them to the MTFP for the very first time.

130   Next, Shi and Hao (2013) formulated the MTFP with a multi-criteria decision-making

131   ranking approach involving the individuals' social networks. Then, Teixeira and Huzita

132   (2014) approached the MTFP considering the human resources' contextual information

133   (culture, idiom, temporal distance and previous experience), besides task requirements and

134   the interpersonal relationships among human resources. Our proposed model will also take

135   advantage of similar constructs in order to create a multi-dimensional model. Also, Agrawal

136   et al. (2014) focused on educational settings allowing the MTFP to be implemented without

137   allowing overlaps between the different student teams, a feature that will also be considered

138   in our model. Still in the same year, Awal and Bharadwaj (2014) tried to capture the synergy

139   produced among team members by means of a new ad-hoc concept named 'Collective

140   Intelligence' and also used a Genetic algorithm to solve their problem formulation. In this

141   paper, the solution of the case study proposed later will also make use of a genetic algorithm

142　approach as the way this ad-hoc index was defined share some similarities with our objective

143　function.

144　　　　Although there have been many other recent works published on the MTFP, these will

145　not be recounted here as they are not directly germane to this study. However, one that is

146　perhaps worth highlighting is the work from Gutiérrez et al. (2016) which formally included

147　sociometric preferences among individuals in the MTFP. Our proposed model also shares a

148　similar approach for modeling group cohesion. However, the algorithmic approach will be

149　totally different to Gutiérrez et al.'s as our model includes other dimensions, which makes

150　our model no longer quadratic.

151

152　　　*Group heterogeneity and faultlines*

153　　　　Research on how team effectiveness is influenced by the team composition has been

154　abundant too. Most of this research has focused precisely on measuring and analyzing the

155　effects of group heterogeneity on team performance. Group heterogeneity (homogeneity)

156　refers to a measurement of how different (similar) the members' demographic attributes (age,

157　sex, ethnicity, etc.) are with each other. There are many reviews on group heterogeneity (see

158　Earley and Gibson (2002) for a comprehensive one) but they will not be recounted here

159　either. In this piece of research, we are focusing on the quantitative aspects of how

160　heterogeneity is measured and what are its effects on team performance, rather than the

161　mechanisms or factors that cause it.

162　　　　With this in mind, the first indices that captured quantitatively how diverse

163　(homogeneous/heterogeneous) a group can be were defined by Blau (1977) and Allison

164　(1978). Generally, these and other later indices involved measuring group homogeneity as the

165 members' demographic attribute overlaps. With those indices, heterogeneity was also

166 generally defined as the inverse of homogeneity, that is heterogeneity=1/homogeneity.

167   Additionally, for a long time, it was believed that the presence of faultlines

168 (demographic features that divide a bigger group into two or more relatively homogeneous

169 subgroups) was detrimental to group performance (Lau and Murnighan 2005). It was not

170 until the work of Gibson and Vermeulen (2003), who proposed a new metric for measuring

171 group heterogeneity – the Subgroup Strength – , that it was understood that the presence of

172 subgroups (faultlines) could indeed promote team learning behavior and improve their

173 performance. The Subgroup Strength (SS) has many advantages over previous homogeneity

174 metrics (indices) as it allowed researchers to identify group faultlines much more effectively.

175 Indeed, it was shown recently by Meyer and Glenz (2013) in a comprehensive comparative

176 study that the SS is one of the simpler, yet more powerful metrics for measuring group

177 heterogeneity in the presence of two or more subgroups. For these reasons, SS will also be

178 used in our model later to describe subgroups' heterogeneity.

179   Finally, Gibson and Vermeulen (2003) also showed that a team's performance

180 seemed to vary by up to 10% depending on the SS. Again, this was supported recently by

181 another study by Chen et al. (2017). This study also confirmed another speculation of Gibson

182 and Vermeulen's: that the relationship between SS and team performance was an inverted U-

183 shape whose minima (lower performance) were to be expected for extremely homogeneous

184 and heterogeneous groups. Finally, many other works have been published on the effects of

185 group heterogeneity on intra- and cross-subgroups demographic faultlines (Lau and

186 Murnighan 2005), but only some related to group cohesion will be reviewed later in the

187 *Discussions* to clarify the effect of possible collinearities between both variables.

188

Group cohesion and sociometry

Group cohesion is a desirable attribute because research has proven it to be positively

related to team performance, as well as a wide range of other positive behavioral outcomes

(better individuals' attitude, well-being, lower absenteeism, etc.) (Chang and Bordia 2001;

Chen et al. 2017b). However, very few pieces of research have actually quantified the extent

to which team performance is influenced by group cohesion or dissociation.

One exception is a recent and comprehensive review performed by Evans and Dion

(2012). These authors, beyond concluding that there is a positive relationship between

cohesion and performance, recounted that cohesive groups seem to perform around 18

percentile points on average above the average (uncohesive) groups. This figure will be used

later in our model as other research has also corroborated the cohesion-performance

relationship even when different settings (e.g. business, education, research) or group sizes

are considered (Castaño et al. 2013). Furthermore, because existing research on cohesion and

performance has operationalized cohesion almost completely in terms of interpersonal

attraction (see evidence from Lott and Lott (1965) to Beal et al. (2003) for instance), it makes

theoretical sense for our model to adopt sociometry to model group cohesion.

Sociometry was devised by Jacob Levy Moreno (Moreno 1941) and is a method that

can be used for estimating the quality of group dynamics. It is one of the few methods that

allows the gathering of quantitative information about the informal structure of a group that is

difficult to obtain in other ways. Sociometry was extensively used between the 40s and 60s at

schools, companies and research settings to examine social interrelations and communication

patterns within groups (Salo 2006). In sociometry, interpersonal relations are measured by

asking group members to express their preferences and rejections for particular companions

in a certain situation or activity (Festinger et al. 1950). Hence, the advantageous simplicity of

sociometry is, at the same time, its major limitation: it requires that group members are

214   truthful and open in stating who they prefer and not prefer to work with. A reasonable

215   question then is whether group cohesion can be adequately represented by sociometric

216   choices and if these choices r can be eventually captured by means of questionnaires that

217   request group members to state their preferences and rejections towards other group

218   members. In fact, both aspects have been subjected to multiple research studies in many

219   varied settings. An example of a brief but reassuring and confirmatory review can be found in

220   Salo (2006).

221   Finally, there is one question that needs to be addressed before formulating the model.

222   As stated earlier, the proposed model will group individuals under different projects that have

223   some minimum staff (areas of expertise and levels of competence) requirements. According

224   to a recent piece of research (Mathieu et al. 2015), when people with the right combination of

225   expertise work together, as expected, this is positively related with team performance.

226   However, this same piece of research also showed that this is unrelated to team cohesion.

227   With this in mind, we will allow our model to effectively separate the effect of the constraints

228   (i.e. minimum project staffing requirements) from the group performance variables (i.e.

229   group heterogeneity and cohesion metrics).

230

231   **Materials and methods**

232   *Model outline*

233   In this section, an OR model that allocates a pool of skilled individuals to a series of

234   simultaneous projects with specific staffing (expertise and competence) requirements is

235   proposed and mathematically described in detail. This model will take into account how

236   similar (homogeneous) these individuals are and how they get along with each other (group

237   cohesion).

Mathematical notation

240   Let us assume two individuals i and j where i, j belong to a set of n people (workers)

241 who are available to be allocated into teams. Let us assume that these individuals can be

242 combined into a number of non-overlapping teams (subgroups) where each team is noted by

243 the letter k and whose size is noted as n_k (number of members of team k).

244   For every individual i (or j) it is assumed that the following information is known as

245 illustrated in the following examples:

246 • Professional level of competence l_i where $l_i \in L$ and $L=\{$junior, intermediate, senior$\}$

247 • Functional department d_i where $d_i \in D$ and $D=\{$architecture, civil, mechanical, electrical$\}$

248 • Age a_i where $a_i =$ positive integer.

249 • Gender g_i where $g_i \in G$ and $G=\{$Male, Female$\}$

250 • Ethnicity e_i where $e_i \in E$, and where E, for simplicity, will be assumed here as the

251   continent of origin, that is $E=\{$African, Antarctican, Asian, Australian, European, North

252   American, South American$\}$

253 • Team tenure (seniority in the same group or company) t_i where $t_i =$ positive integer.

254 • Sociometric preference of individual i towards individual j, that is s_{ij} where $i \neq j$, $s_{ij} \in S$ and

255     $S=\{-1, 0, +1\}$. Particularly, $s_{ij}= -1$ means i dislikes working with j, $s_{ij}= 0$ means i is

256   neutral towards (or has never worked with) j, and $s_{ij}= +1$ means i likes working with j.

257   The set of all values s_{ij} correspond to a non-symmetrical matrix of size $n \times n$.

258   Sociometric preferences aside, these individuals' attributes have been selected here as

259 they were the ones adopted by Gibson and Vermeulen (2003) in their seminal work on group

260 faultlines. This set of attributes has been widely tested in subsequent research (e.g. Chen et

261   al. 2017a; Meyer and Glenz 2013) and it is still largely accepted that they provide a robust

262   representation of group diversity.

263   Hence, given n people available from whom we know their l_i, d_i, a_i, g_i, e_i, t_i and s_{ij}, we

264   will create subsets (subgroups/teams) of n_k individuals, each of which will be working on a

265   different project k. Individuals can only be allocated to either a single group k or no subgroup

266   at all (those unallocated individuals will be idle resources). This implies that no individual

267   can be present in two or more subgroups, even if they could only work part-time in several

268   projects. We use this simplified assumption to make this model more accessible from the

269   point of view of its first mathematical formulation.

270   Therefore, as implied above, every subgroup k will be allocated to a single project and

271   we will note projects and subgroups (teams) with the same subscript k from now on. Each

272   project k will have specific staffing requirements (p_k). For instance, $p_k=\{1$ senior Architect, 1

273   intermediate civil engineer, 1 junior civil engineer, 2 intermediate electrical engineers$\}$. Any

274   subgroup of workers n_k that matches or exceeds (both in number and/or competence) these

275   requirements will be considered a feasible subgroup that can potentially be allocated to

276   project k.

277

278   *Team performance measurement*

279   In order to determine which feasible allocation of subgroups is most desirable, it is

280   necessary to anticipate how much better each possible alternative allocation of subgroups

281   would perform if eventually chosen. Additionally, it is worth emphasizing that each feasible

282   allocation might encompass multiple subgroups as each subgroup will be allocated to one

283   project. Therefore, it is necessary to create an index that captures, not just how efficient each

284   subgroup is, but also how efficient all groups are on average; that is, how efficient the

285 allocation is altogether. This index will be named 'Global Efficiency (E)' and will correspond

286 to a weighted average calculated from the subgroup Efficiencies of each subgroup k (noted as

287 E_k), that is:

$$E = \sum E_k \cdot w_k \tag{1}$$

289 In this expression, w_k corresponds to the weight of each subgroup k. This way w_k can

290 be calculated, for instance, proportionally to each project k's budget (b_k). Alternatively, w_k

291 can also be calculated proportionally to the number of people n_k from each project, divided

292 by the total people available n (allocated or not) or the total number of allocated people only

293 (Σw_k). These alternatives are expressed in equations (2) and (3), respectively:

$$w_k = \frac{b_k}{\sum b_k} \tag{2}$$

$$w_k = \frac{n_k}{\sum n_k} \quad \text{or} \quad w_k = \frac{n_k}{n} \tag{3}$$

296 With the global (allocation) Efficiency E defined in (1) as a function of each

297 subgroup's E_k and w_k values, now it is necessary to detail how E_k values can be calculated.

298 E_k is a composite efficiency index obtained as the product of two other indices that

299 represent the expected performance of that subgroup k in terms of its homogeneity (P_k^{SS}) and

300 social cohesion (P_k^{S}). Namely,

$$E_k = P_k^{SS} \cdot P_k^{S} \tag{4}$$

302 Particularly, P_k^{SS} estimates the Performance of a subgroup k based on the Subgroup

303 Strength (*SS*) as defined by Gibson and Vermeulen (2003). To calculate the SS value of a

304 subgroup k (noted as SS_k), it will be necessary to calculate the subgroup k's homogeneity

305 value h_k first, as well as the individuals' degree of overlaps in terms of different diversity

306   factors (we will use: functional department, age, gender, ethnicity, and team tenure as

307   justified later).

308   P_k^S is an index that measures the differential level of performance expected for

309   subgroup k given a particular level of cohesion, which is measured by sociometric indices. In

310   this case, S_k will be calculated as the interpersonal social preferences and rejections stated by

311   all members belonging to subgroup k.

312   What follows are the details on how P_k^{SS} and P_k^S are calculated. Once these two

313   values are known for each potential subgroup k, obtaining E_k will be straightforward with (4).

314   Let us start with P_k^{SS}, the performance metric coming from the Subgroup Strength

315   metric. Conventionally, a subgroup k's homogeneity h_k has been defined as:

$$
316 \qquad h_k = \frac{\sum_{i<j}\left\{O_{ij}^d + O_{ij}^a + O_{ij}^g + O_{ij}^e + O_{ij}^t\right\}}{\dfrac{n_k(n_k-1)}{2}} = \frac{\sum_{i<j}O_{ij}}{\dfrac{n_k(n_k-1)}{2}} \qquad (5)
$$

317   Where O_{ij} is the total overlap between individuals i and j, and which is computed as

318   the sum of O_{ij}^d, O_{ij}^a, O_{ij}^g, O_{ij}^e and O_{ij}^t which, in turn, represent the overlaps between two

319   individuals i and j on functional department, age, gender, ethnicity and team tenure,

320   respectively. The sum in the numerator is restrained to $i<j$ (but it could have also been $i>j$

321   indistinctly) to avoid the cases where $i=j$ (individuals' self-overlaps) as well as to prevent the

322   symmetrical O_{ij} values (that is $O_{ij}=O_{ji}$) from being counted twice.

323   Also in the same vein, the factor $n_k(n_k-1)/2$ in the denominator of (5) corresponds to

324   the total number of pairs analyzed (all possible combinations of i and j, excluding those cases

325   where $i \geq j$).

326   With all this in mind, and according to Gibson and Vermeulen (2003), the different

327   overlaps between a group of individuals can be calculated as follows:

328   Functional department overlap: $O_{ij}^d = 1$ if $d_i = d_j$, else 0   (6)

329   Age overlap: $O_{ij}^a = \dfrac{\min(a_i, a_j) - 18}{\max(a_i, a_j) - 18}$ (7)

330   Gender overlap: $O_{ij}^g = 1$ if $g_i = g_j$, else 0   (8)

331   Ethnicity overlap: $O_{ij}^e = 1$ if $e_i = e_j$, else 0   (9)

332   Team tenure overlap: $O_{ij}^t = \dfrac{\min(t_i, t_j)}{\max(t_i, t_j)}$ (10)

333   Overlap values can vary between [0, 1]. Hence, values of h_k will vary between [0, 5].

334   We are aware that other diversity factors could have also been included in the definition of h_k

335   such as for example, language, education, experience. However, in the interest of keeping to

336   the model's simplicity and for illustrative purpose in the case study which follows, we

337   deemed it reasonable to stick to the diversity factors in the definition of h_k as proposed by

338   Blau (1977) and Allison (1978).

339   And now that the overlaps of all individuals O_{ij} and the subgroup k's homogeneity

340   value h_k have been detailed, the Subgroup Strength of a subgroup k (SS_k) is defined as the

341   population standard deviation of the O_{ij} values from all n_k members belonging to subgroup k,

342   that is:

343        $$SS_k = \sqrt{\dfrac{\sum_{i<j}\left(O_{ij} - h_k\right)^2}{\dfrac{n_k(n_k - 1)}{2}}} = Std.\,Dev.\,O_{ij}$$ (11)

344   As defined, SS_k will vary from 0 to 1.25 (since h_k domain was restricted to [0,5]).

345   Additionally, Gibson and Vermeulen (2003) proved that team diversity (represented by

346   means of SS_k) and group performance were quadratically related (inverted U-shape)

347   approximately as described in Figure 1a.

348   **<Insert Figure 1 here>**

349   Also, a recent study by Chen et al. (2017) suggested that this quadratic expression is

350   quasi-symmetrical and that the value of δ seems generally close to 10% on average.

351   Therefore, the subgroup k's performance P_k^{SS} can be calculated from the subgroup strength

352   SS_k value as:

$$P_k^{SS} = -2.56\delta\,SS_k^2 + 3.2\delta\,SS_k + 1 - \delta \qquad \text{with } \delta \approx 0.10 \qquad (12)$$

354   Expression (12) can vary between [1−δ, 1] and is obtained from a quadratic

355   polynomial which is forced to cross the points: (0,1−δ), (1.25/2, 1) and (1.25,1−δ).

356   On the other hand, the subgroup k's cohesion-related performance index P_k^{S} is

357   calculated from the subgroup k members' sociometric preferences s_{ij} towards each other (i.e.

358   preferences and rejections to work with a particular individual). These preferences and

359   rejections do not have to be symmetrical (that is, $S_{ij} \neq S_{ji}$ or $S_{ij} = S_{ji}$). Hence, we define a

360   subgroup k's cohesion S_k as:

$$S_k = \frac{\sum\limits_{i \neq j} s_{ij}}{n_k(n_k - 1)} \qquad (13)$$

362   Similarly, the term $n_k(n_k - 1)$ corresponds to the total number of pairs analyzed

363   excluding the choices of individuals with themselves. So, as s_{ij} can be equal to −1 (meaning i

364   dislikes j), 0 (i is neutral or have not met j), or +1 (i likes j), S_k actually represents how well

365   (or badly) all subgroup k's members get along with each other on average. Analogously, S_k

366   can take on values within the range [-1, 1].

367   Finally, previous researchers' results suggest that the average cohesive group seems

368   to perform around 18% better than average (non-cohesive or non-uncohesive) groups (Evans

369   and Dion 2012). For the purpose of this paper, this performance differential will be called φ .

370   However, it is worth pointing out that in those previous pieces of research it is not always

371   clear how group cohesion is measured or quantified. Also, there is a total absence of studies

372   clarifying whether the cohesion-performance relationship is linear or if it indeed follows a

373   different pattern. In light of this, it seems prudent to take the simplest alternative and assume

374   that group cohesion (represented now by S_k) and performance (P_k^S) will just be linearly

375   related as represented in Figure 1b. Hence:

376
$$P_k^S = 1 + \varphi S_k \qquad \text{with } \varphi \approx 0.18 \qquad (14)$$

377   After defining expression (13), all variables involved have been presented and related

378   to each other. We are now able to calculate the global group efficiency (E) from the different

379   simultaneous subgroups' efficiencies E_k and their respective weights w_k. This is summarized

380   at the bottom of Figure 1. Hence, from now on, every possible subgroups' allocation can be

381   measured in relative performance terms and each feasible complete group allocation can be

382   compared against each other. The following is an example to illustrate how we can apply the

383   model based on a fictitious case study which reflects as much as possible, a real project

384   environment.

385

386 **Application**

387   The case study follows approximately the same order of calculations that was

388 presented in the previous section. For the interested reader, the complete step-by-step

389 calculations can be found in an Excel file accessible from the *Supplemental Online Material*.

390   Particularly, this case study comprises a group of 20 individuals with different levels

391 of professional competence and who belong to four functional departments. The entire

392 professional, demographic (homogeneity-related) and sociometric (cohesion-related)

393 information from the 20 individuals is described in Figure 2.

394   **<Insert Figure 2 here>**

395   These 20 individuals are to be allocated to three simultaneous projects, each of which

396 has different staffing (professional level and functional department) requirements as well as

397 budgets. This information is detailed in Figure 3. Also, at the bottom of Figure 3, the weights

398 of each project have been calculated as a function of the project budgets according to

399 expression (2).

400   **<Insert Figure 3 here>**

401   Any subgroup allocation that meets or exceeds the staffing requirements described in

402 Figure 3 will be a feasible solution. What is necessary now is to be able to calculate the

403 global efficiency E from any feasible grouping solution. With this aim in mind, the first step

404 will be to obtain all individuals' overlaps concerning functional department, age, gender,

405 ethnicity and team tenure, so that these values can be reused anytime when two individuals

406 are put together in the same subgroup. Due to its length (5 tables, one per type of overlap),

407 these calculations have been included as *Supplemental Online Material*. Figure 4 just

408 summarizes the total overlaps, which have been obtained from the simple addition of all the

409 individuals' overlap values.

410   **\<Insert Figure 4 here\>**

411   What remains is calculating, for any potential and feasible subgroup k, its

412   homogeneity h_k (with expression (5)), subgroup strength SS_k (with expression (11)), and

413   cohesion S_k (with expression (13)) values. Then, with SS_k and S_k, known, calculating the

414   homogeneity-related P_k^{SS} performance metric (with expression (12)) and the cohesion-related

415   P_k^{S} performance metric (with expression (14)) can be performed. Next, with P_k^{SS} and P_k^{S}

416   known, we can calculate E_k (by means of expression (4)). Once the values of E_k are all known

417   for all the simultaneous subgroups (three in our example, as there are three projects), and by

418   knowing the weight of each subgroup w_k (with expressions (2) or (3), and as detailed at the

419   bottom of Figure 3), it is possible to obtain the global efficiency E of that group configuration

420   by means of expression (1). This series of calculations are represented vertically from top to

421   bottom in the lower half of Figure 5.

422   **\<Insert Figure 5 here\>**

423   In Figure 5, a random solution directly allocating the individuals available to meet the

424   project staffing requirement, but without any further (homogeneity, nor cohesion)

425   considerations, is presented. At the top of Figure 5, one can find the allocation of each

426   individual to each subgroup/project. The column to the right sums each individual's

427   allocations and verifies that no individual is allocated more than 100%, that is, to more than

428   one project. These are necessary but not sufficient problem constraints which need to be met

429   to qualify any allocation as feasible.

430   However, every time there is any change (for instance a member is allocated to a

431   different project/subgroup), all values need to be recalculated. Therefore, the only way of

432   finding good solutions is by iterating these calculations multiple times while testing as many

433 feasible solutions as possible. Hence, for the model to be practically useful, this task must be

434 automated by an optimization algorithm.

435   The global efficiency of the random solution depicted in Figure 5 corresponds to

436 0.981. By definition, the value of the global efficiency E will vary between $[1-\delta-\varphi, 1+\varphi]$.

437 Hence, the closer the value of E to $1+\varphi$, the higher the expected groups' performance. Now,

438 in looking for that optimum solution, there is one last point to be discussed.

439   As discussed earlier, the proposed model falls within a particular case of the MTFP.

440 The MTFP is NP-hard, and that opens the door to the use of metaheuristics when looking for

441 (near) optimum solutions. Among common metaheuristics, Genetic Algorithms (GA) are one

442 of the quicker and simpler, but also effective, options. On top of that, they are usually

443 available within commercial solvers included by default in spreadsheet software like

444 Microsoft Excel ®. Moreover, GA have been in use in resource-constrained allocation for a

445 long time and they have been considered as one of the most efficient metaheuristics when

446 dealing with the MTFP in recent studies (e.g. Ahmadian Fard Fini et al. 2016; Awal and

447 Bharadwaj 2014). For all these reasons, we will use GA for solving multiple instances of our

448 case study and find a quick and good (despite maybe less than optimal) solution.

449   Therefore, once the model is implemented in a spreadsheet where every time a new

450 allocation is proposed all the subgroup calculations can be automatically and instantly

451 updated, the GA can start looking for new solutions. The problem constraints are the ones

452 specified in grey cells (one per individual's maximum allocation time plus one per project

453 staffing requirements check). The objective function corresponds to E, which on this

454 occasion is to be maximized. On resorting to Excel Solver, the best solution was found in

455 seconds by our GA as shown in Figure 6.

456   **<Insert Figure 6 here>**

457   The solution shown in Figure 6 (with E=1.087) is comparatively much more efficient

458   than the one from Figure 5 (with E=0.981). If the same GA would have been aimed at

459   minimizing E, the worst solution found (not included) would have had an E=0.911. Within

460   the [1-δ-φ, 1+φ] interval, the three solutions correspond to the following percentiles: 56.7%

461   (the random solution), 79.8% (the best solution) and 41.5% (the worst solution). As can be

462   seen, based on the results, there seems to be valid reasons to try to optimize the model

463   outputs with the help of an optimization algorithm. Mostly, when doing this manually, would

464   have been an unsurmountable task.

465

466   **Validation**

467   In the previous section it was shown how the model can be implemented to fulfill its

468   most common purpose: finding the optimum (or near optimum) allocation of a set of

469   available human resources into a series of projects, each with not necessarily equal staffing

470   requirements. However, before accepting that the model outputs constitute a fair description

471   of reality, it is necessary to verify whether its parameters actually influence different levels of

472   team performance. Particularly, the most relevant model parameters are the ones proposed in

473   equations (12) and (14), that is, the group diversity-related performance (P_k^{SS}) and the social

474   cohesion-related performance (P_k^{S}). Hence, if higher values of these two parameters exhibit

475   correlation with higher values of team performance, the model will be of some value.

476   Conversely, if there is no such correlation, the model, at least as currently formulated, would

477   render useless.

478   With this purpose in mind, a first exploratory and validation study was conducted

479   comprising the academic performance of fifteen MSc Civil Engineering students at the

480   Universidad de Talca (Chile). This group of students were enrolled in a module named

481   'Projects' which is a transversal integration module and its purpose is to determine how well

482   students can apply knowledge and understanding from previous related modules. The module

483   was led by one of the authors in the second semester of 2017. It required that fifteen students

484   submitted three assignments (projects) each. The three projects which will be named Project

485   1, Project 2 and Project 3, had progressive submission dates every two months. Students

486   worked in groups of five to deliver these three projects. After each project was completed, the

487   groups were reshuffled so that most students had to work with different team mates in the

488   next project.

489   In short, for the first assignment (Project 1), there were three groups with 5 students

490   (named here as groups A, B and C) each submitting a different project. The same happened

491   for Project 2 and 3, but with groups whose member composition was different from Project 1.

492   Each of these three projects was assessed and given a mark between 0 and 100. In total, there

493   were 9 different marks: one per assignment (Project 1, 2 and 3) and group (A, B and C).

494   However, each student only received three marks (one from each Project) whose average

495   resulted in the module's final mark for him/her.

496   The demographic attributes of the fifteen students can be found in Figure 7. By

497   columns, the five individuals' attributes had a close equivalence with the five attributes

498   described in our model: background (akin to functional department), age, gender, ethnicity

499   and work experience (akin to team tenure). However, as expected from a group of students,

500   the sample was also relatively more homogeneous than other real-life projects (most

501   individuals had similar ages, similar experience, and a less varied set of

502   backgrounds/degrees).

503   **<Insert Figure 7 here>**

504   The group demographic attributes were directly retrieved from their registrations

505   information. This MSc programme required a minimum work experience of 2 years as an

506   admission criterion. This is the reason why most students exhibit similar years of experience,

507   but also similar ages. Additionally, most were local students, which meant most of them were

508   South American.

509   The Sociometric individuals' preferences matrix was populated using the registration

510   of the same students for a series of lab sessions which ran in parallel to this module.

511   Particularly, before allocating the fifteen students to those lab sessions, they were asked with

512   whom they would like to carry out the lab sessions and whom they would prefer to avoid.

513   Although it was not compulsory for the instructors to implement those preferences, those

514   registers proved useful later for allocating the students to the Project groups, and also to

515   populate the sociometric matrix.

516   Finally, the last three columns in Figure 7 correspond to the three marks that each

517   student was awarded at the end of the module.

518   The information from Figure 7 is enough to develop a first, simple, and representative

519   correlation analysis between the model parameters and team performance. For this purpose,

520   the groups' homogeneity, subgroup strength and social cohesion values were calculated for

521   the nine five-student groups that submitted the three projects. With these values, calculating

522   the group diversity- and cohesion-related performances was straightforward. These

523   calculations are all presented, along with the students' allocations, in Figure 8.

524   **\<Insert Figure 8 here\>**

525   Values highlighted in blue, red and green correspond to Projects 1, 2 and 3, which

526   were also identified in the last three columns of Figure 7. For reference purposes, the project

527   marks were also shown at the bottom row of Figure 8.

528   The last step consists of showing how the regression plots of the variables included in

529   the model align with the expected performance outputs. For this purpose, several plots are

530   shown in Figure 9 from the numerical data represented in the lower rows of Figure 8.

531   **<Insert Figure 9 here>**

532   Figures 9a) and 9b) show how subgroup strength and group social cohesion are

533   related to group diversity-related and group cohesion-related performance, respectively,

534   based on equations (12) and (14). Additionally, in Figures 9d) and 9e), we can see how group

535   diversity-related performance and group-cohesion related performance are both related to

536   team performance as well (team performance is represented by the project marks). The very

537   fact that these two graphs exhibit approximately linear trends between the X and Y variables

538   indicate that the regression expressions represented in Figures 9a) and 9b) were supported.

539   This is because expressions (12) and (14) are actually transforming the group diversity-

540   related (from Figure 9a) and group cohesion-related performance (from Figure 9b) into a

541   series of points with a linear correlation with Team Performance. If that had not been the

542   case, then there would be no linear relationship, and quite possibly, no trend would be found

543   at all.

544   Finally, Figure 9c) represents the Y-axis variables from Figures 9a) and 9b) and

545   barely shows any trend. This proves that the level of correlation between subgroup strength

546   and group cohesion is very low. This relationship was also hypothesized earlier and this is

547   proven numerically and graphically here.

548   Therefore, a quick observation of the three plots at the bottom of Figure 9 show

549   evidence of a moderate/strong correlation between the model parameters (independent

550   variables) and the project marks (dependent variable). As the project marks can be considered

551   as a good proxy for group performance, we can conclude that the model formulation seems to

552   be fairly representative and is correctly indicating that certain heterogeneity-related and

553   cohesion-related group attributes can ultimately lead to higher (or lower) team performances.

554   　　Of course, the conclusions of this validation case study have to be taken with some

555   caution too. The analysis is based on an academic environment, rather than a real project.

556   Real life projects tend to consist of a more diverse group of professionals (higher dispersion

557   of the demographic attributes) with generally many more variables which may be difficult

558   (but necessary) to control. Notwithstanding this, we acknolwedge further validation using

559   real projects is needed in order to improve the validity of the model. However, resorting to an

560   academic environment also has numerous advantages. First, the outcome of 'project'

561   performance can be known (under some simplifying assumptions) as all assignments are

562   graded and awarded a mark. And second, these project cycles are usually faster which also

563   allows data retrieval to be generated faster than in real-life projects.

564   　　Other limitation of our validation case study is the reduced number of points (only

565   nine) and the reduced variation of some of the performance measurements. In connection

566   with the latter, the cohesion-related performance values of Projects 2 and 3 are very close to

567   each other, obscuring the type of relationship that more dispersed values could have shown.

568   Also, although the rest of the cases show clearer trends, it is necessary to point out that these

569   might not be necessarily linear. This, despite us resorting to three points, two of them still

570   remain too close in the cohesion-related performance graph to infer properly potentially non-

571   liner trends.

572   　　Finally, it is clear from Figure 9 that Project 1 seemed to be more challenging to the

573   students as they all got lower marks (probably because it was the first assignment), whereas

574   the other two seemed easier (they received higher marks). Similarly, for future validation

575   studies, it will be advisable to gather individual marks from each student (by means of

576   individual exams, for example). Only with this additional piece of information, will it be

577 possible to better compare different levels of group members' performance (as groups made

578 up of bright people usually perform better than ones with mediocre students).

579

580 **Discussion**

581 In this paper, a new model for allocating human resources that considers team

582 functional requirements, group heterogeneity and social cohesion has been proposed and

583 validated. In formulating the model, a few simplifications and constraints were assumed.

584 These will be now be reviewed and discussed in detail.

585 First of all, as stated earlier, this model has necessarily oversimplified the nature of

586 real life work collaboration issues. Real life team work is complex and dynamic. Certainly, it

587 cannot be reduced to two variables –group diversity and social cohesion– without neglecting

588 aspects that make from group collaboration something rich and distinct from other

589 engineering and technical challenges. In real life, group members' exhibit behaviors and

590 possess attributes that have not been included in this model (e.g. how introvert/extrovert

591 group members are; their dedication, devotion, preferences or just personal or professional

592 interests or goals; their soft skills or motivation to work in groups; the asymmetrical personal

593 relationships as a consequence of the lines of command, etc.). However, the intention here

594 was not to include an exhaustive list of group attributes but to present a simple and self-

595 contained model. And despite all the necessary simplifications, the model still seems to be

596 robust, at least, based on the preliminary validation results shown here. The inclusion of

597 further variables will be something that, no doubt, will be considered in future versions of the

598 model when it is applied in real project settings.

599 Secondly, one might raise the question that the way group heterogeneity and cohesion

600 have been defined in this paper might lead to some collinearity or, at least, covariance

601   between the two constructs. This is because there is a possibility that both may be capturing

602   some common aspects of a group configuration. Our model, however, has instrumented both

603   constructs in a multiplicative way, that is, $P_k^{SS} \times P_k^{S}$, not additive, because they do not

604   substitute for one another when contributing to subgroup performance E_k. All the same, we

605   agree that this might be an over simplification, but existing research so far does not seem to

606   have reached an agreement on whether this is an untenable assumption.

607   For example, Festinger et al. (1950) in an early attempt found contradicting results in

608   two experiments analyzing the group heterogeneity-cohesion relationship. Much more

609   recently, Dion (2000), on performing analysis in two houses of war veterans found again

610   inconclusive findings indicating that in one house cohesion was related with homogeneity,

611   whereas in the other it was not. And even more recently, in a study conducted by Chiocchio

612   and Essiembre (2009), it was shown that a group's homogeneity or heterogeneity does not

613   appear to affect the social cohesion-behavioral performance correlations in either academic or

614   organizational settings. In line with this, probably the most enlightening stance has been the

615   one taken by Sturgis et al. (2014), who claimed that the relationships between the different

616   subcomponents of group heterogeneity and cohesion might be very different from each other,

617   even cancelling out each other's effects. They also emphasized that more research is

618   necessary to validate this.

619   However, and fortunately, because our model only tries to relatively (not absolutely)

620   generate the most desirable subgroups allocations from the same pool of human resources,

621   the effect of potential (if existing) collinearities between subcomponents of heterogeneity and

622   cohesion will not be that critical so as to invalidate the model. This, as despite correlation

623   between both variables might cause some scale distortion, the relative rank (order) of

624   solutions should not have altered much.

625   Additionally, other simplifications have been assumed along the model formulation.

626 Probably the two most relevant have been limiting the allocations of individuals to be in full-

627 time working arrangement and not part-time. Also, the relationship between group cohesion

628 and group performance has been assumed to be linear.

629   The first simplification is relatively easy to address but it would complicate the

630 mathematical expressions to a point where they are no longer that intuitive. In this paper, we

631 have tried to encourage understanding of the model's utility and to avoid distractions by

632 complicating it too much. However, allowing part-time allocations might make finding better

633 solutions somewhat easier for an optimization algorithm. This, as the objective functions of

634 many OR models are generally easier to optimize when the decision variables are closer to

635 being continuous (Gutiérrez et al., 2016).

636   Finally, the second simplification cannot be satisfactorily addressed until there is

637 more research to determine the nature of the cohesion-performance relationship. This might

638 be a critical aspect for further model development. It may indeed lead to some adjustments in

639 some of the equations (probably in expression (4) and surely in expression (14)), but for now

640 there is no point in us speculating how it might impact the model formulation, or indeed if

641 there is such an impact at all.

642

643   **Conclusions**

644   A model that allocates human resources to multiple projects with specific staffing

645 requirements while also considering group homogeneity and cohesion has been proposed.

646 This model constitutes a powerful and practical tool for any project manager who needs to

647 efficiently allocate human resources and who wants to maximize the expected productivity of

648 his/her group members. The mathematical expressions are, in general, quite straightforward

649   and can be easily implemented by means of a spreadsheet. The optimization algorithm for

650   finding near-optimal solutions can also be implemented with the aid of a very simple

651   commercial solver like Excel Solver (currently a free, despite capped, version of Frontline

652   Solvers®).

653   Human resources are a key component of project success, but there is a lack of

654   practical, quantitative tools that allow project managers to efficiently allocate these resources

655   and build high performing teams. There are many reasons that can keep a team from

656   functioning effectively. In this paper, two factors that are found to strongly and consistently

657   influence group performance – group homogeneity and group cohesion – have been

658   incorporated within the model. This model allows the measuring and comparing of any set of

659   feasible subgroup allocations to several projects simultaneously.

660   Namely, group homogeneity has been defined by the subgroup strength metric and the

661   sum of overlaps between subgroup members on five different demographic sub-factors

662   (functional department, age, sex, ethnicity and team tenure). Group cohesion has been

663   defined as the degree of acceptance (or rejection) that all members have with each other. The

664   information on the five sub-factors in the group cohesion construct is generally very easy to

665   obtain from the group members' professional profiles. In terms of the degree of

666   acceptance/rejection that each group member has toward the rest of their group members,

667   these can generally be known by using sociometric questionnaires. The latter, despite its

668   limitations, have also been proven in previous research to be quite representative and

669   relatively easy to use and update. Basically, these questionnaires require asking all group

670   members who have finished a project: "Who would you like to keep working with?" and

671   "Who would you prefer not to work with? From the group members' answers it is possible to

672   populate (and keep updating) a sociometric matrix that is eventually useful for measuring

673   how cohesive each potential subgroup is or can be.

674   Furthermore, previous research has proven that group homogeneity can

675 reduce/increase group performance by up to 10% on average. Similarly, group cohesion is

676 responsible for average increases (or decreases) of group performance by up to 18%. Both

677 figures have been included in the proposed model and allow the objective measuring of the

678 relative group performance differences between multiple feasible subgroups. Feasible

679 subgroups are those who fulfill the minimum project staffing requirements stated by some

680 simultaneous projects.

681   With all this, the proposed mathematical model has been detailed concerning all its

682 components and variable relationships. A fictitious case study involving twenty workers who

683 are allocated to three projects have been proposed and solved by means of a simple Genetic

684 Algorithm. Finally, a validation case study based on an academic setting has also been

685 included which involved fifteen MSc students who were allocated to three groups and were

686 required to complete three sequential projects.

687   The proposed model is a simple and yet powerful way of addressing the

688 commonplace challenges of a typical project manager in efficiently allocating human

689 resources in projects. Despite some intentional simplifications, the model shows promise in

690 helping project managers to make more objective and efficient decisions about their human

691 resource allocations. However, more validating studies will be required in the future to test

692 the actual utility of the model in real project contexts.

693   Although validation with real projects is necessary, this will also increase the

694 complexity of the model's application due to the number of variables to be considered, as

695 well as generally bigger team sizes. Indeed, this wider range of variables will have some

696 human resource implications in terms of the sturcture of social cohesion of individuals within

697 the projects. For example, the interactions amongst members in real projects may be

698 underpinned by career-related imperatives, and hence, are likely to be more dynamic and

30

699　nuanced, when compared with students'. In this vein, a potentially fruitful avenue for future

700　research would be to use real life projects in conjunction with using academic projects as

701　controlled experiment to enable researchers to study the nature and structure of social

702　cohesion more precisely.
