- 1 Abstract
- 2

The impact of flavonoids on fatigue has not been investigated in Relapsing and Remitting Multiple
Sclerosis (RRMS).

5

Objective: To determine the feasibility and estimate the potential effect of flavonoid-rich cocoa on
fatigue and fatigability in RRMS.

8

9 Methods: A randomised double-blind placebo-controlled feasibility study in people recently

10 diagnosed with RRMS and fatigue, throughout the Thames Valley (ISRCTN: 69897291). During a six

11 week intervention participants consumed a high or low flavonoid cocoa beverage daily. Fatigue and

12 fatigability were measured at three visits (weeks 0, 3 and 6). Feasibility and fidelity were assessed

13 through recruitment and retention, adherence and a process evaluation.

14

15 **Results:** 40 pwMS (10 men, 30 women, age 44 ± 10 yrs) were randomised and allocated to high

16 (n=19) or low (n=21) flavonoid groups and included in analysis. Missing data was <20% and

adherence to intervention of allocated individuals was >75%. There was a small effect on fatigue

18 (Neuro-QoL: effect size $\{ES\}$ 0.04; confidence interval $\{CI\}$ -0.40-0.48) and a moderate effect on

19 fatigability (six-minute walk test: ES 0.45; CI -0.18 - 1.07). There were seven adverse events (four

20 control, three intervention), only one of which was possibly related and it was resolved.

21

22 Conclusion: A flavonoid beverage demonstrates the potential to improve fatigue and fatigability in23 RRMS.

24 Introduction

25 Ninety percent of people with Multiple Sclerosis (pwMS) experience fatigue [1]. Fatigue and

26 fatigability are difficult to treat and greatly affect health related quality of life in pwMS [2].

27 Fatigability is a term derived from the broader definition of fatigue which refers to an inability to

28 maintain both physical and cognitive performance [3]. The aetiology of fatigue in MS is complex

- including possible neural, inflammatory, metabolic and psychological mechanisms [2] [4]. Whilst a
- 30 number of behavioural and drug approaches for fatigue management have been explored, to date the

31 strongest evidence of success in reducing MS related fatigue is from exercise interventions [5] [6].

32 However success is limited and other approaches or combination therapies need to be investigated [7].

33 Dark chocolate containing 70-85% cocoa solids is well known for its high antioxidant and 34 flavonoid content. Over a four week period, dark chocolate consumption has been shown to improve 35 subjective fatigue in those with Chronic Fatigue Syndrome (CFS) [8] [9], and results from a small 36 randomised controlled pilot study using a short-term cocoa intervention suggested an increase in sleep 37 quality and reduction in fatigue [10]. A simple dietary supplement could be implemented alongside 38 other behavioural interventions early after diagnosis as an adjunctive therapeutic approach to support pwMS to manage fatigue. There is currently limited evidence-based guidance to inform tailored 39 40 dietary advice for symptom management in pwMS. Most diet based studies to date have looked at the 41 risk of development or relapses in MS [11] [12]. However, modifiable lifestyle factors strongly correlate to clinically significant fatigue and remain a target for therapeutic trials [13]. To date there 42 43 has been limited research assessing the effect of dietary interventions in pwMS [14], but they have 44 identified good adherence to dietary interventions.

We propose that a flavonoid approach for managing MS related fatigue may be moderately effective, inexpensive, and safe [15] and that it may be exerting its effects by reducing inflammation and oxidative stress. The aim of the current trial was to evaluate the feasibility and estimate potential effect to inform a follow-on substantive trial. The following key objectives were assessed: 1) The acceptance of the study design and diet intervention by participants; 2) Monitoring recruitment rate and the process of randomisation, adherence to the protocol and loss to follow up; 3) Efficiency of data collection methods; 4) The estimate of effect size for fatigue, fatigability and other measures.

- 52
- 53

54 Methods

- 55 This was a parallel, randomised, double-blind placebo-controlled trial to assess feasibility and
- 56 efficacy (Trial registration ISRCTN: 69897291; Ethical approval National Research Ethics Service
- 57 {Solihull West Midlands} reference: 199515). Oxford Brookes University acted as sponsor and the
- 58 study was conducted in accordance with the Declaration of Helsinki.
- 59

60 Recruitment

- 61 Recruitment was through neurology clinics in the Thames Valley, UK. In addition, local MS Society
- branches were made aware of the trial and given contact details, and an advertisement for the study
- along with the participant information sheet (PIS) was made available on the MS Society website.
- 64 Individuals were able to self-refer to the study by contacting the researchers.
- 65
- 66 Setting

67 The intervention took place in the home of each participant. All testing took place at Oxford Brookes

68 University (OBU), Oxford, UK except for optional home visits at week 3. Assessments took place

between 7.30 and 10 am and the intervention lasted a total of 6 weeks with three testing visits

- 70 (baseline, week 3 and 6).
- 71

72 Randomisation and allocation

73 After recruitment, participants were allocated the next available study number by the blinded assessor.

- 74 The study number related to a computer-generated randomisation list held by the principle
- rs investigator and randomised individuals (1:1) into the intervention or the control group. The
- randomisation list used minimisation to balance groups for gender and if individuals were on disease

77 modifying treatments (DMTs) at baseline. The list provided a three digit code that related to a code on

- 78 identical pre-package sachets (made up by a co-investigator) containing either intervention or control
- 79 cocoa. The sachets were then dispensed to the participant. The intervention began three days after
- 80 baseline. Group allocation was concealed throughout the study and analysis.
- 81

82 *Eligibility*

- Eligibility criteria were: adults aged ≥ 18 years with a <10 year clinical diagnosis of RRMS, either treatment naïve or taking first line DMTs (supplementary file 1), no relapse or sudden change in MS symptoms within the previous three months, no contraindications to providing a blood sample or tolerating the cocoa drink, fatigue greater than 4 out of 7 on the Fatigue Severity Scale (FSS) [16], had no other conditions that may be associated with fatigue (e.g. anaemia), not on medication for the treatment of depression, an Expanded Disability Status Scale (EDSS) score of < 4.5 [17], sufficient mental capacity to consent, able to walk with or without a walker for at least 16 meters, no condition
- 90 affecting the central nervous system other than MS (migraine and headache were allowed), not

91 pregnant or lactating and no objection to the researchers contacting their general practitioner (family92 doctor) and neurologist.

93

94 Intervention

95 Participants were provided with cocoa by the lead researcher at baseline and at week three, and they were asked to consume the drink in their homes daily. Cocoa was consumed after an overnight fast at 96 97 the same time each morning. After the consumption of the drink, they were instructed to wait 30 98 minutes before consuming any other food or beverage and/ or take their medication. Participants were instructed to take their medication and to follow their usual diet for the rest of the day. The cocoa 99 100 drinks (intervention and control) were designed to differ only in flavonoid content (low versus high 101 flavonoid; supplementary file 2). Cocoa powder was provided to participants in air tight individual 102 sachets. They were asked to add the sachet content to a mug and to add heated rice milk prior to 103 consuming the drink. Instructions on preparation were provided to ensure all participants followed the 104 same protocol. Unused cocoa powder was collected by the researcher at the next assessment.

105

106 *Outcomes*

107 The primary aim was to assess feasibility of the dietary intervention in terms of recruitment rate and

108 the process of randomisation, adherence to the protocol and loss to follow up, safety and process. We

109 documented adverse events (AEs). Duration of participation and dropout from the intervention were

also recorded. Appropriateness of data collection methods was determined through completion of

111 questionnaires and missing data, and through the process evaluation, and estimates of effect {effect

sizes (ES) and confidence intervals (CI) were calculated for the measures and demographics were

113 collected at baseline.

114

115 *Fatigue and fatigability*

116 Throughout the six-week intervention participants were asked to rate their level of fatigue on a

numerical rating scale (NRS) through daily 'fatigue texts' sent at 10:00, 15:00 and 20:00 every day,

rating their fatigue between 1-10 (10 worst). They replied to the text message of 'on a scale from 1-

119 10, with 1 being no fatigue and 10 being the worst fatigue you have experienced, how fatigued are

120 you at the current time?'. They did this at 10 am, 3 pm and 8 pm every day for six weeks. Fatigability

- 121 was measured at baseline and week 6 using the six minute walk test (6MWT) [18]. Participants were
- asked to walk at their normal, comfortable walking pace back and forth on a measured 16-metre track
- in a University corridor. Distance walked was measured. At baseline, week 3 and 6 the levels of
- subjective fatigue experienced over the past seven days were measured using the Neuro-QOL short
- form questionnaire [19]. The Adult Memory and Information Processing Battery (AMIBP) [20] was
- used to measure cognitive fatigue. The AMIPB required the second highest number in each row to be

- circled, with 15 rows of five double digit numbers. Participants had two minutes and their attemptswere timed, with incorrect answers being noted.
- 129

130 Questionnaires administered at baseline, week 3 and 6 were: the Physical Activity Scale for the

131 Elderly (PASE) [21], EQ5D-5L [22], Preference-Based Multiple Sclerosis Index (PBMSI) [23] and

the Hospital Anxiety and Depression Scale (HADS) [24]. Demographic information was collected. A

- previously published protocol paper gives detail about each measure [25]. Activity was monitored
- 134 with seven-day wrist worn accelerometers (Axivities ®) prior to, and over two separate weeks of the
- trial (week 2-3 and 5-6).
- 136
- Blood markers of inflammation were measured including: TNF-alpha, reduced glutathione, a markerof antioxidant status and lipid peroxidation.
- 139

140 Detailed description of measures can be found in supplementary file 1.

141

142 *Process evaluation*

143 Upon exiting the study at week 6, each participant was interviewed about the intervention process,

ease of adherence, tolerance and acceptability of the flavonoid drink and the collection of outcome

- 145 measures. Participants were asked their opinion on the importance of the research question proposed
- to inform future trials. The thirteen topics used included difficulties with intervention delivery,
- scheduling of assessments and outcome measure acceptability and suggestions on how to improve the
- 148 intervention process. A proportion of the data (20%) was coded by two different team members to
- 149 check on reliability of the coding scheme. Transcripts of interviews were examined to identify themes
- and categories. Codes were applied to these broad themes, which were then broken down further into
- sub-codes. Agreement on concepts and coding by blinded assessors were sought between two
- 152 members of the research team to ensure reliability.
- 153

154 Analysis

- 155 Feasibility was analysed through evaluation of eligibility, recruitment and retention [26].
- 156 Completeness of outcome measures was reported and 80% was set as a criterion for success.
- 157 Retention was measured by the proportion of participants who were lost to follow-up. Successful
- adherence to the intervention was defined as at least 75% of the participants having completed cocoa
- 159 consumption. Further aspects of adherence were measured by the percentage of fatigue texts
- 160 completed by participants.

Primary analysis followed the intention to treat principal utilised the complete case data set.
Results were presented using point estimates and 95% confidence intervals. For the fatigue texts the
fatigue NRS was calculated as the area under the curve (AUC) for each group, ignoring area beneath

- 164 the baseline, and was calculated geometrically [27]. Data was transformed to improve model fit, or 165 different regression approaches were used (e.g. Negative Binomial, or Poisson regression). The results 166 for the 6MWT are reported as mean \pm SD and for the comparison of baseline and post-intervention as 167 mean difference ± standard error [(SE); 95% (CI)]. A Linear Mixed Model (LMM) was used to differences between groups throughout all time points. Alternatively and wherever the variables were 168 categorical, such as the EQ5D-5L sub categories, a generalized estimating equation (GEE) with 169 170 appropriate distributions (e.g. Negative Binomial) method was implemented. Both methods used SAS/STAT 14.3. Fatigue and fatigability measures including the Neuro-QoL short form fatigue, the 171 6MWT and the AMIPB were further analysed to determine difference between responders and non-172 responders and relative risk scores then calculated. Responders on the NeuroQol, for both the control 173 174 and intervention groups, were classified as those who had a clinically meaningful change of 10 points 175 out of 100 (with the questionnaire total score converted from an original total of 40 between baseline 176 and week 6. Responders on the 6MWT were classified as those who had a minimally important 177 change (MIC) in covered distance of 21.6m [27] between baseline and week 6. 178 Data over three time points for activity data was analysed using a Freidman's test and between group effects were calculated using a Mann-Witney test. Process evaluation included 179 frequencies for adhering to the intervention, session content and progression which was analysed 180
- 181 descriptively with confidence intervals and regression where possible. A standard content analysis

techniques were employed.

184	Results
185	
186	Between May 2016 and August 2017, 40 pwMS were recruited from four neurology clinics including:
187	Oxford University Hospitals NHS Trust (John Radcliffe Hospital site), Milton Keynes hospital, Royal
188	Berkshire hospital or Buckingham hospital or through advertisements and online media (MS Society
189	webpage and MS Trust Facebook page).
190	
191	Figure 1 shows participant flow. It was not possible to determine the total number of people screened.
192	
193	
194	
195	Feasibility
196	Fifty-three people showed an initial interest in the trial, but decided not to take part due to: not having
197	enough time to take part in the trial, did not like chocolate, or were unable to take part in nutrition
198	trials due to being on weight loss programs or having gastric surgery. All but one person consumed
199	the cocoa with rice milk (one consumed almond milk). One person discontinued the control
200	intervention but was not lost to follow up and one person consented to be on the trial but decided not
201	to consume the cocoa from the start of the intervention. Adherence to intervention overall was 100%
202	(19/19) for the intervention group and 90% $(19/21)$ for the control group. Missing data from NRS was
203	less than 20% of total responses, but reporting did drop in week 6. Blood measures were only
204	achieved in 20 participants (after a maximum of three attempts). Overall missing data for secondary
205	measures was less than 20%. There were seven AEs during the trial, caused by worsening fatigue,
206	feelings of nausea, or a general feeling of being unwell. AEs were considered unlikely to be related
207	(five), possibly related but expected/ resolved (one) and not related to the intervention (one). Four
208	AEs were associated with the control cocoa and three with the high flavonoid cocoa. There were no
209	incidences of un-blinding of the researcher nor participant. Five out of 40 people were seen at home at
210	week 3.
211	Demographic and clinical data are shown in Table 1. There were no significant differences
212	for demographics between the groups at baseline (p>0.05).
213

220 Table 1. Demographic information at baseline for both groups

221

Values are means ± standard deviations, or total number of people in () considering the percentage of
the total sample population. FSS and Barthel Index totals are reported as medians ± ranges. An
independent t-test was used to compare means for age, BMI, PASE. A Mann-Witney U test was used
to compare medians for FSS and BI for non-parametric measures to determine differences between
the intervention groups. A chi-squared test was used to compare means for nominal data. There were
no significant differences between groups for any baseline measures (p>0.05).

257	Outcome measures
258	
259	Between group effect sizes were considered from all three assessments points. Efficacy potential of
260	fatigue and feasibility was determined. A breakdown of the outcome measures is shown in Table 2.

b. Effect sizes and CI's are Cohen's d, based on non-central t distributions of least squares means differences for continuous variables, using SAS 9.4 and Cliff's delta, for categorical variables, using R 3.5.

c. Relative risks were calculated for measure of fatigue and fatigability for responders versus non responders.

290 [Insert Table 3]

291 292

Table 3. Physical activity levels (reported in minutes per day on average) using an accelerometer watch prior to
 the intervention, between 9 to 16 days (3 weeks) into the intervention and between 35 to 42 days(6 weeks) at the
 end of the intervention, broken down into sedentary light moderate and vigorous classification.

Vales are means ± SE. Total activity for each participant was broken down into sedentary, light, moderate and
 vigorous and average for all participants in each group, over each 7-day time period.

312 313

314 *Fatigue and fatigability*

315 Fatigue was further analysed to determine difference between responders and non-responders. There

- 316 was no difference in means between groups (p>0.05) yet the Relative Risk (RR) for those who
- responded and therefore had improved fatigue in the intervention group (11 out of 19 responders) to
- the control group (8 out of 20 responders) was 1.45. The AMIPB was assessed in a similar way with a
- change in 1 SD of an improvement in 11.5 seconds considered clinically meaningful. Based on these
- 320 criteria only one person improved in the intervention group and no one in the control group and
- 321 therefore a RR was not calculated.

- There was a medium effect size for distance walked in six minutes (0.45 {CI 0.18-1.07}) between the groups with the intervention showing a larger increase in the metres walked in 6 minutes after the intervention (Table 2). The RR for responders in the intervention group compared to control was 1.80 in favour of the intervention group.

Process evaluation

Both groups had similar positive experiences about the scheduling of the assessments. 13/19 in the intervention vs 18/20 people in the control indicated no impact of the measurement instruments used on weekly routine over the six weeks. Similar numbers in both groups identified that the outcome measures were acceptable. Randomisation: Most comments from both groups indicated acceptance towards the process of randomisation. Taste: Similar numbers (8/19 intervention vs 9/20 control) reported positive comments about the taste of the cocoa. Procedures and routine of preparing the *drink:* A few individuals in both groups identified that it was inconvenient to wait for food after drink consumption (4/19 intervention vs 3/20 control), and that the process did not always fit in with their lifestyle e.g., traveling. Other individuals (15/19 intervention vs 17/20 control) identified that they worked it into a routine. Continuation of consuming the drink: half of both groups (9/19 intervention vs 11/20 control) said they would continue the drink if offered. A further four people in both groups said they would continue if it was beneficial or if they could implement their own routine.

350 Discussion

351 PwMS engaged with the dietary intervention, with fatigue and fatigability measures responding more 352 in the intervention group with effect sizes calculated. The current study was shown to be feasible and 353 well received by pwMS, with high adherence to the intervention and excellent data completion. Our 354 study establishes that the use of dietary interventions is feasible and may offer possible long-term 355 benefits to support fatigue management, by improving fatigue and walking endurance. We further 356 propose that considering the possible anti-inflammatory mechanism, flavonoids may be used as an 357 adjunctive approach alongside other therapeutic interventions and suggest the possible benefit of such 358 combined approaches for fatigue management. However further full powered trials would need to be 359 performed.

The time post diagnosis was extended from five to ten years in order to recruit to target (n =360 361 40). Adherence (>75%), retention and amount of missing data (<80%) were within the acceptable 362 ranges. Most missing data was from the NRS texts over the six weeks which is not surprising as this 363 was the most time-consuming part of the assessment. Completion was still above 80% of total with 364 the first five weeks, with week six showing the most missing data. Mild AEs have previously been reported when consuming high flavonoid cocoa including nausea and vomiting, gastrointestinal 365 366 disturbances and headaches [28]. The AEs reported in the current trial did not cause any safety 367 concerns and were similar between groups.

368 This is the first study to suggest the potential for fatigability being improved through a 369 6MWT after six weeks of a flavonoid intervention, with a moderate effect size. In the current study 370 the intervention showed a MIC over time with 33.7m (SE: 8.4) in contrast to the control group 10.2m 371 (SE: 9.6). Fatigue correlates with a decrease of physical endurance [29] and walking speed [30] and 372 therefore a treatment targeting fatigue could also improve walking performance. Flavonoid have been 373 found to increase cerebral blood flow by inducing widespread stimulation of brain perfusion, and this 374 could also influence mood, cognitive performance, fatigue perception and ability to perform specific 375 movement tasks [31]. When considering other symptoms, pain was shown to improve in the flavonoid 376 group over the six weeks as measured by the EQ5D-5L with a moderate effect size. The antioxidant 377 properties of flavonoids are thought to lesson neuropathic pain by alleviating oxidative stress and thus 378 reducing neuron damage caused by lipid peroxidation. [32]. We did not measure objective measures 379 of pain in this trial and therefore further research is warranted to explore the pain improvement. 380 Indeed previous research has pointed towards higher motivation in physical activity in pwMS when symptoms such as pain were improved [33]. This may also allow pwMS to become more active and 381 382 mobile, as noted by the improvements on the 6MWT.

The process evaluation revealed that overall the trial was well accepted, with the timing of assessments and the outcome measures being convenient and low burden, respectively and the participants in both groups found the taste of the cocoa enjoyable, or noted it as neither tasty nor unacceptable. In both groups the blinding and randomisation process were accepted, and a majority of 387 pwMS in both groups declared their willingness to continue consuming the cocoa long term,

388 especially if benefits to fatigue were found. However findings around the preparation of the drink and/

or scheduling the timing of drink consumption into ones routine are factors to consider for futuretrials.

391

392 Limitations

393 As a feasibility study a powered investigation using a sample size of 80 is now needed. For blood 394 measures, the lack of ability of the phlebotomist to collect blood from several of the participants led to missing data. From the data collected, there were small effect sizes in blood indicators, apart from 395 lipid peroxidation which showed a moderate effect size and therefore this area needs further 396 397 investigation. The NRS fatigue data was analysed as a total whole change over the six weeks, and 398 therefore more sensitive analysis may have discovered changes within the six weeks. Fatigue may be 399 both physical and cognitive and coexists with and is impacted by a number of factors including 400 anxiety and depression. This study measured a number of these factors including: motor (6MWT) and 401 cognitive (AMIPB) fatigue, and anxiety and depression (HADS) which could be further investigated in a study powered for this. In this pilot we set out to reduce variability from these factors where 402 403 possible, for example we excluded individuals with a clinical diagnosis or receiving treatment for 404 depression (such as individuals on antidepressants)

405

It should be considered that, while we used a wide range of recruitment methods reducing the risk of
recruitment bias, participants were recruited from affluent areas of the UK. Acknowledging this
limitation, we nevertheless propose the responses in outcome measures are largely generalizable to
relatively healthy pwMS.

410

411 Conclusion

412

The use of dietary approaches to reduce fatigue and associated factors in pwMS may be an easy, safe and cost effect way to impact on quality of life and independence, allowing people to feel more in control of their condition. A full evaluation including wider geography, longer follow up and cost effectiveness is now indicated. This technology has the potential to be implemented in the UK and worldwide, and alongside other rehabilitation including exercise, DMTs and physiotherapy.

Figure 1 Flow of recruitment legend: The screening and enrolment process for a 6 week randomised
double-blind placebo-controlled feasibility trial in people with Multiple Sclerosis. A total of 40 people
were included in the final analysis, and reasons for not receiving the allocated intervention (cocoa

422 drink) and discontinuation are presented.
