Limit Operators, Compactness and Essential Spectra on Bounded Symmetric Domains

Raffael Hagger*

April 12, 2018

Abstract

This paper is a follow-up to a recent article about the essential spectrum of Toeplitz operators acting on the Bergman space over the unit ball. As mentioned in the said article, some of the arguments can be carried over to the case of bounded symmetric domains and some cannot. The aim of this paper is to close the gaps to obtain comparable results for general bounded symmetric domains. In particular, we show that a Toeplitz operator on the Bergman space A_ν^p is Fredholm if and only if all of its limit operators are invertible. Even more generally, we show that this is in fact true for all band-dominated operators, an algebra that contains the Toeplitz algebra. Moreover, we characterize compactness and explain how the Berezin transform comes into play. In particular, we show that a bounded linear operator is compact if and only if it is band-dominated and its Berezin transform vanishes at the boundary. For $p = 2$ “band-dominated” can be replaced by “contained in the Toeplitz algebra”.

Keywords: Toeplitz operators, Bergman space, bounded symmetric domains, compactness, essential spectrum, limit operators, band-dominated operators, essential norm

1 Introduction

In the introduction of [16] it was mentioned that “similar results are expected to hold for more general domains” and that “there are some open problems in the most general case”. In short, the aim of this paper is to solve these open problems and thus prove the “similar results”. As it turns out, the solution not only generalizes the domain, but also the set of eligible operators.

Before we jump into details, let us first recall the basic setting. Let Ω denote a bounded symmetric domain in its Harish-Chandra realization and let $L_\nu^p := L^p(\Omega, v_\nu)$ denote the corresponding L^p -space for some weighted Lebesgue measure v_ν and $p \in (1, \infty)$. Now consider the (closed) subspace of holomorphic functions $A_\nu^p \subset L_\nu^p$ and assume that there is a bounded projection P_ν onto A_ν^p . Then for every bounded function $f: \Omega \rightarrow \mathbb{C}$ we may consider the corresponding Toeplitz operator, which is defined by

$$T_f g = P_\nu(f \cdot g)$$

for $g \in A_\nu^p$. Denote by $\mathfrak{T}_{p,\nu}$ the Banach algebra generated by all such Toeplitz operators.

*Institut für Analysis, Leibniz Universität, 30167 Hannover, Germany, raffael.hagger@math.uni-hannover.de

A natural (and non-trivial) question to ask is under which conditions a Toeplitz operator T_f is compact (e.g. [2, 11, 22, 23, 27, 28, 31]). For $p = 2$ a satisfactory answer was given by Engliš in [11, 12], namely, T_f is compact if and only if the Berezin transform of f vanishes at the boundary. In fact, Engliš showed a little bit more. He showed that if A can be written as a finite sum of finite products of Toeplitz operators, then A is compact if and only if the (generalized) Berezin transform $\mathcal{B}(A)$ vanishes at the boundary. This result gives rise to the question whether this is true for all bounded linear operators on A_ν^p . One direction is actually quite simple: If A is a compact operator on A_ν^p , then $\mathcal{B}(A)$ vanishes at the boundary. However, the other direction turns out to be wrong (see e.g. [2]). This suggests that there is some condition missing here. For $p = 2$ we observe that the ideal of compact operators has to be fully contained in $\mathfrak{T}_{2,\nu}$ because $\mathfrak{T}_{2,\nu}$ is an irreducible C^* -algebra and contains non-trivial and hence all compact operators. In the case of the unit ball \mathbb{B}^n , Suárez ([28], see [22] for the weighted case) proved that this remains true for arbitrary $p \in (1, \infty)$. Hence the new conjecture would read “ A is compact if and only if $A \in \mathfrak{T}_{p,\nu}$ and $\mathcal{B}(A)$ vanishes at the boundary”. For the unit ball this was shown in [22, 28] and it is widely conjectured that this holds for arbitrary bounded symmetric domains (e.g. in [23]). We now show this conjecture in the case $p = 2$ and present an alternative description for general p by using band-dominated operators, which were introduced by the author in [16]. More precisely, we show that a bounded linear operator on A_ν^p is compact if and only if it is band-dominated and its Berezin transform vanishes at the boundary:

Theorem A. *An operator $K \in \mathcal{L}(A_\nu^p)$ is compact if and only if K is band-dominated and*

$$\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0.$$

Using the argument above, “band-dominated” can be replaced by “contained in the Toeplitz algebra” for $p = 2$:

Corollary. *An operator $K \in \mathcal{L}(A_\nu^2)$ is compact if and only if $K \in \mathfrak{T}_{2,\nu}$ and $\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0$.*

In a similar vein Fredholmness of a band-dominated operator can be characterized. Using the techniques developed in [16], we show that a band-dominated operator is Fredholm if and only if all of its limit operators are invertible, where limit operators occur as strong limits of certain operator nets (see Section 4 for a precise definition). One of the key parts here is to actually show the existence of these strong limits. For Toeplitz operators on the unit ball this was done in [22, 28]. However, the proof there involves some direct computations, which are not accessible in the case of general bounded symmetric domains. We thus use the theory of band-dominated operators once again to show the existence of these limit operators. As a bonus, we obtain existence for all band-dominated operators rather than just the Toeplitz algebra. After the existence is settled, we follow the lines of [16] to obtain our next main result:

Theorem B. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then the following are equivalent:*

- (i) *A is Fredholm,*
- (ii) *A_x is invertible for all $x \in \beta\Omega \setminus \Omega$ and $\sup_{x \in \beta\Omega \setminus \Omega} \|A_x^{-1}\| < \infty$,*
- (iii) *A_x is invertible for all $x \in \beta\Omega \setminus \Omega$,*

Here, $\beta\Omega$ denotes the Stone-Čech compactification of Ω and the operators A_x are the limit operators of A . It is worth mentioning that a similar result was also obtained for the Fock space in [15].

As observed in [16], the Toeplitz algebra is contained in the set of band-dominated operators (see Section 3 and Definition 12 for the precise statement) and thus all of the above can be applied to Toeplitz operators. At this point we should probably mention that we use slightly different conventions here than used in previous work. Most importantly, we replaced the compactification of Ω that labels our limit operators. In [16, 22, 24, 28] and also in [4, 15] the maximal ideal space of bounded uniformly continuous functions was used. In this paper we use the Stone-Čech compactification¹ instead to simplify a few arguments. It is then easy to see that one can use smaller compactifications if the operator permits. More precisely, if all limit operators of A with respect to another compactification exist, then the same results hold with the Stone-Čech compactification replaced by the new compactification. Informally, the more complicated the operator in question behaves towards the boundary, the more complicated compactifications we need. We note that the authors of [23] also used the Stone-Čech compactification to show convergence of the operator nets, but there was no need to actually label the limit operators at that point. Furthermore, we use a slightly different definition for limit operators here. This change turns out to be merely cosmetic and is certainly just a matter of taste. We refer to Remark 7 for a short discussion.

Last but not least, we discuss some applications of Theorem B. The simplest case one could imagine would be if every limit operator of an operator A was just a multiple of the identity. We show that this happens if and only if the (generalized) Berezin transform of A has vanishing oscillation at the boundary. If this is the case, the essential spectrum of A is equal to the image of the Berezin transform $\mathcal{B}(A)$ restricted to the Stone-Čech boundary of Ω . In particular, this applies to Toeplitz operators whose symbols have vanishing mean oscillation at the boundary:

Corollary. *Let $f \in \text{VMO}_{\partial}(\Omega) \cap L^{\infty}(\Omega)$. Then*

$$\text{sp}_{\text{ess}}(T_f) = \tilde{f}(\beta\Omega \setminus \Omega) = \bigcap_{r>0} \overline{\tilde{f}(\Omega \setminus D(0, r))},$$

where f denotes the Berezin transform of f (or equivalently T_f).

The paper is organized as follows. We start with a short introduction to bounded symmetric domains in Section 2. All results in that section are well-known and documented in the literature. In Section 3 we recall the definition and some major results of band-dominated operators, which were established in [16] and are then extensively used throughout this paper. Section 4 then proceeds with the definition of limit operators. In particular, their existence is shown and it will get clear why band-dominated operators are the right objects to consider here. In Section 5 we characterize compactness with the help of limit operators and explain the connections to the Berezin transform. We then follow [16] for the characterization of Fredholmness of band-dominated operators in Section 6. In Section 7 we present some applications to Toeplitz operators.

2 Bounded Symmetric Domains

In this section we provide definitions and basic properties of bounded symmetric domains. All results in this section are well-known and may be found in the literature (e.g. [1, 9, 11, 13, 14, 18, 19, 29, 30, 32]).

¹The Stone-Čech compactification can be seen as the maximal ideal space of bounded continuous functions.

A domain $\Omega \subset \mathbb{C}^n$ is called a bounded symmetric domain if it is bounded and for every $z \in \Omega$ there exists a biholomorphic involution ϕ_z that interchanges 0 and z . A bounded symmetric domain is called irreducible if it is not biholomorphic to a product of two non-trivial domains. The irreducible bounded symmetric domains can be classified as follows²:

- $I_{n,m}$: unit ball of $n \times m$ complex matrices for $n \geq m \geq 1$
- II_n : unit ball of $n \times n$ complex symmetric matrices for $n \geq 2$
- III_n : unit ball of $n \times n$ complex antisymmetric matrices for $n \geq 5$
- IV_n : the Lie ball $\left\{ z \in \mathbb{C}^n : \left| \sum_{j=1}^n z_j^2 \right| < 1, 1 + \left| \sum_{j=1}^n z_j^2 \right|^2 - 2|z|^2 > 0 \right\}$ for $n \geq 5$
- V : the unit ball of 1×2 matrices over the 8-dimensional Cayley algebra
- VI : the unit ball of 3×3 self-adjoint matrices over the 8-dimensional Cayley algebra

By Cartan's classification theorem, these are all possible cases up to biholomorphisms. We may therefore always assume that Ω is convex, circular and centered at the origin. This is usually called the Harish-Chandra realization of Ω . Throughout this paper we will assume that Ω is a irreducible bounded symmetric domain in its Harish-Chandra realization, i.e. Ω is equal to one of the cases $I - VI$. Note that case $I_{n,1}$ is isomorphic to the standard unit ball \mathbb{B}^n of \mathbb{C}^n .

Let $\text{Aut}(\Omega)$ denote the group of all biholomorphic endomorphisms of Ω and $G := \text{Aut}(\Omega)_0$ the connected component of $\text{Aut}(\Omega)$ that contains the identity. Moreover, let K denote the subgroup of linear mappings in G . By Cartan's linearity theorem, K coincides with the subset of elements in G that stabilize the origin. Therefore Ω may also be realized as the quotient G/K via $z \mapsto \phi_z K$.

Another description of bounded symmetric domains Ω can be given in terms of so-called Jordan frames, i.e. there exists a set of \mathbb{R} -linear independent vectors $\{e_1, \dots, e_r\}$ such that every $z \in \mathbb{C}^n$ can be written as $k \sum_{j=1}^r t_j e_j$ with $k \in K$, $t_j \geq 0$ and it holds $z \in \Omega$ if and only if $t_j < 1$ for all $j \in \{1, \dots, r\}$. Such a decomposition is called a polar decomposition. The numbers t_j are unique up to permutation and do not depend on the chosen Jordan frame. In particular, the positive integer r is an invariant and called the rank of Ω . In case of the unit ball \mathbb{B}^n the rank is 1 and K is equal to the full unitary group $U(n)$, i.e. the polar decomposition is just the usual one with $t_1 = |z|$ and e_1 an arbitrary unit vector.

Besides the rank r , there are other geometric invariants of Ω . These include the complex dimension n , the numbers a, b , which have to do with root multiplicities of the Lie algebras associated with G and K , and the genus $g := a(r-1) + b + 2$. In fact, the triple (r, a, b) determines the bounded symmetric domain Ω uniquely. However, we do not really need the exact values of these invariants in this paper. We thus refer to [11] for a list of numbers.

Using this polar decomposition, we can define the so-called Jordan triple determinant $h: \mathbb{C}^n \times \mathbb{C}^n \rightarrow \mathbb{C}$, which is uniquely determined by the diagonal

$$h(z, z) = \prod_{j=1}^r (1 - t_j^2)$$

²The order of II_n and III_n is sometimes interchanged. The restrictions on n and m are due to the fact that in small dimensions some of the domains are not irreducible or isomorphic to another domain in the list, e.g. $I_{1,1}$, II_1 , III_2 and IV_1 all describe the unit disk.

and the requirement that h is holomorphic in the first and antiholomorphic in the second argument. In fact, $h = h(z, w)$ is a polynomial in z and \bar{w} . This polynomial has a lot of important properties that we will use frequently in this paper. Most of them follow immediately from the definition and/or some complex analysis. Here is a quick summary:

- (i) $|h(z, w)| > 0$ for all $z \in \bar{\Omega}$, $w \in \Omega$
- (ii) $h(z, z) = 0$ for all $z \in \partial\Omega$
- (iii) $h(z, 0) = 1$ for all $z \in \mathbb{C}^n$
- (iv) $h(w, z) = \overline{h(z, w)}$ for all $w, z \in \mathbb{C}^n$
- (v) $h(kz, kw) = h(z, w)$ for all $w, z \in \mathbb{C}^n$, $k \in K$

Using the Jordan triple determinant, we may define a Riemannian metric on Ω as follows:

$$g_{ij}(z) := -g \frac{\partial}{\partial z_i} \frac{\partial}{\partial \bar{z}_j} \log h(z, z).$$

The integrated form of this metric will be denoted by $\beta(\cdot, \cdot)$ and is called the Bergman metric on Ω . Note that β is unbounded, i.e. $\beta(0, z) \rightarrow \infty$ as $z \rightarrow \partial\Omega$. For $\Omega = \mathbb{B}^n$ this metric is given by the usual hyperbolic metric on \mathbb{B}^n .

The metric space (Ω, β) satisfies a certain local finiteness condition, which can be formulated as follows. There is a fixed integer N such that for every $t \in (0, 1)$ there is a disjoint cover of Ω by Borel sets $(B_{j,t})_{j \in \mathbb{N}}$ satisfying

- for every $z \in \Omega$ the set $\{j \in \mathbb{N} : \text{dist}_\beta(z, B_{j,t}) \leq \frac{1}{t}\}$ has at most N elements,
- there is a constant $C(t)$ such that $\text{diam}_\beta(B_{j,t}) \leq C(t)$ for every $j \in \mathbb{N}$.

Setting $\Xi_{j,t,k} := \{z \in \Omega : \text{dist}_\beta(z, B_{j,t}) \leq \frac{k}{3t}\}$ for $k = 1, 2, 3$, we can obtain a subordinate partition of unity consisting of functions $\varphi_{j,t} : \Omega \rightarrow [0, 1]$ satisfying

- (a) $\sum_{j=1}^{\infty} \varphi_{j,t}(z) = 1$ for all $z \in \Omega$,
- (b) $\text{supp } \varphi_{j,t} = \Xi_{j,t,1}$ for all $j \in \mathbb{N}$, $t \in (0, 1)$,
- (c) $|\varphi_{j,t}(z) - \varphi_{j,t}(w)| \leq 6Nt\beta(z, w)$ for all $w, z \in \Omega$, $j \in \mathbb{N}$ and $t \in (0, 1)$.

Similarly, we may obtain functions $\psi_{j,t} : \Omega \rightarrow [0, 1]$ satisfying

- (d) $\psi_{j,t}(z) = 1$ for all $z \in \Xi_{j,t,2}$, $j \in \mathbb{N}$ and $t \in (0, 1)$,
- (e) $\text{supp } \psi_{j,t} = \Xi_{j,t,3}$ for all $j \in \mathbb{N}$ and $t \in (0, 1)$,
- (f) $|\psi_{j,t}(z) - \psi_{j,t}(w)| \leq 3t\beta(z, w)$ for all $w, z \in \Omega$, $j \in \mathbb{N}$ and $t \in (0, 1)$.

An explicit construction of these functions can be found in [16, Section 3]. We remark that in the printed version of [16] there is an incorrect reference for the existence of the integer N . The correct reference is [8] and was corrected in a later version. The number $N - 1$ is called the asymptotic dimension of the metric space and studied in coarse geometry. We refer to [7] for equivalent

definitions and an overview of the whole subject, also mentioning the result of [8] that we need here.

For $z \in \Omega \setminus \{0\}$ we now consider the geodesic reflection in the midpoint between 0 and z (with respect to β , of course). This defines an isometric and involutorial biholomorphism, which we denote by ϕ_z . Let us fix this notation here once and for all. For $z = 0$ we set $\phi_0(w) = -w$. Moreover, for $\nu > -1$ we define the probability measure³ v_ν as

$$dv_\nu(z) := c_\nu h(z, z)^\nu dv(z),$$

where v denotes the usual Lebesgue measure on \mathbb{C}^n restricted to Ω and c_ν is a suitable constant such that $v_\nu(\Omega) = 1$. It is worth noting that

$$(vi) \quad \int_\Omega h(z, z)^\nu dv(z) < \infty \text{ if and only if } \nu > -1.$$

The Jordan triple determinant h and the measure v_ν transform with respect to ϕ_z as follows:

$$(vii) \quad h(\phi_z(x), \phi_z(y)) = \frac{h(z, z)h(x, y)}{h(x, z)h(z, y)} \text{ for all } x, y, z \in \Omega$$

$$(viii) \quad dv_\nu(\phi_z(w)) = \frac{h(z, z)^{\nu+g}}{|h(w, z)|^{2(\nu+g)}} dv_\nu(w) \text{ for all } w, z \in \Omega$$

For $p \in (1, \infty)$ and $\nu > -1$ let $L_\nu^p := L^p(\Omega, v_\nu)$ denote the usual Lebesgue space of p -integrable functions and A_ν^p the closed subspace of holomorphic functions in L_ν^p . The orthogonal projection P_ν from L_ν^2 onto A_ν^2 is given by

$$(P_\nu f)(z) = \int_\Omega f(w) h(z, w)^{-\nu-g} dv_\nu(w)$$

(see [14, Section 3]). For general p we can try to take the same formula to get a projection onto A_ν^p . However, this integral operator, again denoted by P_ν , is not bounded in general (see [6, Theorem II.8]). Let us call $(\alpha, \nu, p) \in \mathbb{R}^2 \times (1, \infty)$ admissible if the following inequalities are satisfied:

$$p(\alpha + 1) > \nu + 1 + \frac{(r-1)a}{2} > p \frac{(r-1)a}{2}. \quad (2.1)$$

By [16, Proposition 1], this implies that P_α is a bounded projection from L_ν^p onto A_ν^p . Throughout this paper we will always assume that ν is sufficiently large such that (ν, ν, p) is admissible and P_ν is bounded as a consequence. Note that for $\alpha = \nu$ there exist more optimal conditions than (2.1) (e.g. [11, Lemma 9]). Even for $\alpha \neq \nu$ one can actually improve these inequalities. However, we refrain from doing that because (2.1) also assures that we can use the Rudin-Forelli estimates (i.e. [11, Proposition 8]) appropriately. This will get more clear later on.

For $\alpha = \nu$, we can reformulate the condition (2.1) as follows:

$$1 + \frac{(r-1)a}{2(\nu+1)} < p < 1 + \frac{2(\nu+1)}{(r-1)a}. \quad (2.2)$$

Note that $1 + \frac{(r-1)a}{2(\nu+1)}$ is exactly the dual exponent of $1 + \frac{2(\nu+1)}{(r-1)a}$. This of course makes sense as $(L_\nu^p)^* \cong L_\nu^q$ and $(A_\nu^p)^* \cong A_\nu^q$ via the usual dual pairing. Therefore P_ν is bounded on L_ν^p if and only if P_ν^* is bounded on L_ν^q . But P_ν^* is formally the same as P_ν , so that P_ν is bounded on L_ν^p if and

³Sometimes the weight is parametrized by $\lambda := \nu + g$ instead.

only if it is bounded on L_ν^q . In that case we can consider Toeplitz operators $T_f := P_\nu M_f|_{A_\nu^p}$ for bounded functions $f: \Omega \rightarrow \mathbb{C}$ and corresponding multiplication operators M_f . The function f is called the symbol of T_f and M_f . For every bounded symbol f , the corresponding Toeplitz operator is bounded with $\|T_f\| \leq \|P_\nu\| \|f\|_\infty$.

We conclude this section with a few notations. The set of all bounded linear operators on a Banach space X will be denoted by $\mathcal{L}(X)$. The ideal of compact operators will be denoted by $\mathcal{K}(X)$. An operator $A \in \mathcal{L}(X)$ is called Fredholm if the coset $A + \mathcal{K}(X)$ is invertible in the Calkin algebra $\mathcal{L}(X)/\mathcal{K}(X)$. The essential spectrum of A is given by $\{\lambda \in \mathbb{C} : A - \lambda I \text{ is not Fredholm}\}$ and denoted by $\text{sp}_{\text{ess}}(A)$. The usual spectrum is denoted by $\text{sp}(A)$. The closed subalgebra of $\mathcal{L}(A_\nu^p)$ generated by all Toeplitz operators with bounded symbol will be denoted by $\mathfrak{T}_{p,\nu}$. The commutator of two operators $A, B \in \mathcal{L}(X)$ will be denoted by $[A, B] = AB - BA$.

3 Band-dominated operators

In [16] band-dominated operators on L_ν^p were defined. We quickly recall the definition and some basic facts in this short section.

Definition 1. ([16, Definition 6])

An operator $A \in \mathcal{L}(L_\nu^p)$ is called a band operator if there exists a positive real number ω such that $M_f A M_g = 0$ for all $f, g \in L^\infty(\Omega)$ with $\text{dist}_\beta(\text{supp } f, \text{supp } g) > \omega$. The number

$$\inf \{ \omega \in \mathbb{R} : M_f A M_g = 0 \text{ for all } f, g \in L^\infty(\Omega) \text{ with } \text{dist}_\beta(\text{supp } f, \text{supp } g) > \omega \}$$

is called the band width of A . An operator $A \in \mathcal{L}(L_\nu^p)$ is called band-dominated if it is the norm limit of band operators. The set of band-dominated operators will be denoted by BDO_ν^p .

Proposition 2. ([16, Proposition 13])

BDO_ν^p has the following properties:

- (i) It holds $M_f \in \text{BDO}_\nu^p$ for all $f \in L^\infty(\Omega)$.
- (ii) BDO_ν^p is a closed subalgebra of $\mathcal{L}(L_\nu^p)$.
- (iii) If $A \in \text{BDO}_\nu^p$ is Fredholm, then every regularizer B of A is again in BDO_ν^p . In particular, BDO_ν^p is inverse closed.
- (iv) BDO_ν^p contains $\mathcal{K}(L_\nu^p)$ as a closed two-sided ideal.
- (v) It holds $A \in \text{BDO}_\nu^p \iff A^* \in \text{BDO}_\nu^q$ for $\frac{1}{p} = \frac{1}{q} = 1$. In particular, BDO_ν^2 is a C^* -algebra.

(Extensions of) Toeplitz operators are particular examples of band-dominated operators as the following proposition shows. This fact is one of our main motivations to study band-dominated operators.

Proposition 3. Let (α, ν, p) be an admissible triple. Then $P_\alpha \in \text{BDO}_\nu^p$. In particular, $AP_\alpha \in \text{BDO}_\nu^p$ for $A \in \mathfrak{T}_{p,\nu}$.

Proof. Follows directly from (the proof of) [16, Theorem 7]. □

The following estimate will be crucial for subsequent results. It is quite remarkable that it holds simultaneously for all band operators of a fixed band width ω .

Lemma 4. ([16, Lemma 12])

Let $\omega > 0$ and let $a_{j,t}: \Omega \rightarrow [0, 1]$ be measurable functions for $j \in \mathbb{N}$ and $t \in (0, 1)$. If

$$\liminf_{t \rightarrow 0} \inf_{j \in \mathbb{N}} \text{dist}_\beta(a_{j,t}^{-1}(U), a_{j,t}^{-1}(V)) \rightarrow \infty$$

for all sets $U, V \subset [0, 1]$ with $\text{dist}(U, V) > 0$, then for every $\varepsilon > 0$ there exists a $t_0 > 0$ such that for all $t < t_0$ and every band operator of band width at most ω the estimate

$$\sup_{j \in \mathbb{N}} \|[A, M_{a_{j,t}}]\| \leq 3 \|A\| \varepsilon$$

holds.

4 Limit Operators

Let $\lambda \in \mathbb{R}$. Since $h(w, z) \neq 0$ for all $w, z \in \Omega$ and Ω is simply connected ([18, Theorem VIII.7.1]), we can choose a branch of $h(w, z)^\lambda$ such that $h(w, z)^\lambda$ is holomorphic in w and \bar{z} and $h(w, w)^\lambda > 0$ for all $w \in \Omega$. For $z \in \Omega$ we now define $U_z^p \in \mathcal{L}(L_\nu^p)$ by

$$(U_z^p f)(w) = f(\phi_z(w)) \frac{h(z, z)^{\frac{\nu+q}{p}}}{h(w, z)^{\frac{2(\nu+q)}{p}}}.$$

A standard computation shows that U_z^p is a surjective isometry with $(U_z^p)^2 = I$. Moreover, U_z^p maps holomorphic functions to holomorphic functions.

Lemma 5. The map $z \mapsto \phi_z(w)$ is continuous for all $w \in \Omega$.

Proof. Considered as a Riemannian manifold, Ω is simply connected and has non-positive sectional curvature (see [18, Theorem V.3.1, Theorem VIII.4.6, Theorem VIII.7.1]). Thus, by Cartan-Hadamard, the exponential map $\exp_w: T_w\Omega \rightarrow \Omega$ is a homeomorphism for every point $w \in \Omega$. Let z^* denote the midpoint of the geodesic connecting 0 and $z \in \Omega$ (i.e. the point of reflection of the symmetry ϕ_z) and let $w \in \Omega$. Then by definition of the exponential map, we have $\phi_z(w) = \exp_w(2 \exp_w^{-1}(z^*))$. Similarly, $z^* = \exp_0(\frac{1}{2} \exp_0^{-1}(z))$. It follows that $z \mapsto \phi_z(w)$ is indeed continuous. \square

Proposition 6. Let $\beta\Omega$ denote the Stone-Ćech compactification of Ω and $A \in \mathcal{L}(L_\nu^p)$. Consider the map $\Psi_A: \Omega \rightarrow \mathcal{L}(L_\nu^p)$ defined by $\Psi_A(z) := U_z^p A U_z^p$. Then Ψ_A has a weakly continuous extension $\tilde{\Psi}_A: \beta\Omega \rightarrow \mathcal{L}(L_\nu^p)$, i.e. $\tilde{\Psi}_A$ is weakly continuous and $\tilde{\Psi}_A|_\Omega = \Psi_A$.

Proof. Let $f \in L_\nu^p$ be continuous. Then the map $z \mapsto (U_z^p f)(w)$ is continuous for every $w \in \Omega$ by Lemma 5. As U_z^p is an isometry for every $z \in \Omega$, Scheffé's Lemma implies that $z \mapsto U_z^p f$ is continuous in L_ν^p . Therefore, as continuous functions are dense in L_ν^p , $z \mapsto U_z^p$ is strongly continuous by Banach-Steinhaus. This also implies that Ψ_A is strongly continuous, hence weakly continuous. Moreover, we have $\|\Psi_A(z)\| = \|A\|$ for every $z \in \Omega$. As bounded sets are relatively compact in the weak operator topology, Ψ_A admits a weakly continuous extension to $\beta\Omega$. \square

We will use the notation

$$A_x := \tilde{\Psi}_A(x) = \text{w-}\lim_{z \rightarrow x} U_z^p A U_z^p, \quad (4.1)$$

where the limit is understood in the sense of nets, and call A_x a limit operator of A if $x \in \beta\Omega \setminus \Omega$.

Remark 7. Note that in previous work ([16, 22, 28]) limit operators were defined slightly differently, namely by $A_x = \text{w-}\lim_{z \rightarrow x} U_z^p A (U_z^q|_{A_\nu^q})^*$ for $A \in \mathcal{L}(A_\nu^p)$, where q denotes the dual exponent of p . There are two small differences to our definition here. First of all, we start by defining limit operators on L_ν^p and then later restrict them to A_ν^p (see Definition 12). As Proposition 14 shows, this approach results to the same expression as (4.1), but with the additional benefit that we can use tools for band-dominated operators in this approach. More importantly, we choose to not use the adjoint in the definition. Fortunately, the two definitions only differ by an invertible operator independent of A (i.e. the limit of $(U_z^q|_{A_\nu^q})^* U_z^p$, see Proposition 17 below) and they are even the same for $p = 2$. The reason we choose (4.1) as our definition of limit operators is that in this way the behavior under multiplication is somewhat better ($U_z^p U_z^p = I \neq (U_z^q|_{A_\nu^q})^* U_z^p$ for $p \neq 2$). On the other hand, we lose the property $(A_x)^* = (A^*)_x$ and we will see that (4.1) behaves slightly worse under the Berezin transform. As we value multiplication just a little bit more in this paper, we chose to use (4.1) instead of the previous choice. We do not claim that doing it in this way is better in general, though. It is rather a matter of taste and we will come back to this at the end of this section (Proposition 17).

The following properties of limit operators are still intact and follow directly from the properties of U_z^p and/or the weak operator convergence.

Proposition 8. *Let $A, B \in \mathcal{L}(L_\nu^p)$, $\lambda \in \mathbb{C}$ and $x \in \beta\Omega$. Then $(A + B)_x = A_x + B_x$, $(\lambda A)_x = \lambda A_x$ and $\|A_x\| \leq \|A\|$. Moreover, if $(A_n)_{n \in \mathbb{N}}$ is a sequence in $\mathcal{L}(L_\nu^p)$ that converges to A in norm, then $(A_n)_x$ converges to A_x in norm.*

Moreover, limit operators of band-dominated operators are again band-dominated. To show this we need the following auxiliary result that is obtained by a direct computation (see e.g. [16, proof of Proposition 19]):

Proposition 9. *Let $\xi \in L^\infty(\Omega)$. Then $U_z^p M_\xi U_z^p = M_{\xi \circ \phi_z}$ for all $z \in \Omega$.*

Proposition 10. *Let $A \in \text{BDO}_\nu^p$. Then $A_x \in \text{BDO}_\nu^p$ for all $x \in \beta\Omega$. Moreover, if A is a band operator of band width ω , then all operators A_x are band operators of band width at most ω .*

Proof. In view of Proposition 2 and Proposition 8, it suffices to show that limit operators of band operators are again band operators and that the band width does not increase. So assume that $A \in \text{BDO}_\nu^p$ is a band operator of band width ω . Then $M_f A M_g = 0$ for all $f, g \in L^\infty(\Omega)$ with $\text{dist}_\beta(\text{supp } f, \text{supp } g) > \omega$. For $U_z^p A U_z^p$ we observe $M_f U_z^p A U_z^p M_g = U_z^p M_{f \circ \phi_z} A M_{g \circ \phi_z} U_z^p$ and since ϕ_z is an isometry, $\text{dist}_\beta(\text{supp}(f \circ \phi_z), \text{supp}(g \circ \phi_z)) = \text{dist}_\beta(\text{supp } f, \text{supp } g)$. Therefore $U_z^p A U_z^p$ is a band operator of band width ω for all $z \in \Omega$. This argument directly generalizes to weak limits, i.e. every A_x is a band operator of band width at most ω . \square

Lemma 11. *Let $A \in \text{BDO}_\nu^p$ and assume that $\{a_{j,t} : j \in \mathbb{N}, t \in (0, 1)\}$ is a family of measurable functions $a_{j,t} : \Omega \rightarrow [0, 1]$ with $\liminf_{t \rightarrow 0} \inf_{j \in \mathbb{N}} \text{dist}_\beta(a_{j,t}^{-1}(U), a_{j,t}^{-1}(V)) \rightarrow \infty$ for all sets $U, V \subset [0, 1]$ with $\text{dist}(U, V) > 0$. Then*

$$\lim_{t \rightarrow 0} \sup_{x \in \beta\Omega} \sup_{j \in \mathbb{N}} \|[A_x, M_{a_{j,t}}]\| = 0.$$

Proof. First assume that A is a band operator. Then by Proposition 10, every A_x is again a band operator of the same band width. Since also $\|A_x\| \leq \|A\|$ for all $x \in \beta\Omega$ by Proposition 8, the assertion follows from Lemma 4. Now let $A \in \text{BDO}_\nu^p$ be a general band-dominated operator. Then

for every $\varepsilon > 0$ there is a band operator B such that $\|A - B\| < \varepsilon$. Using the above and Proposition 8 again, we get

$$\lim_{t \rightarrow 0} \sup_{x \in \beta\Omega} \sup_{j \in \mathbb{N}} \|[A_x, M_{a_{j,t}}]\| \leq \lim_{t \rightarrow 0} \sup_{x \in \beta\Omega} \sup_{j \in \mathbb{N}} \|[B_x, M_{a_{j,t}}]\| + \lim_{t \rightarrow 0} \sup_{x \in \beta\Omega} \sup_{j \in \mathbb{N}} \|[A_x - B_x, M_{a_{j,t}}]\| < 2\varepsilon. \quad \square$$

Definition 12. We will call an operator $A \in \mathcal{L}(A_\nu^p)$ band-dominated if $AP_\nu \in \mathcal{L}(L_\nu^p)$ is band-dominated. Moreover, we define $A_x := (AP_\nu)_x|_{A_\nu^p}$ for every $x \in \beta\Omega$.

Remark 13. According to Proposition 3, all operators in the Toeplitz algebra $\mathfrak{T}_{p,\nu}$ are band-dominated. We thus emphasize that all subsequent results about band-dominated operators are of course valid for Toeplitz operators and, more generally, for all operators in the Toeplitz algebra.

Proposition 14. Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then for every net (z_γ) in Ω converging to some $x \in \beta\Omega$ the net $U_{z_\gamma}^p A U_{z_\gamma}^p|_{A_\nu^p}$ converges strongly to A_x .

Proof. Let $f \in A_\nu^p$, $B := AP_\nu \in \text{BDO}_\nu^p$ and fix $t \in (0, 1)$. Choose a Lipschitz continuous function $a_t: \Omega \rightarrow [0, 1]$ with compact support, Lipschitz constant t and $\|f - a_t f\| \leq t$. Then

$$\|(B_{z_\gamma} - B_x)f\| \leq \|M_{a_t}(B_{z_\gamma} - B_x)f\| + \|M_{1-a_t}(B_{z_\gamma} - B_x)f\|. \quad (4.2)$$

As $B_{z_\gamma} = U_{z_\gamma}^p A U_{z_\gamma}^p$ maps holomorphic functions to holomorphic functions, we have $B_{z_\gamma} = P_\nu B_{z_\gamma}$ for all γ . By Proposition 6, B_{z_γ} converges weakly to B_x and as weak limits are unique, this also implies $B_x = P_\nu B_x$. As $M_{a_t} P_\nu$ is compact by [16, Proposition 15], the first term in (4.2) tends to 0 as $z_\gamma \rightarrow x$. For the second term we have

$$\begin{aligned} \|M_{1-a_t}(B_{z_\gamma} - B_x)f\| &\leq \| [M_{1-a_t}, B_{z_\gamma} - B_x]f \| + \|(B_{z_\gamma} - B_x)M_{1-a_t}f\| \\ &\leq \| [I - M_{a_t}, B_{z_\gamma} - B_x]f \| + \|B_{z_\gamma} - B_x\| \|M_{1-a_t}f\| \\ &\leq \| [M_{a_t}, B_{z_\gamma} - B_x]f \| + \|B_{z_\gamma} - B_x\| t \\ &\leq 2 \sup_{y \in \beta\Omega} \| [M_{a_t}, B_y]f \| + 2 \sup_{y \in \beta\Omega} \|B_y\| t. \end{aligned}$$

Since a_t is Lipschitz continuous with Lipschitz constant t , the first term tends to 0 as $t \rightarrow 0$ by Lemma 11. The second term may be estimated by $2\|B\|t$ and thus tends to 0 as well. It follows that the second term in (4.2) can be made as small as desired. We conclude that $U_{z_\gamma}^p A U_{z_\gamma}^p|_{A_\nu^p} = B_{z_\gamma}|_{A_\nu^p}$ converges strongly to $B_x|_{A_\nu^p} = (AP_\nu)_x|_{A_\nu^p}$. \square

Similarly as in Proposition 8, the following properties hold for band-dominated operators on A_ν^p . Note that due to the strong convergence we additionally have multiplicativity.

Corollary 15. Let $A, B \in \mathcal{L}(A_\nu^p)$ be band-dominated and $x \in \beta\Omega$. Then $(A + B)_x = A_x + B_x$, $(AB)_x = A_x B_x$ and $\|A_x\| \leq \|A\|$. Moreover, if $(A_n)_{n \in \mathbb{N}}$ is a sequence of band-dominated operators in $\mathcal{L}(A_\nu^p)$ that converges to A in norm, then $(A_n)_x$ converges to A_x in norm.

We also have the following corollary to Proposition 14.

Corollary 16. For all band-dominated $A \in \mathcal{L}(A_\nu^p)$ the map $A_\bullet: \beta\Omega \rightarrow \mathcal{L}(A_\nu^p)$, $x \mapsto A_x$ is bounded and continuous with respect to the strong operator topology. In particular, the two sets $\{A_x : x \in \beta\Omega\}$ and $\{A_x : x \in \beta\Omega \setminus \Omega\}$ are strongly compact.

We conclude this section with an observation that will allow us to use some duality arguments.

Proposition 17. *Let $\frac{1}{p} + \frac{1}{q} = 1$. Then $T_{b_z} := (U_z^q|_{A_\nu^q})^* U_z^p|_{A_\nu^p} \in \mathcal{L}(A_\nu^p)$ is invertible for every $z \in \Omega$. Moreover, if (z_γ) is a net in Ω that converges to some $x \in \beta\Omega$, then $T_{b_{z_\gamma}}$ converges strongly to an invertible operator T_{b_x} and the inverses $T_{b_{z_\gamma}}^{-1}$ converge strongly to the inverse $T_{b_x}^{-1}$.*

Proof. Let $z \in \Omega$. As U_z^p is an isometry, its restriction $U_z^p|_{A_\nu^p}$ is an isometry, too. Since $(U_z^p)^2 = I$ and $U_z^p(A_\nu^p) \subseteq A_\nu^p$, we get $U_z^p(A_\nu^p) = A_\nu^p$, i.e. $U_z^p|_{A_\nu^p}$ is surjective. In particular, $T_{b_z} = (U_z^q|_{A_\nu^q})^* U_z^p|_{A_\nu^p}$ is invertible with

$$T_{b_z}^{-1} = U_z^p(U_z^q|_{A_\nu^q})^*.$$

In fact, we may also compute $(U_z^q|_{A_\nu^q})^*$ explicitly. Let $f \in A_\nu^p \cong (A_\nu^q)^*$ and $g \in A_\nu^q$. Then, via the usual dual pairing and the standard transformation formulas, we obtain

$$\begin{aligned} ((U_z^q)^* f)(g) &= f(U_z^q g) \\ &= \int_\Omega \overline{f(w)} g(\phi_z(w)) \frac{h(z, z)^{\frac{\nu+g}{q}}}{h(w, z)^{\frac{2(\nu+g)}{q}}} dv_\nu(w) \\ &= \int_\Omega \overline{f(\phi_z(y))} g(y) \frac{h(z, z)^{\frac{\nu+g}{q}}}{h(\phi_z(y), z)^{\frac{2(\nu+g)}{q}}} \frac{h(z, z)^{\nu+g}}{|h(y, z)|^{2(\nu+g)}} dv_\nu(y) \\ &= \int_\Omega \overline{f(\phi_z(y))} g(y) \frac{h(y, z)^{\frac{2(\nu+g)}{q}}}{h(z, z)^{\frac{\nu+g}{q}}} \frac{h(z, z)^{\nu+g}}{|h(y, z)|^{2(\nu+g)}} dv_\nu(y) \\ &= \int_\Omega \frac{h(y, z)^{(\frac{2}{q}-1)(\nu+g)}}{h(z, y)^{(1-\frac{2}{p})(\nu+g)}} \overline{f(\phi_z(y))} \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(z, y)^{\frac{2(\nu+g)}{p}}} g(y) dv_\nu(y) \\ &= \int_\Omega \frac{h(y, z)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}}{h(z, y)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}} \overline{(U_z^p f)(y)} g(y) dv_\nu(y). \end{aligned}$$

This implies $(U_z^q|_{A_\nu^q})^* = P_\nu(U_z^p)^* = T_{b_z} U_z^p|_{A_\nu^p}$ with

$$b_z(y) := \frac{h(z, y)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}}{h(y, z)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}},$$

which also explains the notation T_{b_z} , i.e. T_{b_z} is a Toeplitz operator with symbol b_z .

Now let (z_γ) be a net in Ω that converges to some $x \in \beta\Omega \setminus \Omega$. Clearly, there is a subnet that converges to some point $\alpha \in \partial\Omega$ with respect to the Euclidean topology on $\overline{\Omega}$. Assume that there is another subnet that converges to a different point $\beta \in \partial\Omega$. This would imply that every continuous function on $\overline{\Omega}$ would coincide in α and β . As this is not the case, the whole net (z_γ) has to converge to the point α .

As $F(z, y) := b_z(y)$ extends to a continuous function on $\overline{\Omega} \times \Omega$, we obtain that b_{z_γ} converges uniformly on compact sets to $b_\alpha = F(\alpha, \cdot)$. Therefore $T_{b_{z_\gamma}}$ converges strongly to $T_{b_\alpha} =: T_{b_x}$ as $z_\gamma \rightarrow x$. Similarly, $T_{b_{z_\gamma}}^* = T_{b_{z_\gamma}}^-$ converges strongly to $T_{b_x}^* = T_{b_x}^- \in \mathcal{L}(A_\nu^q)$. Moreover, $\|T_{b_z}^{-1}\| \leq \|P_\nu\|$ implies $\|T_{b_z} f\| \geq \|P_\nu\|^{-1} \|f\|$ for all $f \in A_\nu^p$ and $z \in \Omega$. Similarly, $\|T_{b_z}^* g\| \geq \|P_\nu\|^{-1} \|g\|$ for all $g \in A_\nu^q$ and $z \in \Omega$. Taking the limit yields $\|T_{b_x} f\| \geq \|P_\nu\|^{-1} \|f\|$ and $\|T_{b_x}^* g\| \geq \|P_\nu\|^{-1} \|g\|$ for all $f \in A_\nu^p$, $g \in A_\nu^q$, which implies that T_{b_x} is again invertible. $T_{b_{z_\gamma}}^{-1} \rightarrow T_{b_x}^{-1}$ strongly as $z_\gamma \rightarrow x$ follows easily as well. \square

As a corollary we obtain the following important result.

Corollary 18. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated and $\frac{1}{p} + \frac{1}{q} = 1$. Then for every net (z_γ) in Ω converging to some $x \in \beta\Omega$ the net $U_{z_\gamma}^q A^* U_{z_\gamma}^q|_{A_\nu^q}$ converges strongly to $T_{b_x}^{-1}(A_x)^* T_{b_x}$. In particular, $(A^*)_x$ is invertible if and only if A_x is.*

Proof. As $A^* P_\nu = (A P_\nu)^*$ (with the usual identification of $(A_\nu^p)^*$ and A_ν^q), Proposition 2 implies that A^* is band-dominated. By Proposition 14, $U_{z_\gamma}^q A^* U_{z_\gamma}^q|_{A_\nu^q}$ converges strongly to $(A^*)_x$. On the other hand,

$$\left(U_{z_\gamma}^q A^* U_{z_\gamma}^q|_{A_\nu^q} \right)^* = (U_{z_\gamma}^q|_{A_\nu^q})^* A (U_{z_\gamma}^q|_{A_\nu^q})^* = T_{b_{z_\gamma}} U_{z_\gamma}^p A U_{z_\gamma}^p T_{b_{z_\gamma}}^{-1}$$

converges strongly to $T_{b_x} A_x T_{b_x}^{-1}$ by Proposition 17. As strong limits are unique, this implies $((A^*)_x)^* = T_{b_x} A_x T_{b_x}^{-1}$, or equivalently, $(A^*)_x = T_{b_x}^{-1}(A_x)^* T_{b_x}$. \square

5 Compactness

Before we proceed with the characterization of Fredholmness in terms of limit operators, we need to characterize compactness. The next proposition shows that all limit operators of compact operators vanish.

Proposition 19. *Let $K \in \mathcal{L}(A_\nu^p)$ be compact. Then K is band-dominated and $K_x = 0$ for all $x \in \beta\Omega \setminus \Omega$.*

Proof. That K is band-dominated follows immediately from Proposition 2. Proposition 14 thus implies that $U_{z_\gamma}^p K U_{z_\gamma}^p|_{A_\nu^p}$ converges strongly to K_x for every net (z_γ) that converges to $x \in \beta\Omega \setminus \Omega$. Fix $f \in A_\nu^p$ and set $D(w, R) := \{z \in \Omega : \beta(w, z) < R\}$ for $R > 0$ and $w \in \Omega$. Proposition 9 and the fact that $U_{z_\gamma}^p$ is an isometry imply

$$\begin{aligned} \left\| U_{z_\gamma}^p K U_{z_\gamma}^p f \right\| &\leq \left\| U_{z_\gamma}^p K P_\nu M_{\chi_{D(0,R)}} U_{z_\gamma}^p f \right\| + \left\| U_{z_\gamma}^p K P_\nu M_{1-\chi_{D(0,R)}} U_{z_\gamma}^p f \right\| \\ &\leq \|K P_\nu\| \left\| M_{\chi_{D(0,R)}} U_{z_\gamma}^p f \right\| + \|K P_\nu M_{1-\chi_{D(0,R)}}\| \|f\| \\ &= \|K P_\nu\| \left\| M_{\chi_{D(z_\gamma, R)}} f \right\| + \|K P_\nu M_{1-\chi_{D(0,R)}}\| \|f\|. \end{aligned}$$

As $\chi_{D(z_\gamma, R)}$ converges pointwise to 0, the first term tends to 0 for every fixed $R > 0$ as $z_\gamma \rightarrow x$. On the other hand, $1 - \chi_{D(0,R)}$ converges pointwise to 0 as $R \rightarrow \infty$. Therefore $M_{1-\chi_{D(0,R)}}$ converges strongly to 0 and since K is compact, $K P_\nu M_{1-\chi_{D(0,R)}}$ tends to 0 in norm as $R \rightarrow \infty$. Therefore, if R is chosen sufficiently large, the second term can be made as small as desired. We thus conclude $\left\| U_{z_\gamma}^p K U_{z_\gamma}^p f \right\| \rightarrow 0$ as $z_\gamma \rightarrow x$. As this is true for every $f \in A_\nu^p$, $K_x = 0$ follows. \square

Our goal for this section is to show that the converse is true as well, i.e. if $K \in \mathcal{L}(A_\nu^p)$ is band-dominated and $K_x = 0$ for all $x \in \beta\Omega \setminus \Omega$, then K must be compact. For this we need a few auxiliary results.

Proposition 20. *Let $\alpha = (\frac{2}{p}-1)g + \frac{2\nu}{p}$ and assume that (α, ν, p) is admissible. Then $P_\alpha U_z^p = U_z^p P_\alpha$.*

Proof. Using the usual transformation formulas, we get

$$\begin{aligned}
(P_\alpha U_z^p f)(x) &= \int_\Omega f(\phi_z(w)) \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(w, z)^{\frac{2(\nu+g)}{p}}} h(x, w)^{-\alpha-g} dv_\alpha(w) \\
&= \int_\Omega f(y) \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(\phi_z(y), z)^{\frac{2(\nu+g)}{p}}} h(x, \phi_z(y))^{-\alpha-g} \frac{h(z, z)^{\alpha+g}}{|h(y, z)|^{2(\alpha+g)}} dv_\alpha(y) \\
&= \int_\Omega f(y) \frac{h(z, z)^{\frac{\nu+g}{p}} h(y, z)^{\frac{2(\nu+g)}{p}}}{h(z, z)^{\frac{2(\nu+g)}{p}}} \frac{h(x, z)^{-\alpha-g} h(\phi_z(x), y)^{-\alpha-g}}{h(z, y)^{-\alpha-g}} \frac{h(z, z)^{\alpha+g}}{|h(y, z)|^{2(\alpha+g)}} dv_\alpha(y) \\
&= \frac{h(z, z)^{-\frac{\nu+g}{p} + \alpha+g}}{h(x, z)^{\alpha+g}} \int_\Omega f(y) h(y, z)^{\frac{2(\nu+g)}{p} - \alpha-g} h(\phi_z(x), y)^{-\alpha-g} dv_\alpha(y) \\
&= \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(x, z)^{\frac{2(\nu+g)}{p}}} \int_\Omega f(y) h(\phi_z(x), y)^{-\alpha-g} dv_\alpha(y) \\
&= (U_z^p P_\alpha f)(x). \quad \square
\end{aligned}$$

Let $r_t := \sup_{j \in \mathbb{N}} \text{diam}_\beta \text{supp } \varphi_{j,t}$ for $t \in (0, 1)$. By property (b) of the functions $\varphi_{j,t}$, r_t is finite for all t . Similarly as in [16, 17], we define

$$\|A|_F\|_t := \sup \{ \|Af\| : f \in L_\nu^p, \|f\| = 1, \text{supp } f \subseteq D(w, r_t) \cap F \text{ for some } w \in \Omega \}$$

and

$$\|A|_F\| := \sup \{ \|Af\| : f \in L_\nu^p, \|f\| = 1, \text{supp } f \subseteq F \}$$

for $t \in (0, 1)$, $A \in \mathcal{L}(L_\nu^p)$ and a Borel set $F \subseteq \Omega$.

Proposition 21. *Let $A \in \text{BDO}_\nu^p$. Then for every $\varepsilon > 0$ there exists a $t \in (0, 1)$ such that for all Borel sets $F \subseteq \Omega$ and all operators B in the set*

$$\{A\} \cup \{A_x : x \in \beta\Omega \setminus \Omega\}$$

it holds

$$\|B|_F\| \geq \|B|_F\|_t \geq \|B|_F\| - \varepsilon.$$

Proof. The first inequality is clear by definition. For the second inequality we first assume that A is a band operator. Then, by Proposition 10, all limit operators A_x have the same band width as A . Let $B \in \{A\} \cup \{A_x : x \in \beta\Omega \setminus \Omega\}$, $F \subseteq \Omega$ a Borel set and choose $f \in L_\nu^p$ with $\|f\| = 1$ and $\text{supp } f \subseteq F$ such that

$$\|Bf\| \geq \|B|_F\| - \frac{\varepsilon}{2}.$$

Moreover, let $\varphi_{j,t}$ and $\psi_{j,t}$ be as defined in Section 2. Then

$$\left(\sum_{j=1}^{\infty} \left\| BM_{\varphi_{j,t}^{1/p}} f \right\|^p \right)^{1/p} = \left(\sum_{j=1}^{\infty} \left\| BM_{\varphi_{j,t}^{1/p}} M_{\psi_{j,t}} f \right\|^p \right)^{1/p}$$

$$\begin{aligned}
&\geq \left(\sum_{j=1}^{\infty} \|M_{\varphi_{j,t}^{1/p}} Bf\|^p \right)^{1/p} - \left(\sum_{j=1}^{\infty} \|M_{\varphi_{j,t}^{1/p}} B M_{1-\psi_{j,t}} f\|^p \right)^{1/p} \\
&\quad - \left(\sum_{j=1}^{\infty} \|[B, M_{\varphi_{j,t}^{1/p}}] M_{\psi_{j,t}} f\|^p \right)^{1/p}
\end{aligned}$$

by Minkowski's inequality. The first term is exactly $\|Bf\|$ since $\sum_{j=1}^{\infty} |\varphi_{j,t}(z)| = 1$. The second term vanishes if $\text{dist}_{\beta}(\text{supp } \varphi_{j,t}, \text{supp}(1 - \psi_{j,t})) = \frac{2}{3t}$ exceeds the band width of A . The third term can be estimated as

$$\begin{aligned}
\left(\sum_{j=1}^{\infty} \|[B, M_{\varphi_{j,t}^{1/p}}] M_{\psi_{j,t}} f\|^p \right)^{1/p} &\leq \sup_{j \in \mathbb{N}} \|[B, M_{\varphi_{j,t}^{1/p}}]\| \left(\sum_{j=1}^{\infty} \|M_{\psi_{j,t}} f\|^p \right)^{1/p} \\
&\leq N^{1/p} \sup_{j \in \mathbb{N}} \|[B, M_{\varphi_{j,t}^{1/p}}]\|
\end{aligned}$$

because every $z \in \Omega$ is contained in at most N sets $\text{supp } \psi_{j,t}$ and $\|f\| = 1$. Now observe that the functions $\varphi_{j,t}^{1/p}$ satisfy the assumptions in Lemma 4. Indeed, let $U, V \subset [0, 1]$ with $\text{dist}(U, V) > 0$ and $w_{j,t} \in (\varphi_{j,t}^{1/p})^{-1}(U)$, $z_{j,t} \in (\varphi_{j,t}^{1/p})^{-1}(V)$. Clearly, we have $\text{dist}(U^p, V^p) > 0$ as well and therefore

$$\beta(z_{j,t}, w_{j,t}) \geq \frac{1}{6Nt} |\varphi_{j,t}(z_{j,t}) - \varphi_{j,t}(w_{j,t})| \geq \frac{1}{6Nt} \text{dist}(U^p, V^p) \rightarrow \infty$$

as $t \rightarrow 0$. Lemma 4 thus implies that for every $\delta > 0$ there is a $t > 0$ such that

$$\left(\sum_{j=1}^{\infty} \|[B, M_{\varphi_{j,t}^{1/p}}] M_{\psi_{j,t}} f\|^p \right)^{1/p} \leq \delta \|B\| \leq \delta \|A\|.$$

We thus choose $\delta = \frac{\varepsilon}{2\|A\|}$ and obtain

$$\left(\sum_{j=1}^{\infty} \|B M_{\varphi_{j,t}^{1/p}} f\|^p \right)^{1/p} \geq \|Bf\| - \frac{\varepsilon}{2} \geq \|B|_F\| - \varepsilon = (\|B|_F\| - \varepsilon) \left(\sum_{j=1}^{\infty} \|M_{\varphi_{j,t}^{1/p}} f\|^p \right)^{1/p}.$$

This implies, in particular, that there exists a $j \in \mathbb{N}$ such that

$$\|B M_{\varphi_{j,t}^{1/p}} f\| \geq (\|B|_F\| - \varepsilon) \|M_{\varphi_{j,t}^{1/p}} f\|$$

for sufficiently small t . Since $\text{supp}(M_{\varphi_{j,t}^{1/p}} f) \subseteq \text{supp } \varphi_{j,t} \subseteq D(w, r_t)$ for some $w \in \Omega$ by definition, this implies $\|B|_F\|_t \geq \|B|_F\| - \varepsilon$ for all $B \in \{A\} \cup \{A_x : x \in \beta\Omega \setminus \Omega\}$. As t is chosen independently of F (as it is chosen independently of f) and B , the assertion follows for band operators A .

For general band dominated operators the result follows by approximation. Just observe that

$$\begin{aligned}
\|(A - A_n)|_F\|_t &\leq \|(A - A_n)|_F\| \leq \|A - A_n\| \quad \text{and} \\
\|(A_x - (A_n)_x)|_F\|_t &\leq \|(A_x - (A_n)_x)|_F\| \leq \|A - A_n\|.
\end{aligned}$$

□

The next theorem now shows that $\sup_{x \in \beta\Omega \setminus \Omega} \|A_x\|$ is equivalent to $\|A + \mathcal{K}(A_\nu^p)\|$, the quotient norm of $A + \mathcal{K}(A_\nu^p) \in \mathcal{L}(A_\nu^p)/\mathcal{K}(A_\nu^p)$, for all band-dominated operators.

Theorem 22. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then*

$$\frac{1}{\|P_\nu\|} \|A + \mathcal{K}(A_\nu^p)\| \leq \sup_{x \in \beta\Omega \setminus \Omega} \|A_x\| \leq \|A + \mathcal{K}(A_\nu^p)\|.$$

In particular, $K \in \mathcal{L}(A_\nu^p)$ is compact if and only if K is band-dominated and $K_x = 0$ for all $x \in \beta\Omega \setminus \Omega$.

Proof. Let $x \in \beta\Omega \setminus \Omega$, $K \in \mathcal{K}(A_\nu^p)$ and choose a net (z_γ) in Ω that converges to x . As K is compact, we get $K_x = 0$ by Proposition 19. Corollary 15 thus implies

$$\|A_x\| = \|A_x + K_x\| = \|(A + K)_x\| \leq \|A + K\|.$$

As this is true for all $K \in \mathcal{K}(A_\nu^p)$ and $x \in \beta\Omega \setminus \Omega$, the second inequality follows.

For the first inequality we observe that

$$\|AP_\nu + K\| = \sup_{\|f\|=1} \|(AP_\nu + K)f\| \geq \sup_{\substack{f \in A_\nu^p, \\ \|f\|=1}} \|(AP_\nu + K)f\| = \sup_{\substack{f \in A_\nu^p, \\ \|f\|=1}} \|(A + K)f\| = \|A + K|_{A_\nu^p}\|$$

for all compact operators $K: L_\nu^p \rightarrow A_\nu^p$. Thus

$$\|A + \mathcal{K}(A_\nu^p)\| \leq \inf_{K \in \mathcal{K}(L_\nu^p, A_\nu^p)} \|AP_\nu + K\|.$$

We will now show

$$\inf_{K \in \mathcal{K}(L_\nu^p, A_\nu^p)} \|AP_\nu + K\| \leq \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\|. \quad (5.1)$$

This will imply the desired inequality since

$$\|T_{b_x}^{-1} P_\nu\| \leq \sup_{z \in \Omega} \|U_z^p P_\nu (U_z^q)^* P_\nu\| = \sup_{z \in \Omega} \|U_z^p (P_\nu U_z^q P_\nu)^*\| = \sup_{z \in \Omega} \|U_z^p (U_z^q P_\nu)^*\| \leq \|P_\nu\|,$$

where we used that U_z^p and U_z^q are isometries and $U_z^q(A_\nu^q) \subseteq A_\nu^q$. So assume that (5.1) is violated, i.e. that there is an $\varepsilon > 0$ such that

$$\inf_{K \in \mathcal{K}(L_\nu^p, A_\nu^p)} \|AP_\nu + K\| > \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\| + \varepsilon.$$

In particular,

$$\|AP_\nu|_{\Omega \setminus D(0,s)}\| = \|AP_\nu M_{1-\chi_{D(0,s)}}\| = \|AP_\nu - AP_\nu M_{\chi_{D(0,s)}}\| > \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\| + \varepsilon$$

for all $s > 0$ since $P_\nu M_{\chi_{D(0,s)}} \in \mathcal{K}(L_\nu^p, A_\nu^p)$ (see e.g. [16, Proposition 15]). Now, by Proposition 21, there is a $t \in (0, 1)$ such that for all $s > 0$ we have

$$\|AP_\nu|_{\Omega \setminus D(0,s)}\|_t \geq \|AP_\nu|_{\Omega \setminus D(0,s)}\| - \frac{\varepsilon}{2} > \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\| + \frac{\varepsilon}{2}.$$

In particular, for every $s > 0$ we get a $w_s \in \Omega$ such that

$$\left\| AP_\nu M_{\chi_{D(w_s, r_t)}} \right\| \geq \left\| AP_\nu M_{\chi_{D(w_s, r_t) \setminus D(0, s)}} \right\| > \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\| + \frac{\varepsilon}{2}.$$

It is clear that $w_s \rightarrow \partial\Omega$ as $s \rightarrow \infty$ (otherwise we would get 0 at some point in the middle term). Moreover,

$$\begin{aligned} \left\| U_{w_s}^p A(U_{w_s}^q|_{A_\nu^q})^* P_\nu M_{\chi_{D(0, r_t)}} \right\| &= \left\| U_{w_s}^p A(P_\nu U_{w_s}^q P_\nu)^* M_{\chi_{D(0, r_t)}} \right\| = \left\| U_{w_s}^p A(U_{w_s}^q P_\nu)^* M_{\chi_{D(0, r_t)}} \right\| \\ &= \left\| AP_\nu (U_{w_s}^q)^* M_{\chi_{D(0, r_t)}} (U_{w_s}^q)^* \right\| = \left\| AP_\nu M_{\chi_{D(w_s, r_t)}} \right\| \\ &> \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\| + \frac{\varepsilon}{2}, \end{aligned}$$

where we used the fact that both $U_{w_s}^p$ and $U_{w_s}^q$ are surjective isometries, $U_z^q(A_\nu^q) \subseteq A_\nu^q$ and $(U_{w_s}^q)^* M_{\chi_{D(0, r_t)}} (U_{w_s}^q)^* = M_{\chi_{D(w_s, r_t)}}$ (cf. Proposition 9).

As $\beta\Omega$ is compact, (w_s) has a convergent subnet, again denoted by (w_s) , converging to some $y \in \beta\Omega \setminus \Omega$. Proposition 14 and Proposition 17 imply $U_{w_s}^p A U_{w_s}^p|_{A_\nu^q} \rightarrow A_y$ and $T_{b_{w_s}}^{-1} \rightarrow T_{b_y}^{-1}$ strongly and hence

$$\left\| U_{w_s}^p A(U_{w_s}^q|_{A_\nu^q})^* P_\nu M_{\chi_{D(0, r_t)}} \right\| = \left\| U_{w_s}^p A U_{w_s}^p T_{b_{w_s}}^{-1} P_\nu M_{\chi_{D(0, r_t)}} \right\| \rightarrow \left\| A_y T_{b_y}^{-1} P_\nu M_{\chi_{D(0, r_t)}} \right\|$$

since $P_\nu M_{\chi_{D(0, r_t)}}$ is compact. This yields

$$\left\| A_y T_{b_y}^{-1} P_\nu M_{\chi_{D(0, r_t)}} \right\| \geq \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\| + \frac{\varepsilon}{2},$$

which is certainly a contradiction. Thus $\inf_{K \in \mathcal{K}(L_\nu^p, A_\nu^p)} \|AP_\nu + K\| \leq \sup_{x \in \beta\Omega \setminus \Omega} \|A_x T_{b_x}^{-1} P_\nu\|$ and the theorem follows as mentioned above. \square

In [22, 28] the unit ball \mathbb{B}^n was considered and compactness was characterized in terms of the Berezin transform. Using Theorem 22, we can generalize this characterization to bounded symmetric domains Ω . In [23] a similar result was obtained for what the authors call “Bergman-type spaces” in case $p = 2$.

For $\frac{1}{p} + \frac{1}{q} = 1$ we define

$$k_z^{(p)}(w) := \frac{h(z, z)^{\frac{\nu+q}{q}}}{h(w, z)^{\nu+q}}.$$

For $p = 2$ this function is called the normalized reproducing kernel. A quick computation using the Rudin-Forelli estimates [11, Proposition 8] shows that $k_z^{(p)}$ is contained in A_ν^p and that $C_p := \sup_{z \in \Omega} \|k_z^{(p)}\|$ is finite if (ν, ν, p) is admissible, which, as already mentioned a few times, is assumed throughout this paper (see Section 2). As (ν, ν, p) is admissible if and only if (ν, ν, q) is admissible, this also implies $C_q := \sup_{z \in \Omega} \|k_z^{(q)}\| < \infty$ (see Equation 2.2). We may thus define the Berezin transform $\mathcal{B}(A): \Omega \rightarrow \mathbb{C}$ of an operator $A \in \mathcal{L}(A_\nu^p)$ as

$$(\mathcal{B}(A))(z) := \int_{\Omega} (A k_z^{(p)})(w) \overline{k_z^{(q)}(w)} dv_\nu(w).$$

Using Hölder's inequality, it is not difficult to see that $\mathcal{B}(A)$ is bounded and uniformly continuous with respect to the Bergman metric. Moreover, we have $\mathcal{B}(A) = 0$ if and only if $A = 0$ by standard arguments (see e.g. [26, Section 2] or [32, Section 7.2]).

Theorem A. *An operator $K \in \mathcal{L}(A_\nu^p)$ is compact if and only if K is band-dominated and*

$$\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0.$$

Proof. We will show that $K_x = 0$ for all $x \in \beta\Omega \setminus \Omega$ if and only if $\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0$. The result then follows by Proposition 19 and Theorem 22.

Choose a net (z_γ) in Ω that converges to some $x \in \beta\Omega \setminus \Omega$ and let $K_x = 0$. Consider the functions $f_z \in A_\nu^p$ defined by $f_z(w) := h(w, z)^{(\nu+g)(1-\frac{2}{p})}$ for $w, z \in \Omega$. It holds

$$(U_z^p f_z)(w) = h(\phi_z(w), z)^{(\nu+g)(1-\frac{2}{p})} \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(w, z)^{\frac{2(\nu+g)}{p}}} = \frac{h(z, z)^{(\nu+g)(1-\frac{2}{p})}}{h(w, z)^{(\nu+g)(1-\frac{2}{p})}} \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(w, z)^{\frac{2(\nu+g)}{p}}} = \frac{h(z, z)^{\frac{\nu+g}{q}}}{h(w, z)^{\nu+g}},$$

i.e. $U_z^p f_z = k_z^{(p)}$. In particular, we have $\sup_{z \in \Omega} \|f_z\| \leq C_p$ because U_z^p is an isometry for all $z \in \Omega$.

Moreover,

$$(\mathcal{B}(K))(z) \leq \|K k_z^{(p)}\|_p \|k_z^{(q)}\|_q = \|U_z^p K U_z^p f_z\|_p \|k_z^{(q)}\|_q \leq C_q \|U_z^p K U_z^p f_z\|_p.$$

As in the proof of Proposition 17, (z_γ) converges to some $\alpha \in \partial\Omega$ in the Euclidean topology. Using that $h(w, z)$ is a polynomial in w and \bar{z} and $|h(w, z)| > 0$ on $\Omega \times \bar{\Omega}$, we get that f_{z_γ} converges uniformly on compact sets to a bounded function f_α . In particular, $f_{z_\gamma} \rightarrow f_\alpha$ in A_ν^p and $f_\alpha \in A_\nu^p$. But this implies

$$\|U_{z_\gamma}^p K U_{z_\gamma}^p f_{z_\gamma}\|_p \leq \|U_{z_\gamma}^p K U_{z_\gamma}^p f_\alpha\|_p + \|U_{z_\gamma}^p K U_{z_\gamma}^p (f_{z_\gamma} - f_\alpha)\|_p \leq \|K_{z_\gamma} f_\alpha\|_p + \|K\| \|f_{z_\gamma} - f_\alpha\|_p,$$

which converges to 0 by assumption. Thus $\lim_{z_\gamma \rightarrow x} (\mathcal{B}(K))(z_\gamma) = 0$. As the net (z_γ) was arbitrary, we get

$$\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0.$$

Conversely, let $x \in \beta\Omega \setminus \Omega$ and assume that $\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0$. Choose a net (z_γ) in Ω that converges to x . By Proposition 14,

$$K_x = \text{s-lim}_{z_\gamma \rightarrow x} U_{z_\gamma}^p K U_{z_\gamma}^p|_{A_\nu^p}.$$

But let us consider

$$K_x T_{b_x}^{-1} = \text{s-lim}_{z_\gamma \rightarrow x} K_{z_\gamma} T_{b_{z_\gamma}}^{-1} = \text{s-lim}_{z_\gamma \rightarrow x} U_{z_\gamma}^p K (U_{z_\gamma}^q|_{A_\nu^q})^*$$

here instead (cf. Remark 7, Proposition 17). Of course, $K_x = 0$ if and only if $K_x T_{b_x}^{-1} = 0$, so it suffices to show $\text{s-lim}_{z_\gamma \rightarrow x} U_{z_\gamma}^p K (U_{z_\gamma}^q|_{A_\nu^q})^* = 0$. The reason why we want to consider this limit instead is the following computation:

$$\begin{aligned} \left((U_z^q|_{A_\nu^q})^* k_\zeta^{(p)} \right) (w) &= (T_{b_z} U_z^p k_\zeta^{(p)})(w) \\ &= \int_\Omega \frac{h(\zeta, \zeta)^{\frac{\nu+g}{q}}}{h(\phi_z(y), \zeta)^{\nu+g}} \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(y, z)^{\frac{2(\nu+g)}{p}}} \frac{h(z, y)^{(\nu+g)(\frac{1}{q}-\frac{1}{p})}}{h(y, z)^{(\nu+g)(\frac{1}{q}-\frac{1}{p})}} h(w, y)^{-\nu-g} dv_\nu(y) \end{aligned}$$

$$\begin{aligned}
&= h(\zeta, \zeta)^{\frac{\nu+g}{q}} h(z, z)^{\frac{\nu+g}{p}} \int_{\Omega} \frac{h(y, z)^{\nu+g}}{h(z, \zeta)^{\nu+g} h(y, \phi_z(\zeta))^{\nu+g}} \frac{h(z, y)^{(\nu+g)(\frac{1}{q}-\frac{1}{p})}}{h(y, z)^{\nu+g}} \\
&\quad \cdot h(w, y)^{-\nu-g} dv_{\nu}(y) \\
&= \frac{h(\zeta, \zeta)^{\frac{\nu+g}{q}} h(z, z)^{\frac{\nu+g}{p}}}{h(z, \zeta)^{\nu+g}} \int_{\Omega} \frac{h(y, z)^{(\nu+g)(\frac{1}{q}-\frac{1}{p})}}{h(y, w)^{\nu+g}} \overline{h(\phi_z(\zeta), y)^{-\nu-g}} dv_{\nu}(y) \\
&= \frac{h(\zeta, \zeta)^{\frac{\nu+g}{q}} h(z, z)^{\frac{\nu+g}{p}}}{h(z, \zeta)^{\nu+g}} \frac{h(z, \phi_z(\zeta))^{(\nu+g)(\frac{1}{q}-\frac{1}{p})}}{h(w, \phi_z(\zeta))^{\nu+g}} \\
&= \frac{h(\zeta, \zeta)^{\frac{\nu+g}{q}} h(z, z)^{\frac{\nu+g}{q}}}{h(z, \zeta)^{\frac{2(\nu+g)}{q}} h(w, \phi_z(\zeta))^{\nu+g}} \\
&= \frac{h(\zeta, z)^{\frac{(\nu+g)}{q}} h(\phi_z(\zeta), \phi_z(\zeta))^{\frac{\nu+g}{q}}}{h(z, \zeta)^{\frac{(\nu+g)}{q}} h(w, \phi_z(\zeta))^{\nu+g}} \\
&= \frac{h(\zeta, z)^{\frac{(\nu+g)}{q}}}{h(z, \zeta)^{\frac{(\nu+g)}{q}}} k_{\phi_z(\zeta)}^{(p)}(w)
\end{aligned}$$

for all $w, z, \zeta \in \Omega$, where we used the usual transformation identities a few times and the fact that P_{ν} is the identity on holomorphic functions. Note that the overline indicates complex conjugation here. Similarly, we get $\left((U_z^p |_{A_{\nu}^p})^* k_{\zeta}^{(q)} \right) (w) = \frac{h(\zeta, z)^{\frac{(\nu+g)}{p}}}{h(z, \zeta)^{\frac{(\nu+g)}{p}}} k_{\phi_z(\zeta)}^{(q)}(w)$ for all $w, z, \zeta \in \Omega$. Thus

$$\begin{aligned}
(\mathcal{B}(K_{z_{\gamma}} T_{b_{z_{\gamma}}}^{-1}))(\zeta) &= \int_{\Omega} \left(U_{z_{\gamma}}^p K(U_{z_{\gamma}}^q |_{A_{\nu}^q})^* k_{\zeta}^{(p)} \right) (w) \overline{k_{\zeta}^{(q)}(w)} dv_{\nu}(w) \\
&= \frac{h(\zeta, z_{\gamma})^{\frac{(\nu+g)}{q}} h(z_{\gamma}, \zeta)^{\frac{(\nu+g)}{p}}}{h(z_{\gamma}, \zeta)^{\frac{(\nu+g)}{q}} h(\zeta, z_{\gamma})^{\frac{(\nu+g)}{p}}} \int_{\Omega} (K k_{\phi_{z_{\gamma}}(\zeta)}^{(p)})(w) \overline{k_{\phi_{z_{\gamma}}(\zeta)}^{(q)}(w)} dv_{\nu}(w) \\
&= b_{z_{\gamma}}(\zeta)^{-1} (\mathcal{B}(K))(\phi_{z_{\gamma}}(\zeta)).
\end{aligned} \tag{5.2}$$

As $|b_{z_{\gamma}}(\zeta)^{-1}| = 1$, $\phi_{z_{\gamma}}(\zeta) \rightarrow \partial\Omega$ and $K_{z_{\gamma}} T_{b_{z_{\gamma}}}^{-1} \rightarrow K_x T_{b_x}^{-1}$ strongly as $z_{\gamma} \rightarrow x$, we get

$$(\mathcal{B}(K_x T_{b_x}^{-1}))(\zeta) = \lim_{z_{\gamma} \rightarrow x} (\mathcal{B}(K_{z_{\gamma}} T_{b_{z_{\gamma}}}^{-1}))(\zeta) = \lim_{z_{\gamma} \rightarrow x} b_{z_{\gamma}}(\zeta)^{-1} (\mathcal{B}(K))(\phi_{z_{\gamma}}(\zeta)) = 0$$

for all $\zeta \in \Omega$. Hence $K_x T_{b_x}^{-1} = 0$ and thus $K_x = 0$. \square

For $p = 2$ things are a little bit simpler because $\mathfrak{T}_{2,\nu}$ is an irreducible C^* -algebra containing a non-trivial compact operator and hence contains all compact operators. As Toeplitz operators are band-dominated (Proposition 3, see also Remark 13) the next corollary immediately follows.

Corollary 23. *An operator $K \in \mathcal{L}(A_{\nu}^2)$ is compact if and only if $K \in \mathfrak{T}_{2,\nu}$ and $\lim_{z \rightarrow \partial\Omega} (\mathcal{B}(K))(z) = 0$.*

6 Fredholmness

In the previous section we showed that compactness can be characterized in terms of limit operators. In this section we show that the same can be done with Fredholmness, i.e. we show that a band-dominated operator is Fredholm if and only if all of its limit operators are invertible. As we

gathered all the ingredients we need in the previous sections, we may follow now the lines of [16] to obtain the result. One direction is actually quite easy and follows directly from the compactness characterization:

Proposition 24. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. If A is Fredholm, then A_x is invertible for every $x \in \beta\Omega \setminus \Omega$ and $\sup_{x \in \beta\Omega \setminus \Omega} \|A_x^{-1}\| < \infty$. Moreover, if B is a Fredholm regularizer of A and (z_γ) is a net in Ω that converges to $x \in \beta\Omega \setminus \Omega$, then $U_{z_\gamma}^p B U_{z_\gamma}^p$ converges strongly to A_x^{-1} as $z_\gamma \rightarrow x$.*

Proof. Let B be a Fredholm regularizer of A and denote by $Q_\nu := I - P_\nu \in \text{BDO}_\nu^p$ the complementary projection to $P_\nu \in \text{BDO}_\nu^p$. Then $B P_\nu + Q_\nu \in \mathcal{L}(L_\nu^p)$ is a Fredholm regularizer of $A P_\nu + Q_\nu$. By Proposition 2, this implies $B P_\nu + Q_\nu \in \text{BDO}_\nu^p$ and hence B is band-dominated. Similarly, AB is band-dominated. Therefore, by Proposition 14, for every net (z_γ) converging to some $x \in \beta\Omega \setminus \Omega$ the strong limits of $U_{z_\gamma}^p B U_{z_\gamma}^p|_{A_\nu^p}$ and $U_{z_\gamma}^p A B U_{z_\gamma}^p|_{A_\nu^p}$ exist and they are equal to B_x and $(AB)_x$, respectively. Moreover, $AB - I$ and $BA - I$ are compact, hence $(AB - I)_x = (BA - I)_x = 0$ by Theorem 22. It follows

$$0 = (AB - I)_x = A_x B_x - I$$

by Corollary 15, i.e. $A_x B_x = I$. Together with the reversed equality we get $B_x = A_x^{-1}$ and hence $\|A_x^{-1}\| \leq \|B\|$ by Corollary 15 again. \square

The other direction is more difficult to show and needs some more preparation. For $p \leq 2$ and $\alpha = (\frac{2}{p} - 1)g + \frac{2\nu}{p}$ and $A \in \mathcal{L}(A_\nu^p)$ we will use the notation \hat{A} for the extension $AP_\alpha + Q_\alpha \in \mathcal{L}(L_\nu^p)$, where $Q_\alpha := I - P_\alpha$ is the complementary projection. Note that since

$$AP_\alpha + Q_\alpha = AP_\nu P_\alpha + Q_\alpha \quad \text{and} \quad AP_\nu = (AP_\alpha + Q_\alpha)P_\nu,$$

A is band-dominated if and only if \hat{A} is (cf. Proposition 3). Also note that

$$\widehat{A_x} = (AP_\nu)_x P_\alpha + Q_\alpha = \text{w-lim}_{z_\gamma \rightarrow x} U_{z_\gamma}^p AP_\nu U_{z_\gamma}^p P_\alpha + Q_\alpha = \text{w-lim}_{z_\gamma \rightarrow x} U_{z_\gamma}^p (AP_\alpha + Q_\alpha) U_{z_\gamma}^p = (\hat{A})_x$$

for any net (z_γ) converging to $x \in \beta\Omega$ by Proposition 20. We may therefore just write \hat{A}_x without creating any ambiguities.

Lemma 25. *Let $p \leq 2$, $\alpha = (\frac{2}{p} - 1)g + \frac{2\nu}{p}$, let $\xi \in L^\infty(\Omega)$ have compact support and let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Further assume that (z_γ) is a net in Ω converging to some $x \in \beta\Omega$ such that A_x is invertible. Then there is a γ_0 such that for all $\gamma \geq \gamma_0$ there are operators $B_\gamma, C_\gamma \in \mathcal{L}(L_\nu^p)$ with $\|B_\gamma\|, \|C_\gamma\| \leq 2(\|A_x^{-1}\| \|P_\alpha\| + \|Q_\alpha\|)$ and*

$$B_\gamma \hat{A} M_{\xi \circ \phi_{z_\gamma}} = M_{\xi \circ \phi_{z_\gamma}} \hat{A} C_\gamma.$$

Proof. First observe that $p \leq 2$ implies $\alpha \geq \nu$ and hence (α, ν, p) is always admissible if (ν, ν, p) is, which is assumed throughout this paper (see Section 2, in particular Equation (2.2)). Moreover, if $x \in \Omega$ and $A_x = U_x^p A U_x^p|_{A_\nu^p}$ is invertible, then A is invertible and so the assertion holds trivially. We may therefore assume that $x \in \beta\Omega \setminus \Omega$.

Let $D(0, R) := \{z \in \Omega : \beta(0, z) < R\}$, where $R > 0$ is chosen sufficiently large such that $\text{supp } \xi \subseteq D(0, R)$. By Proposition 14, $U_{z_\gamma}^p A U_{z_\gamma}^p|_{A_\nu^p}$ converges strongly to A_x . Moreover, the operator $P_\alpha M_{\chi_{D(0, R)}}$ is compact by [16, Proposition 15]. Combining these facts and using Proposition 20, we get

$$\left\| (\hat{A}_{z_\gamma} - \hat{A}_x) M_{\chi_{D(0, R)}} \right\| = \left\| \left(U_{z_\gamma}^p (AP_\alpha + Q_\alpha) U_{z_\gamma}^p - A_x P_\alpha - Q_\alpha \right) M_{\chi_{D(0, R)}} \right\|$$

$$= \left\| \left(U_{z_\gamma}^p A U_{z_\gamma}^p - A_x \right) P_\alpha M_{\chi_{D(0,R)}} \right\| \rightarrow 0$$

as $z_\gamma \rightarrow x$. \hat{A}_x is invertible with $(\hat{A}_x)^{-1} = \widehat{A_x^{-1}}$, which implies that there exists a γ_0 such that $R_\gamma := (\hat{A}_x)^{-1}(\hat{A}_{z_\gamma} - \hat{A}_x)M_{\chi_{D(0,R)}}$ satisfies $\|R_\gamma\| < \frac{1}{2}$ for all $\gamma \geq \gamma_0$. In particular, $I + R_\gamma \in \mathcal{L}(L_\nu^p)$ is invertible for all $\gamma \geq \gamma_0$. Using Proposition 9, it is now easy to see that

$$U_{z_\gamma}^p (I + R_\gamma)^{-1} (\hat{A}_x)^{-1} U_{z_\gamma}^p \hat{A} M_{\xi \circ \phi_{z_\gamma}} = M_{\xi \circ \phi_{z_\gamma}}$$

and the first assertion follows (cf. [16, Proposition 19]).

For the second assertion note that $M_{\chi_{D(0,R)}} P_\alpha$ is compact as well (see [16, Proposition 15]). Thus

$$\left\| M_{\chi_{D(0,R)}} (\hat{A}_{z_\gamma} - \hat{A}_x) \right\| = \left\| M_{\chi_{D(0,R)}} P_\alpha \left(U_{z_\gamma}^p A U_{z_\gamma}^p - A_x \right) P_\alpha \right\| \rightarrow 0$$

and we obtain

$$M_{\xi \circ \phi_{z_\gamma}} \hat{A} U_{z_\gamma}^p (\hat{A}_x)^{-1} (I + S_\gamma)^{-1} U_{z_\gamma}^p = M_{\xi \circ \phi_{z_\gamma}}$$

for sufficiently large γ and $S_\gamma := M_{\chi_{D(0,R)}} (\hat{A}_{z_\gamma} - \hat{A}_x) (\hat{A}_x)^{-1}$. \square

Now we are ready to prove the other direction. Together with Proposition 24, we get the following theorem.

Theorem 26. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then A is Fredholm if and only if A_x is invertible for every $x \in \beta\Omega \setminus \Omega$ and $\sup_{x \in \beta\Omega \setminus \Omega} \|A_x^{-1}\| < \infty$.*

Proof. In Proposition 24 we have seen that if A is Fredholm, then A_x is invertible for every $x \in \beta\Omega \setminus \Omega$ and $\sup_{x \in \beta\Omega \setminus \Omega} \|A_x^{-1}\| < \infty$.

For the converse assume that A is a band-dominated operator such that all limit operators A_x are invertible and their inverses are uniformly bounded. Without loss of generality we may assume $p \leq 2$ because otherwise we could just pass to the adjoint and use Corollary 18. As in Lemma 25 we set $\alpha = (\frac{2}{p} - 1)g + \frac{2\nu}{p}$.

Let $\psi_{j,t}$ be the functions defined in Section 2 and assume that A is not Fredholm. Note that

$$[\hat{A}, P_\alpha] = (AP_\alpha + Q_\alpha)P_\alpha - P_\alpha(AP_\alpha + Q_\alpha) = AP_\alpha - P_\alpha AP_\alpha = 0$$

as $A \in \mathcal{L}(A_\nu^p)$. Moreover, \hat{A} is band-dominated because A is. In this particular case [16, Proposition 17] provides a criterion for $A = \hat{A}|_{A_\nu^p}$ to be Fredholm. As this would contradict our assumption, this criterion cannot be satisfied. In short, its negation reads

$$\nexists M > 0 : \forall t \in (0, 1) \exists j_0 \in \mathbb{N} : \forall j \geq j_0 \exists B_{j,t}, C_{j,t} \in \overline{B_{\|\cdot\|}(0, M)} : B_{j,t} \hat{A} M_{\psi_{j,t}} = M_{\psi_{j,t}} = M_{\psi_{j,t}} \hat{A} C_{j,t},$$

where $\overline{B_{\|\cdot\|}(0, M)} := \{B \in \mathcal{L}(L_\nu^p) : \|B\| \leq M\}$ denotes the closed ball of radius M in $\mathcal{L}(L_\nu^p)$. This is equivalent to

$$\forall M > 0 \exists t \in (0, 1) : \forall j_0 \in \mathbb{N} \exists j \geq j_0 : \forall B, C \in \overline{B_{\|\cdot\|}(0, M)} : B \hat{A} M_{\psi_{j,t}} \neq M_{\psi_{j,t}} \text{ or } M_{\psi_{j,t}} \neq M_{\psi_{j,t}} \hat{A} C.$$

In particular, there is a $t \in (0, 1)$ and a strictly increasing sequence $(j_m)_{m \in \mathbb{N}}$ such that

$$B \hat{A} M_{\psi_{j_m,t}} \neq M_{\psi_{j_m,t}} \quad \text{or} \quad M_{\psi_{j_m,t}} \neq M_{\psi_{j_m,t}} \hat{A} C$$

for all $m \in \mathbb{N}$ and all $B \in \mathcal{L}(L_\nu^p)$ with $\|B\| \leq M := 2 \left(\sup_{x \in \beta\Omega \setminus \Omega} \|A_x^{-1}\| \|P_\alpha\| + \|Q_\alpha\| \right)$. By choosing a suitable subsequence if necessary, we may assume that either always the first or always the second inequality happens. As both cases can be treated in the same way, we may assume that

$$B \hat{A} M_{\psi_{j_m, t}} \neq M_{\psi_{j_m, t}} \quad (6.1)$$

for all $m \in \mathbb{N}$ and $B \in \overline{B_{\|\cdot\|}}(0, M)$. Now by property (e) of the functions $\psi_{j, t}$, the diameters $\text{diam}_\beta \text{supp } \psi_{j, t}$ are bounded by a constant not depending on $j \in \mathbb{N}$. Thus every $\text{supp } \psi_{j_m, t}$ is contained in a Bergman ball $D(w_m, R)$ for a fixed radius R . As every $\text{supp } \psi_{j_m, t}$ at least contains a Bergman ball of radius $\frac{1}{t}$ and for every $z \in \Omega$ the set $\{m \in \mathbb{N} : z \in \text{supp } \psi_{j_m, t}\}$ has at most N elements, it is also clear that the sequence of midpoints $(w_m)_{m \in \mathbb{N}}$ tends to the boundary $\partial\Omega$ as $m \rightarrow \infty$. By compactness of $\beta\Omega$, this sequence has a subnet (w_{m_γ}) that converges to some $x \in \beta\Omega \setminus \Omega$. Thus, by choosing $\xi = \chi_{D(0, R)}$ in Lemma 25, we obtain a γ_0 such that for all $\gamma \geq \gamma_0$ there is an operator $B_\gamma \in \overline{B_{\|\cdot\|}}(0, M)$ with

$$B_\gamma \hat{A} M_{\chi_{D(w_{m_\gamma}, R)}} = B_\gamma \hat{A} M_{\chi_{D(0, R)} \circ \phi_{w_{m_\gamma}}} = M_{\chi_{D(0, R)} \circ \phi_{w_{m_\gamma}}} = M_{\chi_{D(w_{m_\gamma}, R)}}.$$

By multiplying with $M_{\psi_{j_{m_\gamma}, t}}$ from the right, we obtain a contradiction to (6.1). Therefore A has to be Fredholm. \square

Next we will show that the uniform boundedness condition for the inverses is actually redundant. The argument is very similar to the unit ball and the sequence space case, cf. [16, 21]. First, we need an analogue of $\|\cdot\|_F$ (cf. Section 5).

Recall that $r_t = \sup_{j \in \mathbb{N}} \text{diam}_\beta \text{supp } \varphi_{j, t} < \infty$. For every $t \in (0, 1)$, $A \in \mathcal{L}(L_\nu^p)$ and every Borel set $F \subseteq \Omega$ we define

$$\nu_t(A|_F) := \inf \{ \|Af\| : f \in L_\nu^p, \|f\| = 1, \text{supp } f \subseteq D(w, r_t) \cap F \text{ for some } w \in \Omega \}$$

and

$$\nu(A|_F) := \inf \{ \|Af\| : f \in L_\nu^p, \|f\| = 1, \text{supp } f \subseteq F \}.$$

Moreover, $\nu(A) := \nu(A|_\Omega)$.

The following lemma is immediate (see e.g. [16, Proposition 22] or [20, Lemma 2.38]).

Lemma 27. *For all $A, B \in \mathcal{L}(L_\nu^p)$, $t \in (0, 1)$ and all Borel sets $F \subseteq \Omega$ it holds*

$$|\nu(A|_F) - \nu(B|_F)| \leq \|(A - B)M_{\chi_F}\| \quad \text{and} \quad |\nu_t(A|_F) - \nu_t(B|_F)| \leq \|(A - B)M_{\chi_F}\|.$$

The next proposition is the analogue of Proposition 21. A large part of the proof is actually the same, so we just sketch it here.

Proposition 28. *Let $A \in \text{BDO}_\nu^p$. Then for every $\varepsilon > 0$ there exists a $t \in (0, 1)$ such that for every Borel set $F \subseteq \Omega$ and every $B \in \{A\} \cup \{A_x : x \in \beta\Omega \setminus \Omega\}$ it holds*

$$\nu(B|_F) \leq \nu_t(B|_F) \leq \nu(B|_F) + \varepsilon.$$

Proof. By Proposition 8 and Lemma 27, we may assume that A is a band operator. Moreover, the first inequality is clear by definition. For the second inequality observe that all limit operators A_x have the same band width as A . So let $B \in \{A\} \cup \{A_x : x \in \beta\Omega \setminus \Omega\}$, $F \subseteq \Omega$ a Borel set and choose $f \in L_\nu^p$ with $\|f\| = 1$ and $\text{supp } f \subseteq F$ such that

$$\|Bf\| \leq \nu(B|_F) + \frac{\varepsilon}{2}.$$

Moreover, let $\varphi_{j,t}$ and $\psi_{j,t}$ be defined as in Section 2. Then

$$\begin{aligned} \left(\sum_{j=1}^{\infty} \|BM_{\varphi_{j,t}^{1/p}} f\|^p \right)^{1/p} &= \left(\sum_{j=1}^{\infty} \|BM_{\varphi_{j,t}^{1/p}} M_{\psi_{j,t}} f\|^p \right)^{1/p} \\ &\leq \left(\sum_{j=1}^{\infty} \|M_{\varphi_{j,t}^{1/p}} Bf\|^p \right)^{1/p} + \left(\sum_{j=1}^{\infty} \|M_{\varphi_{j,t}^{1/p}} BM_{1-\psi_{j,t}} f\|^p \right)^{1/p} \\ &\quad + \left(\sum_{j=1}^{\infty} \|[B, M_{\varphi_{j,t}^{1/p}}] M_{\psi_{j,t}} f\|^p \right)^{1/p} \end{aligned}$$

by Minkowski's inequality. As in the proof of Proposition 21, the first term is equal to $\|Bf\|$ and the other two terms tend to 0 (uniformly in f and B) as $t \rightarrow 0$. Thus, for sufficiently small t , we get

$$\left(\sum_{j=1}^{\infty} \|BM_{\varphi_{j,t}^{1/p}} f\|^p \right)^{1/p} \leq \|Bf\| + \frac{\varepsilon}{2} \leq \nu(B|_F) + \varepsilon = (\nu(B|_F) + \varepsilon) \left(\sum_{j=1}^{\infty} \|M_{\varphi_{j,t}^{1/p}} f\|^p \right)^{1/p}.$$

This implies, in particular, that there exists a $j \in \mathbb{N}$ such that

$$\|BM_{\varphi_{j,t}^{1/p}} f\| \leq (\nu(B|_F) + \varepsilon) \|M_{\varphi_{j,t}^{1/p}} f\|$$

for sufficiently small t . As $\text{supp } (M_{\varphi_{j,t}^{1/p}} f) \subseteq \text{supp } \varphi_{j,t} \subseteq D(w, r_t)$ for some $w \in \Omega$, the assertion follows. \square

The next lemma allows us to centralize certain functions. This will be crucial in the subsequent lemma. Again, we focus on the case $p \leq 2$ as we can always pass to the adjoint if necessary. Recall that we defined $\hat{A} := AP_\alpha + Q_\alpha$ for $\alpha = (\frac{2}{p} - 1)g + \frac{2\nu}{p}$.

Lemma 29. *Let $p \leq 2$, $\alpha = (\frac{2}{p} - 1)g + \frac{2\nu}{p}$ and $f \in L_\nu^p$ with $\text{supp } f \subseteq D(w, r)$ for some $w \in \Omega$ and $r > 0$. If $A \in \mathcal{L}(A_\nu^p)$ is band-dominated, then for every $x \in \beta\Omega \setminus \Omega$ there exist $y \in \beta\Omega \setminus \Omega$ and $g \in L_\nu^p$ with $\text{supp } g \subseteq D(0, r)$ and $\|g\| = \|f\|$ such that $\|\hat{A}_x f\| = \|\hat{A}_y g\|$. Moreover,*

$$\nu(\hat{A}_y|_{D(0, r+\beta(0, w))}) \leq \nu(\hat{A}_x|_{D(0, r)}).$$

Proof. Another direct computation yields

$$(U_z^p U_w^p f)(\zeta) = (f \circ \phi_w \circ \phi_z)(\zeta) \frac{h(\phi_z(w), \phi_z(w))^{\frac{\nu+g}{p}}}{h(\zeta, \phi_z(w))^{\frac{2(\nu+g)}{p}}} \left(\frac{h(w, z)}{|h(w, z)|} \right)^{\frac{2(\nu+g)}{p}}$$

for $w, z \in \Omega$ (see e.g. [25, Lemma 2.8]). As $(\phi_w \circ \phi_z \circ \phi_{\phi_z(w)})(0) = 0$ and $\phi_{\phi_z(w)}$ is an involution, we obtain $\phi_w \circ \phi_z = V \circ \phi_{\phi_z(w)}$ for some $V \in K$ by Cartan's linearity theorem (see Section 2). This implies

$$U_z^p U_w^p = \left(\frac{h(w, z)}{|h(w, z)|} \right)^{\frac{2(\nu+g)}{p}} U_{\phi_z(w)}^p V_*,$$

where $V_* f := f \circ V$ is a composition operator and, by taking inverses, also

$$U_w^p U_z^p = \left(\frac{h(w, z)}{|h(w, z)|} \right)^{-\frac{2(\nu+g)}{p}} V_*^{-1} U_{\phi_z(w)}^p.$$

Combining these two equalities, we get

$$U_w^p U_z^p A U_z^p U_w^p|_{A_\nu^p} = V_*^{-1} U_{\phi_z(w)}^p A U_{\phi_z(w)}^p V_*|_{A_\nu^p}$$

for any band-dominated $A \in \mathcal{L}(A_\nu^p)$. Note that V of course depends on w and z . We now fix $w \in \Omega$ and choose a net (z_γ) that converges to some $x \in \beta\Omega \setminus \Omega$. As K is a closed subgroup of the unitary group, there is a subnet of (z_γ) , again denoted by (z_γ) , such that V converges to some $\tilde{V} \in K$ as $z_\gamma \rightarrow x$. In particular, $V_*|_{A_\nu^p}$ converges strongly to $\tilde{V}_*|_{A_\nu^p}$ and $V_*^{-1}|_{A_\nu^p}$ converges strongly to $\tilde{V}_*^{-1}|_{A_\nu^p}$. Moreover, using Corollary 16, we may assume that $U_{\phi_{z_\gamma}(w)}^p A U_{\phi_{z_\gamma}(w)}^p|_{A_\nu^p}$ converges strongly to A_y for some $y \in \beta\Omega$. Since $\phi_{z_\gamma}(w) \rightarrow \partial\Omega$ as $z_\gamma \rightarrow \partial\Omega$, it is clear that $y \in \beta\Omega \setminus \Omega$. As the limit of a strongly convergent net is unique and $\text{s-}\lim_{z_\gamma \rightarrow x} U_{z_\gamma}^p A U_{z_\gamma}^p|_{A_\nu^p} = A_x$ by Proposition 14, we obtain

$$U_w^p A_x U_w^p|_{A_\nu^p} = \tilde{V}_*^{-1} A_y \tilde{V}_*|_{A_\nu^p}.$$

Now observe that P_α commutes with both U_w^p and \tilde{V}_* . Indeed, the former was shown in Proposition 20, the latter follows from the fact that $h(z, w)$ is invariant under K (see Section 2):

$$\begin{aligned} (P_\alpha \tilde{V}_* f)(z) &= \int_{\Omega} f(\tilde{V} w) h(z, w)^{-\alpha-g} dv_\alpha(w) \\ &= \int_{\Omega} f(w) h(z, \tilde{V}^{-1} w)^{-\alpha-g} dv_\alpha(w) \\ &= \int_{\Omega} f(w) h(\tilde{V} z, w)^{-\alpha-g} dv_\alpha(w) \\ &= (\tilde{V}_* P_\alpha f)(z). \end{aligned}$$

Therefore we also have

$$U_w^p \hat{A}_x U_w^p = \tilde{V}_*^{-1} \hat{A}_y \tilde{V}_*.$$

Now clearly, if $f \in L_\nu^p$ with $\text{supp } f \subseteq D(w, r)$ for some $w \in \Omega$ and $r > 0$, then $g := \tilde{V}_* U_w^p f$ satisfies $\|g\| = \|f\|$ and $\|\hat{A}_x f\| = \|\hat{A}_y g\|$. Moreover,

$$\text{supp } g = \overline{\{z \in \Omega : g(z) \neq 0\}} = \overline{\{z \in \Omega : f(\phi_w(\tilde{V} z)) \neq 0\}} \subseteq D(0, r)$$

because $\phi_w(D(0, r)) = D(w, r)$ and $\tilde{V}(D(0, r)) = D(0, r)$.

For the second assertion consider $f \in L_\nu^p$ with $\text{supp } f \subseteq D(0, r)$. Then $g := \tilde{V}_* U_w^p f$ satisfies $\|g\| = \|f\|$, $\|\hat{A}_x f\| = \|\hat{A}_y g\|$ and $\text{supp } g \subseteq \tilde{V}_*^{-1}(\phi_w^{-1}(D(0, r))) \subseteq D(0, r + \beta(0, w))$ as above. \square

To actually show that the uniform boundedness condition is redundant, we show that the infimum $\inf \left\{ \nu(\hat{A}_x) : x \in \beta\Omega \setminus \Omega \right\}$ is always attained. The assertion then follows from the fact that $\nu(B) = \|B^{-1}\|^{-1}$ for invertible operators B .

Lemma 30. *Let $p \leq 2$, $\alpha = (\frac{2}{p} - 1)g + \frac{2\nu}{p}$ and let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then there exists a $y \in \beta\Omega \setminus \Omega$ with*

$$\nu(\hat{A}_y) = \inf \left\{ \nu(\hat{A}_x) : x \in \beta\Omega \setminus \Omega \right\}.$$

Proof. Recall $r_t = \sup_{j \in \mathbb{N}} \text{diam}_\beta \text{supp } \varphi_{j,t}$. Choosing $\varepsilon = 2^{-(k+1)}$ for $k \in \mathbb{N}_0$ in Proposition 28, we obtain a sequence $(t_k)_{k \in \mathbb{N}_0}$ with $\nu_{t_k}(B|_F) \leq \nu(B|_F) + 2^{-(k+1)}$ for all $F \subseteq \Omega$ and $B \in \{\hat{A}\} \cup \{\hat{A}_x : x \in \beta\Omega \setminus \Omega\}$. Without loss of generality we may assume $r_{t_{k+1}} > 2r_{t_k}$ for all $k \in \mathbb{N}_0$. Now choose a sequence $(x_n)_{n \in \mathbb{N}}$ in $\beta\Omega \setminus \Omega$ such that

$$\lim_{n \rightarrow \infty} \nu(\hat{A}_{x_n}) = \inf \left\{ \nu(\hat{A}_x) : x \in \beta\Omega \setminus \Omega \right\}.$$

For every $n \in \mathbb{N}$ we may choose a function $f_n^0 \in L_\nu^p$ with $\|f_n^0\| = 1$, $\text{supp } f_n^0$ contained in some $D(w, r_{t_n})$ and

$$\|\hat{A}_{x_n} f_n^0\| \leq \nu_{t_n}(\hat{A}_{x_n}) + 2^{-(n+1)} \leq \nu(\hat{A}_{x_n}) + 2^{-n}.$$

Using Lemma 29, we obtain a boundary point $y_n^0 \in \beta\Omega \setminus \Omega$ and a function $g_n^0 \in L_\nu^p$ with $\|g_n^0\| = 1$, $\text{supp } g_n^0 \subseteq D(0, r_{t_n})$ and

$$\|\hat{A}_{y_n^0} g_n^0\| = \|\hat{A}_{x_n} f_n^0\| \leq \nu(\hat{A}_{x_n}) + 2^{-n}.$$

Applying the same argument to $\hat{A}_{y_n^0}|_{D(0, r_{t_n})}$ we obtain a function $f_n^1 \in L_\nu^p$ with $\|f_n^1\| = 1$, $\text{supp } f_n^1 \subseteq D(w, r_{t_{n-1}}) \cap D(0, r_{t_n})$ for some $w \in \Omega$ and

$$\|\hat{A}_{y_n^0} f_n^1\| \leq \nu_{t_{n-1}}(\hat{A}_{y_n^0}|_{D(0, r_{t_n})}) + 2^{-n} \leq \nu(\hat{A}_{y_n^0}|_{D(0, r_{t_n})}) + 2^{-n+1}.$$

It is clear that $w \in D(0, r_{t_n} + r_{t_{n-1}})$, otherwise $D(w, r_{t_{n-1}}) \cap D(0, r_{t_n})$ would be empty. Using Lemma 29 again, we can choose a boundary point $y_n^1 \in \beta\Omega \setminus \Omega$ and a function $g_n^1 \in L_\nu^p$ with $\|g_n^1\| = 1$, $\text{supp } g_n^1 \subseteq D(0, r_{t_{n-1}})$ and

$$\|\hat{A}_{y_n^1} g_n^1\| = \|\hat{A}_{y_n^0} f_n^1\| \leq \nu(\hat{A}_{y_n^0}|_{D(0, r_{t_n})}) + 2^{-n+1}.$$

In particular,

$$\nu(\hat{A}_{y_n^1}|_{D(0, r_{t_{n-1}})}) \leq \nu(\hat{A}_{y_n^0}|_{D(0, r_{t_n})}) + 2^{-n+1} \leq \nu(\hat{A}_{x_n}) + 2^{-n+1} + 2^{-n}.$$

If we iterate this procedure for $k = 2, \dots, n$, we obtain a boundary point $y_n^k \in \beta\Omega \setminus \Omega$, a midpoint $w \in D(0, r_{t_{n-k+1}} + r_{t_{n-k}})$, a function $f_n^k \in L_\nu^p$ with $\|f_n^k\| = 1$, $\text{supp } f_n^k \subseteq D(w, r_{t_{n-k}}) \cap D(0, r_{t_{n-k+1}})$ and

$$\|\hat{A}_{y_n^{k-1}} f_n^k\| \leq \nu_{t_{n-k}}(\hat{A}_{y_n^{k-1}}|_{D(0, r_{t_{n-k+1}})}) + 2^{-n+k-1} \leq \nu(\hat{A}_{y_n^{k-1}}|_{D(0, r_{t_{n-k+1}})}) + 2^{-n+k}$$

and a function $g_n^k \in L_\nu^p$ with $\|g_n^k\| = 1$, $\text{supp } g_n^k \subseteq D(0, r_{t_{n-k}})$ and

$$\|\hat{A}_{y_n^k} g_n^k\| = \|\hat{A}_{y_n^{k-1}} f_n^k\| \leq \nu(\hat{A}_{y_n^{k-1}}|_{D(0, r_{t_{n-k+1}})}) + 2^{-n+k}.$$

Thus, if we combine these estimates, we get

$$\begin{aligned} \nu(\hat{A}_{y_n^k}|_{D(0, r_{t_{n-k}})}) &\leq \nu(\hat{A}_{y_n^{k-1}}|_{D(0, r_{t_{n-k+1}})}) + 2^{-n+k} \leq \dots \leq \nu(\hat{A}_{y_n^0}|_{D(0, r_{t_n}})}) + 2^{-n+k} + \dots + 2^{-n+1} \\ &\leq \nu(\hat{A}_{x_n}) + 2^{-n+k} + \dots + 2^{-n+1} + 2^{-n} \leq \nu(\hat{A}_{x_n}) + 2^{-n+k+1}. \end{aligned}$$

Fix an integer $l \leq n$ and choose $k = n - l$. Then, by collecting all the shifts being made during the process above and repeatedly applying the second part of Lemma 29, we get

$$\begin{aligned} \nu(\hat{A}_{y_n^{n-l}}|_{D(0, r_{t_l})}) &\geq \nu(\hat{A}_{y_n^{n-l+1}}|_{D(0, r_{t_l} + r_{t_l} + r_{t_{l-1}})}) = \nu(\hat{A}_{y_n^{n-l+1}}|_{D(0, 2r_{t_l} + r_{t_{l-1}})}) \\ &\geq \nu(\hat{A}_{y_n^{n-l+2}}|_{D(0, 2r_{t_l} + r_{t_{l-1}} + r_{t_{l-1}} + r_{t_{l-2}})}) = \nu(\hat{A}_{y_n^{n-l+2}}|_{D(0, 2r_{t_l} + 2r_{t_{l-1}} + r_{t_{l-2}})}) \\ &\geq \dots \geq \nu(\hat{A}_{y_n^n}|_{D(0, 2r_{t_l} + 2r_{t_{l-1}} + 2r_{t_{l-2}} + \dots + 2r_{t_1} + r_{t_0})}) \geq \nu(\hat{A}_{y_n^n}|_{D(0, 4r_{t_l})}), \end{aligned}$$

where we used $r_{t_{k+1}} > 2r_{t_k}$ for the last inequality.

Consider the diagonal sequence defined by $y_n := y_n^n$. Corollary 16 implies that the sequence $(A_{y_n})_{n \in \mathbb{N}}$ has a strongly convergent subnet that converges to A_y for some $y \in \beta\Omega \setminus \Omega$. Let us denote this subnet by $(A_{y_{n_\gamma}})$. Then

$$\|(\hat{A}_{y_{n_\gamma}} - \hat{A}_y)M_{\chi_{D(0, 4r_{t_l})}}\| = \|(A_{y_{n_\gamma}} - A_y)P_\alpha M_{\chi_{D(0, 4r_{t_l})}}\| \rightarrow 0$$

because $P_\alpha M_{\chi_{D(0, 4r_{t_l})}} \in \mathcal{L}(L_\nu^p)$ is a compact operator (see [16, Proposition 15]). By Lemma 27 we thus obtain $\nu(\hat{A}_{y_{n_\gamma}}|_{D(0, 4r_{t_l})}) \rightarrow \nu(\hat{A}_y|_{D(0, 4r_{t_l})})$. It follows

$$\begin{aligned} \nu(\hat{A}_y) &\leq \nu(\hat{A}_y|_{D(0, 4r_{t_l})}) = \lim_\gamma \nu(\hat{A}_{y_{n_\gamma}}|_{D(0, 4r_{t_l})}) \leq \lim_\gamma \nu(\hat{A}_{y_{n_\gamma}^{n_\gamma-l}}|_{D(0, r_{t_l})}) \leq \lim_\gamma \nu(\hat{A}_{x_{n_\gamma}}) + 2^{-l+1} \\ &= \inf \left\{ \nu(\hat{A}_x) : x \in \beta\Omega \setminus \Omega \right\} + 2^{-l+1}. \end{aligned}$$

Since y does not depend on l , we get $\nu(\hat{A}_y) = \inf \left\{ \nu(\hat{A}_x) : x \in \beta\Omega \setminus \Omega \right\}$ as claimed. \square

Let us now summarize this section.

Theorem B. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then the following are equivalent:*

- (i) A is Fredholm,
- (ii) A_x is invertible and $\|A_x^{-1}\| \leq \|(A + \mathcal{K}(A_\nu^p))^{-1}\|$ for all $x \in \beta\Omega \setminus \Omega$,
- (iii) A_x is invertible for all $x \in \beta\Omega \setminus \Omega$ and $\sup_{x \in \beta\Omega \setminus \Omega} \|A_x^{-1}\| < \infty$,
- (iv) A_x is invertible for all $x \in \beta\Omega \setminus \Omega$,

Proof. The equivalence of (i) and (iii) is Theorem 26. Moreover, if B is a Fredholm regularizer of A , Corollary 15 and Proposition 24 imply that the inverses are bounded by $\|B\|$. As this is true for every regularizer B , this means $\|A_x^{-1}\| \leq \|(A + \mathcal{K}(A_\nu^p))^{-1}\|$ for all $x \in \beta\Omega \setminus \Omega$. Hence (i) is also equivalent to (ii).

Clearly, (iii) implies (iv). To show that (iv) implies (iii) it suffices to consider the case $p \leq 2$ (cf. Proposition 17). If A_x is invertible, then $(\hat{A}_x)^{-1}$ is also invertible with $(\hat{A}_x)^{-1} = A_x^{-1}P_\alpha + Q_\alpha$. Moreover, it holds $\nu(B) = \|B^{-1}\|^{-1} > 0$ for invertible operators B (see e.g. [20, Lemma 2.35] for a quick proof). Therefore we get $\sup_{x \in \beta\Omega \setminus \Omega} \|\hat{A}_x^{-1}\| < \infty$ by Lemma 30. Since $A_x^{-1} = \hat{A}_x^{-1}|_{A_\nu^p}$, this implies (iii). \square

The following corollary is now immediate.

Corollary 31. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then*

$$\text{sp}_{\text{ess}}(A) = \bigcup_{x \in \beta\Omega \setminus \Omega} \text{sp}(A_x).$$

7 Applications to Toeplitz operators

As Toeplitz operators are band-dominated by Proposition 3, we obtain the following important corollary of Theorem B.

Corollary 32. *Let $A \in \mathfrak{T}_{p,\nu}$. Then A is Fredholm if and only if all of its limit operators are invertible. In particular,*

$$\text{sp}_{\text{ess}}(A) = \bigcup_{x \in \beta\Omega \setminus \Omega} \text{sp}(A_x).$$

In the rest of this section we study some applications of Corollary 32 for particular Toeplitz operators. First, we observe the following:

Proposition 33. *For $f \in L^\infty(\Omega)$ and $z \in \Omega$ we have $U_z^p T_f U_z^p = T_{b_z}^{-1} T_{(f \circ \phi_z) b_z}$.*

Proof. With the usual tricks we get

$$\begin{aligned} (U_z^p T_f U_z^p g)(w) &= \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(w, z)^{\frac{2(\nu+g)}{p}}} \int_{\Omega} g(\phi_z(x)) \frac{h(z, z)^{\frac{\nu+g}{p}}}{h(x, z)^{\frac{2(\nu+g)}{p}}} f(x) h(\phi_z(w), x)^{-\nu-g} \, dv_\nu(x) \\ &= h(w, z)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)} \int_{\Omega} g(y) f(\phi_z(y)) h(y, z)^{(\frac{1}{p}-\frac{1}{q})(\nu+g)} h(w, y)^{-\nu-g} \, dv_\nu(y) \end{aligned}$$

and hence

$$\begin{aligned} (T_{b_z} U_z^p T_f U_z^p g)(x) &= \int_{\Omega} \int_{\Omega} g(y) f(\phi_z(y)) \frac{h(z, w)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}}{h(y, z)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}} h(w, y)^{-\nu-g} h(x, w)^{-\nu-g} \, dv_\nu(y) \, dv_\nu(w) \\ &= \int_{\Omega} g(y) f(\phi_z(y)) \frac{h(z, y)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}}{h(y, z)^{(\frac{1}{q}-\frac{1}{p})(\nu+g)}} h(x, y)^{-\nu-g} \, dv_\nu(y) \\ &= (T_{(f \circ \phi_z) b_z} g)(x) \end{aligned}$$

for all $g \in A_\nu^p$ and $x, z \in \Omega$. \square

Combining Proposition 33 with Proposition 17, we get the following corollary.

Corollary 34. *Let $f \in L^\infty(\Omega)$, $x \in \beta\Omega \setminus \Omega$ and (z_γ) a net in Ω that converges to x . Further assume that $f \circ \phi_{z_\gamma}$ converges to a function $g \in L^\infty(\Omega)$ uniformly on compact subsets of Ω . Then $(T_f)_x = T_{b_x}^{-1}T_{g \cdot b_x}$.*

For $p = 2$ this simplifies to $(T_f)_x = T_g$. Moreover, if f is uniformly continuous with respect to the Bergman metric β , the condition in Corollary 34 is always satisfied. The set of bounded and uniformly continuous functions $f: \Omega \rightarrow \mathbb{C}$ will be denoted by $\text{BUC}(\Omega)$.

Proposition 35. *Let $f \in \text{BUC}(\Omega)$ and $x \in \beta\Omega \setminus \Omega$. Then $(T_f)_x = T_{b_x}^{-1}T_{g \cdot b_x}$, where $g \in \text{BUC}(\Omega)$ is the pointwise limit of the net $(f \circ \phi_{z_\gamma})$.*

Proof. As $z \mapsto \phi_z(w)$ is a continuous function by Lemma 5, $z \mapsto f(\phi_z(w))$ is a bounded and continuous function for every $w \in \Omega$. Therefore there is a unique extension to the Stone-Ćech compactification $\beta\Omega$. In particular, for every convergent net (z_γ) in Ω the net $f \circ \phi_{z_\gamma}$ converges pointwise to a bounded function g . As

$$|g(w) - g(y)| = \lim_\gamma |f(\phi_{z_\gamma}(w)) - f(\phi_{z_\gamma}(y))|$$

and $\beta(\phi_{z_\gamma}(w), \phi_{z_\gamma}(y)) = \beta(w, y)$, g is uniformly continuous just like f . It remains to show that $f \circ \phi_{z_\gamma} \rightarrow g$ uniformly on compact sets. So let $K \subset \Omega$ be compact and $\varepsilon > 0$. As f and g are uniformly continuous, there is a $\delta > 0$ such that $|f(w) - f(y)| < \varepsilon$ and $|g(w) - g(y)| < \varepsilon$ whenever $\beta(w, y) < \delta$. Moreover, there is a finite set $\{w_1, \dots, w_k\}$ such that $\min_{j=1, \dots, k} \beta(w, w_j) < \delta$ for all $w \in K$. Now choose γ sufficiently large such that $|f(\phi_{z_\gamma}(w_j)) - g(w_j)| < \varepsilon$ for all $j = 1, \dots, k$. It follows

$$|f(\phi_{z_\gamma}(w)) - g(w)| \leq |f(\phi_{z_\gamma}(w)) - f(\phi_{z_\gamma}(w_j))| + |f(\phi_{z_\gamma}(w_j)) - g(w_j)| + |g(w_j) - g(w)| < 3\varepsilon$$

for all $w \in K$, where j is obviously chosen in such a way that $\beta(\phi_{z_\gamma}(w), \phi_{z_\gamma}(w_j)) = \beta(w, w_j) < \delta$, respectively. As ε was arbitrary, the conclusion follows. \square

Proposition 35 gets particularly simple if g happens to be a constant function. As we will show next, this is the case if and only if the Berezin transform $\mathcal{B}(T_f)$ is of vanishing oscillation at the boundary $\partial\Omega$. For a bounded continuous function f , we define its oscillation at a point $z \in \Omega$ as

$$\text{Osc}_z(f) := \sup \{|f(z) - f(w)| : w \in \Omega, \beta(z, w) \leq 1\}.$$

We say that f is of vanishing oscillation at the boundary, $f \in \text{VO}_\partial(\Omega)$, if $\text{Osc}_z(f) \rightarrow 0$ as $z \rightarrow \partial\Omega$.

Theorem 36. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated. Then A_x is a multiple of the identity for every $x \in \beta\Omega \setminus \Omega$ if and only if $\mathcal{B}(A) \in \text{VO}_\partial(\Omega)$. In this case $A_x = (\mathcal{B}(A))(x) \cdot I$.*

Proof. Assume that $\mathcal{B}(A)$ has vanishing oscillation at the boundary and let (z_γ) be a net in Ω that converges to $x \in \beta\Omega \setminus \Omega$. By Equation (5.2), which does not require compactness of A , we have

$$\begin{aligned} (\mathcal{B}(A_x T_{b_x}^{-1}))(\zeta) &= \lim_{z_\gamma \rightarrow x} (\mathcal{B}(A_{z_\gamma} T_{b_{z_\gamma}}^{-1}))(\zeta) = \lim_{z_\gamma \rightarrow x} b_{z_\gamma}(\zeta)^{-1} (\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) \\ &= b_x(\zeta)^{-1} \lim_{z_\gamma \rightarrow x} (\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) \end{aligned}$$

for every $\zeta \in \Omega$. In particular, setting $\zeta = 0$ and using that $b_z(0) = 1$ for all $z \in \Omega$, we get

$$(\mathcal{B}(A_x T_{b_x}^{-1}))(0) = \lim_{z_\gamma \rightarrow x} (\mathcal{B}(A))(\phi_{z_\gamma}(0)) = \lim_{z_\gamma \rightarrow x} (\mathcal{B}(A))(z_\gamma) = (\mathcal{B}(A))(x). \quad (7.1)$$

Now let $\zeta \in \overline{D(0,1)}$, i.e. $\beta(0, \zeta) \leq 1$. Then

$$\begin{aligned} \lim_{z_\gamma \rightarrow x} |(\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) - (\mathcal{B}(A))(x)| &\leq \lim_{z_\gamma \rightarrow x} |(\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) - (\mathcal{B}(A))(\phi_{z_\gamma}(0))| \\ &\quad + \lim_{z_\gamma \rightarrow x} |(\mathcal{B}(A))(\phi_{z_\gamma}(0)) - (\mathcal{B}(A))(x)| \\ &\leq \lim_{z_\gamma \rightarrow x} \text{Osc}_{z_\gamma}(\mathcal{B}(A)) \\ &= 0 \end{aligned}$$

because of Equation (7.1) and $\beta(\phi_{z_\gamma}(0), \phi_{z_\gamma}(\zeta)) = \beta(0, \zeta) \leq 1$. By repeating this argument, we see that this generalizes to all $\zeta \in \Omega$. Thus

$$(\mathcal{B}(A_x T_{b_x}^{-1}))(\zeta) = b_x(\zeta)^{-1} (\mathcal{B}(A))(x) \quad (7.2)$$

for all $\zeta \in \Omega$. Now consider the case $A = I$. If $A = I$, then obviously $A_x = I_x = I$ for all $x \in \beta\Omega \setminus \Omega$ and hence

$$(\mathcal{B}(T_{b_x}^{-1}))(\zeta) = (\mathcal{B}(I_x T_{b_x}^{-1}))(\zeta) = b_x(\zeta)^{-1} (\mathcal{B}(I))(x) = b_x(\zeta)^{-1} \quad (7.3)$$

for all $\zeta \in \Omega$. Combining (7.2) and (7.3), we get

$$\mathcal{B}((A_x - (\mathcal{B}(A))(x) \cdot I) T_{b_x}^{-1}) = 0$$

by linearity and $A_x = (\mathcal{B}(A))(x) \cdot I$ by the injectivity of \mathcal{B} (see Section 5).

Conversely, assume that A_x is a multiple of the identity for every $x \in \beta\Omega \setminus \Omega$, i.e. $A_x = \lambda_x \cdot I$ for some $\lambda_x \in \mathbb{C}$. Choose a net (z_γ) in Ω that converges to $x \in \beta\Omega \setminus \Omega$. Using Equation (5.2) again, we get

$$b_x(\zeta)^{-1} \lim_{z_\gamma \rightarrow x} (\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) = \lim_{z_\gamma \rightarrow x} (\mathcal{B}(A_{z_\gamma} T_{b_{z_\gamma}}^{-1}))(\zeta) = \lambda_x \cdot (\mathcal{B}(T_{b_x}^{-1}))(\zeta)$$

for all $\zeta \in \Omega$. Equation (7.3) thus implies

$$\lim_{z_\gamma \rightarrow x} (\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) = \lambda_x \quad (7.4)$$

for every $\zeta \in \Omega$ and $x \in \beta\Omega \setminus \Omega$. In particular, setting $\zeta = 0$, $\lambda_x = (\mathcal{B}(A))(x)$. Now assume that $\mathcal{B}(A)$ is not contained in $\text{VO}_\partial(\Omega)$. Then there are $\varepsilon > 0$ and two sequences $(z_n)_{n \in \mathbb{N}}$, $(w_n)_{n \in \mathbb{N}}$ with $\beta(z_n, w_n) \leq 1$ such that $w_n \rightarrow \partial\Omega$ and

$$|(\mathcal{B}(A))(z_n) - (\mathcal{B}(A))(w_n)| > \varepsilon \quad (7.5)$$

for all $n \in \mathbb{N}$. Since $\beta(0, \phi_{z_n}(w_n)) = \beta(z_n, w_n) \leq 1$ for all $n \in \mathbb{N}$, we can assume without loss of generality that the sequence $(\phi_{z_n}(w_n))_{n \in \mathbb{N}}$ converges to some $\zeta \in \overline{D(0,1)}$. Moreover, we may take a subnet (z_γ) of $(z_n)_{n \in \mathbb{N}}$ that converges to some $x \in \beta\Omega \setminus \Omega$. The corresponding subnet of $(w_n)_{n \in \mathbb{N}}$ we denote by (w_γ) . Consider

$$|(\mathcal{B}(A))(w_\gamma) - (\mathcal{B}(A))(z_\gamma)| \leq |(\mathcal{B}(A))(w_\gamma) - (\mathcal{B}(A))(\phi_{z_\gamma}(\zeta))| + |(\mathcal{B}(A))(\phi_{z_\gamma}(\zeta)) - (\mathcal{B}(A))(\phi_{z_\gamma}(0))|.$$

The second term on the right-hand side tends to 0 by Equation (7.4). For the first term we observe that $\beta(w_\gamma, \phi_{z_\gamma}(\zeta)) = \beta(\phi_{z_\gamma}(w_\gamma), \zeta)$ tends to 0 by construction and since $\mathcal{B}(A)$ is uniformly continuous, the first term tends to 0 as well. But this is a contradiction to (7.5). Therefore $\mathcal{B}(A)$ has to be contained in $\text{VO}_\partial(\Omega)$. \square

Corollary 37. *Let $A \in \mathcal{L}(A_\nu^p)$ be band-dominated with $\mathcal{B}(A) \in \text{VO}_\partial(\Omega)$. Then*

$$\text{sp}_{\text{ess}}(A) = \bigcup_{x \in \beta\Omega \setminus \Omega} (\mathcal{B}(A))(x) = (\mathcal{B}(A))(\beta\Omega \setminus \Omega) = \bigcap_{r>0} \overline{(\mathcal{B}(A))(\Omega \setminus D(0, r))}.$$

In what follows we will use the standard abbreviation $\tilde{f} := \mathcal{B}(T_f)$. Note that this definition is independent of p . A bounded function f is then called of bounded mean oscillation, denoted as $f \in \text{VMO}_\partial(\Omega) \cap L^\infty(\Omega)$, if

$$(\text{MO}(f))(z) := \left(|f - \tilde{f}(z)|^2 \right)^\sim(z) \rightarrow 0$$

as $z \rightarrow \partial\Omega$.

Corollary 38. *Let $f \in \text{VMO}_\partial(\Omega) \cap L^\infty(\Omega)$. Then*

$$\text{sp}_{\text{ess}}(T_f) = \tilde{f}(\beta\Omega \setminus \Omega) = \bigcap_{r>0} \overline{\tilde{f}(\Omega \setminus D(0, r))}.$$

Proof. By Corollary 37 it suffices to show that $\tilde{f} = \mathcal{B}(T_f)$ is contained in $\text{VO}_\partial(\Omega)$. For the unweighted case this was shown in [5, Theorem F, Corollary 2]. The same proof also applies to the weighted case and was (essentially) carried out in [3, Proposition 4.8]. \square
