Introduction

This conference was an unusual and interesting event. Celebrating 25 years of *Construction Management and Economics* provides us with an opportunity to reflect on the research that has been reported over the years, to consider where we are now, and to think about the future of academic research in this area. Hence the sub-title of this conference: "past, present and future". Looking through these papers, some things are clear. First, the range of topics considered interesting has expanded hugely since the journal was first published. Second, the research methods are also more diverse. Third, the involvement of wider groups of stakeholder is evident. There is a danger that this might lead to dilution of the field. But my instinct has always been to argue against the notion that Construction Management and Economics represents a discipline, as such. Granted, there are plenty of university departments around the world that would justify the idea of a discipline. But the vast majority of academic departments who contribute to the life of this journal carry different names to this. Indeed, the range and breadth of methodological approaches to the research reported in *Construction Management and Economics* indicates that there are several different academic disciplines being brought to bear on the construction sector. Some papers are based on economics, some on psychology and others on operational research, sociology, law, statistics, information technology, and so on. This is why I maintain that construction management is not an academic discipline, but a field of study to which a range of academic disciplines are applied.

This may be why it is so interesting to be involved in this journal. The problems to which the papers are applied develop and grow. But the broad topics of the earliest papers in the journal are still relevant today. What has changed a lot is our interpretation of the problems that confront the construction sector all over the world, and the methodological approaches to resolving them. There is a constant difficulty in dealing with topics as inherently practical as these. While the demands of the academic world are driven by the need for the rigorous application of sound methods, the demands of the practical world are quite different. It can be difficult to meet the needs of both sets of stakeholders at the same time. However, increasing numbers of postgraduate courses in our area result in larger numbers of practitioners with a deeper appreciation of what research is all about, and how to interpret and apply the lessons from research. It also seems that there are contributions coming not just from construction-related university departments, but also from departments with identifiable methodological traditions of their own. I like to think that our authors can publish in journals beyond the construction-related areas, to disseminate their theoretical insights into other disciplines, and to contribute to the strength of this journal by citing our articles in more mono-disciplinary journals. This would contribute to the future of the journal in a very strong and developmental way. The greatest danger we face is in excessive self-citation, i.e. referring only to sources within the CM&E literature or, worse, referring only to other articles in the same journal. The only way to ensure a strong and influential position for journals and university departments like ours is to be sure that our work is informing other academic disciplines. This is what I would see as the future, our logical next step. If, as a community of researchers, we are not producing papers that challenge and inform the fundamentals of research methods and analytical processes, then no matter how practically relevant our output is to the industry, it will remain derivative and secondary, based on the methodological insights of others. The balancing act between methodological rigour and practical relevance is a difficult one, but not, of course, a balance that has to be struck in every single paper.

Turning to the conference, we have published 168 papers in this conference from 311 abstracts that were submitted in response to the call for papers. Of these, ten were rejected immediately as out of scope and 301 papers were invited, with comments from the abstract review, often making suggestions about how the paper might be focused. By the cut-off date, this resulted in 181 papers being submitted to the conference, of which 168 were finally accepted and published. All of these papers were reviewed by the Scientific Committee, supplemented by other authors from the conference, with at least two referees per paper. The corresponding authors represent 39 countries, which is a tremendously wide geographical spread. In organizing the schedule for the three days, I was presented with the usual problem faced by conference organizers of trying to fit all the papers in, at the same time as making this a meaningful experience for the participants. As well as the usual parallel sessions, I wanted to be sure that there was going to be good opportunities for discussion, and a new approach was tried. Associated with each of the four keynote addresses, I selected 5 papers from among those already accepted, looking for resonances with a keynote. I invited those authors to take part in a plenary session where they would make a two-minute bare bones presentation of their work (with no slides), one after the other. Thus, for each session of the conference, we started with a keynote, immediately followed by five very short presentations, and then a long discussion period picking up the themes of the keynote and the other presentations to tease out an interesting dialogue between panel members and audience. We still had the usual parallel sessions after these plenary sessions, but I felt that these helped to ensure that there was plenty to talk about, and it enabled those whose work was selected for the plenary session to get a much better engagement with a larger audience than might otherwise have been the case. I think that it is important to keep developing our approach to conferences and meetings, as otherwise there is a danger that it all becomes a bit too formulaic.

The origins of the journal may not be known to everyone: *Construction Management and Economics* was established in 1982 by Philip Read who worked for a publishing company called E & F N Spon, a company that specialized in construction books and well-known for its price books. Representing a publisher that specialized in construction, Philip Read made it his business to be aware of who was doing what in this field. So he approached Professor John Bennett at the University of Reading to be the editor of this new journal, and the first issue was published in 1983. Under John's editorship, the journal grew from about 240 pages per year to roughly double that size. In 1992, Ranko Bon and I took over as editors. This partnership lasted for 12 years until Ranko's retirement. While the journal continued to grow under my sole editorship, it became clear that the work was too much for one editor, so this year, I invited Andy Dainty and Frank Schultmann to join the editorial team, and between us we now preside over the production of about 1300 pages per year. The growth in the scale of the journal is clear from Figure 1, which shows how many pages have been published in each volume since the journal started.

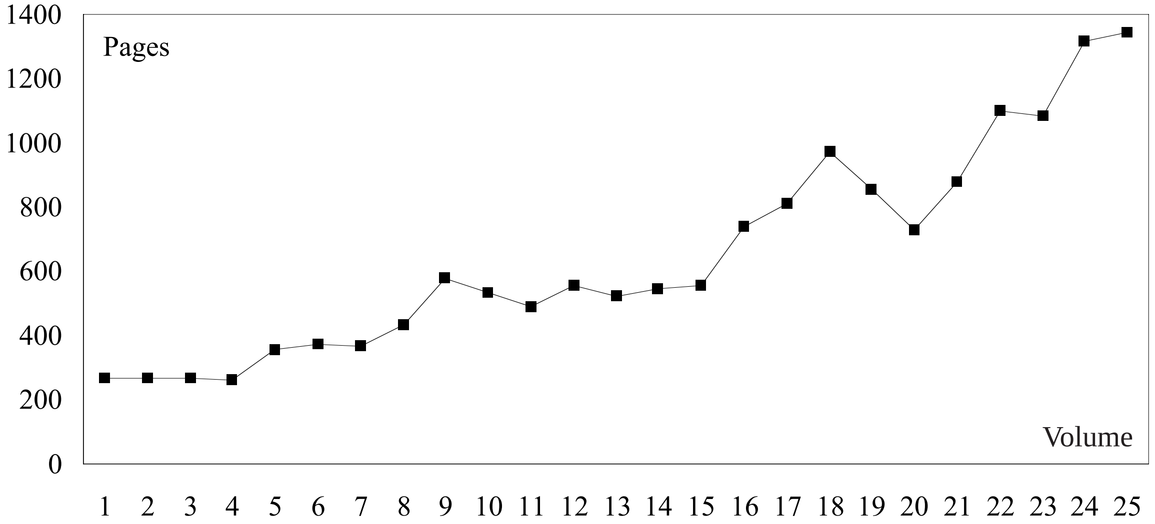

Figure 1: Numbers of pages per volume

The growth of the journal is undoubtedly linked to the growth in academic departments around the world. As academics in these departments develop their research profiles and seek outlets for their work, *Construction Management and Economics* is one of the main journals to which their work is submitted. Figure 2 shows the inexorable growth in the flow of papers into the journal, as well as the changes in numbers of papers accepted/rejected. The rejection rate appears fairly constant, hovering around 50%

One question that often arises when I show Figure 2 to various audiences is about the impact of the occasional Research Assessment Exercises (RAE) in the UK. Observers often assume that there must be a peak in submissions immediately prior to these. The lowest line in Figure 2 shows that number of papers received from UK authors

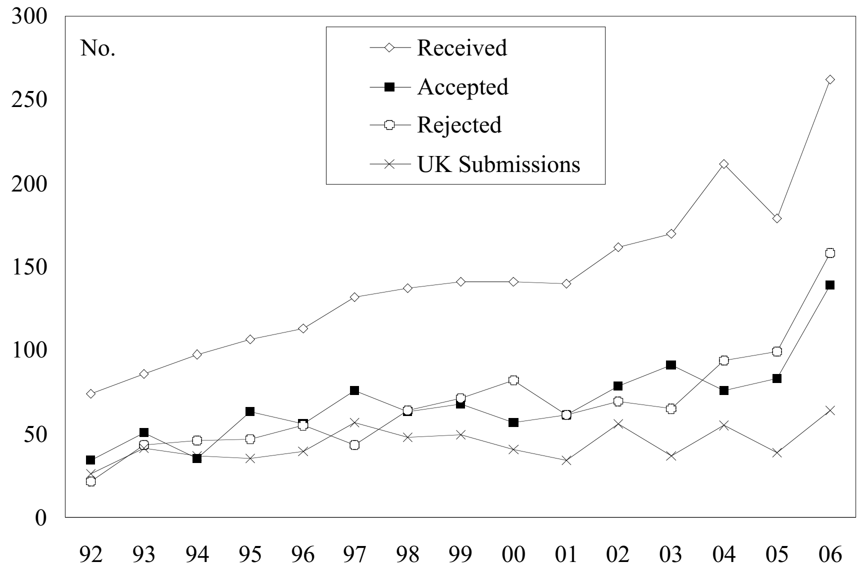

Figure 2: Annual copy flow

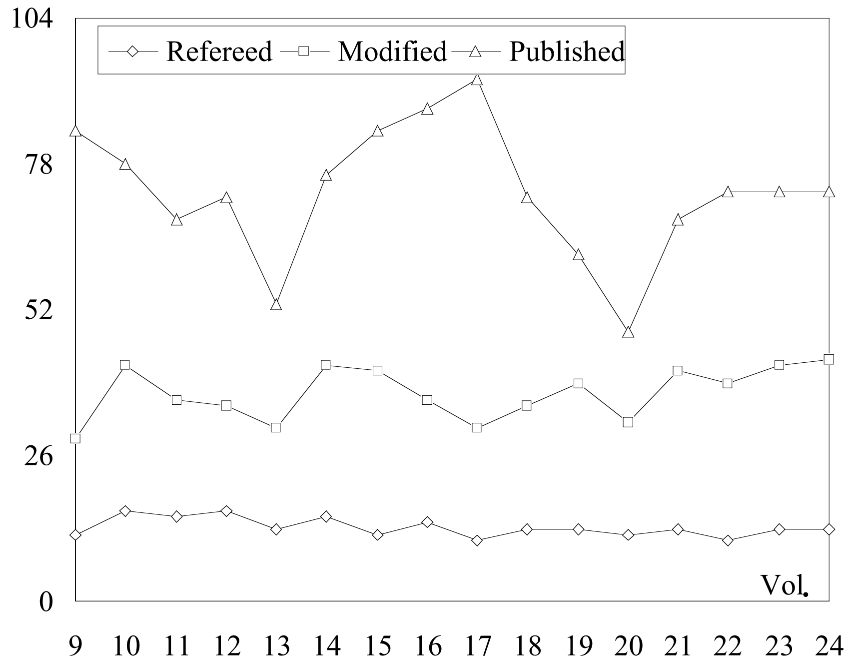

Figure 3: Performance by volume (weeks)

each year. While there is clearly a surge in 2006 (from 39 to 64) there is no similar surge immediately prior to the RAE exercises in 1996 and 2001. Moreover, the surge in submission from UK authors coincides with a surge from all authors, generally. These statistics show that UK authors are not unduly influenced into last minute submissions to this journal, an observation which runs contrary to popular belief, but may be somewhat reassuring for those who feel that the RAE process brings about publication for the sake of it. A more interesting statistic from Figure 2 is the relative constancy of copy flow from the UK, hovering around 50 papers per year, plus or minus about 10. In other words, the intense growth in the size of the journal is accounted for almost exclusively by the international scene.

One important aspect that we review every time we are considering the performance of the journal is the time it takes for papers to pass through the publication process. Figure 3 shows the average number of weeks from date of first submission to each of three points in the process: time to return referee reports after first round of refereeing, time to acceptance (including subsequent rounds of refereeing) and time to publication. The first one of these is primarily under the control of the editorial office. Despite asking referees to turn their reports around in two weeks, and despite being very diligent about sending reminders, it appears almost impossible to get this much below 13 weeks, give or take a couple of weeks. One of the reasons for this is the number of people who either fail to respond, or who let us know that they simply cannot complete the task at the moment, because of their other commitments. Clearly, non-responses slow the process a lot more than negative responses. But the consequence is that we have to invite at least eight referees to get four reports, often inviting more than 20 referees, in order to get the four reports we seek. It is the discovery of four willing and able referees that occupies most of the time in getting the papers reviewed. The distance between the first line and the second line on the graph is primarily the responsibility of authors. If their papers are well-written and

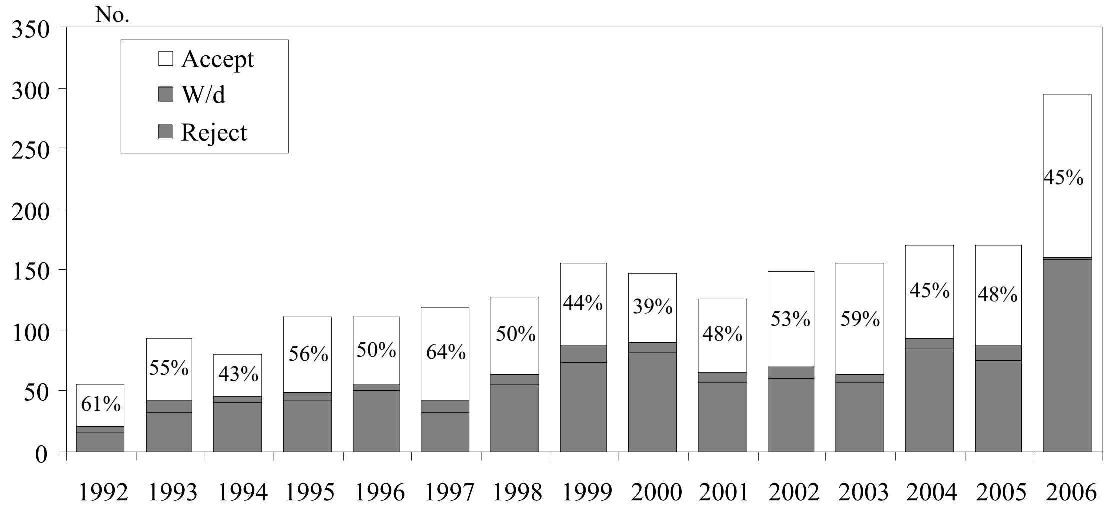

Figure 4: Annual acceptance rates

clear, reporting the results of interesting and useful research, then there will be few revisions, and little need for repeated iterations of the refereeing process. The average time spent in this phase for published papers is around six months. The distance between the second and third lines is largely the responsibility of the publisher, and indicates the length of the queue of papers that have been accepted and await publication. For the last few years this has been fairly stable at around 30 weeks. The whole process is taking 73 weeks, and this has been exactly the same for three years in a row. Relative to others, this is a good record for an academic, refereed journal.

The annual acceptance rates, as shown in Figure 4, are superimposed on the absolute number of papers accepted, withdrawn and rejected. This rate is not a target, but simply a result of the editors' interpretation of referees' reports. It is fairly constant

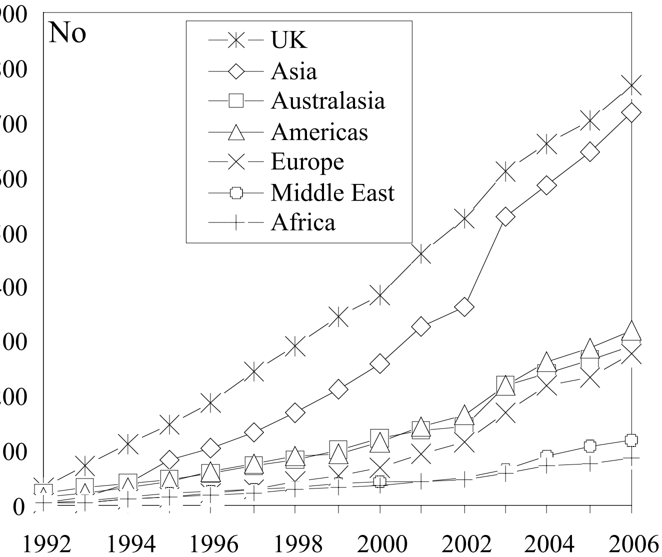

Figure 5: Origin of papers (cumulative)

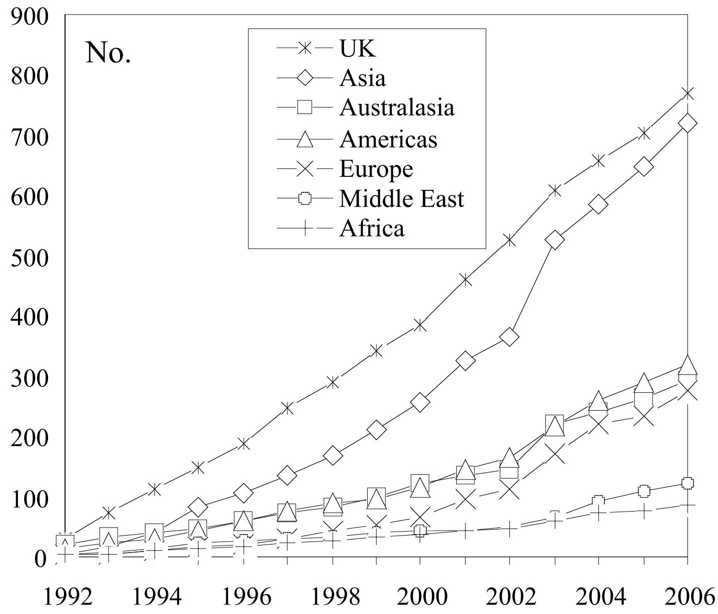

Figure 6: Origin of referees used each year

despite big changes in the numbers of papers dealt with each year.

The final category of statistics routinely produced for the journal are those regarding the origin of papers and referees. Figure 5 shows the cumulative picture of where papers are coming from since 1992. The majority of papers are still from the UK, although the cumulative data shows that the rate of growth in regions like Asia and the Americas, in particular has shown surges in recent years. As the top two lines converge, we will be continuing to see an increasing proportion of papers from outside the UK, as confirmed in Figure 2. There are clearly many diverse and inter-related reasons for the regional balance in terms of where papers are being submitted from. For most parts of Europe other than UK, for example, there is first a language barrier, and second a difference in the way that academic cases for promotion are dealt with. It is not standard practice in all countries for journal papers to play a major role in promotion cases. We are likely to see more papers from those countries where promotion is linked to publication. The huge growth of the construction sector in places like China, and the consequential growth of research and education to support it, would account for the surge in papers from that part of the world. But the large size of the USA market is not reflected in papers to this journal, perhaps because there are several well-established American journals to which American authors would turn first, before considering journals from other countries.

Finally, Figure 6 shows which regions referees are drawn from each year. This graph is not cumulative, and shows that our pool of referees is growing as rapidly as the number of papers submitted. This is bound to be the case, given that all authors are immediately entered into the referee pool. But given the difficulty of finding referees with the time to actually review papers, we are constantly on the look out for new people to add to the database. One way of providing exposure for the journal in places where it may not be well known is to invite academics from such places to review papers. This is achieved either through existing contacts making recommendations to us, or sometimes just browsing university web pages from places with appropriate academic departments, looking for research-active academics who could fulfil this role.

The statistical review of the performance of the journal provides the context for thinking about our strategy. Clearly, there are perennial questions about regional and topical coverage, quality of papers, presence in citation indexes, role of the editorial board members, and so on. These issues are the things that are regularly dealt with in our annual editorial board meetings. Although we can bring some influence to bear on the spread of papers by, for example, carefully selecting topics and guest editors for special issues, many of these characteristics are emergent, representing where the field is, rather than where the editorial team things it ought to be. We think this is a great strength of this journal. For the future, what we would like to do is to help authors in this field to have more of an influence on academic life in general, not just in construction-related departments. We shall be seeking to extend the citation indexes in which the journal's papers are listed, to help with identifiable impact factors, which seem to be developing in their importance in many countries. We will be encouraging authors to cite definitive sources from outside the journal itself, and continuing to bend every effort to make the papers in this journal the best quality that we can achieve. In this, we need the support of every author and referee in our research community – a level of support that has been constant and reliable since the journal started.

To conclude, I would like to thank the authors, referees, publishers and conference organizers for their tireless support for this excellent journal. And here's to another 25 years of a stimulating and influential journal! I hope you enjoy these conference papers.

INDUSTRY DEVELOPMENT

MILLENNIUM DEVELOPMENT GOALS AND CONSTRUCTION: A RESEARCH AGENDA

George Ofori[1]

Department of Building, National University of Singapore, 4 Architecture Drive, Singapore 117566

The Millennium Development Goals (MDGs) were set in a charter signed by the world's leaders in 2000 with the aim of attaining the sustainable development of the poorer countries and improving the quality of life of their peoples. Specific targets were agreed, to be achieved by 2015, including: eradication of hunger and poverty; achievement of universal primary education; reduction of child mortality; improvement of maternal health; and combating HIV/AIDS, malaria and other fatal diseases. The charter highlights the need for a global partnership for development. The MDGs have guided the work of international organizations such as the World Bank and various United Nations agencies. The construction industry can contribute to the attainment of the MDGs. A review of the literature shows that progress towards attaining the millennium goals has been slow although there are some encouraging results. Poor performance of the construction industry is a contributing factor to the lack of progress. Research is required to formulate initiatives which can be taken to enable the industry to make its due contribution.

Keywords: construction, developing countries, global partnership performance targets.

MILLENIUM DECLARATION

In a summit meeting in New York on 6–8 September 2000 attended by almost 150 heads of state, member countries of the United Nations (UN) adopted the Millennium Declaration. It reaffirmed the commitments of the members to the UN charter, and outlined 'certain fundamental values … essential to international relations in the twenty-first century' (UN 2000), including: freedom, equality, solidarity, tolerance, respect for nature and shared responsibility. It set out the following objectives 'to translate these shared values into actions': (1) peace, security and disarmament; (2) development and poverty eradication; (3) protecting our common environment; (4) human rights, democracy and good governance; (5) protecting the vulnerable; (6) meeting the special needs of Africa; and (7) strengthening the United Nations. The following clauses (UN 2000: section iii, paras 19 and 20), under the objective of 'development and poverty eradication' state targets which have been summarized into the Millennium Development Goals (MDGs) shown in Table 1.

19. We resolve further:

- To halve, by the year 2015, the proportion of the world's people whose income is less than one dollar a day and the proportion of people who

[1] bdghead@nus.edu.sg

suffer from hunger and, by the same date, to halve the proportion of people who are unable to reach or to afford safe drinking water.

- To ensure that, by the same date, children everywhere, boys and girls alike, will be able to complete a full course of primary schooling and that girls and boys will have equal access to all levels of education.
- By the same date, to have reduced maternal mortality by three-quarters, and under-five child mortality by two-thirds, of their current levels.
- To have, by then, halted, and begun to reverse the spread of HIV/AIDS, the scourge of the malaria and other major diseases that afflict humanity.
- To provide special assistance to children orphaned by HIV/AIDS.
- By 2020, to have achieved a significant improvement in the lives of at least 100 million slum dwellers as proposed in the 'Cities Without Slums' initiative.'

20. We also resolve:

- To promote gender equality and the empowerment of women as effective ways to combat poverty, hunger and disease and to stimulate development that is truly sustainable.
- To develop and implement strategies that give young people everywhere a real chance to find decent and productive work.
- To encourage the pharmaceutical industry to make essential drugs more widely available and affordable by all who need them in developing countries.
- To develop strong partnerships with the private sector and with civil society organizations in pursuit of development and poverty eradication.
- To ensure that the benefits of new technologies, especially information and communication technologies … are available to all.'

MILLENNIUM DEVELOPMENT GOALS

In summary, the MDGs, to be achieved by 2015, are:

1. Eradicate extreme poverty and hunger.
2. Achieve universal primary education.
3. Promote gender equality and empower women.
4. Reduce child mortality.
5. Improve maternal health.
6. Combat HIV/AIDS, malaria and other diseases.

7. Ensure environmental sustainability.
8. Develop a global partnership for development.

The eight MDGs have been translated into 18 specific targets, and 48 indicators have been developed for monitoring progress in achieving them (www.developmentgoals.org). It is estimated that, to attain the MDGs, developing countries must grow by 7–8% per annum (World Bank 2004), and that US$50 billion per annum in additional external funds would be required. Official aid flows were projected to rise from US$69 billion in 2003 to US$135 billion in 2006, and then to US$195 billion by 2015 (Millennium Project 2005).

The literature indicates that different sets of global development targets had been set out in the 1990s (Fay *et al*. 2005). The governments of 189 countries and many organizations have committed themselves to a global partnership to achieve the MDGs. The goals have formed the basis of policy formulation and implementation in developing countries, as well as by multilateral organizations such as UN agencies, the World Bank (2006b), regional development banks (ADB 2006), and various non-governmental organizations.

Many major international programmes have been launched. For example, the World Bank's Africa Action Plan of 2005 (www.worldbank.org/afr/aap) focused on achieving development results in good governance, closing the infrastructure gap, building capable states, and more equitable distribution of the benefits of development. There have been commitments to provide more additional resources. At the G8 leaders' summit in 2005, the world's eight richest countries pledged to double development aid to Africa from US$25 billion in 2004 to US$50 billion per year by 2010. They also committed themselves to deepen debt relief especially for countries with sound financial management and a commitment to poverty reduction. However, progress here has been slow.

The private sector has also played a role. For example, with respect to the MDGs, the World Business Council for Sustainable Development (WBCSD) (2005) seeks to: (1) learn by sharing – deliver tools and guides that advance understanding of development challenges and enable all sectors to address them; (2) advocate the business contribution – help business to work with all stakeholders to build synergies among programmes; and (3) learn by doing – demonstrate success through pilot investments and exploit synergies across sectors. The WBCSD has the following 'workstreams' in this area: (1) sustainable production and consumption; (2) SMEs as business partners – strengthening local supply chains, building capacity for SMEs; capital; and (3) monitoring and evaluation of the socio-economic impact of businesses.

MDGS IN THE LITERATURE

There is much discussion in the literature on the MDGs, and the ways and means of achieving them. Fay *et al*. (2005) note that some observers believe that since improvements in most indicators of development are highly co-related with increases in per capita income, MDGs 2 to 8 are superfluous as long as the first goal is tackled. However, studies have found relationships among many of the MDGs. For example, Abu-Ghaida and Klasen (2004) note that many empirical studies have found that gender equity in education promotes economic growth, and reduces fertility, child mortality and under-nutrition. They estimated that countries which failed to attain gender equity by 2005 would suffer 0.1 to 0.3 percentage points lower per capita growth rates, and by 2015, an average of 15 per 1000 higher rates of under-five mortality, and 2.5 percentage points higher prevalence of underweight children under five.

Maxwell (2003) points out that the MDGs might encourage oversimplified interventions emphasizing social indicators at the expense of economic growth. Clemens *et al*. (2007) find fault with the way the MDGs (most of which they consider as overreaching) were set, and assert that they are impossible to meet. They note that focus on the MDGs (which stress not successes, but what remains to be done) encourages unproductive debate on where the fault for the lack of progress lies, and undermines partnership between rich and poor. Clemens *et al*. (2007: 747) observe that indicating that the MDGs can be met merely with increased resources 'contributes to the illusion that the goals are attainable for all countries'. They suggest that the specific MDG targets 'have set up many countries for unavoidable "failure"' (p. 747), even as they pursue good policies and make progress on some development indicators. Moreover, some countries may be distracted from much needed reforms. The Independent Evaluation Group (IEG) of the World Bank (2006) notes that achieving high quality development results takes time, but pressure to show results can divert attention from the quality of results. For example, efforts to attain the MDG of ensuring universal completion of primary education in 2015 have led to efforts to increase enrolments, often at the expense of the attention to learning outcomes. In Uganda, there are now 94 children per classroom, and three children share a textbook, whereas in Ghana, the development programme in the education sector combined policy reforms with the provision of school buildings and teaching materials.

White and Black (2004) note that the MDGs would not be effective as accountability for failing to meet them is diffuse. Clemens *et al*. (2007) suggest that future development goals should: (1) be country-specific and flexible; (2) take historical performance into account; (3) focus more on intermediate targets than outcomes; and (4) be considered benchmarks rather than goals which are technically feasible with sufficient funds alone.

There have been many studies on progress towards achieving the MDGs. Sahn and Stifel (2002) assess progress on six of the MDGs relating to living standards in Africa, and paint a discouraging picture. Baulch (2006) found that most donors are not distributing their aid in a way that is consistent with the MDGs, i.e., they do not direct large shares of their concessionary aid flows to the poorest and most deprived countries. There have also been studies, and some debate, on the effects of possible interventions. Fay *et al*. (2005) found that better access to infrastructure (piped water, sanitation and electricity) has a large and statistically significant effect in reducing infant and child mortality and incidence of malnutrition. Ravallion (2007) disputes these findings, questioning the estimating methods adopted. He also concluded that (contrary to the findings of Fay *et al*.) there was complementarity between basic infrastructure and health care, whereby at sufficiently high levels of initial health care, improvements in basic infrastructure reduce infant and child mortality and the incidence of malnutrition. In response, Fay *et al*. (2007: 930) highlight the complexity of the situation and call for more research. They note that:

> the analysis provided by Ravallion suggests that additional work is needed to properly assess the impact of access to infrastructure, … health care, and schooling on child health. Concluding that infrastructure and health care have no impact, as one might be led to believe in the preferred specification of

> Ravallion, would contradict both common sense and other evidence… The solution to the puzzle will involve better data sets, so that with proper modeling … more robust results can be obtained …

CURRENT RESULTS

The World Bank (2006a) indicates that joint efforts to reach the MDGs are falling short. The world is on target to reduce extreme poverty by half by 2015. However, performance varies among regions. The greatest progress has been made in Asia, especially in China and India. In China, between 1990 and 2005, the number of people living on less than US$2 a day fell by over 400 million. In India, the level of poverty fell from 36% in 1993–94 to 26% in 1999–2000. In particular, sub-Saharan Africa, as a region, is unlikely to meet the goal (World Bank 2006b). The results are also mixed in terms of the other goals: less than 80% of countries are on target to meet the child mortality goal.

Progress has been made in some countries in Africa. The World Bank (2007b) reports that 13 sub-Saharan African countries have attained middle-income status, with another five on course. More than one-third of Africans now live in the 15 countries that have grown by 5.3% per annum for over a decade. Gross primary school enrolments in Africa reached 96% in 2004. Africa is considered the world's third fastest region in the pace of reforms to reduce the time and cost needed to start a business (World Bank and IFC 2006). However, the World Bank (2007b) reports that more than 314 million Africans – nearly twice as many as in 1981 – live on less than $1 a day. Thirty-four of the world's 48 poorest countries, and 24 of the 32 countries ranked lowest on the United Nations Development Programme's Human Development Index, are in Africa. Most African countries remain high-cost, high-risk places to do business (World Bank and IFC 2006). Africa receives only about 10% of foreign direct investment to developing countries. In 2006, many African countries' exports expanded by about 8% owing to higher prices for resources, but this was not enough to offset the continuing decline in the continent's share of world trade.

The Latin America and Caribbean region grew by 6.0%, 4.5% and 5.0% in 2004, 2005 and 2006 respectively because of higher export revenues and volumes resulting from high commodity prices and world growth (World Bank 2007c). The countries have achieved significant progress in education. In Grenada, repetition rates in secondary schools have been reduced from 11.6% to 1.3% between 1994–95 and 2000–01. In Mexico, a project helped increase completion rates in primary education from 66% in 1994–95 to 80% in 2000–01 in disadvantaged communities in 14 of Mexico's poorest states. However, the region continues to face the related development challenges of increasing growth, while reducing poverty and inequality – some 106 million people (nearly 21% of the population) live on less than $2 a day.

CONSTRUCTION AND MDGS

The role of construction in development, and hence in efforts to meet the MDGs is evident in three main ways (Hillebrandt 2000; Ofori 2000). First, buildings and items of infrastructure are inputs for economic and social activity, leading to increased incomes and national development. Second, construction work stimulates activities in other sectors of the economy from which the industry obtains its inputs, such as manufacturing. This contributes to economic growth and development. Finally, construction provides employment opportunities. This can make its workers effective consumers in the economy, further stimulating activities in other sectors. On the other hand, a growing economy, expanding related sectors, and higher employment, individually and together, lead to increased demand for construction (Wells 1986). Thus, there is a cyclic relationship between construction and the attainment of the MDGs. Indeed, Matthews *et al*. (2003) outline the benefits construction firms gain by improving their social performance: they are competitive when tendering for certain projects by demonstrating their ability to meet clients' social performance objectives; they enhance their brand reputation; and they reduce project risks and overruns. In Table 1, the contribution which construction can make towards the attainment of the MDGs is presented, together with Indicators for measuring the progress which the industry makes in this process.

From the above discussion, the construction process can be a bottleneck in the effort to realize the MDGs. Therefore, the capacity of the industry in the developing countries should be enhanced to enable it to deliver a higher volume of output to meet the increased demand as initiatives to realize the MDGs are implemented. The capability of the industries should also be enhanced to enable cost effectiveness and time efficiency on projects. Greater attention to cost performance would mean that more construction would be provided per unit of money; would enable national budgets to cover greater volumes of construction; and widen the pool of clients who can express effective demand for constructed items. Time efficiency would help to remove the constraints which buildings and infrastructure might pose to the process of national development. Quality and durability should also be addressed to provide further elements of value for money.

The literature has long highlighted the employment generation potential of construction (Hillebrandt 2006). This potential can be most effectively realized through the adoption of appropriate procurement approaches and technologies. Greater attention should be paid to technology assessment and selection in construction (see, for example, Howe and Bantje 1995; ILO 2003). Studies have also found that construction sites and their workers contribute to the spread of mosquito-borne diseases (Vijayan and Neo 2007) and HIV/AIDS (Meintjes *et al*. 2007). Thus, working conditions on sites should be improved to reduce the spread of diseases among the industry's workers and the community.

Partnerships between the construction industry and its stakeholders should be established to ensure the effectiveness of the industry's contribution to the attainment of the MDGs. The stakeholders, and their interests and aspirations in relation to construction should be identified; their expectations and views should be ascertained; and the best form of partnership with each stakeholder should be found. Construction firms should be MDG compliant in their operations. They should seek new ways of doing business that lead to mutual gain for themselves and their stakeholders, for example, by adopting the above approaches, in effect, widening the client base and enhancing the people's well-being.

One of the most direct ways in which construction influences the attainment of the MDGs, infrastructure provision, is now considered.

INFRASTRUCTURE DEVELOPMENT AND MDGS

The literature highlights the role of infrastructure in economic growth and development (Han and Ofori (2001) provide a useful review). Fedderke *et al*. (2006) analysed data for South Africa from 1875 to 2001 and found that investment in infrastructure leads to long-term economic growth both directly and indirectly, the latter by increasing the marginal productivity of capital. The World Bank (2007a) notes that improving infrastructure in developing countries is a key factor in reducing poverty and increasing growth; it is vital to the achievement of the MDGs as it improves access to water and electricity, as well as schools, hospitals and markets. The World Bank (2007a) observes that if Africa had attained infrastructure growth rates comparable to those in East Asia in the 1980s to 1990s, it could have achieved annual growth rates about 1.3% higher. Similarly, it is estimated that the lack of investment in infrastructure in the 1990s reduced long-term growth in the Latin America and Caribbean region by 1–3 percentage points, and hindered the region's ability to compete with the dynamic Asian economies (World Bank 2007d). In India, the Minister of Finance, P. Chidambaram, expressed concern over an 'intractable' problem of 'deficit infrastructure', considered to be a severe constraint on the country's development effort; the government has made infrastructure its priority (*The Hindu* 2005).

There are many recent examples of the economic and social stimulus from investments in infrastructure. Two World Bank (2007d) projects in Peru rehabilitated 13 000km of rural roads, reducing travel time by an average of 68%; and increasing school enrolment by 8% and visits to health centres by 55%. In Peru, the rehabilitation of some 11 000km of rural roads in the Sierra countryside improved access to markets for 3 million poor people and created jobs in 410 local road maintenance enterprises. In Morocco, the construction of an all-weather road in rural communities increased girls' primary school attendance from 28% to 68%.

ACTION IN ADDRESSING MDG IN CONSTRUCTION

Action has been taken to use construction to realize the MDGs, especially that on poverty reduction. The International Labour Office (ILO) has had a programme to develop and promote labour-based construction, focusing on roads, since the 1970s. Its work has included the development of design and specifications, technology, procurement methods and capacity building (training and SME development) (see, for example, ILO (2003)). Some professional institutions are relating the MDGs to their efforts in construction industry development. Engineers Against Poverty (2006) sought to identify opportunities to improve the delivery of social development objectives by modifying the way in which public infrastructure projects are procured. It suggested: (1) project identification should be in line with national, local or sector plans and/or based on public consultation; (2) the whole life cycle of the project should be considered during planning and design, and a maintenance strategy developed; (3) social objectives should be clearly identified at the planning stage and incorporated into design; (4) funds should be set aside in the budget for the realization of social objectives; (5) an appropriate procurement approach to deliver the specified social objectives should be chosen; (6) the bidders' social performance and capacity to deliver social obligations should be considered; (7) contractual obligations

Table 1: The Millennium Development Goals and role of construction (source of MDGs: United Nations www.un.org.org/milleniumgoals/images/mdgs_01.gif)

Millennium Development Goal	Contribution of construction	Indicators for construction
Goal 1: Eradicate extreme poverty and hunger * Reduce by half the proportion of people living on less than a dollar a day * Reduce by half the proportion of people who suffer from hunger	* Effective and efficient production of buildings and infrastructure * Maximum linkages of construction to other sectors of national economy to create stimulus * Generation of employment opportunities through appropriate choice of technology and procurement * Continuous development of industry	* Performance of industry, company or project on key indicators, such as time, cost, quality, safety * Features of construction in national input–output tables * Number of jobs created, average wages * Average corporate profits; profits on projects
Goal 2: Achieve universal primary education * Ensure that all boys and girls complete a full course of primary education	* Design and construction of suitable school buildings (in local economic, climatic contexts) * Contribution to economic growth and national development to create jobs for graduates	* Estimate of total capacity of national industry, and that of the firm
Goal 3: Promote gender equality and empower women * Eliminate gender disparity in primary and secondary education preferably by 2005 and in at all levels by 2015	* Creation of job opportunities for women and youth (Goal 8) at all levels in construction, with close attention to working conditions on sites, remuneration and career progression	* Proportion of females in workforce of industry, company, project, at different levels * Average remuneration of employees of different genders
Goal 4: Reduce child mortality * Reduce by two-thirds, the mortality rate among children under five *Goal 5: Improve maternal health* * Reduce by three-quarters, the maternal mortality ratio	* Construction of hospitals and infrastructure * Provision of job opportunities to generate income	* Same indicators as for MDGs 1 and 2
Goal 6: Combat HIV/AIDS, malaria and other diseases * Halt and begin to reverse the spread of HIV/AIDS * Halt and begin to reverse the incidence of malaria and other major diseases	* Effective site management to avoid health hazards * Initiatives to avoid spread of HIV/AIDS by construction workers (through education)	* Industry, company, project performance on health and safety * Industry and company policies and programmes on HIV/AIDS
Goal 7: Ensure environmental sustainability * Integrate the principles of sustainable development into country policies and programmes; reverse the loss of environmental resources * Reduce by half the proportion of people without sustainable access to safe drinking water * Achieve significant improvement in the lives of at least 100 million slum dwellers by 2020	* Sustainable construction – cradle to grave considerations of all aspects of construction * Effective management of completed buildings and infrastructure	* Industry, company, project performance on sustainable construction – waste generation * Average scores in environmental assessment of buildings * Energy performance of various types of buildings
Goal 8: Develop a global partnership for development * Develop further an open trading and financial system that is rule-based, predictable and non-discriminatory, includes a commitment to good governance, development, and poverty reduction—both nationally and internationally * Address the least developed countries' special needs. This includes tariff- and quota-free access for exports; enhanced debt relief for highly indebted poor countries; cancellation of official bilateral debt; and more generous official development assistance for countries committed to poverty reduction * Address the special needs of landlocked and small island developing states * Deal comprehensively with developing countries' debt problems through national and international measures to make debt sustainable in the long term * In cooperation with the developing countries, develop decent and productive work for the youth * In cooperation with pharmaceutical companies, provide access to affordable, essential drugs in the developing countries * In cooperation with the private sector, make available the benefits of new technologies—especially information and communications technologies	* Construction as a partner for development – study the role of construction in development in order to enhance it * Construction as a creator of wealth and less of a burden in imported inputs * Research on, and develop, construction industries in developing countries to enable them to play a role in globalizing economies * Effective logistics of construction in landlocked and small island developing states * Effective construction technology transfer in construction – from research to practice; from industrialized to developing countries * Partnership among industry, government, researchers * Global networks of researchers to study matters on construction and MDGs	* Same indicators as for MDGs 1 and 2

must be monitored and enforced through incentives and/or sanctions; and (8) social performance audits should be conducted with the same rigour as financial audits.

The ILO (2006: 3) suggests that municipalities should launch investment policies and programmes with the following elements: (1) employment-intensive infrastructure development for upgrading unplanned settlements and rehabilitating facilities for people affected by disasters and conflicts; (2) provision of social infrastructure for accessibility, water, health, education, markets, rehabilitation and preservation of national heritage; (3) organization and association building, negotiation and contracting capacity building for communities and informal economy operators, and support to SMEs; (4) provision of support to local governments, community groups and the private sector in pro-poor procurement and community contracting; (5) review of the local regulatory environment to improve their impact on job creation and the quality of jobs created; and (6) integrated employment and environmental impact assessments of urban investment plans.

Matthews *et al*. (2003, 2004) suggest that where appropriate, major construction firms should engage in national debates on policy reform to promote the value-adding role of construction firms in achieving government poverty reduction priorities. They should develop business strategies and tendering approaches which showcase their ability to contribute to the social performance of their clients. They should be proactive in developing relationships with communities in order to better target opportunities for community subcontracting and unskilled or semi-skilled employment at the poor. They should also develop a framework for reporting social performance, especially in areas of local content, skills training and social investment.

The WBCSD (2005) showcases several programmes and projects in which some of its member companies are taking action, moving beyond philanthropy and corporate social responsibility to business relationships. For example, under the ‘House-for-Life’ programme in Sri Lanka, launched in 2005, Holcim, the leading cement provider in the country, has formed a partnership with Ceylinco Grameen (a microfinance institution) to address the housing needs of the poorest citizens. Micro-entrepreneurs borrow money to buy a home designed as a shophouse, which provides each family the premises to run a business. Holcim provides the initial funds and technical skills, and Ceylinco administers the loan. In another example, a subsidiary of GrupoNueva (a company which deals in forest products, water systems and construction materials) in Guatemala (in collaboration with the government and two non-governmental organizations), has provided specially designed drip irrigation systems which help to reduce costs to farmers and ensures efficient availability of water throughout the year. This has helped the farmers to improve their production, and move their crop mix from subsistence to export-oriented produce.

THE FUTURE

Immensity of the task

Despite the continuing debate on their appropriateness, the MDGs are relevant goals which provide a framework for the development effort. The task is immense. It is estimated that by 2050, 85% of the world’s population of nine billion people will be living in developing countries (WBCSD 2005). The poorest countries are in a group of 35 Low-income Countries Under Stress also known as ‘fragile states’. The IEG (2006: 18) notes that they ‘are home to almost 500 million people, roughly half of whom live on less than a dollar a day. These countries face poor governance, conflict or post-conflict transitions, and a multiplicity of problems that make the achievement of development results particularly challenging.’ They face what the World Bank (IEG 2006) calls ‘the largest millennium development challenge-deficit’. They represent 9% of the developing world’s population, but 27% of the extreme poor.

Progress towards meeting the MDGs will not come only from additional foreign aid; supplementary solutions are required. For example, the IEG (2006) found that only two in five of the countries borrowing from the World Bank recorded continuous per capita income growth in 2000–05, and only one in five over 1995–2005. Thus, it is necessary to consider other contributors to the attainment of the MDGs, such as construction activity.

Research agenda

Researchers in construction management and economics (CM&E) can make an important contribution to the efforts to attain the MDGs. It is pertinent for each research study to seek to consider, among its objectives, the extent to which the findings would have an impact on the realization of relevant MDG targets.

CM&E researchers should help to relieve the severe constraints which the non-availability of relevant accurate information and data has on the improvement of both industry performance and research towards this end (Meikle and Grilli 1999). It is necessary to establish appropriate frameworks and methods for collecting, processing and disseminating comprehensive and accurate information on the construction industry, its processes and products in each country (Ofori (1988) presents a framework for such a data bank). Such information would facilitate the setting and monitoring of targets in each country, and inter-country comparisons. There could also be an international research project to determine industry, corporate and project level performance indicators, some of which have been highlighted in Table 1. These would facilitate the monitoring of the contribution of construction to the attainment of the MDGs.

There is need for greater understanding of the direct relationships between construction activity and some of the MDGs and other related key factors and phenomena. Some of the models which are required include: (1) relationship between construction activity and economic growth and development; (2) influence of various individual types of construction projects, such as a road, a bridge or a school, on economic growth; (3) the forward and backward linkages between construction and other sectors of the economy; (4) the amount of employment generated by a unit of different categories of construction work; (5) the relationship between improved construction industry performance and attainment of relevant MDG targets; and (6) the impact of foreign development assistance on economic growth and industry development.

Better understanding of the nature of the construction industry in developing countries is also required. In particular, more work is required on the informal sector, to explore its potential contribution to: (1) the enhancement of the capacity and performance of the industry as a whole; (2) determination of practical solutions which meet the housing needs of the poor; and (3) design and delivery of employment-intensive construction. The construction industry needs to know its stakeholders. More research on the real stakeholders of construction, and how to integrate their possible contributions to the projects is also required. Finally, other relevant topics to the development of the construction industries are: (1) effective public–private and foreign–local partnerships; and (2) effective technology transfer.

SUMMARY AND CONCLUSION: A DECLARATION

The construction industry has a critical role to play in the efforts being made to attain the MDGs. A declaration for the construction industry which could be considered for adoption by CM&E researchers, is now presented.

1. ‘We recognize that all construction is undertaken to benefit people. In this sense, the community is the most important stakeholder of the construction process and its needs and aspirations should be taken into consideration in all our work.
2. ‘We are aware that the buildings and infrastructure designed and produced by the construction industry are critical inputs into the development process which leads to the reduction of extreme poverty and enhancement of the quality of life of all people, and we should continuously seek ways and means to enhance the contribution of these inputs.
3. ‘We should provide value for money for society by producing cost effective, high quality, durable and easy to maintain buildings and items of infrastructure in the most time efficient and sustainable manner.
4. ‘We should select material inputs, technologies and procurement and project management approaches that enable construction activities to provide the maximum stimulus and spin-offs in the local economy, and employment opportunities for the community.
5. ‘We should establish employment practices and working conditions which promote the economic and social, well-being, and health of the industry’s workers, and are conducive to the safe and effective participation of women in construction.
6. ‘We urge researchers in CM&E to give priority in their work to how the construction industry can be enabled to realize the objectives outlined in clauses 1 to 6. In particular, they should develop indicators and benchmarks for assessing and monitoring the performance of the construction industry in each country with regard to the attainment of this objectives in this declaration.
7. ‘We should establish strong partnerships in each country among industry, government, the community and researchers to pursue the development of a construction industry with the attributes outlined in clauses 1 to 6.
8. ‘We call for the establishment of a global partnership among industry, governments and the communities to champion the development of the construction industries in developing countries to enable them to achieve the attributes outlined in clauses 1 to 6.’

FIRST AND SECOND PRICE INDEPENDENT VALUES SEALED BID PROCUREMENT AUCTIONS: SOME SCALAR EQUILIBRIUM RESULTS

Martin Skitmore[1]

School of Urban Development, Queensland University of Technology, Gardens Point, Brisbane Q4001, Australia

A great body of knowledge exists on the theory of auctions and competitive bidding that is of potential relevance to construction contract tendering. Most of this, however, contains assumptions – such as perfect information – that are unlikely to be tenable in practice. The aim, therefore, is to examine the effects of relaxing some of the more restrictive of these assumptions in the construction tendering context. In particular, the effects of additive and multiplicative (scalar) mark-ups in equilibrium are examined for first and second price auctions in situations where bidders have different, uncertain, costs. This is illustrated first by Monte Carlo simulation – by which bids generated randomly from a normal distribution for six bidders and mark-ups are applied systematically for each bidder in turn until equilibrium is reached. An extensive numerical analysis is then applied to obtain equilibrium results for both mark-up values and expected profit from the simple symmetric case through to more complex asymmetric cases for the uniform and normal distributions. In general, it is found that first price auction bidders with relatively high c_v levels and a larger number of bidders involved bid higher in equilibrium but can expect little profit unless the number of bidders involved is small. Where there are asymmetries, stronger bidders (i.e. those with lower costs and less variability) bid much higher and achieve much higher profits in equilibrium. From the seller's point of view, it is cheaper, in equilibrium, to have a homogeneous group of low variability bidders. The work contributes to the body of knowledge on the economic theory of auctions by closing some of the gap between theory and practice.

Keywords: auction theory, bidding, equilibrium, procurement tendering.

INTRODUCTION

While the practice of auctioning goes back to ancient times,[1] the earliest academic treatments are relatively recent, with the contributions of Friedman (1956) from an operations research (decision theoretic) perspective, Vickery (1961) from a game theoretic perspective and Gates (1967) from what has been termed the tendering theory perspective (Runeson and Skitmore 1999). In general, decision and tendering theory seek to inform bidders while game theory seeks to inform sellers. All three approaches have some impractical assumptions. Decision theory (DT), for example, is essentially static, in that it assumes any given bidder's opponents to bid with either a random or constant mark-up. Game theory (GT) on the other hand assumes all bidders somehow always bid optimally irrespective of the value of their cost estimates.

[1] rm.skitmore@qut.edu.au

Of the three, progress has been dominated by the development of the game theoretic approach into a full-blown Bayesian–Nash equilibrium theory, now termed auction theory (AT), under the standard economic assumption of rational utility maximization – so that now 'the auction problem can be understood by applying the usual logic of marginal revenue versus marginal cost' (Klemperer, 1999: 312).[2] One of the major outcomes of this theoretical development has been to discover the equilibrium bidding strategies for independent *private value* (IPV) auctions. This assumes an idealized form of valuation process by which, in procurement auction terms, each bidder estimates the costs involved perfectly accurately. For example, Vickrey (1961) showed that if bidders are symmetric, that is, the resulting bids are assumed to be drawn from the same probability distribution, the expected payment for the client/building owner in English first price (open-cry), sealed bid, second price sealed bid (Vickrey) and Dutch (descending) auctions is the same in equilibrium.

As an alternative to IPV auctions, in which it is assumed that bidders have perfectly estimated but different true costs, the *common value* (CV) model has been studied, in which all bidders are assumed to have the same, but imperfectly estimated, true costs (e.g. Wilson 1969). Clearly, the private and common value assumptions are special cases of a more general model which contains *both* imperfect information *and* different costs for each bidder. One version of this that has received considerable attention (e.g. Myerson 1981; Riley and Samuelson 1981; Milgrom and Weber 1982) is based on the idea of signals. Here it is assumed that each bidder receives a private value signal (cost estimate), but allows each bidder's value (cost) to be a function of all the signals (other bidders' cost estimates). With a suitable definition of this function in terms of the assumed conditional probabilities involved, Milgrom and Weber (1982) were able to develop the general model needed, termed the *affiliated values* model, by using a natural generalization of the monotone likelihood ratio property commonly used in statistical models. This provides several equilibrium results, the most important of which is that the English auction generates the lowest bids followed by the second price and, finally, the Dutch and first price auction.

Milgrom and Weber's work, however, is concerned with the general properties of symmetric auction models when types (values/signals) are *not* independently distributed (Monteiro and Moreira 2006: 1), making the affiliation assumption, as Milgrom and Weber point out, necessarily restrictive. Although, as they say, it may accord well with the qualitative features of some situations, such as the sale of works of art, there are many other situations where it does not (Monteiro and Moreira 2006: 1; de Castro 2004). In fact, de Castro (2004) is particularly critical, claiming the affiliated values assumption to be 'very restrictive'; much more cumbersome to manipulate theoretically, with the monoticity of equilibrium hard to maintain; and leading to conclusions that are misleading if applied to reality. In his view, a return to the search for non-monotonic equilibria is urgently needed, citing Araujo *et al.*'s (2003) general existence result of non-monotonic symmetric equilibria with independent types. Araujo *et al.* (2004), among others, have continued this work to examine multidimensional situations. Meanwhile Lebrun (1996, 1999) has obtained some results for asymmetric first price auctions, that is when bidders' values are differently distributed, while Cantillon (2004) has considered both first and second price asymmetries. Guth *et al.* (2004) provide a summary of much of the asymmetry work. No treatment appears yet to have been made of the equilibria for the asymmetric general independent values (GIV) model which contains both imperfect information *and* different costs – most likely because of the difficulties involved in finding analytical solutions (Rothkopf *et al.* 2003: 72).

To examine the theory further for construction contract auctions, a starting point is to return to the original theme and consider the GIV model where bidders have, independently, both different costs and imperfect estimates of them. In addition, unlike AT where unbounded rationality is assumed, the goal is to maximize profits by the more practical means of mark-up manipulation. This involves finding equilibrium in DT-like scalar strategies rather than AT functions (Rothkopf *et al.* 2003: 73).

Equilibrium multiplicative mark-up strategies in a *symmetric* common value (imperfect estimates but same costs) sealed bid game theoretic setting have been reported in several studies. Rothkopf (1969, 1980a), for example, solves the *n* bidder Weibull distributed first price (FPA) situation analytically, while Oren and Rothkopf (1975) extend this to the situation where a bidder's strategy in one auction affects his competitors' behaviour in subsequent auctions, modelling bidding in a sequence of auctions as a multistage control process. Smith and Case (1975), on the other hand, consider the two bidder loglogistic common value FPA situation for both pure and mixed (randomized) strategies, while Rothkopf (1991) also considers the *n* bidder common value Weibull FPA and second price (SPA) situations in which bidders may submit two or more bids and then withdraw some bids after bids are opened.

For the *asymmetric* situation, Rothkopf (1969, 1980a) has solved the equilibrium multiplicative mark-up strategies for the two bidder *common variance* Weibull distributed FPA situation analytically, and the *n* bidder case numerically.[3] No results have been reported for the fully asymmetric imperfect estimates case, where both location and scale parameters are unique to each bidder. Neither have any equilibrium results been reported for scalar strategies other than multiplicative for either the symmetric or asymmetric situation, with the exception of Rothkopf (1980b), who found, analytically, the equilibrium linear (affine) FPA mark-ups in the Weibull common value *n* bidder situation.

In general, therefore, it is concluded that, despite the difficulties involved in equilibrium asymmetric modelling with cost uncertainties, multiplicative mark-up models at least have had some success. In this paper, both the equilibrium multiplicative *and* additive mark-ups are considered within a general linear mark-up strategy. First, an example is provided describing how results may be obtained by straightforward Monte Carlo simulation to illustrate the simple concept underlying the analysis and identify some of the practical problems involved. Next, a numerical analysis is undertaken for the FPA and SPA for the uniform and normal composite densities and the results provided for some of the more obvious regularities detected. Finally, some practical observations are volunteered on the relevance of the analysis to construction contract bidding in practice.

SIMULATION METHOD

Analysis

Figure 1 (all Figures are in the Appendix) shows the FPA results of simulating 100 000 values for each 0.1% change in (multiplicative) mark-up values by a bidder, assuming other bidders are all bidding with the same mark-up as each other. In this illustration, a typical construction contract auction situation is assumed in which there are six bidders in total, each drawing cost estimates from a normal distribution with 4.3% coefficient of variation. Overheads are calculated by the CIC formula converted to rebased HK$, with project size (HK$value) being loglognormal (mean = 2.872829, s.d. = 0.061078).

To understand Figure 1, first assume all opposing bidders apply a 12% mark-up. The expected profit is then recorded for the reference bidder over series of reference bidder mark-up values. The results of this are shown in Figure 1 as the curve marked ‘12%’. The optimal mark-up, i.e., the mark-up value that provides the maximum expected profit, occurs at the upper turning point of this curve at 6.7% mark-up (point A), giving an expected profit of $21.4m.

Now assume all opposing bidders apply a 11% mark-up. Again the reference bidder’s expected profit is recorded over a series of reference bidder mark-up values and plotted, this time at the curve marked 11%. In this case the optimal mark-up is 6.5%, giving an expected profit of $15.5m. Figure 1 shows the results of this repeated for 10%, … , 5%. Line A–B connects the optimal mark-up values.

For the game theoretic solution the usual approach is to use the Nash criterion. That is, the solution occurs where any alternative solution for any player produces a worst result overall. This can be reached by trial and error as follows. In this case, from Figure 1, assume that all bidders bid at 12% mark-up. Now, as mentioned above, the reference bidder can maximize his profits by bidding a 6.7% mark-up. Unlike the DT approach, where competitors are assumed to be unable to change, the game theoretic approach assumes that all bidders know that bidding at 6.7% mark-up is best against competitors bidding at 12% mark-up. In other words, it has to be allowed that all bidders will bid at 6.7% mark-up under the assumption that their competitors are bidding at 12% mark-up.

Now, assume that all bidders are bidding at 6.7% mark-up. This will be on the line C–D. Our bidder’s best mark-up now is the point on A–B at the same value of the y-axis, i.e. around 8.25% mark-up. Following the same reasoning then, if all bidders bid at 8.25% mark-up, our bidder should bid at around 7% mark-up. Repeating this process enough times results in convergence at 7.4% mark-up, where no bid higher or lower by any bidder will produce a better result. This, then, is the equilibrium solution and occurs where the two lines A–B and C–D intersect, in this case producing an expected profit of approximately $2m.

Figures 2 and 3 show the solution of the SPA. Again A–B gives the optimal results, showing 0% mark-up to be optimal when competitors all bid at greater than 5% mark-up, but increasing quite rapidly when they bid less. The Nash outcome (Figure 3) is 3.6%, producing an expected profit of $1.6m.

Comment

A few issues arise out of this illustrative analysis by simulation. One is that the expected profit for some optimal mark-up values is sometimes negative. That is, it can be an expected loss. Of course, this is unlikely to be the case in a live situation as presumably bidders will prefer not to bid at all rather than make a loss under equilibrium.[4]

Another issue is that using Monte Carlo simulation, although very fast on a modern PC, is still quite time consuming (Figure 1 takes around one hour to produce). While it is useful enough for a one-off auction situation with a fixed set of parameters, it is unlikely to be practicable in an extensive analysis aimed at identifying general relationships and regularities. To do this necessarily requires a massive reduction in computing time. In previous similar studies, the most popular approach to this is to derive general results by analytical means. However, as has been already observed, this is seldom possible beyond the relatively simple symmetric IPV and CV assumptions.

An intermediate approach that has been used previously with some success for more complex situations is numerical analysis. This involves deriving formulae that can be solved by a means other than by finding the solution of a set of differential equations. In this case, the formulae for calculating the expected profit is used together with numerical maximization software from the Numerical Algorithms Group (NAG) Library. The formulae developed are presented in the Appendix for the general linear (additive and multiplicative) mark-up case.

NUMERICAL METHOD: SOME FPA RESULTS

The Nash solution is easily found numerically by using Equation A.2 to first find the mark-up values, $\tilde{v}_{1i}$ and $\tilde{v}_{2i}$ that maximize expected profit $\tilde{E}_i = E_{(k)i}[\theta]$ for bidder *i*, then finding $\tilde{v}_{1j}$ and $\tilde{v}_{2j}$ that maximize $\tilde{E}_j = E_{(k)j}[\theta]$ for the next bidder $(j = 1, \ldots, n;\ j \neq i)$ assuming the first bidder is using $\tilde{v}_{1j}$ and $\tilde{v}_{2j}$, etc., after assuming appropriate starting values. Upon convergence, $v_{1i}^* = \tilde{v}_{1i}$ and $v_{2i}^* = \tilde{v}_{2i}$, etc., $(i = 1, \ldots, n)$ are the equilibrium mark-up values, with associated equilibrium expected profits, $E_i^* = \tilde{E}_i$, etc.

Additive equilibrium mark-up (v_1^*)

In reality, it is most likely that the true parameters for all bidders will be different, i.e. $\mu_1 \neq \mu_2 \neq \ldots \neq \mu_n$ and $\sigma_1 \neq \sigma_2 \neq \ldots \neq \sigma_n$ (Skitmore 1991). However, it is of interest to see what the effects are of some simplifying assumptions. The simplest of these is where the value of all bidders' parameters are equal to our own, i.e. $\mu_1 = \mu_2 = \ldots = \mu_n$ and $\sigma_1 = \sigma_2 = \ldots = \sigma_n$. This is equivalent to the symmetric *common value* model, many of the properties of which have already been established for the formless bid function. However, these are now considered here for the first time for the additive equilibrium mark-up, v_1^*, by fixing $v_2 = 1$. Then the effects are considered of $\mu_1 = \mu_2 = \ldots = \mu_n$ while retaining $\sigma_1 \neq \sigma_2 \neq \ldots \neq \sigma_n$. This is followed by the alternative $\mu_1 \neq \mu_2 \neq \ldots \neq \mu_n$ with $\sigma_1 = \sigma_2 = \ldots = \sigma_n$. Finally, the most general case is examined of $\mu_1 \neq \mu_2 \neq \ldots \neq \mu_n$ and $\sigma_1 \neq \sigma_2 \neq \ldots \neq \sigma_n$.

Common parameters (the symmetrical common value model)

Figure 4 gives the results for v_1^* and E^* for the two bidder symmetric common value model for the uniform distribution for a range of σ values. This indicates that $v_1^* = \sigma\sqrt{3}$ (or $v_i^* = \frac{b-a}{2}$ where *b* and *a* are the upper and lower supports). This is the dominant strategy and true for any value of *n* and μ. Also, $E^* = \frac{2\sigma\sqrt{3}}{n(n+1)}$ (or $E^* = \frac{b-a}{n(n+1)}$), which is true for any value of μ. The equilibrium expected revenue (client's payment) is $R^* = \mu + nE^*$ (or $R^* = \frac{a(n-1)+b(2b+n)}{2(n+1)}$).

v_1^* and E^* are also independent of μ (but not *n*) for the normal distribution provided σ is proportional to μ. This enables the results, although additive, to be stated in more conventional terms as a percentage over a range of coefficients of variation (c_v). These are shown in Figure 5 and Figure 7 for v_1^* and E^* respectively for both the normal (blue) and uniform (red) distributions and are true for any value of μ. As these Figures show, the relationships between c_v and v_1^* (and c_v and E^*) are linear with both $v_1^* \to 0$ and $E^* \to 0$ as $c_v \to 0$. Figure 6 gives an alternative representation of the v_1^* results for the normal distribution, showing an abnormality of values for smaller values of *n* as c_v increases.

Common μ (the asymmetric common value model)
For the asymmetric common value model, $\mu_1 = \mu_2 = \ldots = \mu_n$ and $\sigma_1 \neq \sigma_2 \neq \ldots \neq \sigma_n$. Let $\sigma_{(1)}$ denote the smallest value of σ_i $(i = 1,2,\ldots,n)$ then, for the uniform distribution, $v_{1i}^* = \sigma_i\sqrt{3}$ for $\sigma_i > \sigma_{(1)}$ as with the symmetric model, while $v_{1i}^* > \sigma_i\sqrt{3}$ for $\sigma_i = \sigma_{(1)}$. This is again the dominant strategy and true for any value of *n* and μ. Also, $E_i^* < \dfrac{2\sigma_i\sqrt{3}}{n(n+1)}$ for $\sigma_i > \sigma_{(1)}$ and $E_i^* > \dfrac{2\sigma_i\sqrt{3}}{n(n+1)}$ for $\sigma_i = \sigma_{(1)}$ – again true for any value of μ ($R^* = \mu + \sum_i^n E_i^*$ for all asymmetric cases).

For the normal distribution, the only discernible trend is for the two bidder case, where v_1^* and E^* are proportional to $\dfrac{\sigma_i}{\sigma_j}$. That is $v^*_{1\frac{\sigma_i}{\sigma_j}} = \sigma_i v^*_{1\frac{1}{\sigma_j}}$ and $E^*_{\frac{\sigma_i}{\sigma_j}} = \sigma_i E^*_{\frac{1}{\sigma_j}}$ Figure 8 shows the results for $1/\sigma_j$ (v_1^* and E^* are the same for both bidders) for both uniform and normal distributions. These are true for any value of μ.

Common σ
Similarly, where $\mu_1 \neq \mu_2 \neq \ldots \neq \mu_n$ and $\sigma_1 = \sigma_2 = \ldots = \sigma_n$, $v_{1i}^* = \sigma_i\sqrt{3}$ for the uniform distribution except for the bidder with the lowest μ value, in which case $v_1^* > \sigma_i\sqrt{3}$ for that bidder. $E_i^* < \dfrac{2\sigma_i\sqrt{3}}{n(n+1)}$ except for the bidder with the lowest μ value, in which case $E_i^* > \dfrac{2\sigma_i\sqrt{3}}{n(n+1)}$ for that bidder.

For the normal distribution, the only discernible trend again is for the two bidder case. Figures 9 and 10 show the values of v_{1i}^* and E_i^* for a range of $\mu_i - \mu_j$ for values of σ common to each bidder for both uniform and normal distributions.

Heterogeneous case
For the complex case of $\mu_1 \neq \mu_2 \neq \ldots \neq \mu_n$ and $\sigma_1 \neq \sigma_2 \neq \ldots \neq \sigma_n$, no general results are obtainable except for the two bidder common c_v case. Figures 11 and 12 give the results for v_{1i}^* and E_i^* respectively for c_v = 0.01, 0.05 and 0.10 for a range of $\dfrac{\sigma_i}{\sigma_j}$ values for both uniform and normal distributions for $\mu_i = 1$ (the results being a multiple of μ_i, i.e., $v_{1i\mu_i}^* = \mu_i v_{1i}^*$ and $E_{i\mu_i}^* = \mu_i E_i^*$).

Multiplicative equilibrium mark-up (v_2^*)

Common parameters (the symmetrical common value model)

For the symmetric common value model, v_2^* and E^* are proportional to the coefficient of variation, c_v. Figure 13 gives the results for the two bidder situation for the uniform and normal distributions. This shows $v_2^* \to 1$ as $c_v \to 0$ and $v_2^* \to 0$ as $c_v \to \infty$. In addition, for the uniform distribution, $v_2^* = \frac{1}{2} + \frac{\sqrt{3}}{6}$ at $c_v = 1$ and $v_2^* = 1 + \frac{\sqrt{3}}{3}$ at $c_v = \frac{1}{2}$, reaching a maximum of exactly 1.6 where c_v is exactly 0.625. For the normal distribution, the $v_2^* = 1.3745$ at $c_v = 1$ and $v_2^* = 2.0459$ at $c_v = \frac{1}{2}$, reaching a maximum of 2.1 where c_v is 0.59.

The associated expected profit is a multiple of σ, i.e. $E_\sigma^* = \sigma E^*$ for both uniform and normal distributions. Figure 13 shows the values of E^* for $\sigma = 1$. This indicates that $E^* \to \frac{\sigma}{\sqrt{3}}$ as $c_v \to 0$ and $E^* \to 0$ as $c_v \to \infty$. In addition, for the uniform distribution, $E^* = -\frac{\sigma}{3}$ at $c_v = 1$, reaching a minimum of exactly $-\frac{\sigma\sqrt{3}}{5}$ where c_v is exactly $\frac{\sqrt{3}}{2}$. For the normal distribution, E^* reaches a maximum of 0.6437 where c_v is 0.202 and a minimum of –0.3057 at c_v = 1.408.

Figure 14 shows the results for the *n* bidder situation up to $c_v \leq 0.3$ (convergence becomes highly dependent on starting values for *n*>2 at c_v > 0.3). This indicates that $v_2^* \to 1$ for any *n* bidders as $c_v \to 0$. The associated expected profit for the *n* bidder situation is again a multiple of σ and is shown in Figure 15 for $\sigma = 1$.

Asymmetric model (common c_v)

For the case of two bidders with a common c_v, the v_2^* is proportional to their standard deviations. Figure 16 shows the v_2^* for bidder *i* over a range of $\frac{\sigma_i}{\sigma_j}$ values where both bidders have typical values of c_v = 0.01, 0.05 and 0.10. This suggests that $v_2^* \to \infty$ as $\frac{\sigma_i}{\sigma_j} \to 0$ and $v_2^* \to 1 + 2c_v$ as $\frac{\sigma_i}{\sigma_j} \to \infty$ (the results for $\frac{\sigma_i}{\sigma_j} = 1$ are given in the previous section). Although convergence does occur for typical values, no easily discernible patterns of results were found for expected profit.

NUMERICAL METHOD: SOME SPA RESULTS

Additive equilibrium mark-up (v_1^*)

For the uniform distribution, no second price v_1^* can be found except for the symmetric common value model with *n* = 2, where the v_1^* is zero (if and only if the starting point is zero), with expected profit of $E^* = \frac{\sigma_i\sqrt{3}}{n(n+1)} = \frac{\sigma_i\sqrt{3}}{6}$ (exactly half the value of the FPA[5]) and expected revenue (client's payment) again of $R^* = \mu + nE^* = \mu + 2E^*$.

Second price solutions for the normal distribution are only obtainable for the common value model and when the starting point is zero. As with the first price arrangement, the v_1^* and associated expected profit values are a multiple of σ. Table 1 shows these for $\sigma = 1$. With the exception of R^*, which is again $\mu + nE^*$, all results are independent of the value of μ. It is interesting to note that expected profit at the SPA v_1^* is close to half the expected profit at the FPA v_1^* – equivalent to the known affiliation result that the SPA generates a better return to the seller than does the first price equivalent (Milgrom and Weber, 1982: 1095).

Table 1: Equilibrium results for the standard normal distribution $(E[C] = \mu = 0)$

Multiplicative equilibrium mark-up (v_2^*)
Doesn't converge!

DISCUSSION

Being the first time such an analysis has been undertaken, perhaps the first and most important result of work detailed here is that there are any results at all! Unlike the 'higher' analysis (Rothkopf and Harstad 1994) for conventional analytical approach in AT, being reduced to obtaining numerical solutions is an uncertain business. First there is the problem of finding suitable starting values. Using standard minimizing software routines, as has been done here, can make this a sensitive issue as was often the case for the $n > 2$, and for all the SPA analyses attempted. Next there is the problem of suboptimal solutions and failure to converge. In several cases the iteration loops around a 'strange attractor', fluctuating between two or three values for each bidder. Perhaps most important of all is the possibility of errors in the computer program. There is a profound lack of earlier analyses results upon which to carry out replication tests. In the end, it was possible to adapt the program to replicate some of Maskin and Riley's (2000) and Li and Riley's (1999) asymmetric IPV results although only in a limited way as they use bid functions rather than the scalar strategies used here. As a further precaution, the integration routines were all subject to intensive testing by Monte Carlo simulation.

Turning to the results themselves (Table 2 in the Appendix provides a summary), it is clear that a good number of 'solutions' are obtainable for the FPA symmetric and $n = 2$ situations, with the uniform distribution in particular providing some elegant-looking relations that can surely be derived analytically. This is not surprising as the usual analytical approach is to start with the two bidder symmetric uniform situation before moving on to the *n* bidder situation, followed by a distribution free treatment (the asymmetric situation is often intractable).

Of course, for generality, the results have been obtained for as wide a range of parameters as possible. Construction contract bidding, however, is concerned with a more restricted range. The coefficient of variation, for example, is generally taken to be around 0.05 to 0.10 for construction bidding (Skitmore 1989: Table 7.2). Within this narrower range, the symmetric FPA results suggest the c_v to be rather more important than the number of bidders, with v_1^* ranging between 7–11% for 2–30 bidders at $c_v = 0.05$ to 15–22% for 2–30 bidders at $c_v = 0.10$ (Figures 5 and 6) for these, with a similar order of magnitude for v_2^* (Figure 14). The opposite effect occurs with the associated expected profit, however, where E^* is always small for a large number of bidders, irrespective of c_v. For a small number of bidders, E^* becomes significantly higher generally irrespective of c_v for the multiplicative mark-up (Figure 15) but only for larger c_v values for the additive mark-up (Figure 7) In terms of the differences between the uniform and normal assumption, the v_1^* for the uniform with any number of bidders is approximately the same as that for around eight normal bidders, and quite similar to the normal E^* (Figure 7). The v_2^* for the uniform on the other hand, is generally quite similar when a higher number of bidders is involved, which is the reverse of the situation for the normal distribution (Figure 14).

It is not possible to judge the effect of the number of bidders in the asymmetric situation as no trends were observed for $n > 2$. For the two bidder situation though, the advantage of one (stronger) bidder having a smaller mean or variance is very much pronounced in the v_1^* and E^* values (Figures 9–12), with the results for the uniform and normal being very similar for common variance (Figures 9–12) but with the uniform v_1^* and E^* always being higher than the normal equivalent for the common mean (Figure 8). Similarly, the v_2^* results for the stronger (lower variance) bidder are also very striking (Figure 16), with the c_v level being much more important for the higher variance bidder.

CONCLUSIONS

This paper has presented some numerical equilibrium additive and multiplicative mark-up results for the uniform and normal first and second price construction contract auctions, in which bidders are assumed to have both different costs and imperfect estimates of them. Overall, and bearing in mind the limitations mentioned below, it is clear from this analysis that FPA bidders with relatively high c_v levels and a larger number of bidders involved bid higher in equilibrium but can expect little profit unless the number of bidders involved is small. Where there are asymmetries, stronger bidders (i.e. those with lower costs and less variability) bid much higher and achieve much higher profits in equilibrium. From the seller's point of view, the implications are equally clear. It is cheaper, in equilibrium, to have a homogeneous group of low variability bidders – a result anticipated by Flanagan and Norman

(1985), which they interpret as implying the need for good quality of information to bidders experienced in the type and size of contract under auction (p.159).

There are also indications that the use of SPA and greater numbers of bidders may also be beneficial to sellers, but the analysis is quite limited in this respect – particular as the cost of bidding has not been included. Other well-known limitations of equilibrium analysis are worthy of mention. A major issue is that bidders might not behave optimally (Flanagan and Norman 1984: 155–6), which raises the question of what do about this (Thaler 1988) to at least take advantage of the opportunity costs at stake. As must be expected, the economic basis of equilibrium results assumes all bidders to be acting rationally and so such an analysis is certainly going to lie outside the boundary of economics. A further important issue concerns the limitations of auction theory as a branch of game theory, in that the competitor behaviour is assumed to be limited only to Nash type responses to the optimal moves of others. As Rothkopf and Harstad (1994) comment, many of the common assumptions of game theoretic models – symmetry, common knowledge, isolation, fixed number of bidders and unbending rules – are suspect from an applications point of view. Similarly, there is no allowance here for changes in market conditions (supply of, and demand for, contractors' services) or the capacity of the contractors (Runeson and Skitmore 1999). Finally, as has been mentioned in several seminal contributions in the construction literature (e.g. Raftery 1991; Hillebrandt 2000; Runeson 2000), the extent of the uncertainties involved in forecasting future costs as well as the behaviour of competitors and the market in general requires contract bidders to devote a far greater amount of energy and resources to marketing than is currently admitted in the economic theory of auctions.

ACKNOWLEDGEMENTS

This work has been continuing for many years, during which time I have been fortunate enough to have been ably assisted by a variety of people, the most prominent of which include mathematician/statisticians Roy Thomas, Ernest Wilde, Mike Patefield and John Pemberton all of Salford University. More recently, I am indebted to Ross McVinish of QUT and Flavio Menezes of the University of Queensland. The former, for his help in articulating the GIV model and its limitations. The latter, for summarizing the main AT results and *cul de sacs* to date and the likely prospects for asymmetric models and mark-up form bid functions in general. Thanks also go to Michael Rothkopf for his comments on an earlier draft, drawing my attention to his work on equilibrium linear mark-ups and kind encouragement in general.

NOTES

1. Cassady (1967) mentions a report by the Greek historian Herodotus, who described the sale by auction of women to be wives in Babylonia around the fifth century BC.
2. The most notable contributions have come from Griesmer *et al.* (1967), Wilson (1969, 1977), Milgrom (1979, 1981), Riley and Samuelson (1981), Myerson (1981) and Milgrom and Weber (1982) – see Klemperer (1999) for a comprehensive account.
3. See Rothkopf *et al.* (2003) for references to other examples of multiplicative mark-ups in the game theory approach.
4. I am indebted to Michael Rothkopf for pointing this out.
5. Note that, while AT predicts the FPA and SPA to be the same for this symmetrical case, this analysis, unlike AT, is restricted to the profit maximization by mark-up manipulation, which may account for the difference in outcome.

APPENDIX: FORMULAE FOR NUMERICAL ANALYSIS

Let bidders for an auction be indexed $i = 1,\ldots,n$ and assume each makes a bid

$$t_i = v_{1i} + v_{2i} s_i \tag{A.1}$$

where the cost estimate s_i is a realization of a random variable S_i with composite density $F(\lambda + \mu_i, \sigma_i)$ and v_{1i} and v_{2i} are the additive and multiplicative mark-ups respectively, λ is a parameter denoting the unique common value (nuisance) component of the auction (Skitmore 1991; Hong and Shum 2003), and μ and σ are the mean and variance unique to each bidder. Suppose each bidder knows only the values μ_j, σ_j, v_{1j} and v_{2j} for all $j = 1,\ldots,n$ bidders. Let θ denote the vector of all these values μ_j, σ_j, v_{1j} and v_{2j}. Now, the *expected profit* for bidder *i* is

$$E_{(k)i}[\theta] = P_{(1)i}(\theta)\left(E\left[T_{(k)} \middle| i \text{ wins}\right] - E\left[C_i \middle| i \text{ wins}\right]\right) \tag{A.2}$$

where

$$E\left[T_{(k)} \middle| i \text{ wins}\right] = \int_{-\infty}^{\infty} (v_{1i} + v_{2i}x) \frac{g_{(k)i}(x;\theta)}{P_{(k)i}(\theta)} dx \tag{A.3}$$

with

$$P_{(k)i}(\theta) = \int_{-\infty}^{\infty} g_{(k)i}(x;\theta) dx \tag{A.4}$$

where (k) denotes the *k*th lowest bidder. Assuming estimates are unconditionally unbiased (Flanagan and Norman 1985), the expected cost given *i* wins, $E\left[C_i \middle| i \text{ wins}\right] = \mu_i$.

The function $g_{(k)i}(x;\theta)$ depends on the composite density assumed. For the Uniform density, where $a_i = v_{1i} + v_{2i}(\mu_i - \sigma_i\sqrt{3})$ and $b_i = v_{1i} + v_{2i}(\mu_i + \sigma_i\sqrt{3})$, it can be shown that

$$g_{(1)i}(x;\theta) = \frac{1}{b_i - a_i} \prod_{j \neq i}^{n} \frac{b_j - x}{b_j - a_j} \quad (b \geq x \geq a) \tag{A.5}$$

and

$$g_{(2)i}(x;\theta) = \sum_{j_2 \neq i}^{n} \frac{1}{b_{j_2} - a_{j_2}} \frac{x - a_i}{b_i - a_i} \prod_{\substack{j_1 \neq i \\ j_1 \neq j_2}}^{n} \frac{b_{j_1} - x}{b_{j_1} - a_{j_1}} \quad (b \geq x \geq a) \tag{A.6}$$

for the FPA and SPA respectively.

Likewise, for the Normal density, letting $\mu_i' = v_{1i} + v_{2i}\mu_i$ and $\sigma_i' = v_{2i}\sigma_i$,

$$g_{(1)i}(x;\theta) = \frac{e^{-x^2/2}}{\sqrt{2\pi}} \prod_{j \neq i}^{n} \int_{\frac{\sigma_i' x + \mu_i' - \mu_j'}{\sigma_j'}}^{\infty} \frac{e^{-u^2/2}}{\sqrt{2\pi}} du \quad (\infty > x > -\infty) \tag{A.7}$$

and

$$g_{(2)i}(x) = \sum_{\substack{j_2=1 \\ j_2 \neq i}}^{n} \frac{e^{-\left(\frac{x-\mu'_{j_2}}{\sigma'_{j_2}\sqrt{2}}\right)^2}}{\sigma'_{j_2}\sqrt{2\pi}} \int_{-\infty}^{\frac{x-\mu'_i}{\sigma'_i}} \frac{e^{-u^2/2}}{\sqrt{2\pi}} du \prod_{\substack{j_1=1 \\ j_1 \neq i \\ j_1 \neq j_2}}^{n} \int_{\frac{x-\mu'_{j_1}}{\sigma'_{j_1}}}^{\infty} \frac{e^{-u^2/2}}{\sqrt{2\pi}} du \tag{A.8}$$

for the FPA and SPA respectively.

The optimal value of the mark-ups, v_{1i} and v_{2i}, are then obtained numerically by finding the values that maximize Equation A.2 for bidder *i*. (Note that s_i, although known, is not necessary for this calculation.) Repeating this procedure in turn for each bidder until convergence then enables the equilibrium mark-ups to be obtained.

HAS THE CONSTRUCTION INDUSTRY IMPROVED IN LAST 25 YEARS?

Heng Li[1]

Department of Building and Real Estate, The Hong Kong Polytechnic University, Hong Kong

Within the last 25 years, productivity in the manufacturing industry has improved by 10% on average annually in China and Japan; while the construction industry has only improved by 0.02% in China and slightly deceased in Japan. The question to be asked is why the construction industry has been so slow in productivity improvement. In this paper, I argue that the manufacturing industry possesses three critical successful factors (CSFs) that the construction industry lacks. I further argue that by adopting the construction virtual prototyping (CVP) technology, the construction industry can be equipped with the CSFs and make the same level of productivity and efficiency gain in the future. CVP is the use of integrated product, process and resource models of construction projects to support construction planning in a virtual environment. This paper describes an integrated framework and process for efficient application of CVP to support project teams on construction planning. It includes specific examples of models and objectives as well as detailed suggestions on how to implement CVP in practice.

Keywords: construction virtual prototyping, manufacturing industry, productivity improvement.

INTRODUCTION

It is generally agreed that the construction industry is lagging behind the manufacturing industry. However, it still appears to be surprising to compare the productivity data between these two industries. For example, Table 1 indicates that in Japan, while labour productivity in the manufacturing industry has been improved from 3531 in 1990 to 5131 (Yen/Man/Hour) in 2004, the value of the construction industry has dropped from 3714 to 2731 (Yen/Man/Hour) (JFCC 2006).

Table 1: Comparison of labour productivities in Japan (Unit: Yen/Man/Hour) (JFCC 2006)

Year	Manufacturing	Construction
1990	3531	3714
2004	5131	2731

A similar phenomenon is observable in China. According to the Ministry of Construction (MOC 2006), labour productivity of the manufacturing industry (RMB/Man/Hour) in

[1] bshengli@inet.polyu.edu.hk

China has improved from 24.4 in 2003 to 29.8 in 2008, while the construction industry has merely improved from 17.5 to 17.6, only managing to gain 0.5% improvement.

Table 2: Comparison of labour productivities in China (Unit: RMB/Man/Hour) (MOC 2006)

Year	Manufacturing	Construction
2003	24.4	17.5
2004	29.8	17.6

The reasons for such significant productivity-lag between the manufacturing and construction industries, in my view, are that the former has the following critical successful factors (CSFs), which the latter lacks:

- a well-defined production line in which products and parts, processes and logistics have been fine-tuned over a long period of time;
- the ability to predict risks and errors in design and production; and
- the ability to learn from mistakes and to avoid them in the future.

Although the use of prefabrication technology has indirectly introduced a production line into the construction project delivery process, the construction industry, by and large, does not have the ability to predict risks and errors. As a consequence, the construction industry is notoriously known to be very risky, and rework caused by errors in design and construction contributes up to 14% of the total construction cost (Li *et al*. 2000).

On the other hand, the construction industry lacks an effective platform to capture and reuse the knowledge distilled from its design and production processes. While the manufacturing industry builds and incrementally improves the productivity of the well-defined production line, the construction industry disbands the project team as soon as the project is completed. Except for the erected product, vast amounts of information and knowledge generated during the design and construction processes are often lost, or carried away by individual team members. Because of this, it is an open secret that often the same mistake recurs in future projects.

In this paper, I argue that the use of virtual prototyping (VP) technology can equip the construction industry with the second and third CSFs of the manufacturing industry. Specifically, I contend that VP technology enables the construction industry to predict and eliminate errors and risks in its design and construction processes; and the technology provides an effective platform to learn and reuse knowledge so that incremental improvement can be achieved.

Virtual prototyping (VP) is a computer-aided design process concerned with the construction of digital product models ('virtual prototypes') and realistic graphical simulations that address the broad issues of physical layout, operational concept, functional specifications and dynamics analysis under various operating environments (Pratt 1995; Xiang *et al*. 2004; Shen *et al*. 2005). Dedicated VP technology has been extensively and successfully applied to the automobile and aerospace fields (Choi and Chan 2004). However, the development and application of VP technology in the construction industry (i.e. construction process simulation) has been limited. This is probably because each construction project is unique in terms of the site conditions, requirements and constraints. Sarshar *et al*. (2004) identified three major industrial barriers to the uptake of VP technology, including cultural and risk issues related to information sharing, fragmentation of business interests and the lack of piloting on real construction projects.

The Construction Virtual Prototyping Laboratory (CVPL) at The Hong Kong Polytechnic University has applied VP technology to several real construction projects in Hong Kong. VP technology enables contractors to 'construct the building many times' in the computer. All sorts of scenarios can be previewed and potential problems identified in advance in this simulation process. The simulation process performs such tasks as the production, transportation, handling and assembly of different construction components, including all the associated operational processes. All the variables affecting the construction processes, such as site layout, plant locations, rate of machinery operation, quantities of resources, etc., can be considered in order to evaluate the feasibility of the proposed construction methods and sequences, and to explore possible solutions and improvements to the methodology prior to actual work beginning.

However, the VP technology is unfamiliar to contractors. Contractors expected but doubted the VP application on their projects in the beginning. General contractors and their planners often have little idea about how construction VP can help them. Some regard VP technology as only animation tools that represent their planning ideas more clearly. Although the new technology is useful to construction planning and project management, the misunderstanding of planners can be a major impediment for the adoption of the VP technology in the industry. In order to demonstrate the usefulness of the technology, researchers of the Construction Virtual Prototyping Lab at The Hong Kong Polytechnic University have worked very closely with contractors of several real life projects in Hong Kong. In fact, for each project, a researcher has been seconded to the site office to assist the planning and project monitoring process. Useful experiences and lessons have been drawn within the past two years, which will be reported in the subsequent sections of this paper.

3D/4D models support planners by relating building components from a 3D CAD system to construction activities from a project planning system, using a graphical interface. The construction process can then be simulated by executing the process modeller built in the simulation system and the user can visually check how the process proceeds. 4D CAD systems can be used for construction analysis and communication (de Vries and Harink 2007). Hartmann and Fischer [7] developed an integrated process of how project teams can use 3D/4D models efficiently to support the knowledge communication and generation needed during the constructability review on construction projects. Although 3D/4D models can help the planners to analyse the design, find out the collision and discover any missing or conversed sequence, the 4D process developed by Hartmann and Fischer emphasized the knowledge transfer to engineers or non-construction managers during the construction planning. This application is quite useful because efficient communication is the key factor of successful construction. But most of the time, verifying the appropriate construction method and making sure the construction schedule is feasible are the first issues of concern to the general contractor before transferring the planning knowledge. The experience from our research told us that the process of supporting the construction planning with the VP technology should assist planners to verify their planning as well as transfer their planning knowledge.

The application of the VP technology to the Ho Tung Lau project and the One Island East project in Hong Kong illustrate this effort well. A CVPL researcher (the first author of the paper) worked for one year on each project as part of the project team to support the VP modelling process and to assist the project team in resolving problems that arose during the preconstruction and construction stage. The aim of this paper is to describe an integrated framework and process for general contractors to successfully apply the CVP technology. This integrated process of how general contractors can use VP models to improve the construction planning practice is described first. This process can meet the different planning tasks in the preconstruction and construction stages by adjusting the content of VP models. Specific construction planning examples are presented to describe the adjusted content of VP models. The paper concludes with an overview of the opportunities and challenges for further application of CVP.

COMMON CONSTRUCTION PLANNING PROCESS

Construction project planning has been considered as a critical process in the early project phases that determines the successful implementation and delivery of a project. During this stage, project planners need to develop main construction strategies, to establish construction path and assembly sequences, to arrange construction methods and resources required for the execution of work packages, and even to write daily work instructions for field crews (Koo and Fischer 2000; Jaafari *et al*. 2001; Waly and Thabet 2002). The left part of Figure 1 is a diagram representing the process of construction planning. The planning process requires the transformation of information into analysis, decisions and actions. The general process of the VP models application is shown on the right side of Figure 1. Within this process, VP models support the knowledge generation and transformation at each of the planning steps.

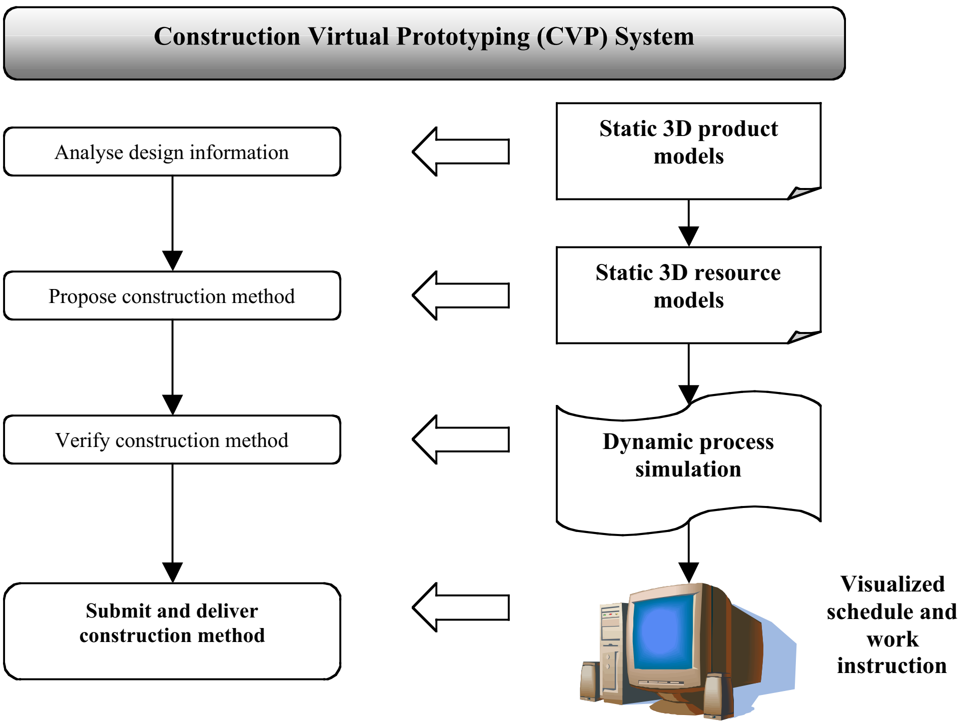

Figure 1: The integrated process of VP-supported construction planning

In the first step of the application process, static 3D product models are built to help the project team analyse and communicate design information. The design errors can be detected in 3D product models. The preparation of 3D product models also includes the modelling of the site environment, which can be used to study the site layout and review the constructability.

The second step is to build static 3D resource models including construction equipment and temporary works. Planners will propose some potential construction methods which may be suitable for the uniqueness of project design and construction site. Using the 3D resource models with the previous product models, the optional construction methods can be expressed in the virtual platform.

The third step is to simulate the construction process. The dynamic process simulation is a series of activities, each of which can have a defined duration, linked with construction components and resources (Figure 2). First, the abstract construction methods can be visualized by assigning the 3D product and resource models. Then the visualized methods can be tested and verified by integrating temporal and spatial considerations.

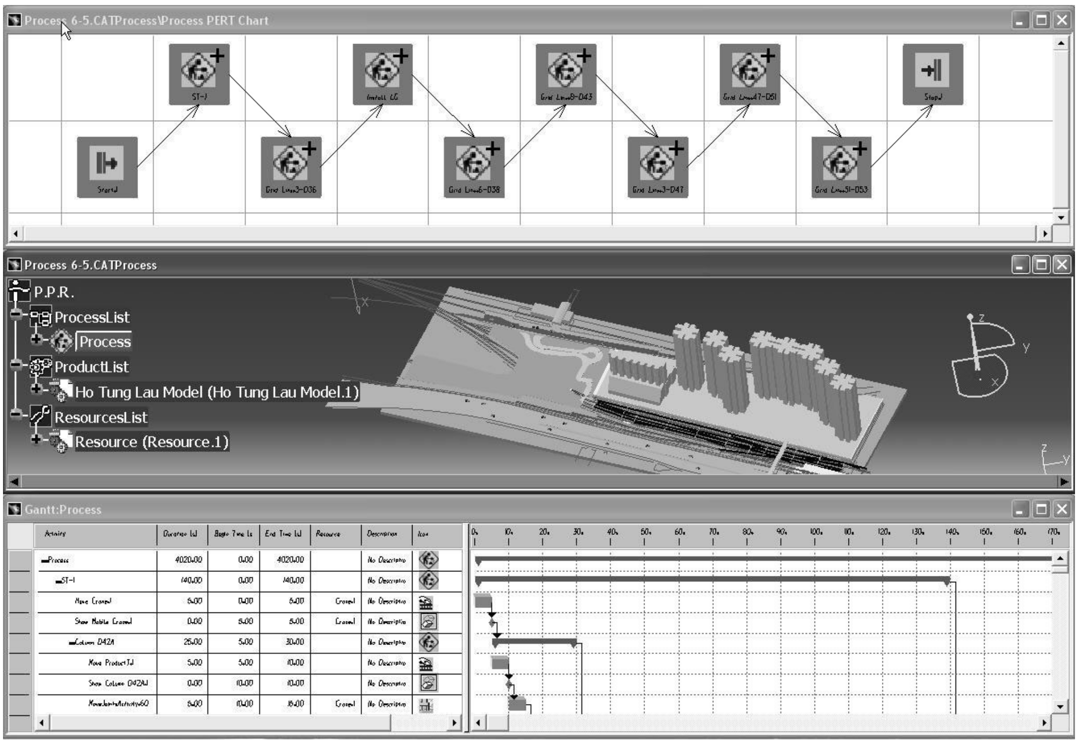

Figure 2: Integrated product, process and resource models of the construction project

In the final step of the construction planning process, the project team needs to submit or deliver the developed construction method to other participants such as project client, subcontractors and field crews. The visualized schedule and work instructions can help the construction planning to be effectively communicated and implemented.

The CVPL researcher’s experience on the several real construction projects shows that the above described integrated process effectively supported the construction planning of project teams. However, owing to the pressure of planning time, the timeliness of VP models is quite important for the efficiency and effectiveness of construction project management. VP models that require information cannot be built after the information is complete. Therefore, the content of VP models varies to satisfy the different stages of construction planning. The construction planning process is usually broken down into two stages: macro and micro planning processes [8]. Although the main process of the planning is the same, the tasks of the planning are different. During the preconstruction stage, the macro planning process involves reviewing the design for constructability improvement, selecting major construction methods and resources, and planning site layout. During the construction stage, the micro planning process develops detailed schedules to instruct the day-to-day operation. The above integrated process in Figure 1 can meet the different planning tasks in the preconstruction and construction stages by adjusting the content of VP models. In the following section, we will describe the content of VP models for different construction planning stages with specific examples. The detailed approach for 3D modelling and process simulation are not covered in this paper and can be found in Huang *et al*. (2007).

THE CONTENT OF VP MODELS

Construction planning case

The Ho Tung Lau project is to construct a deck to be situated above existing buildings by the general contractor. In part of the deck area, the confined site of the works is covered by live track and high voltage overhead cables, portal frames and many other railway facilities and furniture. The structures in this area comprise composite columns, heavy steel truss (weight approx. 285 ton), steel girders (approx. weight 80–100 ton) and precast T-beams spanning between steel girders for decking. Apart from the weight and length of the steel structure, the alignment of the building line varies owing to the existing configuration of Tai Po Road and the level of deck. There is a footbridge at high level over the site of the work. Two portal frames for overhead cables also run across over the entire working area. Other than those as mentioned above, all the works must be carried out during isolated sessions, that is between the times of 11.00 and 16.00. The site work must be cleared and released back to the railway company without any delay at the end of each isolated session.

In this project, the railway safety is of paramount importance; any untoward incident might jeopardize the railway services, which could result in potential claims for damages from the railway company due to delays in train services. Therefore the railway safety, the time periods allowed for construction and the suitability of the method adopted for construction of such steel frames are the major considerations in the selection of the proper method for construction of superstructure works in this work area. The VP technology is applied to support the contractor in selection and verification of the appropriate construction method. The following subsection will describe the content of VP models for the product modelling process, the resource modelling process, method simulation process, and method submission process in the construction planning stage.

3D product model supported analysis of design process

Before proposing the construction method, the planners will analyse the project design and site environment. So the 3D models of product model and site model can provide a virtual experiment platform to review the design, select the construction equipment and method, plan the site layout, and verify the safety issues, etc.

Construction components modelling

To select the construction equipment and method, the project team will review the design drawings and break down the building or facility into major components such as columns, beams, slabs and walls. The 3D component models, on which attributes such as length, volume and weight can be directly measured, can assist planners to study how these components will be built and controlled on site.

In this project, the 3D models of steel columns, steel girders, steel trusses, and precast T-beams are built according to the drawings in the first step. Then the structure components are assembled to the podium (Figure 3(a)). In this step, design error can be identified in the early construction stage. This is especially useful for the contractor if the project's delivery method is design and build. The 3D models can also provide information such as volume, weight and quantity of components to assist the planners in analysing the design.

Site modelling
In Hong Kong, the construction site is quite confined. Site investigation usually occurs at the beginning of the project and includes major issues such as site access and planning [8]. In this example, the construction site is on the live track. The high voltage overhead cables are irregularly distributed on site. The movement of construction equipment is prone to damage the cables. The site survey information was used to build the site model. The models of damageable facilities on site were built in the 3D model, such as the rail line, power cable and cable portal. The models of site boundary, surrounding buildings, site entrance and road were built as these factors may become a constraint while planning. The 3D models can be quickly built because the profiles of the site facilities are usually enough for the planning (Figure 3(b)). The safety zone of the facilities was also added by researchers because the bound of the safety zone is larger than the facility itself and cannot be occupied or intruded upon. The site model is assembled with the 3D product model built in the first step.

The static 3D product model and site model can help the planners to analyse the site constraints, identify the potential problems and plan some possible construction methods.

3D resource model supported proposal of construction method process
Construction equipment modelling
Construction methods are determined by the building products and the construction equipment. After reviewing the design and site survey information, the planners will find some possible construction equipment which is thought to be suitable to the construction product and site. Construction equipment's installation, dismantlement, site layout, loading limit and space requirements while moving are the sorts of concerns in the planning. So, the next step of VP modelling is the construction equipment modelling.

For this project, planners wanted to compare three kinds of possible construction equipment including the mobile crane, mobile gantry and launching girder (Figure 3(c)). At this stage, they usually have not the detail of the design or type of equipment. Planners will draft the profile of equipment and describe the mechanism of main parts. This rough information is used to build the construction equipment model. To put them into the virtual platform, planners will have explicit clues to planning the construction method. With the development of planning, more information can be provided to build the equipment model with detailed attributes.

Temporary works modelling
The temporary works usually cost a large part of any contract. Failure in planning appropriate temporary works affects safety, quality and productivity adversely (Chini and Genauer 1997). At the preconstruction stage, the approximate shape and the location of temporary works will be used to build the temporary works and assemble them into the model. This qualitative visualization will help the planners to think their planning method more clearly. In this project, the temporary works are difficult to set up owing to the protected area for the railway and the power cables. Planners can review the location of temporary works in this virtual environment (Figure 3(d)).

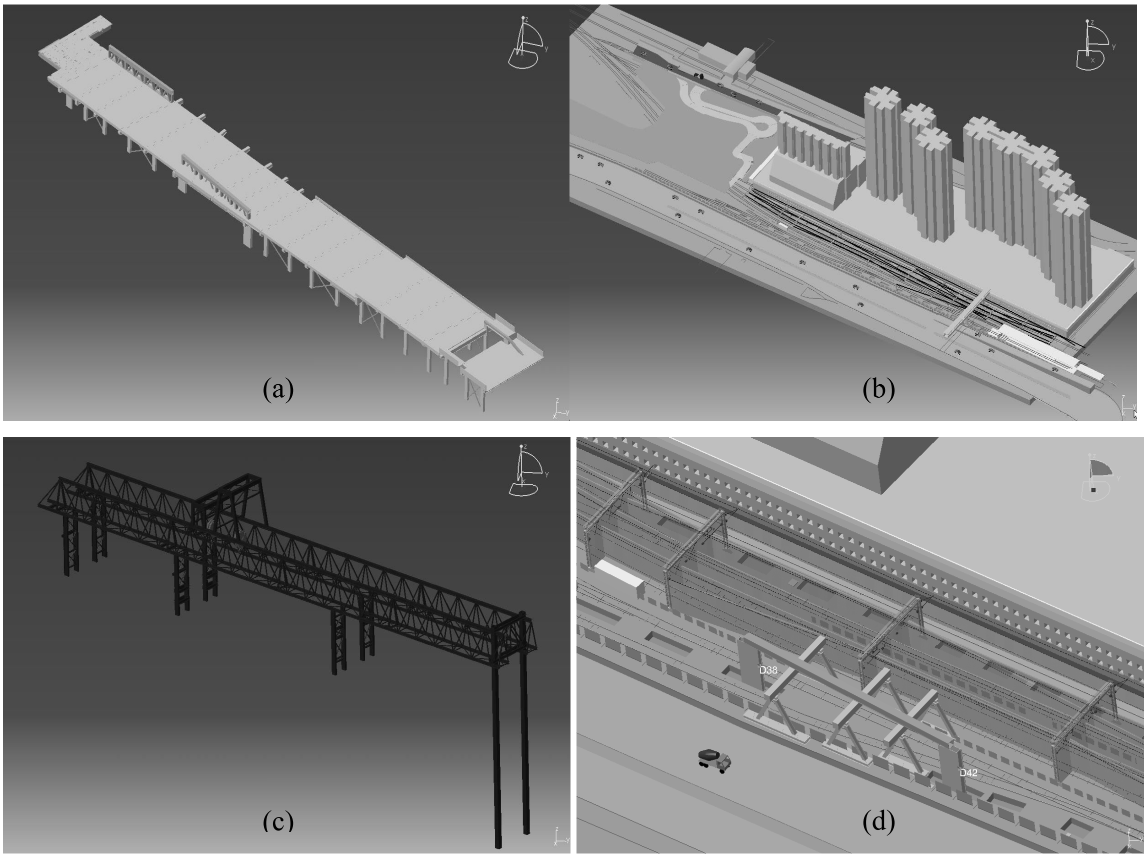

Figure 3: 3D product and resource models of Ho Tung Lau project

Construction method simulation and selection

Construction method visualization

In a traditional planning process, planners need to construct a 3D mental model of the construction project by mentally integrating 2D drawings, CPM-based schedules and other information. This is largely an experience-based process, thus more experienced planners often construct more comprehensive mental models and therefore generate better construction plans. The VP technology overcomes this weakness as it provides a platform to visually simulate the construction process including all 3D models of the design, the site environment and the resources to be used in the project. The simulation can not only provide the same level of understanding to all project participants, but also facilitate effective communication between them. More importantly, the simulation model provides an inexpensive and safe platform for project participants to evaluate different construction methods and identify possible risks and problems.

To develop the VP simulation model, the following information is needed:

- What construction equipment is used for specific components and how does it operate?
- How are the construction components installed and what is the installation sequence?
- What kind of temporary works are needed and where to install them?

With the above information and 3D models of the design and site environment, the construction project can be digitally represented and its processes digitally simulated and evaluated.

Method verification process
Virtual prototyping technology can help planners to study every step of the construction activities by running through the whole construction process in the simulation system. If problems are found, planners need to propose remedial actions and then re-run the simulation process to verify if the proposed remedial actions are workable. This trial and error process continues until the whole construction process is evaluated. Thus, with the use of VP technology, most construction risks and problems can be identified and solved before the commencement of the project.

In the Ho Tung Lau project, the launching girder method was identified and selected as the most appropriate construction method. After selection of the construction method, planners must ensure the safe and smooth operation of the railway line and the power cable by using the detailed, step-by-step, simulation of the construction process. During this simulation, many problems were identified and corrective measures were taken. Figure 4 shows some examples of identified problems such as installation beyond the site boundary and equipment athwart the power cable. After going through the whole project, the contractor has gained sufficient confidence of the selected construction method.

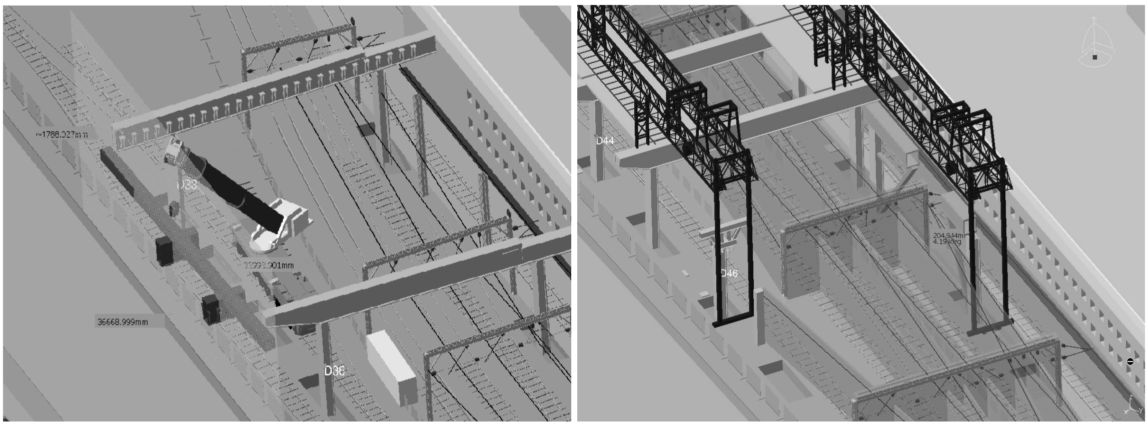

Figure 4: Identified problems during the method verification process

Visualization of construction process as a communication tool between client and contractor
Once the simulation is completed, it can used for many purposes. For example, as the simulation visually presents the construction process, it can be easily understood by the client. In the Ho Tung Lau project, with the help of the simulation model, the project team persuaded the railway company to extend the working hours on some days, in order to complete certain important construction tasks. The project has been completed on time within budget. After completion, both the client and the contractor admitted that it would not have been possible without the use of virtual prototyping technology.

Detail method simulation and delivery

Working space visualization

In the detailed planning process, planners need to optimize the time and resource use based on the master programme. The detail method can be developed to provide work instructions to crews. The working space is an important factor affecting the efficiency of construction work. Planners must develop the detail method and schedule according to the working space. However, it is difficult for planners to image the working space in a mental model. In addition, once the construction joint or the location of the construction equipment is changed, the working space will be different. The VP technology can help planners to visualize the available working space and to develop the detail method. The following further information is needed:

- the location of construction equipment while operating;
- the quantity and size of construction components being installed;
- the size of temporary works needed.

With the above information and visualized construction method, the detailed sequence of activities can be digitally developed and their durations digitally estimated and evaluated based on the available working space.

Visualization of work instructions from general contractor to subcontractors

It is hard for a complex schedule to be understood and implemented by many subcontractors and field crews. At the construction stage, a learning period for field crews is often required. The effective work instruction will shorten this learning period. The pictures extracted from the VP model were used to give subcontractors and field crews visualized work instructions (Figure 5). The project team found that the visualized work instructions can be understood more easily than only oral instructions.

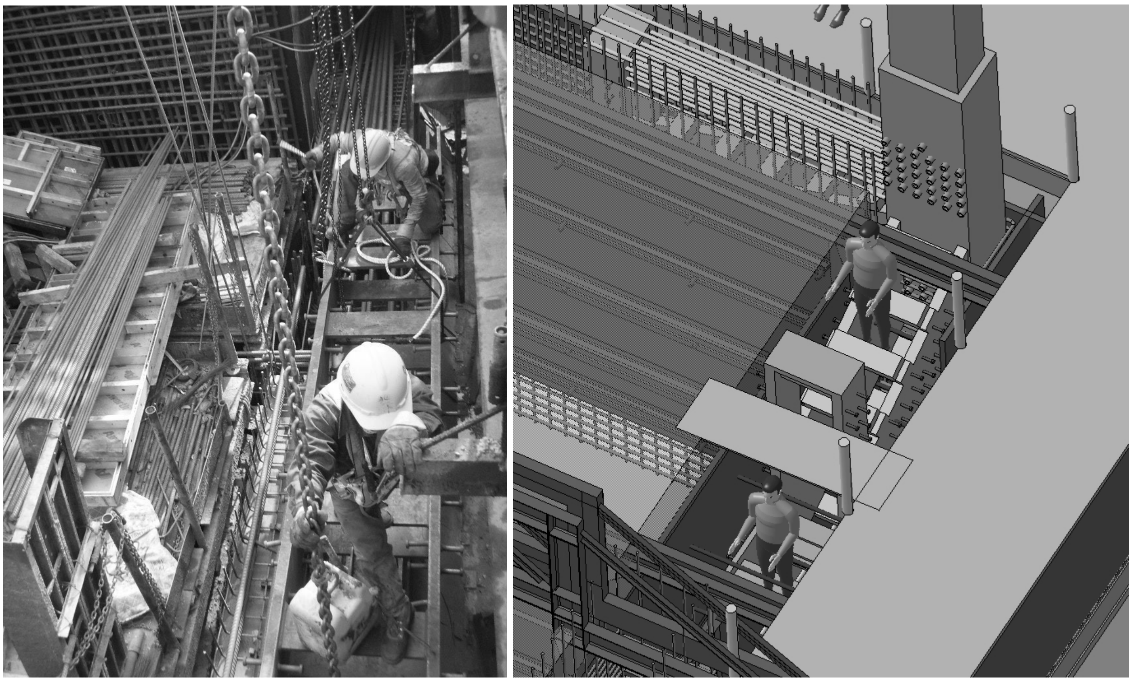

Figure 5: Visualized work instruction versus the real installation

CONCLUSIONS

So, has the construction industry improved within last 25 years? The answer is probably 'yes', but the improvement is less visible than that in the manufacturing industry. This paper argues that through using VP technology, the essence of the manufacturing industry can be learnt and transplanted into the construction industry. The development and application of the virtual prototyping (VP) technology in the construction industry is still relatively new. This paper describes an integrated framework and process for general contractors to apply the VP technology. The process described in this paper can assist planners to verify their plans so that construction risks can eliminated before the commencement of the project.

The benefits of using VP can be summarized as follows:

- the creation, analysis and optimization of construction schedules;
- effective constructability analysis;
- elimination of construction risks through digital mock-up of processes;
- clearer understanding of project scope and better work instructions from general contractor to subcontractors;
- effective communication between the client and contractors;
- effective management of design changes; and
- better capture and reuse of knowledge.

With the use of VP technology, it is now possible to conduct a digital mock-up of the entire construction process so that construction risks can be identified and eliminated. By capturing knowledge gathered during the design and construction stages, it is possible for construction organizations to learn and accumulate knowledge, and this will lead to incremental productivity improvement. Ultimately, the use of VP technology can potentially revolutionize the construction industry.

ACKNOWLEDGEMENTS

Funding for data collection and analysis was supplied through the Research Grants Council of Hong Kong through allocation from the Competitive Earmarked Research Grant for 2005/06 under Grant Number PolyU5103/05E. The research has also been supported by another Competitive Earmarked Research Grant for 2005/06 under Grant Number PolyU5209/05E. I wish to thank Professor Andrew Baldwin, Tim Huang, H L Guo, Neo Chan, Jack Chung and Stephen Kong for their contribution to the work presented in this paper. I wish also to thank Professor Peter Brandon for sharing his vision with us.

INTEGRATION OF THE HUMAN RESOURCE MANAGEMENT FUNCTION INTO LARGE CONSTRUCTION COMPANIES OPERATING IN GHANA

Lily Sena Agbodjah[1], Andrew R J Dainty[2] and Theophilous Adjei-Kumi[1]

[1]*Department of Building Technology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*
[2]*Department of Civil and Building Engineering, Loughborough University, Leicestershire LE11 3TU, UK*

In order to be successful in competitive markets, construction companies need to adopt appropriate people management practices that support their business strategies. The nature and characteristics of the construction industry poses some difficulties for companies in strategizing for their human resource management (HRM) policies and practices. The research reported in this paper examined how the HRM function has been integrated into construction companies operating in Ghana. Descriptive and content analysis methods are employed in examining how these organizations align their HRM practices with their strategic goals. The investigation revealed that in most companies the function is generally regarded as a cost burden and has little strategic influence. Line managers are not equipped with the requisite skills to enable them manage people effectively and they are not generally supported with a robust HR infrastructure to oversee people management strategy at the centre of the business. It is recommended that Ghanaian construction companies should employ specialist personnel to undertake this function or employ the services of HRM Consultants to aid in structuring their people function in such a way as to align with their business objectives.

Keywords: strategic management, human resource management, integration, developing country, Ghana.

INTRODUCTION

The ability to attract, retain and develop talented employees is a key feature of a successful business (Eddy 1981). People management has over the years evolved in the bid to enhance individual and organizational growth and viability of businesses. Some conceptual developments have contributed by enhancing the effects of people management in organizational development and success. These have resulted in the concept of strategic HRM (Armstrong, 2001; Loosemore *et al*. 2003). Strategic HRM is concerned with integrating the HR function advantageously into the functions of an organization for corporate competitive advantage (Armstrong 2001). It is basically concerned with both meeting the human capital needs of an organization and the development of process capabilities. It focuses on actions that differentiate a company from its competitors. There is the need therefore to ensure that the HR function is effectively integrated both vertically (into the overall business strategies of the

[1] sagbodjah.cap@knust.edu.gh

organization), and horizontally (in terms of ensuring the compatibility of the various HRM dimensions) within an organization (Armstrong 2001).

The concept of people management has evolved in the construction industry like other industrial sectors. However, the peculiar characteristics of this industrial sector: fragmented nature; unique, one-off nature of products; reliance on transient workforce, increasingly demanding clients amongst other, has rendered managing people a great challenge to practitioners and researchers alike (Druker *et al*. 1996; Egan 1998; Langford *et al*. 1995; Loosemore *et al*. 2003). This has rendered the efficacy of HRM practices within the construction industry questionable. From a preliminary survey conducted prior to this research, it was realized that research in the subject matter in the Ghanaian construction industry is on a low scale. Also construction companies regard this function as a liability instead of an asset to ensure organizational competitiveness and success.

Huselid *et al*. (1997) noted that existing HRM practices have been shaped by institutional environments of the countries in which companies originate from. Practitioners adopt models and theories made to suit the developed world with little or no consideration to the characteristics of companies in developing economies and resource availability. These models are considered as benchmarks for measurement of performance, productivity and even how some functions should operate. It is in this vain that this research is carried out to investigate how the HR function has been strategically integrated into construction companies operating in Ghana. The paper provides a brief overview of the nature of the Ghanaian industry and the structure of construction companies within the sector. Further the role of the HRM function within companies will be investigated and recommend an appropriate integration of the HR function within these companies considering their peculiar characteristics.

THE GHANAIAN CONSTRUCTION INDUSTRY

The Ghanaian construction industry accounts for a sizeable proportion of the nation's economic and developmental growth (approximately 10% of GDP). In the 2006 national budget, the industry recorded a 7.0% growth whereas its contribution to the overall economic growth stood at 9.8% (The National Budget 2006). It is described as diverse, complex and dynamic industry with increasing uncertainties with regards to technological developments, the national budget and resource availability. Companies operate in a constantly changing environment in the face of volatile economic environment, shifting political climate and a highly competitive market (Dansoh 2004).

History

The industry was developed along lines similar to the pattern in Britain where the bricklayers acted as master builders in project delivery. It has since developed into two sectors: the formal and informal sectors. The latter adopts an approach similar to this historical approach of master craftsman engaging labour in product delivery (Miles and Ward 1991; Mlinga and Wells 2002; Wells 2001; Wells and Wall 2003). In 1886, the British established the Public Works Department to formally oversee construction works in the then Gold Coast, now Ghana. Political independence in 1957 saw to the establishment of the Ghana Highway Authority, the defunct State Construction Corporation and the Architectural and Engineering Services Limited to take over the formal construction sector. The advent of sophistication brought into being the establishment of other state departments as well as private organizations

(Osei-Asante 2005). Developments in the formal sector has however resulted in the adoption of a variety of procurement systems regulated by the Public Procurement Act 2003, Act 663 of the Republic of Ghana (Anvuur and Kumaraswamy 2006)

Structures

Construction companies operating in Ghana register with the Registrar General Department (RGD) as limited liability companies and the Ministry of Water Resources, Works and Housing (MWRWH) and/or the Ministry of Road Transport (MRT) for building and civil engineering works respectively. The Government of Ghana (GoG) has always been the major client funding public sector projects at the District, Metropolitan/Municipal, Regional and National levels (MWRWH and MRT archives). The MWRWH has four categories of companies based on the nature of work they engage in (Ministry of Water Resources Works and Housing, 2004). These are categories D, K, E and G for building, civil engineering, electrical and plumbing works respectively. There are four financial sub-classifications within these categories: 1, 2, 3 and 4 (Appendix 2b). These classifications set the limitations for companies in the respect of their asset, plant and labour holdings (Appendix 1) as well as the nature and size of projects they can undertake. Class 1 companies are large companies by local standards and decreases in resource and asset base through to 4 (Ministry of Water Resources Works and Housing, 2004).

STRATEGIC HUMAN RESOURCE MANAGEMENT

Morley (2004) describes the two core assumptions underlining classical North American HRM models from a comparison of European and North American HRM ideologies in a paper by Chris Brewster. First is the broadly universalist ideology where prescriptions are intended to be workable and applicable in all different circumstances. This applicability, he argues, springs from several sources including managerial discretion and attitude, State *laissez-faire*dom in business and a comparatively weak trade union movement. The second is the involvement of HRM with business strategy. This looks holistically at the business strategy of the organization and how the HRM function can be integrated strategically for a competitive advantage (Morley 2004).

Armstrong (2001) defined Strategic HRM as a term that describes an integrated approach to the development of strategies which will enable the organization achieve its goals. He further described it as an approach to making decisions on the intentions and plans of the organization concerning employment relationship as well as their recruitment, training, development, performance management, reward and employee relations strategies, policies and practices. This he said is linked to the concept of strategy which is defined by Johnson and Scholes (1993) as the direction and scope of an organization over the longer term, which ideally matches its resources to its changing environment, and in particular to its markets, customers and clients to meet stakeholder expectation (Armstrong 2001; Johnson and Scholes 1993).

The HR strategy is integrated in two dimensions: vertically to the business strategy of the organization and horizontally to each other. Armstrong (2001) outlined three basic approaches of attaining this integration as the ‘best practice’, the ‘best fit’ and the ‘configurational’ or ‘bundling’ approach. These approaches help to develop HR strategies that will generate strategic capability by ensuring that the organization has the skilled, committed and well-motivated employees it needs to achieve sustained competitive advantage (Armstrong 2001). There is a broad agreement that a strategic approach to HRM involves designing and implementing a set of internally consistent policies and practices that ensure a firm's human capital (employees' collective knowledge, skills and abilities) contributions to the achievement of its business objectives (Huselid *et al*. 1997).

Strategic HRM has not come without limitations. Armstrong (2001) acknowledged these limitations by recording that; strategic HRM appears to be based on the belief that the formulation of strategy is a rational and linear process. This he said is not the case in reality. In this same light, Mintzberg (1987) emphasized that strategies emerge overtime in response to evolving situations. Tyson (1997) agreed by stating that strategic HRM is always 'about to be' and never existent in the present time (Armstrong 2001; Mintzberg 1987; Tyson 1997). Huselid *et al*. (1997) also concluded after an empirical study that there is evidence that fundamental to the strategic HRM perspective is the assumption that company performance is influenced by the set of HRM practices the company has in place.

The question then is how can strategic integration be achieved? More so in a developing economy. Baldocchino (2001) argued in his paper that small territories, and indeed developing economies, have often blindly accepted an 'industrial relations' (IR) framework that is much more at home in the formalistic, mass production and mass employment based manufacturing economies of the industrialized world. He further added that while IR in these settings is also being called into question today, small territories have been hard put all along to apply their labour relations practice to the structures of these theories (Baldacchino 2001).

Huselid *et al*. (1997) also noted that existing HRM practices have been shaped by institutional environments of the countries in which companies originate from. Practitioners adopt models and theories made to suit the developed world with little or no consideration to the characteristics as well as available resources of companies in developing economies. These models are considered as benchmarks for measurement of performance, productivity and even how certain functions should be operated. This has necessitated this investigation, which seeks to find out how construction companies operating in Ghana integrate the HR function into their businesses and recommends an appropriate integration of the HR function within these.

PURPOSE OF INVESTIGATION

Scholars have over the years developed various HRM models which have been developed from researches in North America and in Europe (Hall 2004). A lot of work has also been undertaken in the area of strategic HRM, the approach in vogue. However, these do not give a cross-national picture in the wake of globalization and internationalization of businesses. Budhwar and Sparrow (2002) in a bid to address this, developed an integrated framework which delineates the main distinctive facets associated with national factors, contingent variables and organizational and HR strategies and policies that may be used to evaluate cross-national comparative HRM policies and practices (Budhwar and Sparrow 2002). Under the dynamic business conditions of this age as well as the difference in culture and characteristics of organization, relevance of lessons learnt from the European and Northern American experience of HRM is questionable if adopted holistically for other economic, geographic and cultural settings. Budhwar and Sparrow (2002) further sets the platform for global investigations into the HRM practices of various industries within particular national and cultural contexts. This has necessitated investigation into how this all-important function has been strategically integrated into the function of construction companies within the Ghanaian construction industry as well as the role it plays in the overall function of these companies. Such an investigation will enable the development of recommendations for ensuring the appropriate strategic integration of this function within construction companies operating in Ghana.

METHOD OF INVESTIGATION

This paper presents the results of a survey conducted in 2005/6, which is part of research being conducted at the Kwame Nkrumah University of Science and Technology (KNUST). This research aims at providing a tool to enhance people management in large construction companies operating in Ghana. The questionnaire developed and used, comprised three sections that sought to investigate the characteristics of companies, their human resource management practices, the role this function plays in the company and their policies. These were supplemented with a set of semi-structured interviews to further examine their HRM practices and policies. Building and Civil Engineering companies registered with the Association of Building and Civil Engineering Contractors of Ghana (ABCECG) as of 2005 were employed as the sample. Forty-nine large companies (Appendix 2a) were adopted as the population for the survey. By employing the Kish formulae, a minimum sample size of 36 was obtained (Barbbie 1995; Kish 1965). Companies were selected by employing stratified and random sampling methods. The regional divisions of the country, 10 in number, were adopted as the strata criteria. By the use of ratios, the strata sample sizes was determined. The companies were thus selected randomly within the various strata. This provided a fair sample representation across the entire country. The data obtained from the survey was analysed by employing descriptive analysis methods with content analysis methods adopted for the analysis of the semi-structured interviews. These methods were selected due to the focus of the instruments which required that the content of the data be analysed to identify key themes, trends, concepts and categories (Easterby-Smith *et al*. 1991). A frame was thus designed with the key concepts and themes on the horizontal axis and the responses from the individual companies on the vertical axis. The trends, themes, concepts and categories, were thus identified for analysing the content of the data.

RESULTS

The questionnaire was administered to 36 companies though only 28 were interviewed. After analysis, it was realized that companies could be grouped into two basic categories based on their origin: foreign and local ownership. There is, however, a third category, which is a partnership between these two basic categories. Local companies are owned by indigenous Ghanaians. Nine of the twenty-six employed in the survey are owned by sole proprietors. Six are in some form of partnership with the remaining eleven being limited liability companies with the board of directors comprising members of a nuclear family. The foreign companies are mainly subsidiaries of an international company hence represented locally by a representative who builds a management team. In addition, companies owned by foreigners living in Ghana are categorized as foreign companies since their practices are similar. As the name depicts, partnership companies are a partnership between local and foreign companies. The results of the entire survey are presented by capturing concepts identified by virtue of the method of analysis adopted. This includes how companies are managed, the nature of the HR function within companies and the role of the HRM departments in the company.

CHARACTERISTICS OF THE HRM FUNCTION, DEPARTMENT AND PERSONNEL

Construction companies operating in Ghana have specific characteristics and cultures due to the peculiarity of the industry and their origins. Management of companies is mainly centralized with the Managing Director (MD) or Chief Executive Officer (CEO) responsible for all major administrative and technical decisions. Artisans and labourers are not considered in general decision making though technical professionals are to some extent considered in technical decision making. Figure 1 shows a typical organizational structure of a construction company operating in Ghana. The levels range between four and eight depending on the number of professionals the company employs and its operational methods. Comparing Table 1 and Figure 1, the level of the personnel in charge of the HR function can be identified.

Dept. - Department

HRM personnel

The personnel in charge of the HRM function in companies are not necessarily directly in touch with the workforce and vary from company to company. The workforce does not necessarily have access to these personnel. This is contrary to HRM literature, which promotes line managers being in charge of some HRM functions to allow for an effective horizontal integration. These personnel are mainly technical experts with little or no HRM training to equip them with the requisite people management skills. In most cases (Table 1), the MD or the General Manager (GM) is in charge of this function. In this case, the HRM needs of the organization are integrated into the overall business goals. This is not to imply that in cases where there is an HR or Personnel Manager, the function is not integrated into the organization. In the foreign and partnership companies who employed the services of these personnel, their job description allows them to contribute in strategizing for the business allowing for integration into the overall business strategy of the company.

Table 2: Roles of department responsible for the HRM function

Category of Company	Role of Department Responsible for HRM Function							
	Business Partner	Strategist	Interventionist	Innovative	Internal Consultancy	Monitoring	Proactive	Reactive

Foreign	2	1	4	2	3	5	3	2
Partnership	1	1	1	1	1	1	1	1
Total No	6	6	7	6	6	13	6	4

HRM departments

Of interest to the research is the rather lackadaisical attitude of the industry as a whole towards the HRM function. It is interesting to note that the MWRWH in their guidelines do not make the existence of an HRM Personnel in companies a requirement resulting in the reluctance of organizations to employ professionals or train existing employees to take up this responsibility. Thus, this function is regarded more as a liable cost rather than an asset to organizations. Half the number of the surveyed companies' recorded that they have a department responsible for the execution of the function though they dubbed it differently (Table 1). The interview revealed that these departments exist more as Personnel Departments concerned with IR, handling legal people issues and workplace conflict management but not involved with the business of companies. A few however listed their roles to include the business partner role, the strategist role, the interventionist role, the innovative role, the internal consultant role, the monitoring role and the proactive and reactive roles (read more in Armstrong (2001) Chapter 5) the frequencies of which are in Table 2. These do not allow for the needed horizontal integration necessary to provide the organization with the needed competitive advantage.

The HRM function

The HRM function is mainly executed by management prerogative. That is to say, HR decisions are taken by management and implemented with no consultations with the general workforce. Fourteen out of the twenty-six local and one foreign company relied mainly on this system. Due to the non-existence of explicit HR policies, companies rely mainly on the Collective Agreement of the ABCECG and the Construction and Building Materials Workers Union of the Trade Union Congress (CBMWU of TUC) which is the dominant employee organization for construction workers in the industry. Four local and three foreign companies manage people by solely employing this document. Eight local, five foreign and the partnership company combine management prerogative and the collective agreement (Table 1).

DISCUSSION

The investigation reveals that not all companies (50%) have specific departments responsible for the execution of the HRM function. In fact, the personnel responsible for HR tend to be allocated this task irrespective of whether or not they have had some training in people management (Table 1). The availability of cheap and abundant labour does not also impress the need for appropriate people management practices to ensure staff retention. Cost, time and quality requirements of projects have however resulted in the need for more committed employees with the requisite skills. Further, the influx of international contractors and the need of other industrial sectors for construction professionals have increased competition for competent employees. This has prompted the need for adequate people management.

Overall, construction companies in Ghana lack well-structured and well-defined organizational structures. This makes it difficult for them to develop well-defined business strategies found in other industries such as financial and manufacturing. Also the nature of the industry does not allow for long-term planning making it difficult for companies to clearly outline their strategies. Most decisions are impromptu, policies are ad hoc and there is seemingly little formal planning underpinning them. The nature of employment (mainly casuals), the outsourcing of jobs and companies not having project security also adds to the instability in the industry.

The role of the department responsible for people management and the level of the personnel in charge of this function in the company has a great impact on how well integrated this function is in the light of all these instabilities. This gives rise to the two perspectives of the HR function: from the HR perspective and the business strategy perspective. Both vertical and horizontal integration of this with the business strategy of the organization will be discussed.

Vertical integration of HR function into company business strategies

Vertical integration is concerned with achieving strategic integration of HR strategies with business strategy. This is to ensure that the company has the skilled, committed and well motivated workforce it needs to achieve its business objectives (Armstrong 2001). The absence of a business strategy impairs the attainment of a vertical integration. Large construction companies within the Ghanaian construction industry, according to the MWRWH guidelines should have a financial ceiling of over five hundred thousand US dollars for a three-year period (Ministry of Water Resources Works and Housing 2004). In spite of this, some 30% of local companies find their turnover to be less than this figure. Local companies have an average of 16 professionals, foreign companies, 39 professionals and the Partnership Company, 19 professionals who are mainly technical staff. Companies reported that it is uneconomical to keep these professionals on when there are no ongoing projects, which is a regular experience especially for the local companies. A mere ten of the entire population had personnel trained in people management employed. It was generally believed that it is woefully uneconomical employing these professionals. The sizes and financial bases of companies make it uneconomical to employ personnel trained in people management. Further, due to high labour turn over which is as a result of poor conditions, companies fear to train other professionals to adequately strategize to integrate the HR function into the business strategy of the organization.

The advantage, if it can be called so, that companies have is the fact that in a majority of the cases, the MD or the GM is responsible for the function. In this case, integration can be said to be considered at the conception of a business strategy. The risk, however, is the focus of these personnel, which is to satisfy the business needs of the company more often than not at the peril of its workforce. Seven local and one foreign company have other professionals (financial or administrative staff) responsible. The disadvantage here is that though this person could be knowledgeable in people management, they are generally not involved in the conception of business strategies to allow for innovative developments and strategic integration of HR strategies. There is therefore a clear gap between formulation of business strategies and that of HR strategies not allowing for the desired fit.

Horizontal integration of a company's HRM dimensions

A horizontal integration is accomplished by developing a coherent and a well-knit range of interconnected and mutually reinforcing HR policies and practices. This requires the use of the 'bundling' approach of HR management (Armstrong 2001). The nature of the industry, however, does not allow for long term planning making it difficult for companies to clearly outline their strategies. The nature of employment, mainly casuals and the outsourcing of jobs contributes to the instability of companies. A company can however have its policies with each project having unique requirement that will call for unique strategies. Site managers are not equipped with the requisite skills and knowledge in managing people adequately. This requires that the HR Manager defines the role of these personnel and they be equipped with the requisite skills so as to take up this responsibility. Achieving horizontal fit will require that the various HR strategies cohere and are mutually supporting. This will require a deliberate attempt to 'bundle' so the process is driven by the needs and characteristics of the business.

Recommendations

It is essential therefore in cases where the MD or GM is in charge of people management to get some form of education on the need for integration, its advantages and how to integrate these functions. Not much can be done about the size and capacity of these companies. Majority of companies, especially local, cannot afford to employ a full time HR Practitioner. They can therefore employ the services of HR Consulting Services to aid in policy development, strategy design and development and general HR activities. Provided with the right information and assistance, companies can adequately integrate their HR strategies with their overall business strategies. HR literature does not specify who should be in charge of a particular HR activity. Therefore, depending on the structure of the organization, roles assigned to personnel should promote horizontal integration of the HRM function within organizations. Personnel should be trained and made responsible for specific HR activities. It will take a huge awareness campaign by stakeholders to ensure that this need for adequate integration of the HR function into the business strategies of organizations is adhered to by construction companies within this industrial sector.

CONCLUSION

The need for adequate integration, both vertically and horizontally, is essential for every organization, more so construction companies considering the nature of the industry. Unfortunately, the entire HR function has been relegated to the background by construction companies in Ghana. The majority of large construction companies in

Ghana do not have HR Practitioners responsible for people management. This is a result of the size of the companies, their resource bases and the fact that they do not see the importance of adequate people management. Fortunately, an influx of international construction companies as well as the industry loosing its professionals to other industrial sectors have introduced competition for employees; requiring local companies and to some extent foreign companies to improve their working conditions and manage people better. Ensuring a vertical integration to ensure the HR strategy is in tune with the business strategies of the company and a horizontal integration of the various HR activities will therefore not only provide companies with the needed competitive advantage but also ensure workforce commitment and increased productivity and performance.

Successful assessment of technology transfer (TT) to developing countries should include a test as to whether such transfers have contributed significantly to providing higher quality inputs into the wider domestic industry, in terms of materials, equipment, labour and management. Higher quality inputs will require proportionately rising absorptive capacity locally to accommodate transfers of embodied and disembodied knowledge in numerous forms. Many developing countries fail in their efforts to modernize construction either on account of investment shortfalls, or simply due to not employing an optimal mix of domestic and imported resources when the investment climate is favourable. Shanghai stands out for its success in gradual modernization of construction using TT from overseas in China's post-1978 reform period. This paper examines, following questionnaire-based surveys and interviews, steps taken in Shanghai to promote TT. China has placed a balanced emphasis on upgrading building materials and equipment, design and construction, and built up an impressive absorptive capacity in urban locations, with modernization of the entire industry in prospect. China has used primarily domestic resources and initiatives, and transferred from overseas resources and skills that are in short supply or not yet developed locally. Yet the task of modernization is only in early stages. The paper draws useful lessons for developing countries from Shanghai's achievements so far in modernization.

Keywords: absorptive capacity, China, developing countries, foreign investment, technology transfer.

TECHNOLOGY TRANSFER AND ABSORPTIVE CAPACITY

Technology transfer in construction is concerned with conveying embodied and disembodied knowledge from one entity to another within a country, or from one country to another. Embodied knowledge is commonly transferred through building designs, equipment, materials and software. Disembodied knowledge is largely concentrated in human skills. The acquisition of more productive human capital in all relevant forms is the critical goal in transfer, absorption and adaptation of new technologies (Dunning 1993: 287; Ganesan and Kelsey 2006). Ultimately the output of construction depends on the quantity and quality of its inputs. Thus technology transfer deals with the entire range of construction inputs and components, not just in their production systems, but in the much fragmented processes leading to their assembly at specific sites. An assessment of technology transfer to developing countries should include a test as to whether such transfers have contributed significantly to providing higher quality inputs into the wider domestic industry, in

[1]sganesan@hkucc.hku.hk

terms of materials, equipment, labour, management or other inputs – whether locally manufactured or imported.

Higher quality inputs will require proportionately rising absorptive capacity locally to accommodate transfers of new embodied and disembodied knowledge in numerous forms (Abbot 1985; Akubue 2002). In a simplified form, absorptive capacity is seen as equivalent to effective demand for any good or services required. Matching incremental increases in effective demand should be the supply of higher quality construction inputs. The investigation of this supply–demand dynamic in a free enterprise economy needs to consider hard issues of incentives for and returns on investments required, as well as users’ ability to pay for construction goods and services. Affordability criteria for significant social construction in developing countries introduces additional burdens in technology transfer.

Because the industry produces a vast range of goods and services in a developing country, varying from the international sector producing luxurious offices, hotels, modern industrial complexes and infrastructure, to conventional or traditional semi-permanent houses and buildings, technology transfer studies must necessarily be based on a disaggregated structure of construction output.

Main features of and barriers to technology transfer

A disaggregated model as defined above facilitates identity of higher quality inputs required, as well as improvement in absorptive capacity needed to match planned improvements in quality and quality of output – say for a sub-sector such as conventional house building. For technology purposes, construction in developing countries can be broadly categorized as follows, and discussion in this paper will be limited to these (Turin 1978; Wells 1986):

- advanced international technologies – buildings and infrastructure;
- modern urban construction;
- conventional construction;
- traditional (largely rural, low income) shelter and buildings.

Further, deficiencies in absorptive capacity can be appreciated readily when we examine the following domains related to domestic construction:

- national policies to expand domestic capacity;
- design knowledge and skills;
- technologies in materials, equipment and energy supplies;
- procurement and collaboration practices;
- construction skills, organization and management.

Professionals and managers in developing countries are likely to promote internal diffusion of advanced technology into any of the above areas if the particular technology can demonstrate the following characteristics:

- increase capital and/or labour productivity and cut costs;
- increase quality of finished products within the user’s means to pay;
- maintain optimal resource balance appropriate for a developing country.

The first of these is a foremost challenge in any country, and is a principal motivation for adoption or adaptation of modern technologies in industrialized countries. The diffusion of advanced technologies into conventional and traditional construction is severely limited in developing countries by the inability of users to pay for them in the absence of public sector subsidies. Ambitious attempts to transfer technologies to conventional and/or traditional construction in particular have faltered on such grounds (Ganesan and Kelsey 2006; Akubue 2002; Simkoko 1992; Imbert 1990). On the other hand, transferring new technology into the modern construction sector is relatively better accomplished because the affluent clients of private construction are able to pay for them, or the national governments underwrite investments in modern public infrastructure projects such as highways, port and harbour or power supply projects where these new technologies are incorporated.

The third issue emerges as a major problem in developing countries with limited foreign exchange earnings or reserves at any time. In these countries, foreign earnings or foreign loans and grants are required for import of technologically advanced inputs, or to manufacture them locally. For internal transfer of technology to be sustainable over the medium to long term within a large recipient industry, like construction, a country in the earlier stages of development should use foreign resources in proportion to its foreign earnings. Advanced technology transfer and domestic capacity growth are not mutually exclusive provided considerations to maximize the productivity of available scarce resources enter the choice of technologies in their use (Streeten and Stewart 1973; Ganesan 1979: 40–1; Streeten 1995). Higher absorptive capacity requires increased expenditure to raise construction output. Many developing countries fail in their efforts to modernize construction either on account of investment shortfalls, or simply due to not employing an optimal mix of domestic and imported resources even when the investment climate is favourable. The 1997 Asian Crisis is a constant reminder of such dangers arsing from resource imbalances (Ganesan 2000: 30–81).

Within a broader understanding of issues affecting technology transfer outlined above, it is possible to evaluate success or failure in technology transfer empirically by examining the changes in inputs and output, considering either a single sub-sector in detail, or aggregate construction, where relevant input data cannot be disaggregated. This may be described as a preliminary, resource-based, input–output approach to evaluate technology transfer. This procedure will be used to study construction industry changes in Shanghai.

Technology transfer in Shanghai

Shanghai stands out for its success in modernization of construction using technology transfer from overseas in the People's Republic of China's post-1978 reform period. China has placed a balanced emphasis on upgrading building materials and equipment, design and construction, and built up an impressive absorptive capacity in urban locations, with modernization of the entire industry in prospect. A number of initiatives were implemented. These are examined below in terms of the five domains listed above, that support advances in domestic construction capabilities.

Policies to expand domestic capacity

The post-1978 reforms in PRC emphasized improvement in productive capacity of the economy and social conditions of the people. Modernization and technological upgrading using foreign resources was a strategic decision of the leadership. A favourable national economic climate fuelled the rapid expansion of absorptive capacity for technology transfer. In the 25-year period from 1978, as GDP went up 9.4 times, construction expanded 10.4 times. Construction's share in GDP rose from 3.8% in 1978 to 6.9% in 2003 (National Bureau of Statistics of China 2005, 3-1: 53–6). The public sector itself is a major investor in vital infrastructure provisions, aided by a rapid increase in state revenues in the recent period. Total government revenue in GDP increased from 11.2% in 1994 to 18.5% in 2003 (National Bureau of Statistics of China 2005, 8-1: 288). The public sector is also a major collaborator with foreign and other domestic parties.

As mentioned above, an appropriate balance in the use of domestic and foreign resources is essential to sustain technological upgrading over the longer term. The government essentially adopted two major strategies towards this end. First, it opened the economy to private domestic and foreign capital and embarked on an export-led development drive. This led to a huge build-up of foreign currency reserves through export of a vast array of goods and services – reported to be US$1 trillion in November 2006 (www.chinability.com accessed 5 March 2007). Second, as foreign investors started taking advantage of China's unlimited and cheap labour supply, including a large pool of relatively better skilled workers, the government gave incentives to foreign direct investment (FDI) as the favoured means to support higher growth and upgrade technologies notably in enterprises targeting the export market. The large domestic market was also a major attraction. From 1978 to 2005, China used US$637 billion in FDI (www.chinability.com accessed 5 March 2007; National Bureau of Statistics of China 2005). Both strategies supported one another. The PRC government set in motion a series of measures to transfer advanced technologies, such as the advanced technology provisions promulgated by the State Science Commission on 4 October 1979 (Wang 1998). FDI passes risk in investments to the investors themselves, and protects the sovereign hold on foreign reserves of the country, adding to overall currency stability. Technology transfers involving FDI usually provided simultaneous transfer of management know-how, personnel training, continuous cooperation between the local and foreign parties involved and better prospects of replication of the same technology in existing or newer enterprises (Zhang 1994).

Urban and infrastructure construction emerged as a key sector in these reforms. The 1978 reforms created a favourable economic climate for rapid build-up of the absorptive capacity for technology transfer in the construction sector. The goals of technology transfer that enhance, in essence, this absorptive capacity are periodically established in the PRC Five Year Plans. For example the Tenth Five-Year Plan (2001–05) emphasizes further improvements in construction capacity, and rising of the standards of design, construction and management to guarantee quality projects. (National Bureau of Statistics of China 2003). In pursuit of advanced technologies, China has been following the strategy of 'upgrading the domestic industry depending primarily on domestic resources and initiatives, and transfer from overseas of resources and skills that are in short supply or not yet developed locally' (Ganesan 2000: 301–2). A number of initiatives were rapidly implemented in Shanghai, Beijing and other urban locations.

Shanghai is the commercial capital of China. The population is currently around 18 million with a per capita income of US$6200, representing over a 20-fold increase since 1978. This has been made possible by a 9–10% annual growth in real GDP during the same period. Total GDP of Shanghai stood at US$109 billion in 2005, representing 5% of China's GDP. Expansion in construction activity was an integral part of this remarkable spurt in economic growth. No other city has built as much as

Shanghai in the last 25 years, and improved its built environment so much. New strategies maximized housing investments through the combined initiatives of the state, local authorities, private and public enterprises and individuals (Zhi 1993: 82). Housing contributed nearly a third of this construction expenditure. Nearly 100 million square metres of housing space were completed in the first two decades of reform, in search of a target of 10 square metres of living area per person.

The massive expansion in construction expenditure has facilitated advanced technology transfer. A rapidly increasing volume of construction at the same time allows a smooth adjustment of a mix of technologies so as to eliminate labour-reducing adverse social consequences. Shanghai attracted the most amounts of foreign investment, contracting for over US$100 billion of FDI till 2005. In 2005, Shanghai contracted FDI of US$13 billion, and actual realized investment was US$6.9 billion. (*People's Daily Online*, 6 December 2005). Construction secures its inputs from practically all other sub-sectors of the economy. Foreign investment in the overall economy helped construction. Specifically, construction and real estate, together with investment in building materials and services amounted to nearly 50% of total foreign investment in Shanghai up to 2000. Foreign investment and related services covered practically all the five domains of construction identified above as significant to technology transfer. The Shanghai Municipal Government periodically issued regulations that facilitated the setting up of foreign funded enterprises (FFEs). Significant among these is the notification titled 'The Measures of Shanghai Municipality on the Administration of the Use of Land by Foreign Invested Enterprises' (Ganesan 2000: 301–38; State Statistics Bureau of China 1997).

Design knowledge and skills

Design is the phase where most of the critical decisions on advancing the technological content of the construction product are taken. China already possessed design and construction skills that were the envy of many less developed nations. Collaboration with foreign firms had the goal of improving the absorptive capacity of local firms. The PRC government laid down rules to support this specific objective.

Foreign design firms have usually been required to cooperate with local design firms at the conceptual design stage – especially in high-tech projects. Detailed designs are normally undertaken by a local design firm. For example, in the landmark Jian Ma Building, a US firm – Skidmore Owings & Merrill – collaborated with the Shanghai Institute of Architectural Design and Research. The owner usually entered into separate contracts with the design parties involved. Similar collaborative arrangements were undertaken with leading international firms from Hong Kong, Japan, USA, Germany, etc. This collaboration enhanced the technological capability of the partnerships, and in the medium term enabled the local architects to absorb additional conceptual design and related skills. Among those skills transferred around 1990 were the following (Ganesan 2000: 318–19):

1. the use of enabling technologies such as computer-based design communications, using advanced design software;
2. the better integration into construction design of comparatively technologically advanced inputs such as:
   - structural steel components;
   - higher strength concrete;

- superior building finishes;
- high speed elevators;

3. the better organization and application of processes such as design coordination, change control and constructability reviews.

The East Asia Design Institute of Shanghai has demonstrated the benefits of such collaboration with its own design of the 456 metre Shanghai Oriental Pearl tower. The Shanghai Opera House (including its acoustics) was also designed solely by this Institute.

Technologies in materials, equipment and energy supplies

China's building material industry was sufficiently developed by the 1970s that buildings of up to 30 storeys were being erected out of locally produced material and components. Under the post-1978 reforms, China adopted dual strategies: First, direct imports were allowed. Second, from the 1980s China set up international joint ventures (IJVs), and particularly from 1992, allowed fully foreign funded enterprises (FFEs) as well, with FDI, to boost local production of building services, materials, fittings, components and finishes to high international standards.

The construction boom of the 1990s, for example, generated a huge demand for imported high quality products: bathroom fittings, escalators and elevators, communication equipment, air-conditioning equipment, marble, glass curtain walls, lightweight and high strength structural steel products, fire safety, security and environmental control equipment, hardware items, floor and wall panelling, etc.

However, a real boost in supply of construction resources came after the enactment of the Provisions of the State Council of the People's Republic of China for the Encouragement of Foreign Investment in China in 1986. Benefiting from the financial and other incentives, FDI in production enterprises grew rapidly. Incentives were granted to construction material, transportation, machinery, communications, metallurgy and other sectors that directly or indirectly supported construction.

Cheap labour and the huge domestic market as well as the potential to export a part of the products, led to a massive increase in manufacturing in these sectors. By the end of 2000, the State Bureau of Building Material Industry (SBBMI) had approved over 5000 new building material industries with overseas funding with a total contract value of over US$15 billion. These included cement, glass and glass products, aerated and structural concrete, steel products, high quality ceramic tiles, sanitary ware and stone products, decorative materials – practically all that were imported during the earlier period of the reforms. It is estimated that output from the FFEs now accounts for 20–30% of national output or sales in many products, such as plastic products, door and window frames, metal products, electrical machinery and tools, and furniture. Probably a quarter of all materials and components used in new construction in Shanghai are from IJVs – though nationally the percentage would be much smaller. In a selected set of the most advanced buildings in Shanghai, the IJV-produced proportion of all materials and components used is estimated to be in the range of 50–80% (Ganesan 2000: 320–5).

Prior to 1978, China had a large construction equipment manufacturing sector, supplying concrete mixers, bulldozers, tower cranes, road rollers, etc. These were also exported. However, a significant technological gap always existed between domestically produced and most internationally traded plant. This was first bridged after 1978 by imports of sophisticated machinery, and now IJVs are active in upgrading manufacturing technology in this sector (State Statistics Bureau of China 1997; Ganesan 2000).

Finally, the expansion of energy supply capacity is probably one of the most important constraints on the growth of both output and productivity in industrial activities in developing countries. In China, nearly a third of all energy used is taken up in (1) production and transport of materials; and (2) building construction and maintenance. Growth in energy supply at 6% per annum in the 1980s had been insufficient to match higher demand from construction (Ganesan 2000: 327–9); however, more recently, China's Primary Energy Production has accelerated from 31.84 quadrillion BTU to 44.10 quadrillion BTU in 2003 (www.eia.doe.gov/ accessed 10 May 2007).

Procurement and collaboration practices

The government gave encouragement to the construction sector to maximize the use of foreign resources including preferential long-term loans to form joint ventures (JVs) within foreign engineering, design, consulting and research institutes in order to enhance technological capability, and increase investments in construction in general. These initiatives enhanced domestic capacity in practically all fields, notably in improving local architectural design and construction skills, technological capability of construction enterprises, R&D for building and energy-saving technologies, bi-lateral and multi-lateral funding for the financing of environmental and urban infrastructure projects (Song 1998; Carrillo 1996). Foreign companies are required to set up their own offices, staff them adequately with technical and management personnel, before they are allocated any work, a condition that encourages integration into the local industry even if only on a temporary basis.

In 1988, there were nearly 1000 foreign construction enterprises (including those from Hong and Taiwan) licensed in China. Foreign companies can form joint ventures with local parties guided by the Law on Joint Venture with Chinese and Foreign Investment and other laws of the Ministry of Construction and other ministries. There were 425 JVs registered in 1998. The foreign contractors on their own or in JVs are allowed design and construction work in fully foreign funded projects or on special projects where there is no local expertise. Many foreign construction companies function as subcontractors – particularly those who are specialist contractors – providing specialist skills and expertise which domestic contractors do not possess. Subcontracting is widespread in China and is actively employed in all construction-related businesses including the JVs.

Construction skills, organization and management

TT efforts covered practically all areas of construction relevant to the achievement of the goals identified in the Five-Year Plans so as to provide a comprehensive framework. For example, the central, provincial and municipal governments have promulgated the Construction Law, the Contract Law and the Tendering Law to guide all related activities in the construction sector. The unified Construction Law was effective from 1 March 1998 (Lu and Fox 2001). It is apparent that many of these laws were influenced by overseas practices that were transferred to China after 1978.

China achieved an impressive volume of construction output in the pre-1978 years. This could not have been achieved without a good deal of organization, self-management and use of conventional management procedures. The then labour-intensive methods of construction were organized with a high ratio of managerial workers. New management skills were demanded for those post-1978 projects that attracted foreign capital flows, including FDI – notably in the areas of import of materials, implementation of new procurement systems, and collaboration with foreign parties. The Ministry of Construction set up advanced management training systems, and often foreign firms organized special programmes to train local workers engaged in JVs (Ganesan 2000: 327). Furthermore, in practice, local construction skills were steadily upgraded through institutional collaboration and subcontracting arrangements employed in the modern foreign funded projects, as described in the preceding section.

PROSPECTS FOR TT: DISCUSSION

The paper identifies the significant role of FDI in general and especially the critical contributions of overseas construction firms and personnel in construction in the technological upgrading in Shanghai and other urban locations in China. We cannot achieve technological upgrading if industrial output is stagnant. It is clear that resources for industrial expansion and technology transfer were mostly mobilized locally or through earnings from export-led economic expansion. Total exports grew from US$194.9 billion in 1999 to US$438.2 billion in 2003. Total imports increased from US$165.7 billion to US$412.8 billion in 2003 (National Bureau of Statistics of China 2005, 18-1: 713). It is noted that foreign investment constituted only 4.7% of total investment in fixed assets in 2003 nationally, indicating its limited but catalytic role (National Bureau of Statistics of China, 2005, 6-1: 187). This supports the theoretical position taken in this paper that a correct balance in the use of domestic and foreign resources is an essential condition for successful technology transfer to developing territories. China’s strategy closely followed this position as pointed out above.

The real tests of successful diffusion of advanced technologies though are whether new knowledge and skills have been permanently transferred to institutions and individuals within the recipient industry; whether such knowledge and skills are being applied to new projects; any technological gaps have been reduced especially design, construction and management deficiencies in the local firms; domestic capacity to reproduce embodied knowledge in materials, components and equipment has increased and finally, sources of funding projects including minimal supplies of foreign exchange are adequately established and moderately sustainable (Kumaraswamy 1994; Devapriya and Ganesan 2004; Ganesan and Kelsey 2006). The increasing number of complex projects being planned and executed within Shanghai, the minor share of foreign resources (less than 5%) in capital construction financing, and the build-up of large foreign currency reserves as evidenced in this paper indicate that internal diffusion of advanced technologies as defined is being achieved.

If transfer of technology can be viewed as a process of introducing higher quality inputs (materials, skills, equipment, etc.) into construction, the success observed in the more developed sub-sectors in Shanghai validates an input-based approach to implementing technology transfer. There was clearly a multi-faceted and integrated attempt to upgrade the quality of all inputs. Equally, the failure to significantly penetrate conventional and traditional construction may be explained by some critical inputs being not available to these sub-sectors in adequate quantities or within affordable prices.

Building materials and components constitute by value the largest input. Particularly impressive are the rapid advances in manufacturing of quality products through IJVs within the past 20–25 years. The example of China has highlighted three issues as being critical to technology transfer especially in manufacturing:

- selection of projects based on advanced technology;
- training of Chinese workers in advanced technology;
- training in management skills.

The joint ventures face problems of technological gap between the parties, underutilization of equipment, competition from cheaper and lower quality products, financial viability, and the ultimate challenge in earning net gains in foreign exchange. The primary objective with respect to technology transfer in the coming decade will vary according to the construction or building material supply sub-sector. Consider the materials sector. The recent expansion in industrial capacity throughout China is remarkable. For example, cement capacity rose from 2.3 million tons in 1999 to 12.7 million tons in 2003 (National Bureau of Statistics of China 2005: 214). The total industrial value added in all building materials in 2003 amounted to an impressive US$17.35 billion. Despite the technological advances in Shanghai, only about a quarter of all building materials supplied are produced to higher quality in the IJVs (Ganesan 2000: 337). The percentage of high quality materials produced on a national scale would be much smaller. Probably the greatest challenge is to modernize those building materials production units established before the 1978 reforms. From the 1960s, there were over 8000 factories set up and managed by the China (New) Building Materials Corporation, affiliated to the State Bureau of Building Materials Industry (SBBMI). These are largely state-owned enterprises (SOEs). Additionally, there are a large number of urban and rural collectives active in production. The materials sector produces over 500 products. Slow increases in factor productivity have led to stagnation (UNIDO 1992: 111). Critical problems in this sector are a product mix unsuitable for the current Chinese market and poor quality of products (Hannan 1995). The sector is known to suffer from archaic equipment, low labour productivity, financial instability, manufacturing delays, etc.

New FDI is planned, therefore, to be directed into these ‘traditional’ enterprises that provide basic inputs like materials and equipment manufacturing, manpower training, etc., in order to modernize them, and have the maximum multiplier effect in achieving the technology transfer goal. In this task, intra-national (domestic) technology transfer can play as important a role as foreign to domestic transfers. The Japanese government has long-established procedures for intranational technology transfer; for example, technologically developed firms operating nationally are required to form joint ventures with local firms when executing regional projects (Ganesan 1982: 153–82). However, restructuring of SOEs in China has not been always successful (Huchet and Richet 1998). Economic viability of restructuring is likely to be determined by the state of technology in current use, construction market conditions and competition from IJVs already set up. If restructured enterprises focus on products for the rural sector, their profit margins are like to be small or even negative. Further, since 1992, foreign investors have preferred to set up fully foreign funded enterprises (FFEs). This preference for FFEs will reduce foreign capital flows to SOEs further (Wang 1998). The pace of modernization of the existing building material sector is likely to influence technological upgrading of all four construction subdivisions especially the conventional and traditional building activities.

Khan (1999) has argued that FDI as a medium of technology transfer has been fairly successful especially in manufacturing. The same conclusion may be drawn with regard to modern urban and infrastructure construction. The FDI component constitutes only a fraction of the total national expenditure on construction. In order to promote technological advances on the scale required in all China, further mobilization of foreign and local resources, advanced manpower training and investment in R&D are necessary. The rate of growth of FDI in key industries and its catalytic role are critical. Limited foreign resources need to be guided into strategic enterprises with the maximum multiplier impact on technology transfer. Essentially this strikes a balance in productive capabilities and planned technological levels (Wang 1998). Cement, glass, natural stone, inorganic non-metal industries and building material manufacturing equipment are among the high-tech units identified by the State Administration of Building Materials industry for further upgrading. A socially responsible employment policy needs to complement technology transfer efforts. It is also noteworthy that little progress in technology transfer will be achieved nationally without improving energy supplies significantly.

Technology transfer is not a politically neutral activity (Ofori 2000). Mainland China’s (PRC) political system is unique. China provides a huge market for every construction sub-sector, and demonstrates unrivalled market power in negotiating technology transfer mechanisms with overseas parties. China’s record foreign earnings in the post-1978 period have provided a firm platform to engage in advanced technology transfer. Yet Chinese experiences are not irrelevant to construction expansion in DCs in general. There are bound to be procedures that can be adopted successfully in different countries regardless of their social systems – admittedly with different degrees of success (World Bank, 1984). One can recognize such common patterns of growth in the proliferation of science and technical knowledge across national boundaries. All things considered, China’s experience in technology transfer since 1978 validates an integrated approach to increasing the supply of higher quality inputs while maintaining a sustainable ratio of foreign to domestic resources. China also provides an outstanding example of the importance of developing a domestic absorptive capacity to integrate advanced technologies from overseas.

CONCLUSIONS

Because of data limitations, this paper has drawn conclusions mainly relevant to construction in Shanghai. In Shanghai, the international technologies sector (complex buildings and modern infrastructure) and modern urban construction have benefited noticeably from technology transfer in the post-1978 period. The 1978 reforms provided a favourable climate for new investment in urban growth and capital construction, with a defined role for FDI in diffusing advanced technologies. Within such a climate, policies adopted within the construction and building materials sectors have produced favourable results in terms of sustained increases in construction output while inputting higher quality resources. It is noted that conventional urban and traditional rural construction are still largely dominated by pre-1978 technologies. Chinese experience confirms that diffusion of advanced technologies is more manageable in the more developed construction sub-sectors servicing the more affluent urban areas.

ACKNOWLEDGEMENT

We are grateful to Professor Zheng Shilling, Professor Zhi Wenjun, Zhou Qing and others from Tongzhi University, who helped us to conduct surveys of design and construction firms in Shanghai.

ARTISANAL MATERIALS FOR SUSTAINABLE CONSTRUCTION IN DEVELOPING COUNTRIES

O A K'Akumu,[1] A Blyth and B Jones

Property and Construction, University of Westminster, School of Architecture and the Built Environment (SABE), 35 Marylebone Road, London NW1 5LS, UK

Sustainable construction is a major challenge to developing countries more so when it comes to the use of artisanal materials in the construction process. This review identifies and examines the challenges facing developing countries in this respect: environmental degradation, poverty, informal settlements, inappropriate regulatory mechanism, inappropriate technology, and neglect in research and development debates. It notes that research and development at local level is necessary for addressing the challenges posed by the use of artisanal materials from sustainable development point of view. Above all, it recommends research into the area of artisanal materials and sustainable construction.

Keywords: building regulation, developing countries, intermediate technology, standardization, technology transfer.

INTRODUCTION

This paper intends to justify the need to undertake research on artisanal material production for purposes of mainstreaming sustainable development in the construction industry of developing countries. The paper defines artisanal materials as well as sustainable construction in a developing country context.

The paper poses questions about the challenges to sustainable construction in developing countries and whether artisanal materials can address these challenges. The aim is to spark debate and stimulate research undertakings in this grey area.

One of the pertinent challenges to sustainable construction in developing countries remains sheer lack of knowledge about it or what it may entail for developing countries. As noted by du Plessis (1999, 2007), the thinking in sustainable construction is dominated by issues to do with developed countries and that are in fact irrelevant to the developing country situation.

The paper is an exploratory work that seeks to persuade that research into the case of artisanal materials is a significant way of addressing the issue of sustainable construction in the developing countries. The paper is merely a review of the situation in order to propose a certain research agenda. For that matter, it does not apply any case study or empirical analysis.

CONCEPTS AND DEFINITIONS

Artisanal materials

The term artisanal is an adjective of the word ‘artisan’ and simply refers to any thing associated with artisans. The English dictionary meaning of an artisan is of a person who applies manual skills to do work. See the following definitions for example:

- ‘Somebody who is skilled at a craft’, Bloomsbury (2005).
- ‘Skilled manual worker or craftsman’, Oxford (1993).
- ‘A worker who has special training in a manual skill’, Collin (2006).
- ‘A skilled workman; craftsman’, Collins (2005).
- ‘One who is employed in any of the industrial arts; a mechanic, handicrafts man, artificer’, Oxford (1971).

These definitions follow the traditional concept of an artisan as an industrial craftsman; who is skilled, trained and specialized in a particular trade. In the pre-industrial revolution era, artisans consisted of guilded workers who were trained through apprenticeship (Eisenberg 1991). In the construction sector, artisans included painters, plasterers, masons, roofers, joiners, carpenters, et cetera (Gould 1993). To date, such artisans still exist in the construction sector whether in developing or developed countries.

Gore (2004) considers the term craft as any human transformation of raw material into another object. This transformation, he notes, can happen:

- By hand.
- With the assistance of machine tools.
- Through the agency of automated manufacturing equipment.

Artisans are the category of workers who undertake this transformation largely by hand or to some extent with the assistance of machine tools.

Artisanal materials are, therefore those human rather than machine made materials used in the building of structural elements in the construction sector. Examples of artisanal materials may include: manually cut dimension stone, manually broken ballast, manually fetched sand, manually made bricks/blocks etc. Artisanal materials may be considered the antinomy of industrial materials as conceptualized in Terner and Turner (1972), i.e. hand crafted and individually made materials that imply:

- Lack of standardization of the final product (production skills and sites are varied, sporadic and may be irregular).
- Lack of concentration of production and marketing (small scale and sporadic/fragmented).
- Lack of mechanization or automation (labour intensive).

In these characteristics lie the challenges and opportunities for artisanal materials in the urban context where demand for construction products remains high due to urbanisation processes and the rate of use of materials is faster thereby favouring industrial production.

This concept of artisanal materials may but does not necessarily include traditional materials. The latter are construction materials that were used by local communities prior to foreign/colonial intervention. For example, in Kenya, makuti (palm fronds) roofing was used in the coastal areas while grass thatch was predominant in the hinterland. Non-traditional materials on the other hand are materials whose usages were introduced through colonial intervention even if some of them were locally available; these include cement, bricks, dimension stone, sawn timber, sand etc. the materials could have been locally available but the technology for exploiting them had not been introduced. Secondly, they may not have been fully integrated into the local construction tradition.

The dichotomy of industrial/artisanal materials is technology/process based while that of traditional/non-traditional is temporal based i.e. past and present or ancient or modern. On the whole, artisanal materials may be either traditional or non-traditional depending on whether they were used by the society in the past or whether they are recent additions from foreign cultures and practices.

Reasons why artisanal producers tend to thrive in developing countries include:

- Some natural resource materials do not exist in substantial quantities to warrant large-scale exploitation.
- The construction that takes place at localized levels is largely undertaken by individual (other than corporate) developers who rely on materials from non-corporate sources usually identified or attained through personal relations.
- It is easier for artisanal producers to reach developers even in remote areas.
- Construction industry in these countries is mainly a preserve of artisan labour force that is able to form linkage with artisanal sources of materials.
- Artisanal producers do not use heavy equipment and hence can move from place to place in search of material which they can accumulate into adequate quantities.
- Artisanal producers are more distributed and hence their impact on the environment is much less visible hence tolerable.
- Artisanal producers can viably supply even very small developers with low demand that is highly fragmented.

It is for the above reasons that artisanal producers dominate production and supply of materials like: sand, dimension stone, slab stone, bricks, and ballast. Sand for example is universally used as small aggregates in the composition of concrete in Kenya; however, the production and distribution of sand is entirely left to the work of artisans.

Sustainable construction

Sustainable construction is perceived as a concept that has been coined for the purpose of mainstreaming the principles and practice of sustainable development in the construction industry (Hill and Bowen 1997; Miyatake 1996). Construction is related to sustainable development to the extent that it affects the environment, economy and society; the three form the key aspects of sustainable development. In all cases, the effect of construction can either be positive or negative or both. In the sphere of environment, for example, Horvath (2004) sees construction as one of the largest users of energy, material resources and water, and also as a formidable polluter. These are negative aspects but the positive ones include the fact that construction improves the human living or working environment to habitable conditions.

Since sustainable construction is based on environmental, economic and social factors that differ globally, it may not be easy to define the term. But du Plessis (2002), who had the mandate to do so, have given a definition that is closer to the developing country situation. The authors define sustainable construction as ‘a holistic process aiming to restore and maintain harmony between the natural and the built environments and create settlements that affirm human dignity and encourage economic equity’ (du Plessis 2002: 8). This definition covers all the three aspects of sustainable development: environment (natural and built), economic and social. The social aspect may not be overtly explicit in the semantics but is well represented in the concepts of dignity and equity. Dignity implies sustainable construction has to ensure socially acceptable living environments while equity implies equitable use and distribution of resources generated or consumed in the process of construction. This definition also clearly captures the aspect of informal settlements, which is the main challenge for sustainable construction in developing countries.

Scholars conceptualize sustainable construction in a cradle to grave imagery. This life cycle approach can be divided into three distinct phases: production phase, use phase and decommissioning phase (Rohracher 2001; Rwelamila *et al*. 2000).

Developing countries

Crump (1991) defines developing countries simply as countries that do not have sophisticated industrial bases to their national economies; their economies are characterized by abundant, cheap, unskilled labour and scarcity of capital for investment. It is these two key factors – abundant labour and scarce capital – that lends these countries’ production set-ups to artisanal production; where production is confined to hand or tools operations as already pointed out under artisanal materials production.

Apart from the low industrial base, developing countries are said to have also a low human development index (HDI). Developing countries are classified under low HDI countries meaning they have low scores on longevity, knowledge and standards of living, a condition that implying a lot of work that has to be done in order to bring the index to the threshold standards (UNDP 2000).

The factors of HDI (longevity, knowledge and standard of living) are issues to do with sustainable development. Also, a great part of the work to be done in this case require establishment of infrastructure which therefore involve construction as a major activity in development endeavours. These contribute to the interconnectedness among low human development, sustainable development and hence sustainable construction as discussed further in this paper.

THE CHALLENGES TO DEVELOPING COUNTRIES

Developing countries face the following challenges concerning sustainable construction.

Rapid development

Developing countries, as the name implies, are in the initial process of economic development or industrialization. This situation entails a great demand on construction products hence high volume of construction activities. In developing countries infrastructure is lacking and has to be hurriedly put in place in order to support various activities for purposes of economic and social progress (Majdalani *et al*. 2006). Infrastructure involves a host of construction products such as buildings (industrial, residential, commercial, social, administrative), and civil engineering structures such as roads, bridges, dams and airports (Bourdeau 1999).

The high volume of construction activities brings certain implications for sustainability; these include the limited environmental resources fro undertaking construction projects and the potential damage to the ecological balance. Construction, for example, require materials that have to be obtained from the natural resource base e.g. cement production involves the mining of limestone. Construction also leads to damage of environmental resources such as loss of flora and fauna in the construction of roads or displacement of people in the construction of dams.

Another aspect of economic development that is common for developing countries involves urban development. Development has brought with it rapid urbanization that puts undue pressure on the supply of construction products. Urban development as part and parcel of economic development therefore builds up the demand for construction products.

Poverty situation

The greatest challenge to developing countries today is the abject poverty that most of their citizens languish in. For that matter, every industry, construction included, is challenged to function toward poverty reduction. Construction is better put in this case because it can provide employment to some of the poorest groups of peoples. It employs unskilled and semi-skilled labour given its labour intensive nature.

Construction materials, apart from the finishes, are largely unprocessed and semi-processed products mean that even the poor can benefit down the supply chain. Construction activity takes place at various scales ranging between small and large. This means that even small-scale operators can participate in the industry, therefore giving opportunity for the poor to make contributions and earn a living.

One other advantage construction has is that it uses materials from within the local area. This enables it to generate a lot of economic opportunities at the grassroots level thereby benefiting local development. Because of these advantages construction is generally seen as a significant industry in the Keynesian economic model that developing countries have adhered to for so long. It is known to have significant multiplier effect in the economy in general. For that matter it can be instrumental in developing sustainable livelihoods for people at local level. This is a novel challenge that has not been explored but that can be of great benefit. Can we integrate construction industry with local livelihood strategies?

Informal settlements

One of the main characteristics of urban development in developing countries is informal settlements. In Kenya, for example, it is estimated that over 60% of the urban dwellers live in squalid conditions in informal settlements (in the form of slums and squatter settlements). Unfortunately, the problems of informal settlements are mainly seen as social problems, i.e. problems of housing, social equity, welfare, or distribution of income and wealth (especially land). The problem is rarely seen as a problem of the construction industry. This proposition reiterates that as much as the problem of informal settlements belongs to the socio-economic realm with its impacts on the physical environment, it is a problem whose immediate causes lie in the structural inefficiencies of the construction industry. Hence its immediate solution lies with restructuring of the industry by recognizing and promoting sustainable construction practices.

Regulatory mechanism
According to van Bueren and Priemus (2002), institutional factors could form the greatest barrier to the attainment of sustainable construction. One of the greatest challenges of sustainable construction in developing countries is the institution of regulatory mechanism. Majdalani *et al*. (2006: 34) observe that ‘inadequate construction standards and lack of sound urban regulations (or enforcement of existing regulations)’ aggravate environmental degradation. In developing countries, the mechanisms may not be there, or if they are there, there may not be political will to enforce them, or they may have been inherited from the colonial past without any aspirations from the local society whom sustainable construction are supposed to benefit.

Lessons from the developed world
The other challenge of sustainable construction is whether these countries can learn from the sustainable construction experiences of the developed countries. The latter countries have faced their own challenges in the development process. The question is, can the developing countries learn from the others’ mistakes and successes so that they do not fall prey to the same development path. According to du Plessis (2007), the level of underdevelopment in developing countries provides them an opportunity to avoid the problems experienced in the developed countries. The question therefore is: are developing countries in a position to learn from the developed world?

Inappropriate technology
Technology involves a serious challenge for sustainable construction in developing countries. Ofori (1998) noted that the diffusion of modern ways of building and the use of materials without consideration of local, environmental and cultural is a practice inimical to the attainment of sustainable construction. The challenge for developing countries is therefore to identify and develop appropriate technological practices to ensure sustainable construction.

Neglect in international debate
Another challenge sustainable construction is facing in the developing countries is lack of recognition in the international arena where issues to do with sustainable construction are being debated, formulated and prioritized for implementation. Du Plessis (1999) decried the developing countries have been excluded in the sustainable construction debates whereas more than two-thirds of the world population live in these environments. But it behoves these countries to have their own specific agenda to present at the debate. Perhaps they have not been included so far because not have not demonstrated any need to be included in the debate.

THE CASE OF ARTISANAL MATERIALS

The challenges of sustainable have particular implications for the use of artisanal materials in developing countries. Does the use of artisanal materials in the construction industry exacerbate or ameliorate the developing country situation?

Damage to the environment

We have noted that construction does a lot of damage to the environment. According to Horvath (2004) opposition to large-scale construction projects is growing world over. This could be because their environmental damage is enormous and obvious. However, many small-scale works, especially those catering to the residential needs of the population, can easily escape the attention of environmentalists. Unfortunately, this is the segment of the industry where artisanal producers operate.

Artisanal exploitation of natural resources in other sectors like mining and fishing have been shown to cause serious environmental damage; see for example Mensah and Antwi (2002), Campredon and Cuq (2001), Hawkins and Roberts (2004), Rutterberg (2001), in the case of fishing; and MMSD (2003), ILO (1999), Quironga (2002) and Ogola *et al*. (2002), in the case of mining. In the construction sector, artisanal exploitation of natural resources for construction purposes may be damaging to the environment but has not been given adequate consideration. Examples here may include alluvial sand mining, stone quarrying, clay brick making, green timber exploitation etc.

Poverty reduction

Artisanal production of materials is a potential means by which the construction sector can contribute to poverty reduction through sustainable livelihood strategies. As in the case of mining, artisanal production has the potential for employment creation since it can be a means of survival for large numbers of workers and their families (Zamora 2000). But economic impact goes beyond the support of workers and their families to include support for whole local economies by creating demand for goods and services (MMSD 2003).

Informal settlements

Informal settlements are where the poor in urban areas live. They are the same people who also provide labour and skills in the use of artisanal materials where construction is concerned. If artisanal materials are well understood and improved through formalization and value addition, they can provide cheaper resources for self-help and low-cost housing. For example, if techniques of production is improved and accessibility and use are encouraged, materials like green timber from traditional forests, soil blocks etc., can be of acceptable use while stone and sand may be cheaper through elimination of inefficiencies.

Regulatory mechanism

Currently, the regulatory mechanism for construction materials in developing countries does not support the artisanal industry. For most of the countries with a colonial past the use of the materials are outlawed through building standards. This means locking out a good chunk of resources from the local economy and consigning it to the informal or black market economy thereby making it difficult for the artisans to earn their living. The regulations force the artisans to pay protection fees to the local governmental agents. Regulations like bans also make it difficult for individual artisans to operate in the exploitation of materials like sand. Cartel networks of middlemen then come in to control the market and buy at low prices from the artisanal producers. These agents only help to make the operations of artisanal producers inefficient in economic terms. On the other hand if these operations were to be formalized and included in the mainstream economy the efficiency in the use of artisanal materials would be increased.

Lessons from the developed world
The development process in the developed world included the industrialization of the construction process. Although industrialization of the construction process and materials has made it possible to produce building at shorter intervals and en masse to meet the rising demand, the transformation of buildings from a craft to manufacturing industry has also come with some unwanted consequences such as loss of aesthetics or threats to health such as sick building syndrome. In countries like the UK today, an obvious longing for the craftsmen's handiwork is seen in the new buildings constructed within elegant facades of the glorious past. The greatest lesson for developing countries is that industrialization, on which they are so keen, is not always the best options where the building industry is concerned. The developing countries could as well build and maintain their own craftsmanship through artisanal materials.

Inappropriate technology
Artisanal materials are what are available locally for building construction. In most cases they require traditional technology. Suppressing the use of artisanal materials therefore means promoting foreign knowledge and technology that may not be appropriate for local conditions. This results into a drain of local resources to foreigners and also makes it difficult for local people to help themselves with local resources hence making them poorer. This is not a sustainable construction industry. In clay brick making, for example, Parry (1979: 3) noted that 'the very high mechanized and automated plants rely on electric power and the high grades of fossil fuels such as natural gas and propane while traditional plants may use scrub wood or even camel dung as their source of process energy (other than human muscle-power)'.

Neglect in international debate
As far as sustainable construction is concerned, the developing countries could as well contribute the issue of artisanal materials. Production of materials by artisans is a rampant phenomenon in the construction industry with serious sustainability implications in developing countries. This requires further research and debate for purposes of development in the industry.

WAY FORWARD

The paper has looked at the challenges sustainable construction as a principle and a practice pose for the developing world. As a principle, it has certain limitations; for example, little is known about it from the developing country perspective. The reason that has been advanced is that developing countries are ignored in the international fora (du Plessis 1999, 2007). But the international community is not guilty of this neglect; because neglect begins at home where scholars and policy makers have not bothered with certain obvious aspects like the use of artisanal materials. The paper therefore recommends that researchers should probe further into the phenomenon of use of artisanal materials in construction at local levels to inform policymakers and contribute to the knowledge of sustainable construction up to the global level.

Research into artisanal materials from sustainable construction perspectives will be able to resolve the pertinent issues to do with environmental damage, sustainable livelihoods, inadequate housing, inappropriate regulatory mechanisms and appropriate technology that currently beset the construction sector in the developing countries.

The first author, for example, is conducting doctoral studies on the economic use of artisanal building materials in Nairobi.

AN ECONOMIC & SOCIAL PERFORMANCE FRAMEWORK FOR ENGINEERING AND CONSTRUCTION FIRMS OPERATING IN DEVELOPING COUNTRIES

Matthew Lynch[1] **and Petter Matthews**

Engineers Against Poverty, 3 Birdcage Walk, Westminster, London, SW1H 9JJ, UK

While most corporate engagement with global poverty centres on philanthropy, the opportunities for firms to contribute to poverty reduction through their core business activities are significantly greater. This particularly applies to the engineering and construction sector due to the significant interface of its value chain with local economic and social development and the fundamental societal importance of creating and maintaining infrastructure. There is broad scope for firms within this sector to identify mutual beneficial action to advance business strategy and contribute to local development and poverty reduction. Drawing upon Porter and Kramer's model for strategic corporate social responsibility (CSR), the Economic and Social Performance Framework (ESPF) has been developed for engineering firms to identify these mutually beneficial or 'shared value' opportunities. The ESPF has been applied to the operations of a large engineering services joint venture in the oil and gas industry in Timor Leste, and it was found to be a useful tool in identifying shared value opportunities to support the joint venture's business objectives.

Keywords: poverty reduction, developing countries, corporate social responsibility, corporate strategy, competitiveness.

INTRODUCTION

There are a growing number of corporations with an interest in poverty and sustainable development in developing countries. Organizations such as the Global Compact, World Business Council for Sustainable Development and Business Action for Africa demonstrate the scale of this interest within the corporate sector. Outside these multi-member platforms, individual firms typically engage with poverty through philanthropic activities. This may be in the form of donations to charitable organizations, support for staff volunteering or running small community service programmes around their developing country operations. The impact of these activities will always be limited relative to the size of the problem.

It is widely accepted that the private sector has a crucial role to play in poverty reduction through generating economic growth (Department for International Development 2006). However, firms can make important positive contributions to poverty reduction and the Millennium Development Goals (MDGs) not just through their role in generating growth,

[1] m.lynch@engineersagainstpoverty.org

but also by the way that they conduct their core business operations (World Bank Institute 2006). It is increasingly recognized that positive impacts on poverty through core business alignment rather than philanthropic approaches are more substantial, scaleable and sustainable (World Business Council for Sustainable Development 2005). These impacts include greater levels of direct and indirect local employment, advancement of productive skills, a more competitive local enterprise sector, local infrastructure development and more effective local institutions.

In a developing country context there is a strong mutual interest in development between the corporate sector and the host society. These societies need the positive social and economic benefits provided by private sector activity. Firms gain from a productive and stable society in a multitude of ways including access to a capable workforce, reliable supply chains, supporting infrastructure and the presence of good governance and the rule of law. This mutual dependence and common interest in development allows opportunities to create ‘shared value’, i.e. outcomes that benefit both business and society (Porter and Kramer 2006).

This opportunity for shared value is particularly strong in the engineering and construction sector. The activities of the sector are of fundamental societal importance, i.e. the creation and maintenance of essential social and economic infrastructure. Improved infrastructure helps reduce poverty directly by improving the access of poor people to services such as clean water and sanitation, health and education and by protecting them against humanitarian disasters. It also contributes indirectly through enhancing economic growth, raising agricultural productivity, reducing transport costs and generating income and employment (Jahan and McCleery 2005). In addition, engineering and construction activities by their nature tend to have a large physical, social and economic ‘footprint’. The scale of this multi-dimensional footprint provides a significant interface with a broad scope for mutually beneficial activities.

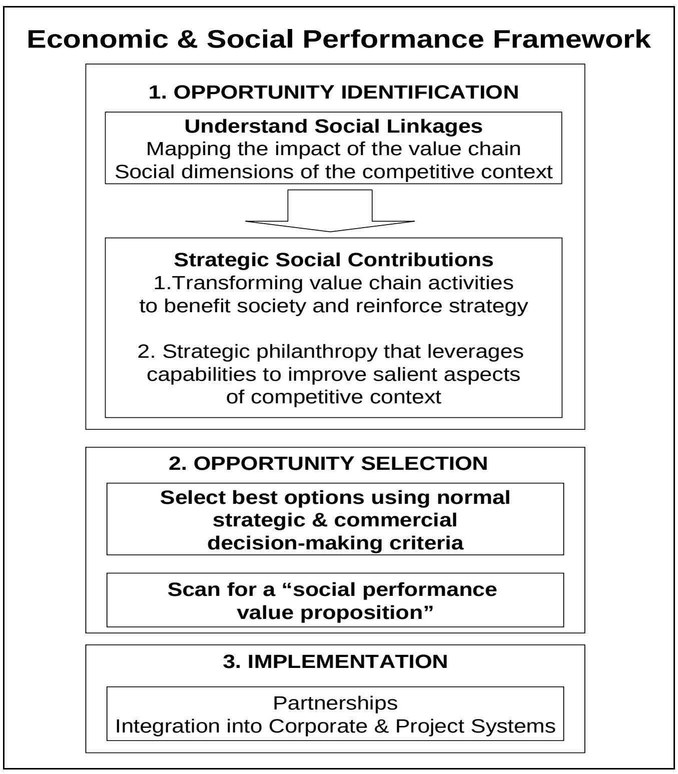
The size of this opportunity is magnified when the broader range of engineering activities outside public infrastructure is also considered. The extractive industries (oil, gas and mining), which are the actual or potential major source of economic wealth for many countries in Sub-Saharan Africa and Asia, require the involvement of engineering services in planning, design, construction, operation and maintenance. The extent of this involvement can be substantial; engineering, procurement and construction (EPC) contractors may be responsible for managing up to ninety percent of the value of potential employment and procurement opportunities in the construction phase of such projects (Overseas Development Institute 2005).

Recent forecasts indicate that by 2015 up to 80% of expenditure on new infrastructure will be in developing countries (Henry 2004). In the energy sector alone, almost half of total energy investment over the three decades to 2030 will take place in developing countries where production and demand are expected to increase most; this equates to approximately US$8 trillion or US$270 billion a year in investment (International Energy Agency 2004). Even in Africa, an area that has historically experienced chronic under-investment is seeing increased expenditure, facilitated in part by the creation of the Infrastructure Consortium for Africa (Department for International Development 2006). This expansion has been informed by the Report of the Commission for Africa (2005), which recommended that to meet the MDGs the region requires additional expenditure on infrastructure of US$10 billion a year up to 2010 with a further increase to $US20 billion a year for the following five years.

The size of the future market for engineering services, the opportunities for mutual benefits, and the urgency of the problem of poverty reduction create a strong imperative for developing a systematic approach for enhancing shared value. Engineers Against Poverty (EAP), in partnership with the Overseas Development Institute Business and Development Performance Programme (ODI), initially developed the Economic and Social Performance Framework (ESPF) as a contribution to this task, focusing on the opportunities presented by large engineering contractors in the oil and gas industry. It is presented in this paper by EAP as a general method, drawing substantially upon a model for strategic CSR developed by Porter and Kramer (2006). It is intended to be applicable for engineering contractors and consultants operating in a broad range of sectors and geographical contexts. The ESPF has been successfully used in practice in Timor-Leste (see Case Study below) and the authors are currently seeking additional opportunities for field application.

ECONOMIC & SOCIAL PERFORMANCE FRAMEWORK

The ESPF analysis is conducted in a similar manner to a strategic planning or risk assessment exercise, using a multi-disciplinary senior management team with knowledge of local operations and competitive context. It may be beneficial to also involve external expertise from the local context (e.g. local academia or social development consultants). The analysis should be conducted as early as possible in the project life cycle or involvement in a particular country or region. Paulson (1976) highlighted how decisions made in the earliest stages of projects have a relatively higher impact and lower cost. It follows from this that when socially beneficial strategies are integrated early in the design process, they are more likely to influence project outcomes and less likely to incur cost premiums. Figure 1 presents an overview of the method.



PF method overview

Opportunity identification

The first step in the ESPF is to identify the range of possible opportunities to make positive contributions to local social and economic development while contributing to business strategy. In the initial instance, this requires an understanding of the two major categories of interaction between a firm and its host society (Porter and Kramer 2006):

- *Value Chain Linkages* – almost every activity in a firm's supply chain touches on communities in which the firm operates, creating either positive or negative social consequences.
- *Competitive Context Linkages* – every firm operates within a competitive context, which significantly affects its ability to carry out its strategy especially in the longer term. Social conditions form a key part of this context particularly in developing countries.

Through the substantial array of likely linkages, the analysis then seeks opportunities to (ibid.):

- Transform value-chain activities to benefit society while reinforcing the firm's corporate strategy.
- Make strategic external contributions to improve salient areas of the firm's competitive context.

Two summary tables have been developed to facilitate this analysis, drawing on previous field research into the social aspects of engineering in developing countries (EAP and ODI 2003, 2004a, 2004b). Table 1 examines typical value chain linkages through project design and delivery, as well as the key supporting functions of procurement, human resources management and financial management. Table 2 examines the four interrelated elements of competitive context from Porter's "diamond" model of competitiveness (Porter 1990), and the social dimensions of each that are typically relevant to engineering activities. These tables are not comprehensive and there are also likely to be location and sector-specific opportunities; however, they can be used as a model to guide the analysis of the ESPF team.

Competitive context generally attracts less attention than value chain impacts; however competitive context can have far greater strategic importance for both companies and societies (Porter and Kramer 2006). One advantage for engineering firms in seeking shared value opportunities through the competitive context is that it reduces the constraints of aligning contributions with client requirements on individual contracts. There is also an increasing recognition of the significant role engineering and construction firms can play in contributing to the broader capacities of developing societies. The United Nations Millennium Project Task Force on Science Technology and Innovation explored this role in the context of the MDGs. The Task Force identified the importance of 'technological learning', a process of building individual and societal level capacities to apply knowledge and innovation to further economic and social improvement. The Task Force noted that (2005: 2): "Infrastructure development provides a foundation for technological learning, because it involves the use of a wide range of technologies and complex institutional arrangements. Policymakers need to recognize the dynamic role infrastructure development can play in economic growth and take the initiative in acquiring the knowledge available through international and indigenous construction and engineering firms".

Table 1: Shared value opportunities in the engineering and construction value chain

Business-Society Interactions in the Value Chain (derived from Porter and Kramer 2006)		**Example Shared Value Opportunities**	**Societal Benefits**	**Business Benefits**
Project Design & Delivery	• Integration of client (or national/local) poverty reduction objectives into design	• Alignment of design and delivery of project with the needs of local poor communities	• Meeting basic needs of local communities	• Reduced risk (reputation, social). • Greater user/customer acceptance
	• Project environmental, social & community impacts	• Comprehensive environmental and social impact analysis (ESIA)	• Minimize negative impacts on local communities	• Reduced risk (regulatory, reputation, social)
	• Utilization of labour-based technologies and construction methods	• Suitable works for application of labour-based methods include: general earthworks; road construction and maintenance; low level bridges; small dams and irrigation structures; water and sewerage reticulation; storm water drainage systems; low voltage electrical reticulation & electrification; and materials manufacture • Even with large complex projects, there are opportunities to use labour-based construction methods for sub-elements of work or ancillary infrastructure	• Additional income and skills for local people. • Evidence from a broad range of developing countries has shown that labour-based approaches created between three and five times as much employment and achieve cost savings of between 10–30% over equipment intensive methods of construction (ILO 2003)	• Reduced costs • Supporting 'social license to operate'
	Stakeholder engagement	• Primary stakeholders (especially local poor communities) fully engaged in design process	• Increased likelihood of community needs being met • Reduced risk of adverse impacts on communities	• Reduced risk (regulatory, reputation, social) • Greater user/customer acceptance
Key Support Functions				
Procurement	• Supply of materials, goods and services • Subcontracting	• Local supply of materials, goods and services. • Use of local subcontractors	• Additional income to local economy • Small suppliers and subcontractors tend use more labour-intensive methods project increasing employment generation	• Access to suitable suppliers • Most efficient and effective supply chain • Advantages over competitors • Supporting 'social licence to operate'
Finance Management	• Financial transactions	• Increased use of local financial institutions for project fund transfers, disbursements etc.	• Assists in building the capacity of local financial institutions	• Reliable local financial services provider
Human Resource Management	• Recruitment polices • Training	• Preferential recruitment of local workers • Formal and on-the-job training programmes	• Additional income and skills for local people • Builds local skill base • Increased incomes for trainees	• Access to skilled local workforce • Advantages over competitors • Supporting "social licence to operate"
	• Health & safety management programmes	• Systems to prevent accidents and injuries in both the directly-employed and subcontractor workforce	• Reduced accident and injuries (and consequent risk of lost income and livelihoods for workers and their families)	• Reduced risk (regulatory, reputation, social)

Table 2: Shared value opportunities in the competitive context

Typical Elements of the Competitive Context (Porter 1990)		Example Shared Value Opportunities	Societal Benefits	Business Benefits
Factor (Input) Conditions Presence of quality specialized inputs available to firms	• Availability of capable local labour	• Support local vocational training initiatives	• Builds skill base of the local economy • Increased incomes for trainees.	• Access to skilled local workforce
	• Efficient physical infrastructure	• Align project or temporary (e.g. site access roads) infrastructure with local economic and social development priorities	• Provision of essential services • Additional economic growth	• Enhanced relationship with government and regulatory bodies
	• Administrative capacity of local government	• Provide technical assistance to third-party programmes (e.g. bilateral and multilateral aid organizations) working to develop local government administrative capacity	• More effective governance • Contribution to “technological learning”	• Enhanced relationship with government, regulatory bodies and third-party organizations
Context for Firm Strategy & Rivalry The rules and incentives that govern competition	• Transparency in procurement for engineering services	• Support for local industry-led or multi-stakeholder anti-corruption initiatives	• Corruption disproportionately affects the poor, potentially increasing the cost of services and siphons off resources that should be spent on communities (DFID 2006)	• Increased likelihood fn non-corrupt businesses winning contracts
	• Government and institutional capacity to identify, procure and manage infrastructure projects	• Provide technical assistance to third-party programmes to develop local government management and technical expertise	• More effective governance • Increased chance of successful delivery of infrastructure projects • Contribution to “technological learning”	• Enhanced relationship with government, regulatory bodies and third-party organizations
Local Demand Conditions The nature and sophistication of local customer needs	• Suitability of infrastructure for local needs.	• Design or pricing measures that provide access to affordable services for all people • Additional works to provide universal access to infrastructure services	• Provision of essential services • Additional economic growth	• Greater user/customer acceptance • Reduced risk (regulatory, reputation, social)
Related and Supporting Industries The local availability of supporting industries	• Availability of local suppliers.	• Support local enterprise development initiatives	• Additional income to local economy • Small suppliers and subcontractors tend use more labour-intensive methods project increasing employment impacts	• Access to suitable suppliers • Most efficient and effective supply chain • Advantage over competitors
	• Presence of industry clusters.	• Support the development of local complementary firms (e.g. survey, CAD/CAM, testing services)	• Additional income to local economy • Technological learning	• Access to suitable suppliers • Most efficient and effective supply chain • Advantage over competitors

Opportunity selection

The second stage of the ESPF process is to select those shared value opportunities that are the most valuable and ideally meet the normal selection criteria applied in the firm's commercial and strategic decision making. This will generally require a quantitative assessment of the costs and benefits. It is noted that many of the potential benefits may be difficult to quantify, requiring subjective judgements by the team conducting the ESPF analysis. Where the benefits are uncertain in terms of their likelihood or impact it may be appropriate to use an expected value approach, essentially considering the opportunities as "positive" project or business risks (Institution of Civil Engineers & Actuarial Profession 2005).

Transforming value chain activities may be attractive as alignment of activities with contract delivery can potentially make the additional cost and management effort minimal; however, the scope may be limited by the specifications or constraints of the client. The assessment of contributions to the firm's competitive context will depend on the firm's strategic time horizon, as these types of initiatives by their nature tend to be longer term. One feature of the engineering and construction sector is the periods between projects or contracts where a firm's resources are not fully utilized. This spare capacity could be used, for example, 'strategically' to support capacity building or training initiatives, simultaneously building the skill base of staff and further developing local knowledge and commercial relationships.

While the case for pursuing individual opportunities may be compelling, there may be also a broader opportunity to establish a social performance dimension to the firm's value proposition, i.e. the set of needs that a firm can deliver for its chosen customers that other cannot. As Porter and Kramer observe: "the number of industries and companies whose competitive advantage can involve social value propositions is growing" (2006: 91). Two examples of potential social value propositions for engineering firms operating in developing countries are explored below.

Superior local value chain

The difficulties of operating successfully in many developing economies particularly for many firms are exacerbated by access to an appropriately skilled workforce and quality suppliers. Building the skill base of local workers and suppliers and establishing productive linkages with these groups can be facilitated by both project-related value chain initiatives or through competitive context contributions. Over time, these linkages can create competitive advantage through both cost and efficiency gains, and advantageous positioning to deliver 'local content'. Many public and private sector clients specify various forms of local content requirement on the delivery of engineering projects and services (Hawkins *et al*. 2006). Oil and gas operators often need to meet challenging local content requirements as part of their agreements with governments and include these requirements in their tendering processes. This provides opportunities for engineering service providers in this industry to differentiate themselves from their competitors based on the strength and capacity of their local value chain.

Integrated social risk management

Projects in developing countries often encounter higher levels of 'social' risk, which arises through the interactions between a project and its local stakeholders. This elevated risk exposure is due to a range of factors including weak local governance, regulatory planning processes which may not fully take into account the views of local stakeholders, and the possible presence of latent or open conflict in the project vicinity. For the engineering industry, this situation is complicated by the increased risk aversion of many clients leading to the adoption of project models and contracting arrangements that transfer more risk to the contractor (Skeggs 2004).

It is increasingly acknowledged that to adequately address social risk, projects need to obtain a 'social license to operate', i.e. the informed consent and support of local stakeholders to construct and operate a project in their area. The well-documented potential risks of not seeking and developing this local support (e.g. protests, site blockades, attacks on property and staff, damage to reputation, reduced operational revenues through lack of user acceptance) can have significant negative financial implications for clients and financiers as well as their engineering consultants and contractors. Maximizing positive local benefits from projects is considered a key component of building a social license to operate. For many projects, aspects within the sphere of influence of engineering consultants and contractors are central to providing the benefits that many communities most value, such as designing for and delivering employment and local business opportunities. When benefits are aligned and delivered as part of the project, they can potentially constitute a cost-effective strategy for building better relationships with communities and managing risk. Engineering firms with specialist competencies in identifying, analysing and managing social risks can not only reduce their own risk exposures but also can offer this as part of an integrated risk management service to clients (EAP & ODI 2004a).

Implementation

The final stage of the ESPF analysis is to ensure that there are appropriate internal mechanisms for the implementation, management and monitoring of the selected shared value opportunities. In the initial instance, this may require modification or addition to core business and project management systems. An example could be a scenario where a firm identifies an opportunity to build a business development strategy based on its capabilities in developing subcontractors within its supply chain. It may be appropriate to make modifications to internal report structures to automatically capture quantitative data about the development of subcontractors (e.g. value of business on contracts, increase in total value of local contractors' business over time). This quantitative data can then be used to strengthen subsequent tender submissions, as well as enhancing the quality of a firm's CSR reporting. This type of integration will reduce or eliminate the additional management time required for administration. When value chain practices and contributions in competitive context are fully integrated, they may be difficult to distinguish from the day-to-day business of the firm (Porter and Kramer 2006).

It is important to note that engineering firms will not necessarily have 'in house' the full range of skills and resources to implement some of shared value opportunities arising from their operations. Multi-sector partnership models, such as that developed by the World Bank's Business Partners for Development Programme (www.bpdweb.com) may provide a suitable mechanism for that enables firms to work with 'non-traditional' partners and to tap into their competencies to meet business and development challenges in a way that adds value for each partner (Matthews 2005). Many governments and development agencies as well as NGOs are seeking opportunities to work with private sector firms as the importance of the private sector in poverty alleviation is increasingly recognized. Such partnerships can also ensure positive benefits are more sustainable and extend beyond the life of an individual contract. A useful starting point for the engineering and construction industry is the substantial body of knowledge developed within the industry in ‘internal’ project partnering i.e. relatively complex partnership arrangements between clients, contractors and subcontractors as a strategy for project delivery (Verschoyle and Warner 2001). Many of the key competencies for the developing and managing these relationships could be applicable in an external context.

TIMOR-LESTE CASE STUDY

This case study presents an analysis of the operations of a large engineering joint venture offering operations and maintenance services to the oil and gas industry in Timor-Leste. The information was initially presented in a report published by EAP and ODI (2007). It demonstrates an engineering firm developing a strong social performance dimension to their value proposition and winning business based on this value proposition. It shows how even specialized engineering services can generate shared value opportunities in supporting activities and contributions to the competitive context. It also provides an overview of the use of the ESPF tool in systematically identifying and analysing shared value opportunities.

The Clough AMEC Joint Venture (CAJV) is a partnership between two major engineering firms: AMEC plc and Clough Limited. In 2004, the CAJV bid for the first operations and maintenance services contract for the offshore assets of ConocoPhillips’ Bayu Undan Project, the first major oil and gas development in the Timor Sea. The contract requires provision of both offshore and onshore maintenance services ranging from minor fabrication work to major offshore shutdowns. The contract period is three years with the option of a two-year extension and with an approximate value of US$40M over the first three years.

The core value proposition of the CAJV is to provide proven high-quality engineering and maintenance services at a competitive price through efficient utilization of a unique global network of suppliers, subcontractors and skilled labour resources. Building on experience on the Shell Malampaya Project in the Philippines (EAP and ODI 2004b), the CAJV also added a social performance dimension to their value proposition i.e. integrating innovative strategies into contract delivery to help overcome barriers to Timor-Leste participation in the oil and gas sector. This social value proposition was informed by the following key strategic and commercial drivers:

- The Timor-Leste Government is seeking to maximize the local employment and commercial content through both the oil companies and their major contractors, and these aspirations are included in the Production Sharing Agreements with the oil companies. However, the lack of local capacity and the presence of established oil and gas support bases in Perth and Darwin in Australia represent strong inhibitors for the growth of a domestic support industry in Timor-Leste.
- ConocoPhillips is seeking to satisfy the aspirations of the Timor-Leste Government (within the commercial, technical and safety requirements of the project), in order to maximize their opportunities to secure additional exploration and production acreage.

As part of its bid offer, the CAJV included two innovative local content proposals aligned with the delivery of the technical requirements of the contract: a national employee resourcing strategy and the development of a common user support base

(CUSB) in Timor-Leste. The resourcing strategy was a rigorous, staged process of building the necessary competencies of successive groups of Timorese trainees to allow them to safely perform skilled trade work on the offshore facilities. The CUSB proposal entailed the construction and operation of a facility to attract suppliers and subcontractors to base themselves in Timor-Leste to provide a range of key support services including fabrication and machining, warehouse storage, lifting and freight services. It was proposed that the CUSB would be developed using a multi-sector partnership model between the private sector, the government and local development agencies, aiming to establish a sustainable long-term business with potential for growth beyond the current needs of the Bayu-Undan project and facilitating significant local skills and technology transfer. The CUSB proposal was accompanied by a detailed business plan.

The CAJV's social value proposition appears to have been highly successful in generating competitive advantage. According to statements made by the local regulatory authority and the client, these innovative proposals were material factors in the CAJV securing the contract. This is an important outcome as it provides direct evidence of the potential strategic and commercial value for engineering firms in establishing a social value proposition, particularly where this is aligned with the strategic priorities of the client.

At the mid-point of the Bayu-Undan contract period, an EAP/ODI research team visited Timor-Leste at the invitation of the CAJV. This visit was to facilitate the use of the ESPF method to scan for further opportunities to support local economic and social development. An earlier version of the ESPF was utilized in this exercise, which has some industry specific elements (e.g. an industry-specific opportunity list); however, the fundamental method is very similar to the version presented in this paper. Working with CAJV project staff, two additional shared value opportunities were identified to make strategic contributions to the local competitive context:

- Expansion of the national employee resourcing strategy to support the phased development of a local skills training capacity rather than relying on foreign training organizations.
- Support for the establishment of a dedicated enterprise development program for local businesses to support the development of their capacity to contribute to the oil and gas industry.

These initiatives would use the leverage created by the CAJV being the only major engineering services firm with operations in Timor-Leste to further consolidate their local competitive position. While the viability of these initiatives needs to be further assessed, the long term strategic focus of the CAJV and the relatively long contract period makes these contributions strategically attractive. In addition, the scanning of the local context identified numerous organizations with potential to provide the resources necessary to support the identified opportunities. Key potential partners include the World Bank, Asian Development Bank, USAID, the German financial development organization GMZ, CARE Timor-Leste and the Dili Institute of Technology. Initial discussions with these organizations indicated a strong willingness to consider partnership or collaboration initiatives. The CAJV was advised to consider positioning itself within a training or enterprise development collaboration as the provider of intermittent specialist and technical support, rather assuming the overall management responsibility and associated risks.

The ESPF was found to be a useful tool for identifying additional measures for the CAJV to contribute to Timor-Leste's development while advancing their own business strategy and competitive positioning. These additional contributions could be invaluable for increasing the capacity of the local economy to benefit from the oil and gas sector and would complement the establishment of the CUSB facility. In a broader sense, the Bayu Undan contract and the activities of the CAJV presents one of the single most important opportunities in Timor-Leste for the 'technological learning' process needed to increase the technical and managerial capacities within the local economy.

CONCLUSION

The ESPF is a systematic method for helping engineering firms to identify shared value initiatives that advance their business strategy and contribute to local social and economic development when operating in developing countries. It draws on a model for strategic CSR developed by Porter and Kramer as well as previous field research into the local social and economic development opportunities associated with engineering activities. The ESPF has been found to be a valuable tool for helping a firm refine its social value proposition and integrate it into its core business activities, as demonstrated by its application by an engineering joint venture in the oil and gas industry in Timor-Leste. The method will now be further tested to increase confidence in its general applicability.

SINGAPORE CONTRACTORS AND CONSULTANTS' PROJECT MANAGEMENT PRACTICES IN CHINA

Florence Yean Yng Ling[1], Sui Pheng Low[1], Temitope K. Egbelakin[1] and Shou-Qing Wang[2]

[2]*Department of Construction Management, Tsinghua University, Beijing, China*

China's construction industry presents many opportunities to foreign architectural, engineering and construction (AEC) firms. This paper reviews the general management practices adopted by foreign firms and investigates specific project management practices adopted by them on construction sites in China. Data were collected using a structured questionnaire from Singaporean AEC firms that had undertaken projects in China. A wide range of management practices are adopted by foreign firms in China. The most effective market entry modes are entering China as wholly owned foreign enterprises and forming project joint ventures with Chinese firms. The key business strategies include understanding clients' requirements, and offering superior products and services. At the construction site level, many project management practices focus on improving quality and communication. Unfortunately, risk management is not adequately implemented. It is recommended that foreign firms adopt some of the significant management practices uncovered in this study so that their projects in China may achieve better performance.

Keywords: China, international business, international project, internationalization, project performance.

INTRODUCTION

The growth in China's construction industry has created many opportunities for foreign architectural, engineering and construction (AEC) firms. However, undertaking construction beyond a firm's domestic market (home country) is generally more difficult to manage due to multiple ownerships, elaborate financial provisions, different political ideologies, uncertainties and complex risks that are unique to international transactions (Gunhan and Arditi 2005a). Contracting overseas construction projects such as in China is a high risk business, mostly because of the lack of adequate environmental information and local construction experience (Han and Diekmann 2001).

The objective of this paper is to investigate project management practices adopted by foreign AEC firms when undertaking projects in China. The findings would help identify management practices that could help foreign firms achieve project success in China. This study is important because many foreign firms venturing into China's construction industry for the first time would need to know key management practices that they should adopt to enhance project performance.

GENERAL MANAGEMENT PRACTICES IN CHINA

Gunhan and Arditi (2005b) developed the International Expansion Decision Model to help companies assess if they are ready for international expansion. Ling *et al*. (2005a) investigated entry and business strategies used by foreign AEC firms in China. They found that market entry modes used by foreign firms that lead to project success in China are: (1) setting up wholly owned foreign enterprises; and (2) forming project joint ventures (JVs) with local Chinese firms. Chan *et al*. (1999) also found JVs between Chinese and foreign firms would help bring about project success.

Jin and Ling (2005) developed models for predicting project performance in China using relationship-based factors. Critical relationship-based factors affecting project performance are: sufficient communication; absence of excessive interference by partners; adherence to mutual goals; and empowering staff with authority (Jin and Ling 2006). It can be interpreted that foreign firms should build cooperative and harmonious relationships with Chinese partners so as to achieve project success in China. Luo's (2001) study assessed management and performance of Sino-foreign construction joint ventures. He found that expatriates' high wages are heavy burdens to Chinese partners in Sino-foreign joint ventures. Gale and Luo (2004) investigated factors leading to success in the formation stage of Sino-foreign joint ventures.

Ling *et al*. (2005a) found that for foreign firms to survive in China, they must first bid low to win projects and then demonstrate high capabilities in project delivery by building to specifications and achieving high quality outputs. Ling *et al.* (2005b) identified enablers that would help foreign AEC firms win construction contracts in China. The study found that to win projects in China, foreign AEC firms need to: have good understanding of the Chinese market; provide project financing services; price competitively; and provide superior products or services. The study demonstrated that expertise in a specialized submarket and in a technical discipline can help firms win projects.

Ling *et al*. (2006) identified business factors that contribute to the success of projects undertaken by foreign firms in China. The most significant factor that contributes to project success is the firm's ability to understand clients' requirements. Other significant factors include: offering superior product and service quality; having superior capability; and having an excellent track record. Chan *et al.* (1999) also found that better understanding of national and local regulations, good relationships with local authorities and training of staff would help projects achieve success in China.

Ling (2005) identified benefits that foreign firms derive when undertaking projects in China. They include: diversification of business location; sales growth and expansion; higher profitability; enhanced core competency; acquisition of new capability; and formation of relationships with JV partners and clients from home countries. These benefits explain why there is a continual growth in the number of foreign AEC firms entering China.

PROJECT MANAGEMENT PRACTICES IN CHINA

The many factors that contribute to project success may be grouped into five main categories: project management actions; project-related factors; project procedures; human-related factors; and external environment (Chan *et al*. 2004). The objective of this study is focused on project management practices adopted by foreign AEC firms in China. This study adopted the PMI's nine project management knowledge areas and correspondingly, identified project management actions following PMBOK (PMI 2004). The project management functions or knowledge areas are: project scope, time, cost, risk, quality, human resources, communications and procurement management. The overall integration of these eight functions and the managing of externalities is the ninth project management function.

A review of literature revealed that many studies on project management practices affecting project success have been done. These primarily focused on indigenous firms working in their home countries (e.g. Konchar and Sanvido 1998; Chua *et al*. 1999; Ling 2004; Fortune and White 2006). For example, Ling (2004) investigated how the characteristics of projects, clients, consultants and contractors affect project performance when AEC firms are undertaking projects in their home countries.

Chen and Partington (2004) suggested that project management is not universal but culture-sensitive. It is essential to take account of the implications of cultural differences for people's conceptions of theories and project management practices when transferring them across cultures. Chan and Chan (2002) found salient differences in China's construction industry when compared to international modes of practice. For foreign AEC firms to thrive in China, there is a need to adopt project management practices that are suited for its construction industry.

Dai *et al*. (2006) did a case study of the Three Gorges Dam project in China, but this is not generalizable because it was based on one project. The project management practices adopted by foreign firms on construction sites (project level) remain unclear. This study therefore aimed to fill the gap by exploring the specific project management practices that Singaporean AEC firms adopt in China.

RESEARCH METHOD

This paper reports a part of the findings of a recently completed National University of Singapore funded research project undertaken to determine the international project management practices of foreign firms when handling projects in China. Seventy-eight specific project management practices were operationalized from PMI's (2004) nine knowledge areas, and their level of usage in China was tested in the fieldwork.

The research design was based on a survey, and data were collected through the post and via email. The data collection instrument was a questionnaire specially designed for this study. Respondents were requested to base their responses on one particular project that they or their firms had completed in China. Respondents were asked to indicate the project management practices adopted on a seven-point Likert scale and also their demographic and company characteristics. The questionnaire was pre-tested in a pilot survey before an industry-wide survey was conducted.

The population frame comprised Singaporean AEC firms that had undertaken and completed construction projects in China. The list of targeted respondents (N = 200) was drawn up from the records maintained by the Building and Construction Authority, professional institutions and other published information.

Data were analysed using SPSS software. This paper reports the t-test results. The mean of each variable was compared by conducting an independent sample t-test. A test value of 4 was used to test whether the means were significantly different from a mid-point of 4 on a Likert rating scale of 1 to 7. A project management practice is considered significant when $p< 0.05$.

CHARACTERISTICS OF THE SAMPLE

From the 200 questionnaires sent out, 33 responses were received (17% response rate). Details of the respondents and their projects are given in Table 1: 55% of respondents are contractors, 75% of bidding methods were either selective or negotiated.

Table 1: Characteristics of respondents and their projects

Characteristic	No.	%	Characteristic	No.	%
Designation			*Service provided*		
Upper management	8	24	Design and consultancy	5	15
Middle management	17	52	Management	10	30
Professionals	8	24	Construction	18	55
Experience in industry			*Ownership of project*		
≤ 3 years	8	24	Public sector	4	12
4–10 years	4	12	Public–private joint venture	4	12
11–15 years	4	12	Privately owned	24	75
16–20 years	12	36	*Gross floor area (m^2)*		
21–25 years	3	9	1000–10 000	6	22

The majority of the respondents were middle management. The respondents had worked between three and 30 years (mean = 16 years) in the construction industry. Thirty of the 33 respondents were personally involved in the reported projects.

The respondents' firms engaged between 10 and 6000 employees, with an average of 975 employees. Results show that 62% of the respondents' firms had 500 or fewer employees. Annual revenue averaged US$70M. More than half of the firms had 30% or less of their revenue derived from overseas projects.

Respondents were allowed to report any projects that they had managed and completed in China. The majority of the projects reported by them were concentrated in the eastern region of China. Project sizes ranged from 2000 m^2 to 1 000 000 m^2 (mean = 128 330 m^2). The average contract sum was US$71.7M.

PROJECT MANAGEMENT PRACTICES ADOPTED IN CHINA

Seventy-eight project management practices were investigated, and 38 of them were found to be significantly adopted by Singaporean firms in China (see Table 2). These are now discussed.

Table 2: Significant project management practices adopted in China

Code	PM practices	Mean	t- value	p- value
	Scope management practices			
Scop14	Minimize claims or disputes in the contract	3.36	–2.11	0.04
Scop16	Manage the job as a whole integrated contract	4.24	–3.41	0.00
	Time management practices			
Time21	Early acceptance and approval of the schedule	4.58	2.09	0.04
Time24	Provide adequate equipment to deliver the service	5.39	6.55	0.00
Time25	Respond quickly to changes ordered by clients	4.79	2.74	0.01
Time26	Have one person overall in charge of the project schedule	2.61	–4.28	0.00
	Cost management practices			
Cost31	Have high quality cost data in China	4.70	3.17	0.00
Cost32	Have high quality financial management	4.58	2.38	0.02
Cost33	Have high quality planning in determining the resources required and quantities needed	4.64	2.44	0.02
Cost34	Have good cost control of resources	4.52	2.12	0.04
Cost35	Have a good system to monitor activities to detect cost overruns	4.52	2.23	0.03
Cost36	Have regular cost reporting and very close monitoring by HQ to control cost	4.94	3.60	0.00
Cost37	Have strong financial strength	5.64	8.05	0.00
	Quality management practices			
Qlty41	Have high quality control and quality management plans	4.88	4.23	0.00
Qlty42	Have good health and safety management in the workplace	4.64	2.16	0.04
Qlty43	Engage high quality managerial staff	4.94	4.41	0.00
Qlty44	Engage high quality professionals	4.79	3.44	0.00
Qlty46	Work with clients who demand quality output	5.97	10.82	0.00
Qlty47	Ensure high conformance to the requirements in the contract	5.48	7.42	0.00
Qlty48	Conduct regular reviews to ensure that output conformed to the requirements in the contract	4.70	2.81	0.01
Qlty49	Pay attention to environmental impact, sustainability and protection in the delivery of service	4.58	2.20	0.03
	Risk management practices			
	No significant practice found			
	Human resource management practices			
HRM61	Provide adequate staffing level to deliver the service	5.15	3.28	0.00
HRM64	Engage more Chinese nationals as technical staff/worker	5.30	4.89	0.00
HRM65	Provide extensive skills training for the Chinese workforce	4.76	2.75	0.01
	Communication management practices			
Com71	Have more face-to-face communication	5.03	3.92	0.00
Com72	Work with clients whom you have a good prior working relationship with	5.06	4.18	0.00
Com73	Work with project team members whom you have a good prior working relationship with	5.09	4.88	0.00
Com74	Work with people by whom you are likely to be engaged in future projects	5.15	3.98	0.00
Com75	Have frequent timely communication	4.97	3.64	0.00
Com76	Have high quality communication among team members, in terms of communications planning (information needs)	4.73	2.51	0.02

Code	PM practices	Mean	t- value	p- value
Com77	Have high quality communication in terms of appropriate generation, collection, dissemination, storage and disposition of project information	4.61	2.32	0.03
Com78	Work with project team members who share the same working language and could understand each other easily	4.88	3.02	0.00
Com79	Have well-managed public image and public relations	4.76	3.35	0.00
	Procurement management practices			
Proc85	Collaborate with foreign partners who are experienced and have high technical capability	4.48	1.94	0.06
Proc86	Select partners through negotiation instead of open bidding	4.64	2.03	0.05
	Integration management practices			
Integ91	Engage staff who are flexible and adaptable to China's political, economic and social landscape	5.21	4.47	0.00
Integ93	Communicate prioritized objectives to staff	4.79	3.12	0.00
Integ95	Minimize the use of political backing and outside influence in managing projects	2.91	–3.60	0.00

Scope management practices

Inadequate management of project scope affects contract duration, cost and quality negatively (Ibbs *et al*. 1998). Table 2 shows two significant scope management practices adopted by Singaporean firms in China: minimizing claims or disputes in the contract (Scop14); and managing the job as one whole integrated contract (Scop16). The scope of work within a contract should be properly defined so that claims can be minimized and disputes reduced. It is also recommended that the number of subcontractors be reduced so as to achieve better integration. This is because quality management becomes complex and difficult to implement when many organizations are involved (Love and Irani 2003).

Time management practices

Table 2 shows that a significant time management practice is early acceptance and approval of the schedule by the project team (Time21). This ensures that the project proceeds smoothly as scheduled and time targets are met. Adequate provision of equipment (e.g. computers, plant, machinery) to deliver the service (Time24) is the most important time management practice. A quick and effective response to variations ordered by clients (Time25) is also a key management practice. A quick response usually reduces time loss as a result of variations to the contract (Galloway 2006). The schedule should be monitored by one person (Time26), as having too many people in charge of the schedule could give rise to conflicting ideas and lack of ownership due to diluted responsibilities.

Cost management practices

This study found that there are seven significant cost management practices adopted by foreign firms in China. Most important is for foreign firms to have strong financial strength (Cost37). High quality financial management (Cost32) is important because it helps to maintain positive cash flow and project profitability. Controlling the cost of resources (Cost34) and monitoring project activities to quickly detect and rectify cost overruns (Cost35) are other key project management practices. The findings suggest that foreign firms should set aside adequate financial resources to undertake projects in China, and have headquarters monitoring the China-based project closely (Cost36).

Quality management practices
Foreign AEC firms work for clients that demand quality output (Qty46). To achieve clients' demands, it is important to understand their requirements (Ling *et al*. 2006). AEC firms need to employ high quality managerial (Qty43) and professional staff (Qty44) to boost supervision and control systems. Good quality control and quality management plans (Qty41) must be put in place. These results confirm Ling *et al.*'s (2005a) findings that foreign firms need to offer high quality products and services to demonstrate superior capabilities. Contract requirements must be strictly adhered to (Qty47) and this could be achieved by conducting regular reviews to ensure that firms' output conformed to the requirements in the contract (Qty48). Health and safety management (Qty42) and consideration for environmental impact, sustainability and protection in the delivery of service (Qty49) are also important.

Risk management practices
No significant risk management practices were adopted by Singaporean AEC firms in China. One possibility is that risk is project specific and could not be generalized. Another possible explanation is that these AEC firms did not practise risk management in a formal way.

Human resource management practices
Table 2 shows the importance of providing an adequate staffing level to deliver the service (HRM61). This could be done by employing permanent staff to man the China office. Fabi and Pettersen (1992) also stressed the importance of having adequate personnel in an organizational structure.

Another important practice is to engage Chinese nationals as technical staff or workmen (HRM64). It is cheaper to engage locals than expatriate workers. This further attests to the importance of having local partners from the host country which highlights the nature of international construction whereby many services are supported by the domestic construction industry of the host country. However, because local workers have low skills and are undereducated (Chan *et al*. 1999), it is important to provide them with extensive skills training (HRM65).

Communication management practices
Table 2 shows nine significant communication management practices adopted by Singaporean firms in China. These are by far the largest number of practices under one project management knowledge area, indicating the importance of communication in international construction. The practices adopted include: having more face-to-face communication than written communication (Com71); having high quality communication among team members in terms of communications planning (Com76); quick dissemination of information (Com75) and appropriate generation, collection, dissemination, storage and disposition of project information (Com77). These confirm Harrington *et al*.'s (2000) findings on good communication management. Foreign firms should strive to maintain a good public image and public relations (Com79) by being sensitive to Chinese values and culture. Having good public relations coupled with a good track record lead to a good reputation. AEC firms should adopt a common working language among team members (Com78) so that there would be effective communication. This would help in overcoming the problem of inter-cultural communication in international construction (Victor 1992).

Foreign firms should strive to work with clients (Com72), consultants and contractors (Com73) with whom they had good working relationships in the past. Their behaviour should lead to repeat business (Com74). Long-term relationships engender trust. Individuals who have good working relationships with each other do not exhibit opportunistic behaviour, which yields only short-term benefits (Hill 1990).

Procurement management practices

The results show that partners should not be chosen because they offered low bids through open tenders (Proc86). Latham (1994) criticized the practice of awarding contracts solely based on lowest bid price. The accepted lowest bid does not necessarily equate to actual cost, as contractors' profit is excluded most of the time. Alternative commercial responses of recouping profits will be through variation claims and exploitation of subcontractors' and suppliers' benefits, leading to adversarial relationships. There may also be poor quality performance which eventually increases operational cost. Those who offer low bids may lack technical capability and experience which would constrain growth (Liu *et al*. 2004). It is also important to collaborate with local Chinese firms. A competent local partner would understand better the Chinese environment and help improve a foreign firm's knowledge of the Chinese market (Ling *et al*. 2006).

Integration management practices

The results show that foreign firms should engage staff who are flexible and adaptable to China's political, economic and social landscape (Integ91). This would help in quick understanding of the Chinese business culture and thus reduce their learning curve (Ling *et al*. 2005b). Prioritized objectives should also be communicated to staff (Integ93) so as to allow alignment of objectives. Foreign firms minimized the use of political backing and outside influence on the projects they undertake (Integ95). This suggests that foreign firms in China need to rely on their own merits (e.g. superior capabilities) to secure contracts in China (Ling *et al*. 2006).

CONCLUSION

The literature review of general management practices of foreign AEC firms in China concluded that it is beneficial for foreign firms to enter China; the best market entry modes are entering as wholly owned foreign enterprises and forming project JVs with Chinese firms. The effective business strategies are understanding clients' requirements, and offering superior products and services.

To investigate the project management practices of foreign firms when handling projects in China, a survey of Singaporean AEC firms that had undertaken projects in China was undertaken. Thirty-eight significant project management practices were uncovered. Of these, many practices relate to communication and quality management. These project management practices could serve as a guide to better management of projects in China. No significant practices were found for risk management, suggesting that more should be done to achieve project success.

With increased globalization, AEC firms will undertake projects outside their home countries to survive and grow. The findings may help firms already operating in and those planning to venture into China identify management practices that may help them achieve better project performance.

ANALYSING TENDER SELECTION USING A GEOMETRIC GRAPH ANALYSIS (GGA) APPROACH

Kwo-Wuu Wang[1] and Wen-der Yu[2]

[1]*Department of Civil Engineering, Chung Hua University, No.707 Sec. 2 WuFu Rd. Hsinchu, 300 Taiwan*
[2]*Institute of Construction Management, Chung Hua University, No.707 Sec. 2 WuFu Rd. Hsinchu, 300 Taiwan*

As projects and products become more and more versatile and complex, procurement approaches have also diversified. The traditional competitive bidding method based on lowest price (also named lowest tender, LT) usually results in high competition and low quality. As a result, the most advantageous tender (MT) was brought into the Government Procurement Law (GPL). After several years of practice, the public procurement agencies are still wondering why and how to select LT or MT. This paper proposes a geometric graph analysis (GGA) model adopted 2-D analytical graph for modelling the two most important factors in procurement, i.e. price and quality to develop an analytical tool for answering the above-mentioned questions. It is found that the proposed GGA provides not only a theoretical framework for analysis of suppliers'/contractors' behaviours during the procurement process, but also an efficient tool for procurement strategy planning.

Keywords: lowest tender, most advantageous tender, procurement policy, tender selection.

INTRODUCTION

As projects and products become more and more versatile and complex, procurement approaches have also diversified. The traditional competitive bidding method based on lowest price (also named lowest tender, LT) usually results in high competition and low quality, which is not sufficient for selecting the most appropriate tender in the diversified procurement requirements nowadays. As a result, the most advantageous tender (MT) was brought into the Government Procurement Law (GPL) in 1999 in Taiwan. In contrast to LT, the MT selects the tender that is the most advantageous to the project owner. After several years of practice, the public procurement agencies are still wondering why and how to select LT or MT, the pros and cons of LT and MT, and the reason for poor procurement. It is very desirable to develop an analytical tool for answering the above-mentioned questions.

In this paper, a geometric graph analysis (GGA) approach is proposed to: (1) explore the price effect of LT in procurement; (2) analyse the different procurement methods such as LT and MT; and (3) compare the efficiency of tender selection between LT and MT. The proposed GGA is an analytical approach that expresses two most important factors, price and quality, in a Cartesian Axis. The behaviours of the demander (buyer or project owner) and the supplier (contractor) are modelled and analysed with GGA. In order to demonstrate the applicability of the proposed GGA,

[1] wangkwo4@yahoo.com.tw.

case studies of real world procurement examples are conducted. The rest of this paper is presented in the following manner: the related researches are reviewed first followed by definitions of terms utilized in the paper; then, the theoretical framework of GGA is proposed; application to real world procurement cases is demonstrated in the fifth section; finally, discussions and conclusions are described.

LITERATURE REVIEW

According to the definitions of Taiwan GPL (Article 52), the methods of contract awarding include LT and MT (Wu 2005). The LT method assumes that plans and designs are detailed and clear enough, so that the contractors won't make mistakes during cost estimation. As a result, the contractor with best management capability can offer the service or product with lowest price and thus wins the bid. According to Gransberg and Ellicott (1996), LT creates a business relationship based on a single factor, price. They also found that LT can simplify the process of selection, solicitation preparation and tender review. It is assumed that the quality of LT can be assured via auditing and inspection procedures (Nissen 2006). Such presumption however has not worked out in practice under the GPL in the past seven years. Kashiwagi and Al-Sharmani (1997) pointed out the weakness of LT: that it favours contractors who can provide minimum quality and performance. In LT, no credit is given to a contractor who provides more skilled craftspeople, better construction methods and higher quality materials. Nissen further points out that LT makes flawed assumptions, encourages cost-cutting and underperformance and does nothing to screen out unscrupulous contractors (Nissen 2006).

The US Federal Acquisition Regulation (FAR) 15.605 states: '(in addition to price) … quality also shall be addressed in every source selection' (US Government 1994). In the same article, it also states: 'While the lowest price or lowest total cost to the government is properly the deciding factor in many source selection, in certain acquisitions the government may select the source while proposal offers the greatest value to the government in terms of performance over and above the minimum acceptable level will enhance mission accomplishment and be worth the corresponding increase in cost.' The above regulation has led to the most advantageous tender (MT), which shifts the competition point from price to quality. The 'quality' is defined as the merits that can improve utilities of the buyer/project owner. The above-mentioned merits may include technical advantages, previous performance, safety practice, local experience, worker training and price. In many cases of MT, the price is fixed, and thus the most advantageous is determined by the best quality offered by the suppliers/contractors. Since the fixed price of the project should be developed early, it is found that change orders and litigation were reduced dramatically in MT (Nissen 2006). According to Taiwan GPL (Article 52), the MT method can only be adopted when a procurement contract may result in discrepancies in technology, quality, function, efficiency or the implementation of commercial terms, etc., as it is carried out by different suppliers/contractors (Wu 2005).

Kashiwagi (2003) proposed a 2-D figure (as shown in Figure 1) to model the competition and performance of contractor selection methods in the construction industry. Owing to increasing competition worldwide, quadrants I and Π in Figure 1 are becoming more and more popular for the construction industry. Quadrant I is related to low performance and high competition, which is closed to the LT. Quadrant II is related to high performance and high competition, which is closed to the MT.

Even though subjective comments were found in the literature, an analytical tool for analysis of contractor selection methods is still not available.

DEFINITION OF TERMS

For the convenience of model construction of the proposed GGA, the abbreviations and symbols adopted in this paper are defined in this section and summarized in Table 1. Note that the abbreviations and symbols with a superscript ‘*’ denote the theoretical curves or ranges that the suppliers/contractors do not participate in the bidding of public procurements; while the ones without ‘*’ denote the curves or ranges that the suppliers/contractors participate in bidding of public procurements.

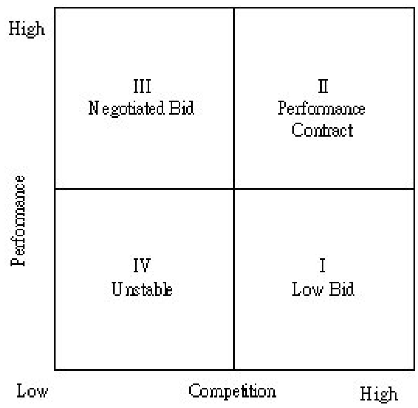

Figure 1: Constructor selection in construction industry (Kashiwagi 2003)

Table 1: Definition of abbreviations and symbols

Abb./symb.	Definition
point (x , y)	Point (x, y) represents a tender with a specific set of price and quality related to the service/product provided by the supplier/contractor under rational basis.
Price	The bid price offered by a supplier/contractor in conformity with the requirements of the buyer/project owner under rational basis.
Quality	A broad definition of quality/merit that improves the utilities of the buyer/project owner including everything except the price during the trade.
P_B	The ceiling price of buyer/project owner, usually relates to the buyer’s/project owner’s budget.
P_L	The bottom price (the lowest allowable price) set up by the buyer/project owner in order to avoid poor quality of obtained service/product.
P_i	A certain price offered by the supplier/contractor lying between P_{MIN} and P_{MAX}, i =0, 1…n. P_i can also be regarded as any possible price that the buyer is willing to pay, thus, P_i will lie between P_L and P_B.
LT	The lowest tender
MT	Most advantageous tender
SS*	The curve of all possible tenders in the free market without constraints of GPL
SS	The curve of all possible tenders awarded by the principle of contract awarding of GPL
HQ*	The curve of the highest quality tenders under rational price in the free market
LQ*	The curve of the lowest quality tenders under rational price in the free market
HQ	The curve of the highest quality tenders awarded by the principle of contract awarding of GPL
LQ	The curve of lowest quality tenders awarded by the principle of contract awarding of GPL
Q^*_{MAX}	The highest quality tenders of service/product in conformity with the requirements of the buyer/project owner in the free market
Q^*_{MIN}	The lowest quality tenders of service/product in conformity with the requirements of the buyer/project owner in the free market
Q_{MAX}	The highest quality tenders of service/product in conformity with the requirements of

	the buyer/project owner in the public procurement
Q_{MIN}	The lowest quality tenders of service/product in conformity with the requirements of the buyer/project owner in the public procurement
P^*_{MAX}	The highest rational price tender in the pool of Q^*_{MAX}
P^*_{MIN}	The lowest rational price tender in the pool of Q^*_{MIN}
P_{MAX}	The highest rational price tender in the pool of Q_{MAX}
P_{MIN}	The lowest rational price tender in the pool of Q_{MIN}
W*	The pool of suppliers/contractors in a free market, which is selected by the buyer/project owner. The region matches buyer's/project owner's requirements and is encircled by curve HQ*, LQ*, Q^*_{MIN}, and Q^*_{MAX}
W	The pool of suppliers/contractors selected by the public buyer/project owner. The region matches the public buyer's/project owner's requirements and is encircled by curve HQ, LQ, Q_{MIN}, and Q_{MAX}

THEORETICAL FRAMEWORK OF GEOMETRIC GRAPH ANALYSIS (GGA)

Basic model

As shown in Figure 2, the proposed GGA model is a two-dimensional graph with the X-axis presenting the broadly defined 'quality' and the Y-axis presenting the 'price' of the service/product provided by the contractor/supplier. There are two curves in Figure 2: (1) LQ* – the lowest quality tenders under rational price in the free market; (2) HQ* – highest quality tenders under rational price in the free market. Both of the curves are subject to the rational price set up by the contractor/supplier in conformity with the requirements of the buyer/project owner. Every point (x, y) in Figure 2 represents a tender with a specific price and quality related to the service/product provided by the supplier/contractor. On the price axis (Y-axis) there is an upper-bound on curve LQ*, P*MAX, which stands for the highest rational price tender of the lowest quality service/product providers; similarly, there is a lower-bound on curve HQ*, P*MIN, which stands for the lowest rational price tender of the highest quality service/product providers. The upper-bound and lower-bound are also found on the quality axis (X-axis), which are Q*MAX, and Q*MIN respectively. In constructing the GGA, two assumptions should be made beforehand:

Assumption 1: rational price

The rational price is set up by the supplier/contractor based on the requirements defined by the buyer/project owner and efforts and costs he/she must spend to meet the requirements.

Assumption 2: continuity of curve

It is assumed that in the considered range of GGA, there is at least one supplier mapping to a tender point (x, y). In the real world, the tenders on the curves in the GGA graph may not be continuous but discrete.

It is noted that the 'quality' in GGA is the broadly defined quality that may improve the utilities of the buyer/project owner apart from price (Fan 1998). On the other hand, the 'price' is determined on a rational basis, which generally takes into account all influential factors such as direct cost, indirect cost, profit margin, competition situation, cost and fixed price of product performance, market price and competitor, etc. It implies that the rational price is closely related to the quality; as the quality increases the rational price increases accordingly (Chen 1994). Such relationship is shown in Figure 2; there HQ* is a concave curve, which means the marginal increase of quality is less than the increased cost. Similarly, LQ* is a convex curve, which means the marginal increase of quality is greater than that of the cost. Such definition conforms to that of value engineering (VE), where the marginal quality increase is less than the increased cost in the high quality area (meaning 'low value' product or 'redundant quality'). Moreover, the HQ* curve is always right and lower to the LQ*. It means that, for the same quality level, the tender on the HQ* is always less expensive than that on the LQ*.

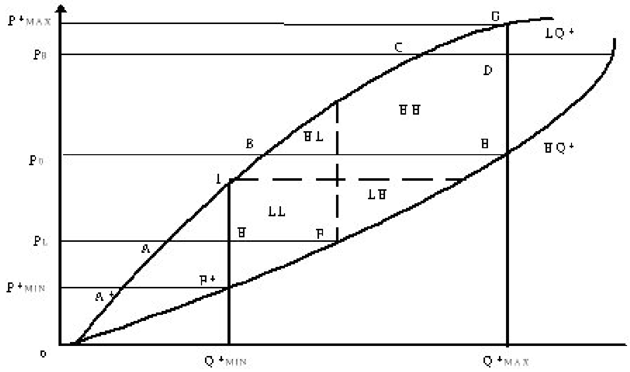

Figure 2: GGA graph

Supplier area (W, W*)

The region GEF*I in Figure 2 bounded by curves HQ*and LQ* represents the area where the potential qualified (met with the buyers'/owners' lowest requirements on quality, Q*MIN) tenders which is the biggest assembling of buyers' considered selection, are distributed. This potential tender area is defined as the 'Supplier area in the free market (W*)'. The region DEFHIC in Figure 2 represents another set (W) of potential qualified tenders under the regulation of GPL. DEFHIC is bounded with the ceiling price of buyer/project owner (PB) and bottom price set up by the buyer/project owner (PL). Under special conditions that PL = P*MIN and PB = P*MAX, W is equal to W*. There are four regions in W*: (1) low price/low quality area (LL); (2) low price/high quality area (LH); (3) high price/high quality area (HH); and (4) high-price /low-quality area (HL). The tenders located in LH are the best candidates for selection in procurement. LL and HH are second choices, while tenders in HL are those that should be avoided by the buyers/project owners.

Tender classification and supplier/contractor selection

Before taking into account the competitive bidding, let us consider a certain price, P0, all tenders on line $\overline{BE}$ are potential candidates for selection. While relaxing single price point P0 to a price range [PL, PB], the best choices are tenders on curve EF and the worst choices are on curve AC. In practical application, the distance between LQ* and HQ* or their shapes on the graph will be different according to the different procurement items. The buyer/project owner often classifies the procurement items into A, B, C classes (see Figure 3) according to the amount in stock, quantity for procurement, the levels of price or value (Fan 1998). The items in Class A mean small quantities, high prices and great value products, which is the 'important minority' in procurement, e.g. high-tech equipment. In contrast, items in Class C mean large quantities and low prices, the insignificant majority in procurement, e.g. standard products.

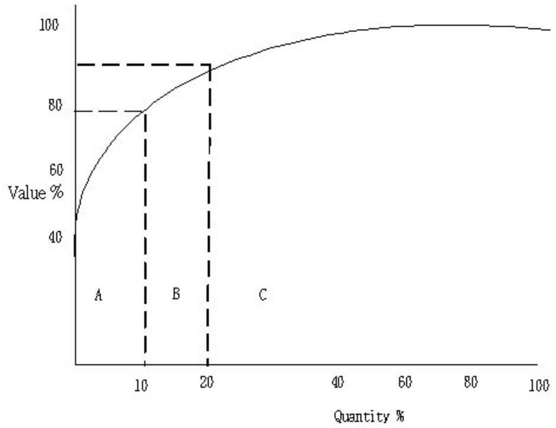

Figure 3: Classification of procurement items

In practical tender selection, Classes A and B require more attention than Class C. The requirements of security, reliability, post-sale service, etc., are higher. The flexibility of Classes A and B is also greater than that of C. As a result in procurement of tenders in Classes A and B, the ranges of [P*MIN, P*MAX] and [Q*MIN, Q*MAX] are wider than that of Class C. The shapes of curves LQ* and HQ* in procurement of tenders in Classes A and B are relatively high, wide and steep, such as those shown in Figure 4. The typical shape of curves LQ* and HQ* in procurement of tenders in Class C is shown in Figure 5.

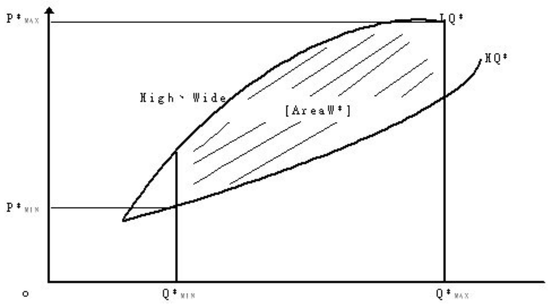

Figure 4: Typical GGA graph of Classes A and B

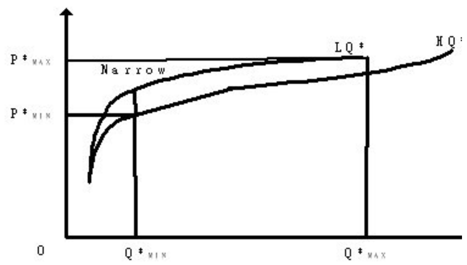

Figure 5: Typical GGA graph of Class C

In this paper, procurements of tenders in Classes A and B are considered. It is also assumed that the curves LQ* and HQ* intersect each other on the origin.

In selection under the ‘performance specification’, the range between curves LQ* and HQ* is also relatively wide compared with those of the technical (prescriptive or descriptive) specifications. It is because that the technical specifications specify the quality of procured items more precisely. Usually, the procurements are performance-based for tenders in Classes A and B, and technical-based for those in Class C.

Adaptation for practical application

The GGA model proposed in this paper is a theoretical framework for procurement analysis. It needs to be modified before application to a real world situation. Before the modification, one assumption (Assumption 3) should be made first:

Assumption 3: sequential order of quality

It is assumed that all tenders in the GGA graph are discriminable in the orders of their quality levels, where the Transitive Law holds. That is, any three different tenders (A, B and C) in procurement can be ordered according to their quality levels. If the quality of tender A is better than that of tender B and the quality of tender B is better than that of tender C, then the quality of tender A is better than that of tender C.

In practical application, a GGA graph should be constructed like the one shown in Figure 6. Based on Assumption 2, the curves in the GGA graph are assumed to be continuous. The tender price and quality information collected from the marketplace are finite. The dots ‘*’ in Figure 6 represent the potential suppliers’ tenders in the marketplace. The upper and lower frontiers of data envelope form the LQ* and HQ* in the GGA graph. Interpolation and extrapolation can be employed for continuous curve construction. Sometimes, ordering of the quality of tenders is difficult. Semi-quantitative methods, such AHP (Saaty 1980), can be adopted for quality ordering. For example, as shown in Figure 6, if the buyer is willing to purchase the item within a budget of $100, theoretically the buyer would never select the supplier with a $120 offer. Only when the supplier lowers his/her price to $100 (in other words, cuts the price by $20) will it be selected by the buyer.

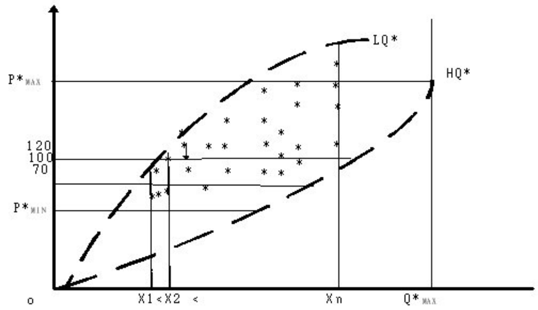

Figure 6: Discrete GGA curves and tenders in practical application

VERIFICATION WITH REAL WORLD CASES

The theoretical model of GGA proposed in the previous section needs to be verified with real world cases. In this section, the diesel engine procurement is considered for study. Take the quotations of diesel engine generators of Americas Generators from the Internet (for example www.GoPower.com). Consider the power rate (KW) of the generator as the quality (X-axis) and the Y-axis relates to its price; two scatter plots are obtained as shown in Figure 7 (20~100 KW) and Figure 8 (50~250 KW).

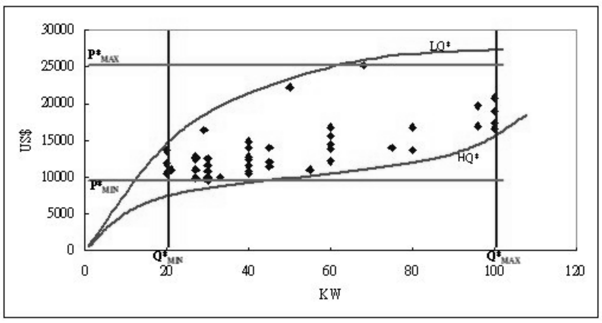

Figure 7: GGA graph for 20-100 KW diesel engine generators

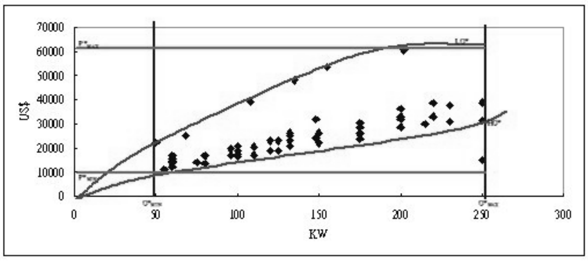

Figure 8: GGA graph for 50-250 KW diesel engine generators

It is found from Figure 7 and Figure 8 that both graphs are in conformity with the typical shapes of GGA graphs. All parameters of GGA can be identified in these graphs. The parameter vector [P*MAX, P*MIN, Q*MAX, Q*MIN] of the GGA graph in Figure 7 is [$25 198, $9999, 100 KW, 20 KW]; the same vector for the GGA graph in Figure 8 is [$60 688, $10 999, 250 KW, 50 KW]. It is also found that the shape of the GGA graph in Figure 7 is similar to that of Figure 5 (Class C), while the GGA of Figure 8 is similar to Figure 4 (Classes A and B).

It is noted in both graphs that generators with the same quality (generation power) are priced differently. There may be some other factors (e.g. durability, weight, noise, fuel consumption rate, etc.) not included in the quality dimension here. The theoretical framework of GGA is verified in the both of the above cases.

APPLICATIONS OF GGA

In this section, the applications of the proposed GGA to procurement analysis are described. The analyses include: (1) the price effect of the lowest tender (LT) on quality; (2) the selection of tenders; and (3) the appropriate contract awarding zone.

Price effect of the lowest tender on quality

It is conceived that under the LT method the suppliers/contractors tend to lower prices in order to win the bid. Based on the theory of GGA, the quality of service/product may also decrease accordingly as the price is decreased. If the price is decreased to the direct variable cost (VC), which refers to production and marketing-related direct cost, the quality of product will be significantly affected by price reduction. In contrast, the government's pollution control and the standard of security requests or the goals of business can make the price rise, shown as in Figure 9 (Chen 1994).

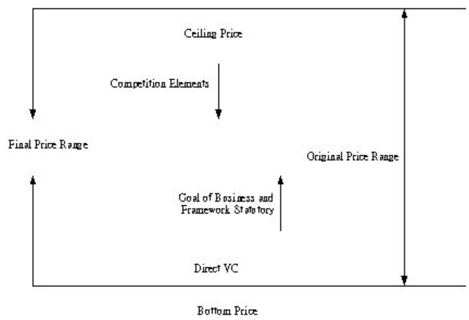

Figure 9: The behaviour of suppliers in response to price reduction

Effect on supplier area (W* and W)

After price reduction under the regulation GPL, the GGA graph is reshaped. The ideal shape of the GGA graph for LT is shown in Figure 10, where the original graph is shifted down (from graph K to graph V). For convenience of comparison, the graphs K and V are merged to graph O in Figure 11. It can be seen that the scope of W is smaller than W *. Because of the high quality regions are expelled due to price reduction.

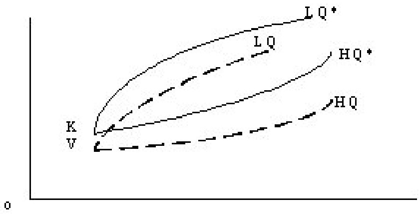

Figure 10: Ideal GGA graph shift in LT under price competition

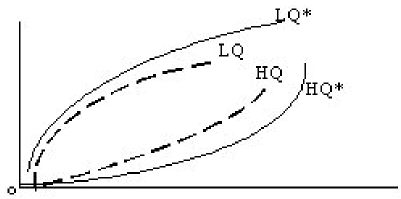

Figure 11: Actual GGA graph in LT after price reduction

Effect on tenders of Class C

In Figure 12, P*MAX is reduced to P MAX. It is not difficult to find a tender B on LQ with the same quality as C on LQ*. For some price-indifferent tenders where price and quality are little different in Classes A and B, the effect is similar; such effect is shown in Figure 13.

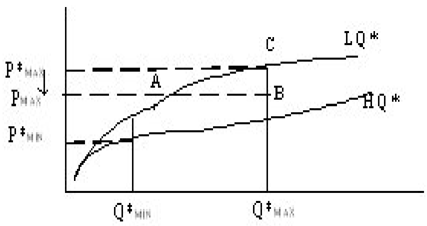

Figure 12: Price reduction effect on the tenders in Class C

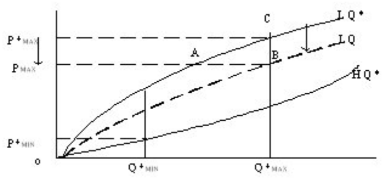

Figure 13: Price reduction effect on the price-indifferent tenders in Classes A and B

In either Figure 12 or Figure 13, the price reduction effect on quality is not significant. This is in conformity with the preconception that LT is suitable for tender selection of Class C (and also for price-indifferent tenders in Classes A and B).

Effect on typical tenders of Class A and B

For the typical tenders in Classes A and B (with high wider ranges between curves LQ* and HQ*), the price reduction will shift the curve HQ* to curve HQ (the Q*MAX is reduced to Q MAX) in Figure 14 and cause loss of suppliers in the area BCD (where the high quality/high price suppliers are unwilling to reduce their quality and price).

After price reduction, the resulting supplier area W is much smaller than W*. The highest quality falls from Q*MAX to QMAX, namely suppliers in region AEBC are expelled due to price reduction. The greater the reduction of price, the more loss of quality. As a result, the LT is not suitable for tender selection in Classes A and B.

Moreover in Figure 14, suppliers in AEDB may be able to reduce their prices to the lowest rational prices without reducing the quality. Among those, suppliers in region AE'D' are more likely to lower their prices to PMAX or lower, but suppliers in region EDBD'E' may be expelled due to less flexibility on price. Because of the AE'D' quality compared to EDBD'E' is lower, it has high price competition. The quality of E' compared to D' is lower, similarly has high price competition, so the position is left and high. The quality of D' is relatively high, has the lower competition, therefore the position is right and lower. Thus below the region of curve E'D' will have high competition.

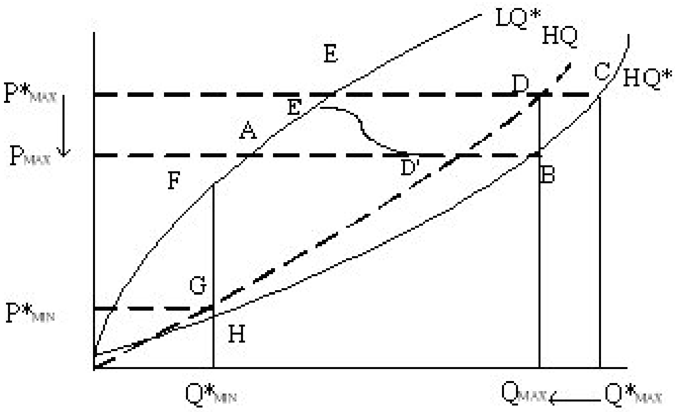

Figure 14: Price reduction effect on typical tenders in Classes A and B

SELECTION OF TENDER

Assume that the buyer is willing to purchase an item with price Pi, and the information of market condition is offered completely, then P*MIN ≤ Pi ≤ P*MAX. According to Assumption 2, no matter which selection method is adopted, there will be a tender to be selected in W. Figure 15 shows that within the budget of the buyer, every possible price Pi will map to the curve SS. Owing to price competition, SS tends to be closed to curve LQ. The basic principle for an efficient tender selection strategy is to force the SS to be closer to curve HQ.

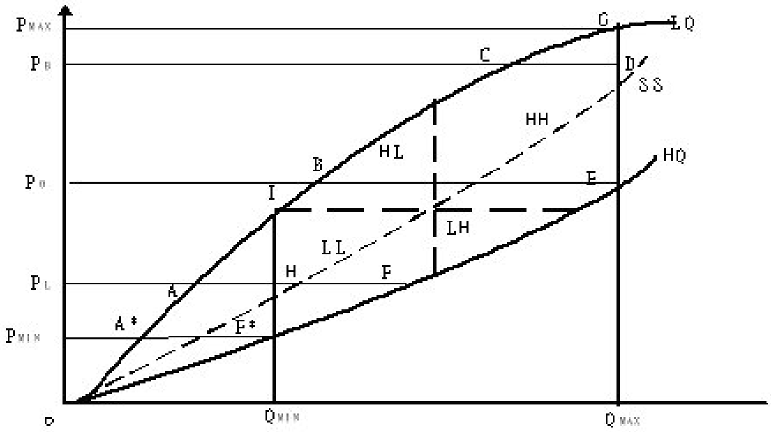

Figure 15: Tender selection curve (TSC)

Contract awarding zone (CAZ)

The proposed GGA can be used for preplanning for the contract awarding zone (CAZ) for procurement in order to select the most appropriate tender. The following discussion is with regard to Figure 15. In the area of HL and LL of Figure 15, the quality index is ‘Low’ and the price index is either ‘High’ or ‘Low’. Thus, when LT is applied, price will govern the competition result, rather than quality. Suppliers should reduce their prices in order to increase the probability of winning the award. Therefore LT is more likely to award to suppliers located in areas LL and HL than MT. On the contrast, the MT is more likely to award the contract to suppliers located in areas LH and HH.

The GGA for tenders in Class C (most are standard services/products) is characterized as: (1) with smaller disparity both from QMIN to QMAX and from PMIN to PMAX; (2) the market information is clear and open; (3) buyer's estimation is accurate, thus is more suitable for LT.

If the procured items belong to Classes A and B with greater quality and price ranges in the GGA graph, the MT will be best choice. Because the procurement items in Classes A and B are greater in disparity from PMIN to PMAX and QMIN to QMAX, improvement of quality is greater than that in Class C.

CONCLUSIONS AND RECOMMENDATIONS

In this paper, a new analytical tool for analysis of both public and private product/service/project procurement processes is proposed, named geometric graph analysis (GGA). The proposed GGA model adopts a 2-D analytical graph for modelling the two most important factors in procurement, i.e., price and quality. Similar to the demand-and-supply diagram in economics, the GGA graph is employed to model the behaviours of suppliers/contractors during the procurement process. The theoretical framework of the proposed GGA model is described in detail. Real world procurement data are employed to verify the proposed GGA model. Potential applications of the proposed GGA model are also discussed in depth in three areas: (1) analysis of the price effect of the lowest tender (LT) on quality; (2) analysis the efficiency of tender selection with LT and MT; and (3) analysis of the appropriate contract awarding zone.

It is concluded that the proposed GGA model not only provides a theoretical framework for analysis of suppliers'/contractors' behaviours during the procurement process, it is also an efficient tool for procurement strategy planning. Further demonstrations and applications adopting the GGA model should be conducted in the future to fully exploit its benefits and functions. Application of GGA to procurement strategy planning is a valuable area for future research, too.

IMPLICATIONS FOR DESIGN AND BUILD CONTRACTORS BIDDING IN PUBLIC–PRIVATE PARTNERSHIP CONSORTIUMS: AN AUSTRALIAN PERSPECTIVE

Denny McGeorge[1], Marcus Jefferies, Katie Cadman and Chen Swee Eng

School of Architecture and Built Environment, Faculty of Engineering and Built Environment, The University of Newcastle, University Drive, Callaghan, NSW 2308, Australia

The term design and build (D&B) is a well-established description of a procurement method in which the roles and responsibilities of the various stakeholders are clearly defined. The advent of public–private partnerships (PPPs) brings a new opportunity for design and build contractors with the concomitant challenge associated with bidding as a member of a private sector consortium with numerous stakeholders. The work described in this paper is based on an ongoing Australian Research Council (ARC) research project that is investigating the costs and the allocation of risks during the bidding process for PPPs. In the course of this research we have explored the implications for design and build contractors bidding for social (as opposed to economic) PPP projects. The conventional wisdom has been to assume that there is little difference between bidding for a conventional design and build contract as compared with submitting a design and build bid as part of a total PPP bid; however the results of our study indicate that there are subtle, and in some instances, significant differences. By way of placing the Australian experience in context, the paper also traces the emergence and growth of social infrastructure PPPs in Australia.

Keywords: bidding costs, design and build (D&B), design and construct (D&C), public–private partnership (PPP), tendering costs.

BACKGROUND

The genesis for this Australian Research Council (ARC) collaborative research project came from the private sector where there would appear to be a widely held view that public private–partnerships (PPPs),[1] particularly with respect to hard social infrastructure projects[2] are partnerships in name only. This line of argument is advanced by Curnow *et al*. (2005) who argue that there is a strong body of opinion to support the contention that current social infrastructure projects in Australia are not true partnerships and there is a clear need to reduce the ‘tokenism’ of Australian PPPs. They argue that the public sector needs to make PPPs more attractive to the private sector and clarify the identification of risk in order to transfer more responsibility to the private sector. This issue is supported by recent industry criticism of PPPs concerning the ‘narrowness’ of the scope of work that is offered to the private sector.

In reality, in many instances, in the view of Curnow, PPP project costs relating to finance, building design, construction, maintenance and waste management amount to less than 15% of the total life cycle cost of the enterprise. As a result, the private sector may be deterred by the high transaction costs of social PPPs, which offer only a

[1] denny.mcgeorge@newcastle.edu.au

marginal increase in scope of business opportunity. This is in direct contrast to opportunities that are available in the much lower cost-to-bid ratio of more standard procurement models or in hard economic PPP projects where the revenue stream from, say, a freeway tollway has a substantial and clearly defined internal rate of return. There is evidence from our own research to support the view that a number of private sector players are either withdrawing from social PPP projects completely or are being highly selective because of the unattractiveness of the projects on offer.

In summary, there is a body of opinion among private sector consortium bidders for hard social infrastructure PPP projects that they are being hit by what might be described as a 'double whammy effect' where the financial rewards are less and the operational demands are more complex than for hard economic PPP projects. Not withstanding this situation, the number of proposed hard social PPP projects in Australia is on the increase and there are a number of private sector players who are willing to bid in this environment.

EMERGENCE OF SOCIAL PPPS

As part of the research a compilation was made of all PPP projects from 1986 onwards undertaken to date in Australia (Table 1). This compilation includes all projects listed by Jones (2003) and Duffield (2005) together with (as far as is known) all PPP projects up to May 2006. The data illustrate (with a few exceptions) that the application of the PPP approach to hard social infrastructure PPPs is a relatively recent trend. However, many of the projects currently under consideration in 2006 are for hard social PPP projects. Whether or not these projects progress to fruition will largely depend on the perceived risks and returns to both the public and private sectors. Table 1 demonstrates the increasing number of social PPPs either in the pipeline or under consideration in Australia.

E Hard economic infrastructure.
S Hard social infrastructure.
U Urban renewal & associated infrastructure.

PRACTICAL ISSUES WITH HARD SOCIAL PPPS

As previously stated the trigger for the research project was the view expressed by private sector players that the current high cost of transaction fees incurred in bidding for hard social PPPs was acting as a deterrent to bidders and that in many cases the concept of partnership was token rather than genuine (Curnow *et al*. 2005). Curnow argues for a broadening of the scope of work to make PPPs more attractive to the private sector whereas Blood (2005) argues more for a transfer of responsibility to the private sector rather than the scope of work per se (although both arguments, if accepted, would perhaps have the same result). Blood’s proposition is that:

> The Government perception of PPPs is that this is private funding for public infrastructure. But this misses the point: PPPs are a shift of responsibility, not of funding. They motivate all parties to take responsibility for their actions and delivery, making projects more accountable and measurable.

In support of his argument Blood makes the case that PPPs should not be used as a scapegoat for Government-led finance or staff cuts and changes but rather should be seen as an opportunity not to reduce staffing but to make staffing more efficient through a better infrastructure for delivery. There are certainly a number of critics, including the trade unions, who would not subscribe to this point of view

These issues, while not necessarily unique to social PPPs, are perhaps more acute than for economic PPPs. If a comparison is made between a large teaching hospital as an example of a social PPP and a tollway as an example of an economic PPP then the contrast in terms of complexity of operation and interaction between the private sector operator and the users is quite marked. In the hospital situation staff costs will represent at least 90% of the total annual operating costs whereas in a tollway staff costs are minimal with the largest item of expenditure being on maintenance. While both types of PPP do carry a number of risks (to both the public and private sectors) the risk potential over the operating period would appear to be greater in social PPPs than for economic PPPs.

THE RESEARCH PROJECT

As previously stated, the initiative for the research project came from the private sector. Our industry collaborators are (with one exception) D&B companies who, in turn, are part of larger holding companies. Our dialogue has, in the main, been with the D&B sector. It has at times been difficult to differentiate between responses that relate specifically to D&B issues and evidence that relates to issues affecting the consortium as a whole. The network of relationships between the various consortium members during the bidding process is highly complex. Although contractually the bid vary quite markedly. Care has to be taken in discussions with industry players in establishing the role of a particular organization in a PPP consortium since not only does this role vary from project to project, but also individuals within one organization can have more than one role in preparing the project bid. In this instance, our research is primarily concerned with PPPs as seen from a design and build contractor's perspective. However, key personnel can have responsibilities in both design and build and facilities management (FM) and in some cases also be a member of the SPV team. A typical consortium structure is illustrated in Figure 1. Additionally, care has to be taken in distinguishing between the cost of bidding and the bid price as problems can and do arise when the cost of preparing the bid is confused with the bid price. During our interviewing process we found that respondents often discussed both the consequences of winning a bid and undertaking the D&B contract under consortium conditions together with the consequences of losing a bid and having to absorb the bid costs into the next round of bidding. We have attempted to make a clear distinction between these quite two different sets of circumstances, but cannot guarantee always to have done so.

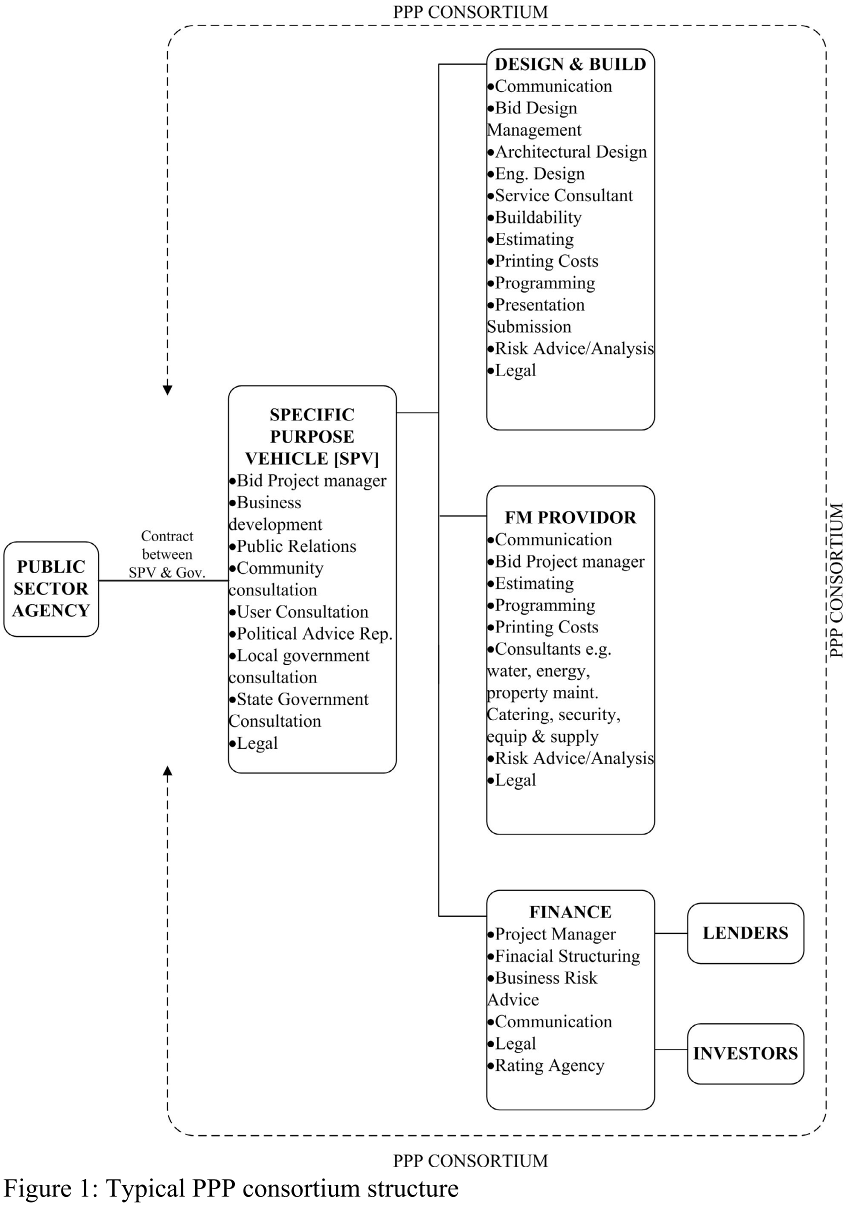

Figure 1: Typical PPP consortium structure

RESEARCH APPROACH

The basic premise underpinning this component of our research project was that there were underlying differences for D&B contractors bidding in a PPP environment as opposed to a standard D&B contractual relationship and that the most appropriate method of determining these differences was through interaction with senior industry experts whose views were taken as representing a distillation of the opinions of major players in the field. This expert opinion approach is, in our view, justified both in terms of research methodological grounds and also on pragmatic grounds given the sensitive and confidential nature of the data. The full research methodology is illustrated in Figure 2.

Review of recent reports of the industry
Comprehensive review of related literature and critical industry reports used to generate list of major challenges facing Australian construction PPP industry. Analysis identified key issues and themes.

↓

Industry Reference Group
Industry Partners made up of three construction groups representing a substantial sector of PPP contractors in Australia. Each Industry Partner nominate 2 experts experienced in PPP bidding and part of consortium.

↓

Research Method
Semi-structured interviews and workshops conducted with nominated experts & support staff. Interviews conducted over series of stages to establish dialogue between researcher and participants and gain both qualitative and quantitative data. Information gained from interviews establishes case studies on various PPP projects.

Quantitative
Quantitative data collected to establish the costs of bidding for PPP projects.

Qualitative
Semi-structured interviews focus on key themes identified from literature review. Industry partners views and key concerns documented & used to corroborate bid costs.

↓

Case Studies
Compilation of case studies based on analysis of information provided by industry partner's nominated experts. Cases studies consist of current major social infrastructure projects procured under the PPP procurement model.

↓

Analysis of Data

Quantitative
Qualitative data of bid cots analysed using descriptive statistics.

Qualitative
Qualitative data analysed using combination of content analysis and grounded theory to group the findings.

RESEARCH FINDINGS: IMPLICATIONS FOR D&B CONTRACTORS

As previously mentioned it has been difficult and in some cases not even possible to separate issues that relate specifically to D&B as an entity of a PPP consortium and issues that relate to the consortium as a whole. For the purposes this paper we have attempted to focus specifically on D&B issues. Our respondents have identified a number of themes, many of which are interrelated. Four dominant themes have been identified and these are discussed in detailed below. They do not encompass all of the issues that we have identified; however, they do provide a framework to describe a major part of our research findings. The themes are as follows:

- tendering/bidding costs;
- legal costs;
- standardization of documentation;
- Public Sector Comparator (PSC)

D&B tendering/bidding costs

One of our basic research questions was 'are tendering costs likely to be higher for a D&B bid in a PPP as opposed to a standard D&B?' Hughes *et al*. (2006) describing a study on the cost of procurement in the construction industry make the statement that there is a 'desperate need for robust data' in respect of tendering costs. While it may appear to be a relatively straightforward matter to identify the costs of bidding for a specific project, in reality this is not the case. To quote from Hughes *et al.*:

> complexity of the data collection places significant hurdles in the way of those who wish to undertake research in this area. This is probably why so few attempts have been made at assessing these costs. The quantification of the costs of tendering that have already been reported in the literature tend to focus on the cost of estimating and bidding, and take no account of the relationship between the distinct stages of a project. Moreover, they are based on impressionistic estimates, rather than analysis of data. However, the fact that they range from 1% to 15% indicates a strong feeling that there is a lot of expenditure in this area, and it is difficult to quantify. Also there is the further conclusion that the value added by this expenditure is not clear.

Hughes *et al.*'s comment on 'impressionistic estimates' is particularly interesting in the context of PPP bidding. We have encountered similar problems in terms of data collection and although we have been able to collect primary data, much of the corroboration of our findings is based on a qualitative rather than a quantitative approach. We certainly empathize with the aptness of Hughes *et al.*'s term 'impressionistic estimating'. In addition to the difficulties associated with accurately allocating costs to a specific tender bid there is the added dimension of the commercially sensitive nature of the data surrounding PPP bidding and also the complex set of commercial relationships that exists within a PPP consortium.

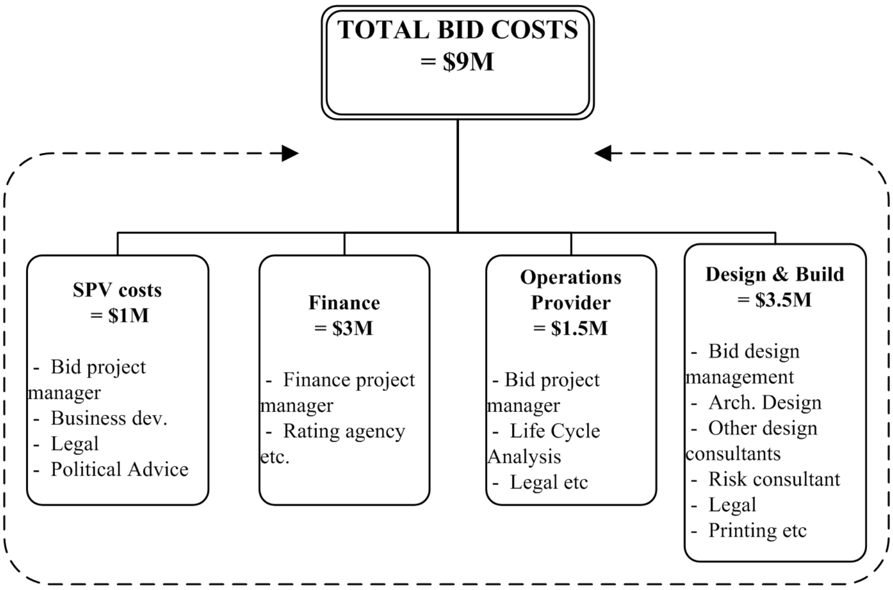

Figure 3: Typical bid costs for $250m PPP social infrastructure project

Note: Bid costs based on the assumption that the bid is successful i.e. to financial closure. If bid is unsuccessful then the financial component, depending on specific circumstances, may be zero.

As can be seen from Figure 3 which illustrates likely (but not actual) bid costs for an AU$250 million social PPP project, the cost of preparing a D&B bid as part of an overall consortium bid cost is likely to exceed one-third of the total cost of bidding. Thus the D&B component is highly significant. We were particularly interested in identifying whether these bid costs would be the same for a standard D&B where the built component was of similar scale and complexity.[3] We have obtained data from our industry collaborators that will allow us to conduct some limited comparative studies and we are in the process of finalizing the collection and analysis of this data. It is not as comprehensive as we had hoped and permission to publish these data still requires clearance by our industry partners.

We have also found that direct comparisons between a ‘standard’ D&B and a D&B as part of a PPP are not as straightforward as might be assumed. There are a number of explanations as to why this might be the case. First, D&B companies may take the view that the utilization of resources in collecting data on the cost of bidding outweighs the benefits. Secondly, whereas external costs (i.e. costs of consultants), are invoiced leaving an accurate paper trail of cost details, internal costs often become absorbed in overheads of the company. D&B companies do not normally operate with very clearly defined cost centres as for example, major accountancy or legal practices, thus the bidding costs of a D&B/PPP (contraction for D&B as part of a PPP) project may be partly absorbed into company overheads and distributed over other non-PPP projects. Further complexities arise in terms of internal relationships within the PPP. For example, D&B contractors may be owned by a larger holding company that may, in turn, be financing the SPV. In this set of circumstances it is likely that that D&B company will automatically be part of the PPP consortium, and will not have to compete to be chosen to be a consortium member. While this would not necessarily affect actual bidding costs it may create cost allocation ‘adjustments’ that would not exist in a standard D&B. On other occasions the SPV may ‘cherry pick’ the D&B contractor from a number of competitors based on criteria determined by the SPV.

An emerging trend in Australia is for construction companies to move away from the provision of equity to the consortium and operate solely as a D&B contractor within the SPV, usually in an attempt to minimize their costs (and risks). However, some financial institutions may insist that contractors provide some upfront equity as a sign of goodwill and a commitment for the duration of the project. Notwithstanding this shift away from providing equity in the consortium, bidding costs for a D&B/PPP are seen as being high and a deterrent to bidding for projects. As a counterpoint there is also the view that bidding in the highly competitive PPP environment could potentially lead to a refinement and sharpening of the bidding process and thus lead to a reduction in the costs of bidding. However, this is likely to be a costly way to gain experience particularly when bids are not successful. In Australia the PPP process has already reduced the pool of bidders. Already fewer competitors function in the market, leading to a reduction in competition, ironically one of the benefits often cited for PPPs. Indeed there would seem to be a general rule of thumb that major PPP players would not be prepared to enter the bidding process where more than three bidders were invited.

In summary we have found the general view to be that the bidding costs for D&B/PPP are higher than for a standard D&B. The basic rationale is that most contractors know what to expect with the standard D&B procurement process, and legal costs are kept to a minimum through the utilization of standardized contract documents. Generally the standard D&B contract process is more predictable, having greater clarity regarding roles and timeframe (the bid period is usually shorter than for a PPP) thus minimizing bid preparation costs. In essence in Australia where standard D&B (or in Australian terminology Design and Construct) has widespread acceptance the fact that it is an established system allows bid preparation costs to be kept to a minimum. By implication, the perceived higher costs of PPP bids are, in part, due to this being a less well-established system with non-standard contracts.

It has been suggested to us that the additional costs could be up to 5–10% higher for a D&B/PPP as opposed to a standard D&B, due, among other things, to the additional legal costs of a PPP bid. Another reason for additional bid preparation costs can occur in the design content where a commercial decision by the consortium to gain a competitive edge could result in higher design costs given that the more developed a design is the more likely it is to be short-listed. Thus, in some cases the design component in a D&B/PPP bid may be more highly developed than for a standard D&B. The expectation for PPP bids is that the submission should have well-developed design documentation. As a corollary to this, the cost of printing is also high with an example provided where the cost of printing contract documentation for a social PPP project valued at AU$300 000 000 was in the region of AU$100 000.

Legal costs

The research described in this paper is primarily concerned with the implications for D&B/PPP contractors when bidding as part of a PPP consortium. Reportage of industry expert opinion on legal costs is therefore focused on legal costs as they relate to D&B. However, it is worth noting that legal costs across the board, i.e. all of the consortium entities, emerged as a dominant theme during our interviews and workshops with industry. The general view was that legal costs are excessively high (although we have not interviewed members of the legal profession to verify this statement). One of the core reasons for the high legal costs cited was lack of standardization of contract documentation. It was acknowledged that legal costs involved in the procurement of infrastructure whether it is a D&B/PPP or a standard

D&B contract were an inevitable corollary of the highly litigious environment in which construction operates. However the general impression given was that legal costs for PPPs were substantially higher than traditional government procurement. It was felt that these costs were a deterrent to some potential bidders. Despite the dissatisfaction expressed regarding high costs, legal costs and associated costs of expert advice, there was general acceptance that this was an integral part of risk mitigation. Furthermore as legal costs are often regarded as non-value added there is perhaps the argument that the issue of legal costs tends to be exaggerated by the construction industry. This is perhaps exacerbated by the fact that social PPP projects tend to be for smaller contract sums and hence attract proportionally higher legal costs. Figure 2 illustrates that legal costs are incurred in all four major entities (SPV; finance; FM provider and D&B) of a PPP bid. Data still being analysed will give us a more precise picture of the legal cost distribution and its ratio to overall bid preparation costs.

The obvious concern of the respondents with legal costs reflects concerns expressed by Evans and Bowman who point out that the legal framework in which the PPP project operates will be a crucial factor to the success of a PPP model: ‘the legal framework within which a PPP project operates will also be a determinant of the optimal PPP model. PPPs will be subjected to legal issues that may encompass many facets of law including (among others) commercial, taxation, insurance, environmental, property, industrial relations and constitutional law’ (2005: 63).

Standardization of legal documents

The consensus view[4] was that there was a lack of consistent principles and practices across the various state jurisdictions in terms of guidelines. Generally it was felt that this lack of consistency increases costs. In an Australian context the Fitzgerald Report (Fitzgerald 2004) recommended that the PPP processes should be streamlined in order to reduce the costs of tenders and encourage wider bidder participation, therefore increasing the competition. It is worth noting that the Public Accounts and Estimates Committee *Report on private investment in public infrastructure* comments that the ‘PPP concept is evolving in different ways in each country’ (2006: 81). There were divergent views on how best to standardize the processes and which model to follow. There was a general concern that international precedents may not reflect the smaller scale of the Australian PPP market. However, the UK PPP model, in which legal/contractual documents have been standardized, is viewed as a reference point for those who recommend standardizing documentation for Australian PPP models. There was general consensus that a reduction in transaction costs could result from standardized templates such as those in the UK. It is worth noting however that despite the introduction of templates in the UK the transaction costs are ‘high and appear likely to remain relatively so despite the development of templates’ (Public Accounts and Estimates Committee 2006: 84).

There was a certain amount of doubt as to whether or not standardization would result in a reduction of legal costs. There was also concern that the process of implementing standardization carried its own costs, requiring a large enough PPP market to justify the initial expenditure.[5]

Public sector comparator

The public sector comparator (PSC) affects all the consortium entities i.e. D&B, FM provider, finance and the SPV, not simply the D&B entity. The PSC purports to provide a benchmark for the complete project life cycle and although the cost to design and build is only one part of the project life cycle it is plays an important part in determining whether the bid is won or lost. It is worth remembering that while the PSC refers to the bid price it may have some influence on the cost of bidding. For example, as previously discussed, there may be commercial pressure to develop designs fully in order to improve the chances of winning the bid and also improve accuracy of costing.

We received a wide-ranging set of views in relation to the value and effectiveness of the public sector comparator (PSC). On the one hand the PSC was seen as a beneficial tool to guide decisions and ensure government accountability; while on the other hand the PSC is often seen as arbitrary and subjective, and consequently of limited value. A commonly held view was that PSC criteria could be manipulated to produce a result that cast the public sector client in a favourable light. These comments are indicative of the current debate both nationally and internationally by commentators and industry representatives regarding the usefulness and accuracy of the PSC (Broadbent *et al*. 2003; Fitzgerald 2004; Corner 2005; Grimsey and Lewis 2005; Public Accounts and Estimates Committee 2006). Critical literature regarding the PSC has incorporated discussion over a variety of issues that have included the appropriate use of the discount rate (English and Guthrie 2003), the failure to take into account risk of failure in the PSC (English 2005: 297) and issues surrounding the public release of the PSC (Grimsey and Lewis 2005: 359).

There would appear to be some disquiet at the differences between Australia's various jurisdictions in relation to the PSC. There was agreement that there should be more consistency in how the PSC is formulated, used and disclosed. PSC polices across the jurisdictions differ in its use and release, ranging from total secrecy to an open general policy of release. Some jurisdictions, such as the Commonwealth and South Australia, do not have a general rule on releasing the PSC. In contrast Victoria, Tasmania and the Australian Capital Territory do have a general rule against full disclosure of the PSC and in Western Australia until the contract is executed the PSC remains confidential (Public Accounts and Estimates Committee 2006: 84).

The failure of some jurisdictions to fully disclose the PSC was particularly criticized by respondents, stating that it was unnecessary for it to remain confidential. Many believed that the process of withholding the PSC was counterproductive, that it increased bidding costs and it would be more beneficial for a project outcome that the PSC was open for general comment. Many were cynical that without disclosing the PSC government would not have to justify how the final PSC costing was derived.

However, a shift towards partial disclosure of the PSC in States that currently withhold the information is evident with the recent recommendations made in February 2006 by the Victorian Department of Treasury and Finance to present the public service comparator early in the bid phase in an effort to reduce bidding costs. Nevertheless the Department of Treasury & Finance has since further qualified the status of this recommendation stating … 'the aim of the presentation is not to disclose the detailed costing of the PSC, rather to further clarify the governments expectations' (Public Accounts and Estimates Committee 2006: 76).

There was some frustration regarding the practice of government authorities withholding of the PSC during the negotiation stage. Bidders are measured against this comparator, but have no insight into the PSC and hence are effectively bidding 'blind'. There were also some concerns expressed that the PSC unduly influenced the size and scope of projects, and whether or not a project proceeded. Criticism in current literature supports this notion that the PSC can be used incorrectly as a pass/fail test despite the 'many uncertainties involved in the calculation and the fact that the numbers could have been manipulated to obtain the desired results' (Bult-Spiering and Dewulf 2006: 100).

CONCLUSIONS

The main thrust of this paper has described what, in our view, is a reasoned distillation of opinions by major industry D&B/PPP contractors on some of the implications of bidding for and undertaking D&B/PPP contracts in the current Australian market. The overall impression presented in this paper may have been one of negativity; however, this is perhaps a reflection on the embryonic nature of the social PPP market in Australia where lack of consistency between the various State governments appears to be a problem specific to Australia. There would seem to be little doubt that a D&B/PPP as opposed to a standard D&B creates additional pressures. These pressures (at least for the larger players) are magnified on social as opposed to economic PPPs where the projects on offer are potentially less lucrative than economic PPPs and where the bid–cost ratio is higher.

The PPP market in Australia, particularly for social PPPs, is gathering momentum but is less mature than that of the UK. The rate of maturation may be inhibited, to some extent, by the scale of the available market (in comparison to the UK) and the compartmentalization of the market on a State-by-State basis. However, as previously discussed, there are moves towards the standardization of documentation (particularly by the Victorian Government) and the existence of a National PPP Forum is encouraging (see http://www.pppforum.gov.au/home).

Fundamentally the challenges to D&B/PPP contractors result from having to interact with a large number of players in a dynamic environment where the SPV and not the D&B contractor are in the dominant position. Throughout this paper the term 'complex' has been frequently used to describe the interrelationship of players in a PPP consortium. Certainly the consortium environment seems to mimic some of the characteristics described in complex systems theory such as 'non-linearity' where systems do unpredictable things and 'emergent properties' where a logical result is achieved, although not necessarily a predictable one. There are reservations among industry players about the efficacy of the PPP approach and some would perhaps prefer to operate in the much more controlled relationship that exists under a standard D&B procurement method. However, notwithstanding any reservations that may exist on PPPs, there is general acceptance that social PPPs are part of the procurement landscape in Australia and likely to remain so for the foreseeable future.

NOTES

[1] The working definition of PPPs for this research is based on that of Akintoye *et al*. (2003): 'a long-term contractual arrangement between a public sector agency and a private sector concern, whereby resources and risk are shared for the purpose of developing a public facility'.

[2] Argy *et al.* (1999, cited in Grimsey and Lewis 2004: 20–1) make the following useful distinctions between types of PPPs:

- hard economic infrastructure e.g. roads;
- soft economic infrastructure e.g. financial institutions;
- hard social infrastructure e.g. hospitals;
- soft social infrastructure e.g. social security.

[3] Since commencing our research Fitzgerald and Duffield (2006) have announced a National Benchmarking Study comparing PPP projects versus more standard procurement strategies. The study focuses on the bid price, not the cost of bidding.
[4] These comments are specific to Australia with its federal system of government as opposed to the Westminster system.
[5] Since the initiation of the research project various government agencies have begun to standardize some of their processes based upon previous lessons learnt or criticism from the private sector. Respondents commented that all levels of government appear to be committed to refining contractual negotiations, in order to reduce extended legal debates which are costly not only for the contractors involved but also for government.

BIDDING MODEL FOR DESIGN/BUILD PROJECTS

Li-Chung Chao[1]

Construction Engineering, National Kaohsiung First University of Science and Technology, 1 University Road, Yenchao, Kaohsiung, 824, Taiwan, Republic of China

A contractor in bidding for a design/build (D/B) project needs to submit a technical proposal for design and construction fulfilling the project brief, along with a price proposal. The owner will compare each bidder's value versus price in determining the 'best value for money' for contract award. Hence, a contractor's bid price decision for a D/B project should reflect not only the cost but also the relative value of the firm's service, making the decision more complex than for a construction-only project. It would be difficult to determine the optimum bid price by using experience and intuition alone. This paper presents a research that focuses on how much mark-up a contractor should apply on top of the estimated cost for a D/B project. It is proposed that the relative value of service is self-assessed using the analytical hierarchy process and according to the owner's evaluation criteria. The probability of winning for a bid is estimated with considerations of the owner's tender evaluation and the competition in the target market. The mark-up that achieves the maximum expected profit after reducing the allowance for project risk is recommended for bid price decision. The proposed model is illustrated using a case project in response to a commonly used approach for contractor selection.

Keywords: bidding, design and build, estimating, pricing, risk analysis.

INTRODUCTION

The design/build (D/B) method of procurement has now been widely adopted by public and private owners in many countries for a variety of construction projects. As a result, D/B projects have become an important source of business for contractors in the construction industry. When the owner uses the D/B method to procure a project, the contractor selection procedure normally requires a bidder to submit a technical proposal for design and construction fulfilling the project brief, along with a price proposal, for the owner's evaluation. Since there are differences in qualifications, experience and technical proposals among the bidders, representing different values, the owner in evaluation of tenders will compare each bidder's value versus the price asked in order to determine the 'best value for money' for contract award, which is unlike awarding a construction-only contract normally to the lowest bid.

While contractor selection for a D/B project becomes more complex and difficult for the owner, preparation of the required proposals and making the bid price decision are more demanding for the contractor. As a response to the owner's evaluation method, a D/B contractor's bid price decision should reflect not only the cost of the project but also the relative value of the firm's service, considering factors that are not present in bidding for construction-only projects. Although the competitors are fewer and the

[1] chaolc@ccms.nkfust.edu.tw

profit margin is likely to be higher as a result of the owner's use of prequalification for screening bidders and the high cost of bid preparation, the bid price of a hopeful contractor still needs to be competitive because only one will win the contract. In addition, because the design is not fully completed at the time of bidding, there are more uncertainties in the cost estimate, while an enlarged scope of contract entails more interfaces and design- and site-related problems to be self-handled, meaning a higher risk for the contractor. These are the reasons why bid price decision for a D/B project is more challenging than for a construction-only project and it is fair to say that considerations for the latter are a subset of those for the former.

The focus of the research reported below is on how much mark-up a contractor should apply in determination of the bid price for a D/B project when the firm has made a cost estimate based on its produced outline design deemed most appropriate for the project. It is difficult to achieve an optimum bid price decision under the complexities mentioned above by using experience and intuition alone. It would be helpful to apply quantitative analysis methods to dealing with the problem. Thus, the purpose of the research is to develop an objective-function-based model for determining the optimum mark-up for a D/B project. The results of a pilot study are presented in this paper.

BACKGROUND STUDY

Because of its importance in construction, the bidding problem has long attracted much research interest and many prescriptive bidding models can be found in the literature. However, few of them are oriented particularly towards the circumstances of D/B projects. For example, based on awarding a contract to the lowest bid, the probability model in Carr (1982) uses statistics of historical bid data for estimating the probability of winning for a given mark-up. The optimum mark-up is determined as the one with the maximum expected profit, where the expected profit for a mark-up is defined as the product of the probability of winning multiplied by the mark-up. Farid and Boyer (1985) proposed a present value model based on a contractor's cash flows analysis for a project and required rate of return to determine the minimum acceptable mark-up for bid price decision. These early models can be termed as academic since they do not include the various subjective and qualitative factors that contractors consider in making the bid decision.

Researches in recent years have turned towards developing models using multiple factors as inputs to reflect the many facets of the mark-up problem. For example, Dozzi *et al*. (1996) used 21 factors identified by Ahmad and Minkarah (1988) and grouped under environment, company and project as the criteria in a multi-attribute utility model. The utility of a project is obtained from the assessments of the factors that are translated by utility functions into utility measurements and the recommended mark-up is derived from the inverse relation between project utility and required mark-up. The neural network model by Moselhi *et al*. (1993) and the fuzzy neural network model by Liu and Ling (2005) are trained with collected data representing a number of bidding situations and the corresponding mark-ups to be applied. Chua and Li (2000) listed 51 factors and evaluated their effects based on a survey, based on which Chua *et al*. (2001) proposed a case-based reasoning model using the identified factors as case attributes. Though these multi-factor models offer various methods for obtaining an optimum mark-up, they do not particularly address D/B projects either.

Mochtar and Arditi (2001) investigated the role of marketing information in bid price decision and proposed pricing strategies using market-based approaches centred on marketing intelligence systems. However, even if there is enough information on market prices collected through efficient marketing systems, making the bid price decision still requires considering the uniqueness and complexities of an individual project. Although the cost estimate would still be the basis of a bid price, the nature of design and build procurement gives more room for product differentiation and hence allows it to be closer to value-based pricing, which is commonly used for products and services in other industries.

MODEL DESCRIPTION

The research requires an understanding of owners' methods for tender evaluation for D/B projects. Palaneeswaran and Kumaraswamy (2000) presented the findings of an investigation of the criteria and practices used by owners in many countries and listed a collection of formulas for combining the technical and price scores. It is obvious that the method used by the owner for tender evaluation influences the way of estimating the chance of winning for a given bid price for a D/B project and hence needs to be considered in the proposed bidding model. In addition, the previously mentioned considerations in bidding for a D/B project, i.e. service value, competition, and project risk, need to be addressed as well, as discussed in the following.

On the premise that profit represents a contractor's global goal in bidding for a project, the bid decision is to maximize the following objective function.

$$EV = P_w \times (r - \bar{c} / c) \qquad (1)$$

where EV = expected profit ratio; P_w = probability of winning; r = bid/cost ratio; $\bar{c}$ = mean project cost; c = estimated project cost.

In Equation 1, r is the decision variable and a bid b is simply the product of r multiplied by c, which includes all required direct costs and site and company overheads. The percentage mark-up of b is $(b – c)/c$ or $r – 1$. The optimum bid corresponds to the r achieving the highest EV. While P_w is a function of r, estimating P_w for a given r will have to take into account the firm's service value and the competition faced. The firm's service value is to be self-assessed within the framework of multi-dimensional analysis. The competition faced is influenced by current economic and market conditions as reflected by the statistics of recent winning bids for similar projects in the target market representing the prevailing bid level. The component of $\bar{c} / c$ relates to project risk and $r - \bar{c} / c$ represents the profit ratio after deducting the allowance for project risk, given that the firm wins the bid. More details on the above are given below.

A bidder's relative service value compared to a competitor can be assessed using the AHP (analytical hierarchy process) method, which is more convenient than the utility theory and has been applied to problems of multi-attribute evaluation in many fields, e.g. evaluation of advanced construction technology (Skibniewski and Chao 1992). Self-assessment using the AHP method is shown in an example here.

Assume that a contractor (the firm) is bidding for a building D/B project, for which the owner's evaluation criteria are: planning and land use (30%), quality of design and construction (40%), maintainability and serviceability (20%), and company's track records (10%). If the firm considers its offered planning and land use slightly better than that of a typical competitor in the target market, then, on a scale of 1 to 9 where 1 indicates parity and 9 indicates absolute superiority, a value of 2 is entered in the comparison matrix in Table 1, producing a principal eigenvector of [0.67, 0.33] as the result of assessment for this criterion. For the other three criteria, the comparison matrices and principal eigenvectors produced are shown in Tables 2 to 4.

Table 1: Self-assessment on planning and land use

Alternatives	Firm	Typical competitor A*
Firm	1	2
Typical competitor A*	1/2	1
Principal eigenvector	0.67	0.33

Table 2: Self-assessment on quality of design and construction

Alternatives	Firm	Typical competitor A*
Firm	1	1/2
Typical competitor A*	2	1
Principal eigenvector	0.33	0.67

Table 3: Self-assessment on maintainability and serviceability

Alternatives	Firm	Typical competitor A*
Firm	1	3
Typical competitor A*	1/3	1
Principal eigenvector	0.75	0.25

Table 4: Self-assessment on company's track records

Alternatives	Firm	Typical competitor A*
Firm	1	1/5
Typical competitor A*	5	1
Principal eigenvector	0.2	0.8

Aggregation of the comparison results in eigenvectors and the weight vector for the owner's evaluation criteria is accomplished by means of matrix multiplication as shown below, to obtain a self-assessment of the firm's service.

$$\begin{bmatrix} 0.67 & 0.33 & 0.75 & 0.20 \\ 0.33 & 0.67 & 0.25 & 0.80 \end{bmatrix} \times \begin{bmatrix} 0.30 \\ 0.40 \\ 0.20 \\ 0.10 \end{bmatrix} = \begin{bmatrix} 0.503 \\ 0.497 \end{bmatrix} \tag{2}$$

If a typical competitor's technical score is normalized as unity, then the firm's self-assessment of service for the D/B project can be reduced to v = 0.503/0.497 = 1.012, slightly better than the norm.

The competition faced for the project can be assessed by referring to the ratios of winning bid to estimated cost for recent similar projects in the same market. The lower the ratios are, the keener the likely competition would be, and the lower the chance of winning for a bid price will be. Together with the obtained self-assessment of the technical proposal and statistics of winning bids, the way of the owner's tender evaluation and the weight given to the price proposal will influence the assessment of the chance of winning for a given bid. A case of tender evaluation is given later to illustrate the quantification of the relation between P_w and r.

In Equation 1, c, the firm's estimated project cost, is produced by aggregating the most likely cost estimates for all items of work, whereas $\bar{c}$, the mean project cost, is obtained from the probability distribution for project cost using a probabilistic cost-estimating technique as an extension of the traditional deterministic estimation.

Because of the existence of many uncertainties in a D/B project relating to productivity, resource prices, design interfaces, etc., the distribution for item cost is usually skewed positively to the right, i.e. the mean cost for an item tends to be higher than the mode. As a result, $\bar{c}$ is usually greater than *c*, i.e. $\bar{c}/c > 1$, which is evidenced by the actual project cost often higher than the estimated project cost. The difference between $\bar{c}$ and *c* is the allowance for project risk in the bid mark-up, hence deducting the risk allowance from the mark-up gives the net profit in a bid, i.e. $b - c - (\bar{c} - c) = b - \bar{c}$ or, as a percentage of *c*, $(b - \bar{c})/c = r - \bar{c}/c$.

ILLUSTRATIVE CASE

The proposed bidding model is illustrated using a case of tender evaluation. The case is the common practice of public sector owners awarding a D/B contract to the lowest adjusted bid, where an adjusted bid, *b'*, is the bid price divided by the technical score, i.e. *b' = b/v*. Assume that for the example building project above the firm produces a cost estimate of *c* = \$35 220 000 based on its outline design. Addressing the various risks involved in the project, the firm obtains a probability distribution for project cost with $\bar{c}$ = \$35 684 000 and $\bar{c}/c$ =1.0132. Now the question is how much mark-up, or equivalently, what bid/cost ratio, should be applied in the bid price decision.

This case of tender evaluation is a variant of the traditional method of awarding a contract to the lowest bid normally used for construction-only jobs. However, because the bids received for a project that uses the traditional contract award method can be considered as having the same service value of *v* = 1, bid data for construction-only contracts, of which there are plenty, can still be referred to in estimating the probability of winning for a bid in the case. Meanwhile, the existing methods of estimation based on the statistics of bid/cost ratios should be adapted to fit the condition of contract award to the lowest adjusted bid that requires considering the effect of the technical score represented by *v*. For example, if for similar projects in the same market the ratio of the lowest opposing bid to the firm's estimated cost is found to be normally distributed with a mean of 1.03 and a standard deviation of 0.04, then with *v* = 1.012 the P_w for a given bid/cost ratio *r* is assessed as:

$$P_w = \int_{r/v}^{\infty} N(\mu, \sigma^2)dy = \int_{r/1.012}^{\infty} N(1.03, 0.04^2)dy \qquad (3)$$

where *N* refers to the normal distribution.

Table 5 shows the obtained probabilities of winning for various bid/cost ratios and the corresponding expected profit ratios from Equation 1. The maximum expected profit ratio is achieved at *r* = 1.055, thus the recommended bid price for the project according to the model is 1.055 × \$35 220 000 = \$37 157 100.

Table 5: Evaluation results for case project

Bid/cost ratio, *r*	Adjusted bid/cost ratio, *r/v*	Probability of winning, Pw	Expected profit ratio, EV
1.035	1.023	0.572	0.0125
1.040	1.028	0.523	0.0140
1.045	1.033	0.474	0.0151
1.050	1.038	0.425	0.0157
1.055	1.042	0.377	0.0158
1.060	1.047	0.332	0.0155
1.065	1.052	0.288	0.0149
1.070	1.057	0.247	0.0141
1.075	1.062	0.210	0.0130

CONCLUSIONS

Bidding for a D/B project has to respond to the owner's contractor selection method. The factors involved in pricing can be summarized in three main points, i.e. service value, competition and project risk, based on which a bidding model is proposed that maximizes an objective function measuring the expected profit of a bid. The critical part is estimating the probability of winning for a given mark-up level, for which the method will vary according to the owner's tender evaluation. Although the presented case of contract award to the lowest adjusted bid can be dealt with easily by using a modification of the existing estimating method, there are other formulas for tender evaluation that are more complex. Studies are currently underway in response to owners using different tender evaluations. In the future, the optimum bid determined by such models needs to be verified using real data. Currently, real D/B case projects are being collected for the purposes of testing and possible adaptation of the proposed model, i.e. an objective function for determining the optimum bid mark-up and the accompanying method for estimating the probability of winning for a given bid mark-up, and the results will be reported in a subsequent paper. It is hoped that with the assistance of a bidding model the more challenging bid decision for a D/B project can be made in a rational way to cope with the expanding D/B markets.

The competitive bidding system and qualification-based selection (QBS) system are two mainstreams of contractor selection today. However, most of the discussions relating to these two systems have concerned the project level viewpoint and little attention has been drawn to the long-range impacts of the contractor selection systems on contractors' competitive behaviour or on the whole construction industry from a holistic and system perspective. This paper broadly adopts the findings of previous research and explicitly depicts the causal relationships between different contractor selection systems and contractors' competitive behaviours to demonstrate (a) how a competitive bidding system generates economic benefit and encourages contractors to improve their capabilities; (b) how a competitive bidding system encourages contractors' opportunistic bidding behaviour which forms adverse cycles and hinders the development of the construction industry; and (c) how a QBS system can reduce the opportunistically abnormal low bids and lead contractors' competitive behaviour into positive paths. Several strategies including improving the construction management system, increasing the use of non-price criteria, and implementing prompt contractor performance rating systems are proposed to promote the project success.

Keywords: bidding, contracting, procurement, systems analysis, tendering.

INTRODUCTION

The contractor selection system is always the most important issue for the client in implementing a construction project. For decades, competitive bidding has been extensively used for almost all kinds of procurement worldwide. Governments utilize competitive bidding for its simplicity and fairness and expect to obtain economic benefit through price competition. However, abnormal low bids and consequently poor project quality have frequently occurred. The qualification-based selection (QBS) system has been considered as an alternative way to find competent contractors. However, most of these studies have concerned the project level viewpoint. To fill this gap, this study aims to analyse the long-range impacts caused by the change of contractor selection systems on contractors' competitive behaviour as well as on the whole construction industry from a holistic and system perspective.

SYSTEMS THINKING AND THE CAUSAL-LOOP DIAGRAM

Systems thinking has its foundation in the field of system dynamics, founded in 1956 by MIT professor Jay Forrester. The approach of systems thinking is fundamentally different from that of traditional forms of analysis. Traditional analysis focuses on separating the individual pieces of what is being studied. In contrast, systems thinking focuses on how the thing being studied interacts with the other constituents of the system. A causal loop diagram is a kind of systems thinking tool. The diagram aids in visualizing how interrelated variables affect one another. Complicated and correlated variables are integrated into a loop relationship, called a ‘feedback loop’. The feedback loops can be divided into two categories based on their effects: (a) the ‘reinforcing feedback loop’ which shows the effects of malign or benign cycles; (b) the ‘balancing feedback loop’ which symbolizes the tendency to maintain a goal.

REVIEW OF COMPETITIVE BIDDING SYSTEM

This section theoretically reviews the previous research and depicts the behaviour feedback loops generated from the use of the competitive bidding system. The feedback loops are classified into three groups: (a) the feedback loops generated from the price competition process; (b) the feedback loops generated from contractors’ cost reduction; and (c) the adverse feedback loops generated from contractors’ opportunistic bidding behaviour.

The feedback loops generated from the price competition process

There are two feedback loops generated from the process of price competition. One is a reinforcing feedback loop and another one is a balancing feedback loop as follows:

The reinforcing feedback loop, R1

The Bertrand competition model of economics proposed that, in a price competition environment, companies will assess and predict prices that their competitors may offer before they determine their own price (Carlton and Perloff 2000). Accordingly, the bidding prices of previous tenders (hereafter termed market price) are important references for bidders of subsequent tenders and have feedback relationships with contractors’ bidding prices as shown in Figure 1. The market price is an index changing with the recent award prices. The previous bidding prices sequentially affect contractors’ pricing in the subsequent tenders and form a reinforcing feedback loop, which allows project owners to obtain economic benefits, as R1 in Figure 1. The positive sign, ‘+’, indicates that a change in the causal variable (market price) will cause a change in the variable (bidding price) it is affecting in the same direction.

The balancing feedback loop, B1

Runeson and Raftery (1998) applied micro-economic theory to analyse the competitive market in the construction industry and proposed that price determination is based on the interaction of demand and supply. Ngai *et al*. (2002) proposed that the changes in demand and/or supply will change the level of competition and the tender price level. The level of competition is usually observed and measured through the number of competitors.

Previous studies have shown that a contractor’s bidding price will be affected by the number of competitors (Freidman 1956; Carr 1983). As the number of competitors increased, contractors’ bidding price decreased. This opposite relationship is represented by a negative sign, ‘–’, as shown in Figure 1. Furthermore, several studies have suggested that companies will leave or enter a market because of changes in profit level (Gruneberg and Ive 2000; Hillebrandt 2000; Runeson 2000). The findings clearly depict an identical causal relationship between market price and number of competitors.

According to the aforementioned, a balancing feedback loop, B1, is discovered. A higher market price will attract more competitors to join the bidding game, but in the meantime, these competitors need to steeply cut prices to win contracts in a fiercely competitive market. Consequently, the market price might drop down to a lower level and force some competitors to quit the market. This feedback process depicts a company’s behaviour in response to the supply and demand relationship until both the market price and the number of competitors are balanced.

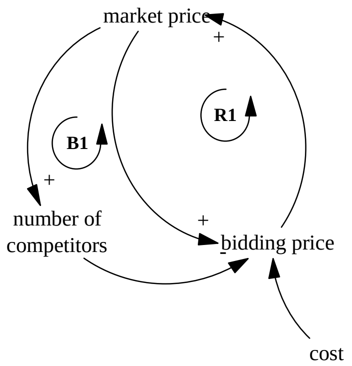

Figure 1: The price competition process

The feedback loops generated from contractors’ cost reductions

This section introduces how the competitive bidding system can encourage contractors to renovate technologies and management skills to reduce costs. Four feedback loops generated from contractors’ cost reductions are discussed as follows:

The reinforcing feedback loops, R2 and R3

Under the price competition system, contractors can win awards by reducing their expected profit and reducing costs. But when competition is intensified to a certain extent, eventually the market price will approach contractors’ costs. Gransberg and Ellicott (1996) proposed that the low-bid method implies that it selects the contractor with the most innovative, cost-effective solution to construct the facility. Thus, contractors have to face issues of innovation and cost reduction, so as to take awards and pursue continuous development. When contractors strive to reduce their costs and expand their market, contractors can have more opportunities to accumulate work experience and to invest in R&D. As a result, their technical and management skills will be improved, so as to reduce bidding prices and their market share will be further increased. Fu *et al.* (2003) have conducted a statistical analysis to corroborate this positive learning effect on contractor’s competitiveness. Two reinforcing feedback loops guiding contractors to continuous development are formed (see loops R2 and R3 in Figure 2).

The balancing feedback loops, B2 and B3

It is recognized that under the competitive bidding system, an owner may award a project to an abnormally low bid, because of cursory cost estimation (Capen *et al.* 1971). This situation can be avoided by improving contractors’ professionalism. From the system perspective, a competent contractor can continuously improve its technical and management skills through R2 and R3 reinforcing loops, so as to reduce the probability of underestimates and form the balancing loops, B2 and B3 (see Figure 3).

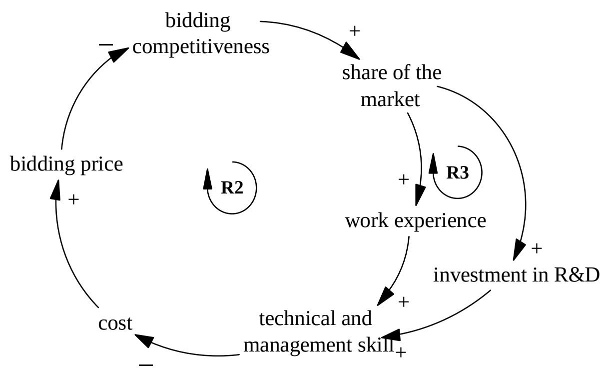

Figure 2: The feedback loops generated as a contractor improves his technical and management skills (a)

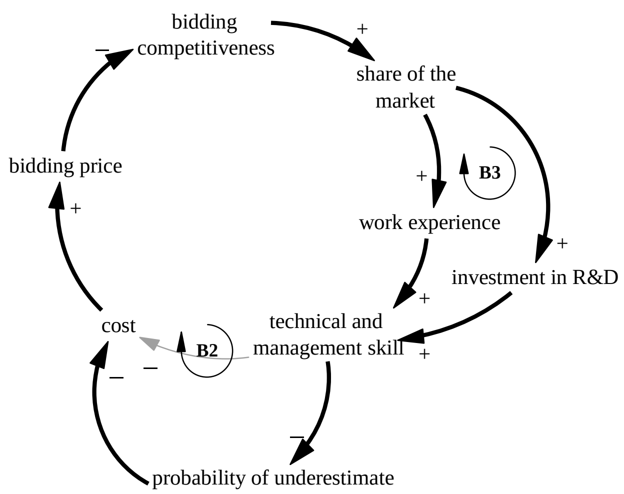

Figure 3: The feedback loops generated as a contractor improves his technical and management skills (b)

The adverse feedback loops

Under the competitive bidding system, contractors may win the bid by tendering an abnormally low bid, accidentally or deliberately (Grogan 1992). Previous studies have suggested that contractors will adopt some strategies to compensate for the deficit, such as cutting corners to lower costs (Winch 2000) and bringing up claims against the owner (Crowley and Hancher 1995a), when they begin the construction with an unfavourable contract price. Doyle and DeStephanis (1990) warned that certain bidders extensively review bid documents, noting mistakes, cataloguing ambiguities, and looking for future change orders or claims. These bidders can lower their bid prices with the knowledge that on subsequent change orders or claims they can recapture monies that were initially sacrificed for the award (Crowley and Hancher 1995b). Ho and Liu (2004) applied game theory to analyse contractors' bidding behaviour and concluded that contractors will lower the bid when they expect profits from claims. Rooke *et al.* (2004) introduced the concept of 'proactive claims' and 'reactive claims' and concluded that claims have been an important source of contractors' profits. Lo *et al.* (2007) considered the cost reductions through cutting corners and the compensations gained from claims as 'beyond-contractual reward' (BCR) and proposed that, when contractors have an expectation to gain BCR, they will opportunistically cut the bid price to take more market share. Based on the aforementioned evidence, six adverse reinforcing feedback loops hidden within the competitive bidding system are discovered as follows:

The reinforcing feedback loops, R4 and R5

Opportunism is one of the most important behavioural assumptions in economic theories. It says that companies always want more of what they like, and this may imply that interests are pursued in an opportunistic fashion (Williamson 1985). Thus, it is reasonable to assume that, when contractors have experienced obtaining BCR in the past, they tend to repeatedly cut corners and raise claims in order to gain the maximum profit, whether the award price is reasonable or not. The reinforcing feedback loops, R4 and R5, are thus formed as shown in Figure 4.

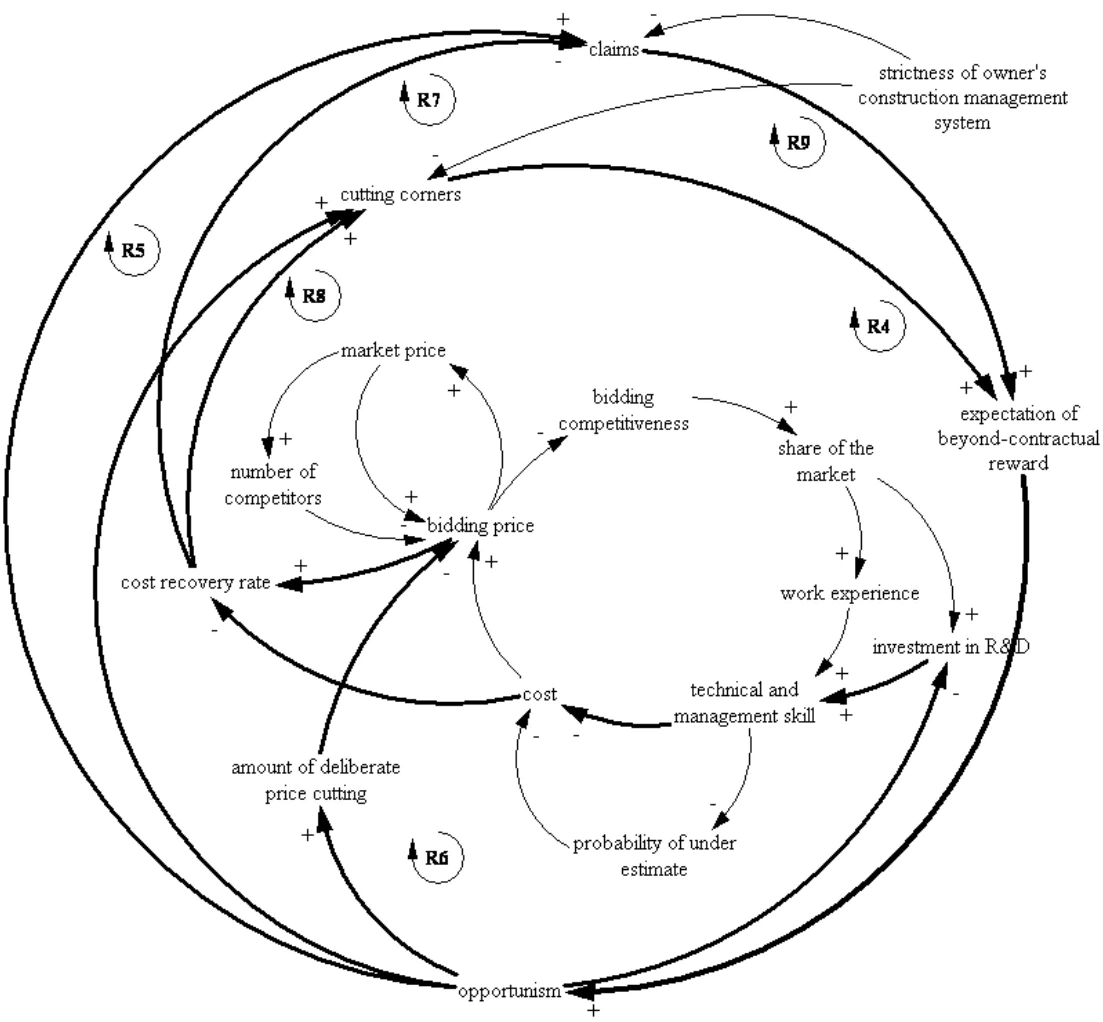

Figure 4: Contractors' opportunistic behaviour under competitive bidding system

The reinforcing feedback loops, R6 and R7

There are two other reinforcing loops with adverse effects shown in Figure 4 as R6 and R7. When a contractor deliberately cuts a price, the cost recovery rate will decrease, making the contractor need to cut corners and raise claims in the project execution phase for survival. After a period of time and with accumulated experience, the contractor may have confident expectations of BCR and offer lower prices for future projects. This reinforcing feedback process will constantly intensify contractors' opportunism and adverse effects.

The reinforcing feedback loops, R8 and R9
Rooke *et al*. (2004) proposed that opportunistic contractors tend to expend more effort on generating profit from claims than from improved construction methods. Accordingly, it is logical to infer that opportunism will discourage contractors' willingness to improve their capabilities, especially when the award price is unreasonably low and most contractors survive upon BCR. The phenomenon is described as reinforcing feedback loops as R8 and R9.

This section introduces six adverse reinforcing feedback loops hidden within the competitive bidding system. Lo *et al*. (2007) have studied this unintended situation called contractors' opportunistic bidding behaviour and analysed its effects on the construction industry through simulation. That paper concluded that opportunistic bidding can seriously damage the ideal functions of the competitive bidding system. In other words, the R1, R2, R3, B1, B2 and B3 can stagnate. Contractors' opportunistic bidding behaviour thus becomes the critical cause of abnormally low bids, poor project quality, and the failure of the competitive bidding system.

CURRENT PRACTICES TO AVOID ABNORMAL LOW-BIDS

Incorporating a pre-qualification procedure into competitive bidding system
In most countries, a selective procedure called a 'pre-qualification' (PQ) is employed to screen out those contractors having low capabilities; the remaining bidders are then evaluated for further consideration (Topcu 2004). Through the PQ procedure, the abnormally low bids should be minimized (Ng and Skitmore 1999).

It seems reasonable to expect that high PQ requirements will result in a competent contractor and consequently deliver a quality product in a timely manner and within budget. However, Lo *et al*. (1999) proposed that improper high PQ requirements can increase (a) the owner's project expenditure because of lack of competition; and (b) the administration cost because of unsuccessful tendering. From a system perspective, the use of PQ may raise a contractor's bidding price, owing to less competition. This may increase a contractor's cost recovery rate and reduce the contractor's BCR seeking behaviour for the deficits, so loops R6–R9 may be remedied. However, there is no guarantee that the pre-qualified contractor will not seek to obtain BCR. Since BCR seeking is the natural behaviour of a profit-maximizing organization, loops R4 and R5 are not resolved by the PQ strategy.

Screening the likely abnormally low bids
Previous studies have developed sophisticated decision models to reject or accept the lowest project bid depending on whether or not the lowest bid price is considered reasonable (Crowley and Hancher 1995a; Crowley and Hancher 1995b; Crowley 1997; Hiyassat 2001). Wang *et al*. (2004) have proposed another method for evaluating competitive bids. A predetermined project ceiling price is used as a threshold or reference point for accepting or rejecting bids (Wang *et al.* 2006).

Assume that the project owners are capable of detecting and screening out all abnormally low bids. So there is no concern about a contractor's accidental underestimate or deliberate price cutting and the cost recovery rate is enhanced. From a system perspective, however, these efforts only remedy the adverse effects of loops R6–R9 aforementioned in Figure 4. The loops R4 and R5, which are caused by the contractor's opportunism, are still an unsolved problem.

EFFECTS OF QBS SYSTEM ON CONTRACTORS' BEHAVIOUR

Compared with the competitive bidding system, the QBS system is designed to find qualified and competent contractors instead of lowest bidders. Besides price, non-price criteria, such as the contractor's past performance, work experience, technical and management skills, etc., are adopted in the contractor selection process. QBS is also recognized as a 'best value' selection system, while some studies distinguish best value selection and the QBS system on whether the price is included or not in the selection criteria (Beard *et al.* 2001; Wardani *et al.* 2006). From a system perspective, the QBS will lead contractors to form seven additional feedback loops as follows:

The reinforcing feedback loops, R1b–R3b

The inclusion of non-price criteria generates reinforcing loops that lead contractors to increase competitiveness and expand their businesses in a positive way. An experienced contractor can gain more competitiveness in the selection phase and consequently obtain more share of the market and more work experience, as loop R1b shows in Figure 5. In addition, QBS usually requires contractors to submit a technical proposal and brief on how projects are planned and what construction methods and materials are chosen. Contractors can create their competitiveness through innovative designs, materials and construction methods, so as to raise the project quality and better satisfy owners' need (Yan *et al.* 2005). Accordingly, reputable contractors with better technical and management skills will be able to prepare quality proposals and win contracts. Consequently, they have more chances to further improve technical and management skills through execution of works and R&D. These positive reinforcing feedback loops are marked as R2b and R3b in Figure 5.

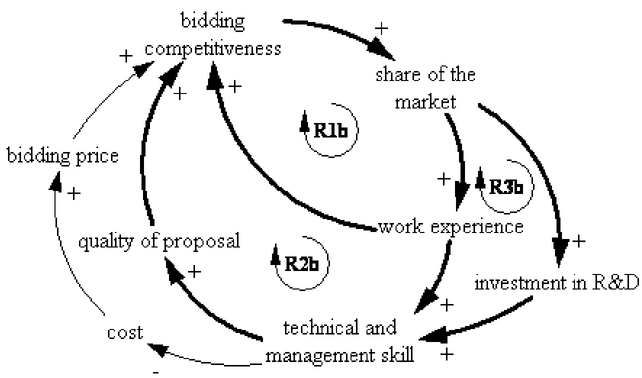

Figure 5: The feedback loops of contractor's behaviour under QBS (a)

The reinforcing feedback loops, R4b–R7b

An exceptional advantage of the QBS system is its capability to deal with opportunistic bidding. Once a contractor's past performance becomes an important criterion to evaluate a contractor's qualification, contractors are forced to minimize corner-cutting behaviour and claims, so as to improve their performance record and competitiveness. This behavioural tendency forms some reinforcing feedback loops: R4b, R5b, R6b and R7b, which provide contractors with an incentive to respect their performance in the construction phase (see Figure 6). With the functions of loops R4b, R5b, R6b and R7b, an opportunistic contractor who tends to obtain BCR will face the loss of competitiveness owing to unfavourable performance record. Since the weighting criteria evaluation method is usually used to select the contractor, the effects of reducing opportunistic bidding can be significantly enhanced as the project owner puts more weight on evaluating a contractor's past performance.

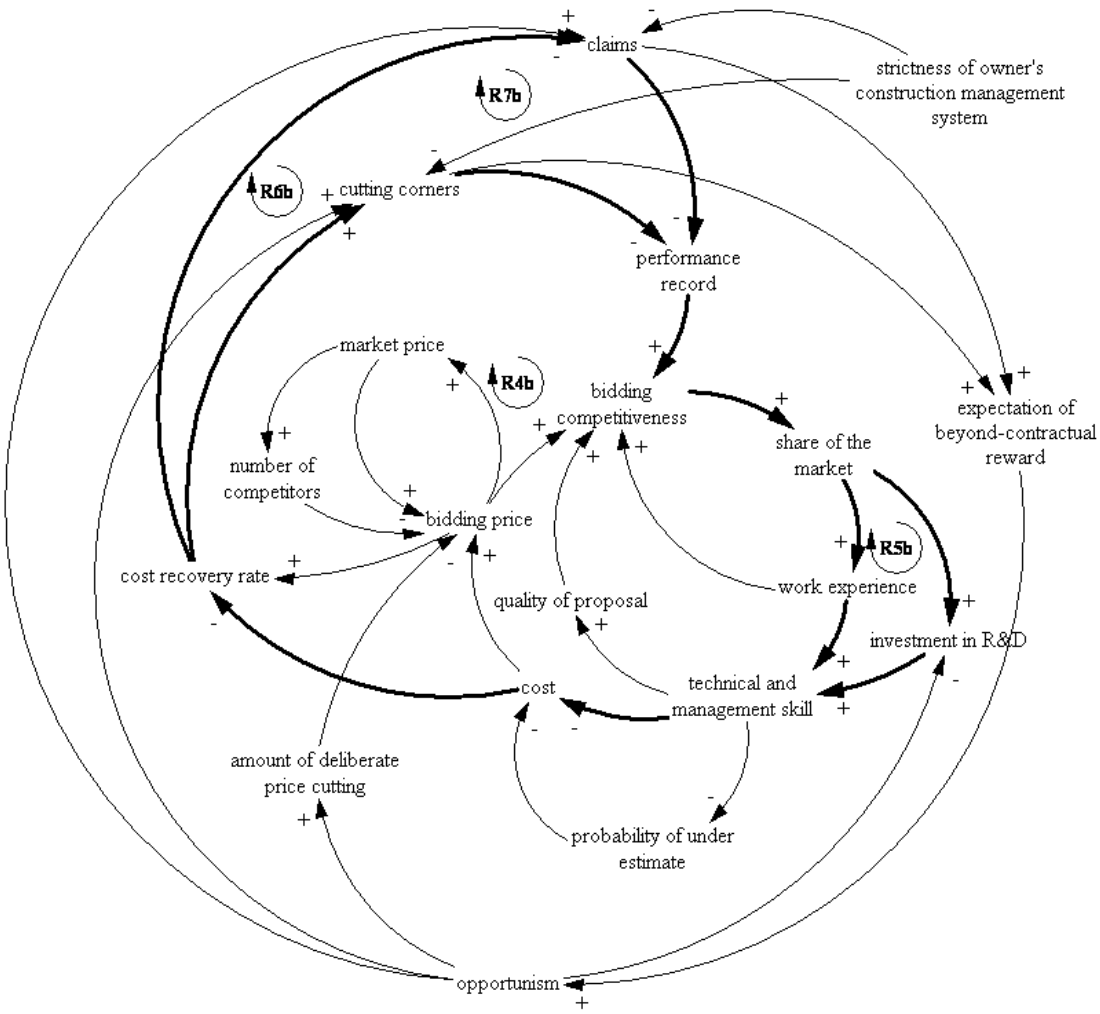

Figure 6: The feedback loops of contractors' behaviour under QBS (b)

STRATEGIES FOR PROJECT OWNERS

According to the systematic analysis of contractors' behaviour, this research derives several strategies for project owners to promote project success.

1. Improving the construction management system. Previous research has indicated that the key motivation in contractors' opportunistic bidding is the potential BCR in the current construction management system (Lo *et al*. 2007). Since contractors' expectation of BCR can intensify their opportunism, reducing the possibility and amount of BCR should always be the most important task for project owners. The owners must put more efforts into improving their construction management system, including the soundness of contracts and strictness of construction supervision. From a system perspective, once the strictness of owners' construction management system is improved, adverse loops R4–R8 may become obsolete.

2. Increasing the importance of non-price criteria in the selection process. The use of non-price criteria has been demonstrated to increase the competitiveness of the non-opportunistic and competent contractors. The owners are encouraged to use more non-price criteria in the selection process. Some useful criteria should include the contractor's past performance, financial capability, work experience, quality of key personnel and technical proposals. Besides,

the owners need to weigh those non-price criteria more so as to enhance the effects of QBS. The benefits of this strategy are interpreted in the aforementioned causal loop diagrams as loops R2–R3 and R1b–R3b.

3. Implementing prompt contractor performance rating systems. It should be noted here that the inclusion of the contractor's past performance has exceptional usefulness in reducing the contractor's willingness to sacrifice project quality and raise claims. The function is demonstrated as loops R4b–R7b. To make those loops more effective, the owners need an objective and sensitive performance rating system. Several researchers are working on this line of research such as contractors' performance prediction (Alarcon and Mourgues 2002), contractor's quality performance assessing model (Yasamis *et al.* 2002), and quality-based contractor rating model (Minchin *et al.* 2005).

CONCLUSIONS

The competitive bidding system and QBS are two mainstreams of contractor selection today. It is worthwhile to comprehensively study the impacts of these two systems on contractors' behaviour and the development of the construction industry. However, too often we have investigated these two systems on the 'events level'. This 'events cause events' orientation doesn't lead to very powerful ways to understand the evolution of contractors' behaviour or alter undesirable situations. With a systems thinking approach, this research takes an alternative viewpoint that the internal structure of the system is often more important than external events in generating the problem. Therefore, instead of showing how one set of events causes a problem, this research focuses on discovering a long-term pattern of contractors' behaviour in the construction market. This paper explicitly depicts the causal relationships between the use of different contractor selection systems and contractors' competitive behaviour. Several important feedback loops of contractors' behaviour are discovered and analysed. Through the understanding of the whole system of contractors' behaviour, project owners' managerial policies can be evaluated and improved.

ICT IN CONSTRUCTION ENGINEERING AND MANAGEMENT: POTENTIAL AND PROMISES

Irtishad Ahmad[1] and Maung Sein[2]

[1]*Department of Construction Management, Florida International University, Miami, Florida, USA*
[2]*Department of Information Systems, Agder University College, 4604 Kristiansand, Norway*

While the construction engineering and management (CEM) community has embraced information and communication technology (ICT), the interest in both practice and academia has been less than thorough. In particular, the academic community is criticized for not addressing the importance of ICT adequately either in research or teaching. This paper reports the results of two surveys, one dealing with the teaching mission of academia and the other with its research mission. The results are not comforting as they confirm the lack of attention paid to ICT. In discussing these findings, suggestions are made for affectively incorporating ICT into the academic milieu of CEM.

Keywords: information management, information technology, construction education, action research, construction organizations.

INTRODUCTION

In today's competitive environment, construction engineering (CE) and construction management (CM) organizations are increasingly dependent on information and communications technology (ICT). This dependence is not only to stay competitive using the latest technology but also to innovate and create new ideas. The function of academia should therefore be two fold: First, it should create knowledge on the use of ICT in CEM by conducting rigorous and relevant research and informing practice. Second, it should propagate this knowledge through educating the future practitioners by incorporating ICT into curricula to meet the growing need for professionals who are competent in ICT.

There is also a seeming lack of conceptual clarity on the role of ICT in CEM. In published articles, for instance, ICT is viewed simply as a tool to automate the construction and management processes. Its transformational potential is not dealt with. Ahmad *et al*. (1995) noted that design and construction organizations can achieve integration of various construction activities by redesigning many of their organizational functions and processes and IT can facilitate redesigning of these processes. Far-reaching impacts of ICT on construction organizations in transforming and re-designing organizational structures, management processes, individual roles and business strategy are seldom covered in the published literature.

In this paper, an attempt is made to sort through these issues by surveying graduate curriculum around the world and then sampling the papers published in leading CEM journals over a decade. The results are then discussed in the light of the potential of

[1] ahmadi@fiu.edu

ICT in helping CEM to innovate and radically change the construction management processes. Specific suggestions are made in this direction.

THE SURVEYS

ICT in CEM curriculum

In this survey, the graduate curriculum and individual courses of 118 universities were examined to assess the degree to which ICT was addressed. Of the total number of universities surveyed, 66 were from North America (56 from US), 23 from Europe (20 from UK), 19 from Asia (six from China and five from Japan) and 10 from other areas (eight from Australia). The curriculum information for the graduate level courses was obtained through the website of the universities. The detailed course descriptions and the specific topics covered in these courses were examined. The departments surveyed were those that were related to construction in some form or other. Examples include civil engineering, construction management and, building science. The full details of the findings are reported elsewhere (Ahmad *et al*. 2006). The following is a summary of the findings of the survey:

- ICT is a small part of the curriculum in CM and CE:
  - 45% of universities do not offer any ICT-related course.
- The most common topics in the courses include:
  - Computer-aided engineering (CAE). Examples are “Computer Applications in Structure”, “Computer Methods in Transportation” or “Computer Applications in Construction Engineering”.
  - Visualization, simulation and modeling (VSM) includes different construction processes like transportation modeling, traffic simulation and virtual design.
  - Human-oriented courses: artificial intelligence, knowledge-based expert systems, decision support system, fuzzy logic applications.
  - Use of Geographic Information Systems applications.
  - General content such as information technology for construction, computers in construction, construction information.
- Popular and current topics such as e-business and web-based applications are not commonly offered.
- When covered, focus is purely functional (e.g. introduction to tools):
  - They aim to provide ICT-based solutions for general engineering problems rather then being construction-industry oriented.
- Vital aspects that are ignored include:
  - Organizational and process change.
  - Impacts of ICT on the industry, its organizations and the fundamental issues of construction.

The conclusion that can be drawn is that CE and CM institutions are more interested in introducing the concept of a tool and its practical implementation rather than providing in-depth conceptual understanding. While it is difficult to incorporate in-depth technical education on ICT in a typical CEM curricula the argument can be made that the current extent of coverage is not adequate and is unproductive. It does not lead to thinking about innovative use of ICT and the realization of the potential of ICT for CEM.

ICT in CEM journals

In this survey, all articles published during the time period 1996–2006 in five leading journals in construction were examined to find out how many of them were ICT related. This information was collected by conducting keyword search electronically using "information technology" as the keywords, except for the *ASCE Journal of Computing in Civil Engineering*. (It was found that the list of designated keywords of these journals does not include "information and communication technology," as used in this paper, but "information technology".) It should be noted that the results of the search depended on whether the keywords "information technology" were chosen by the author(s) to describe their papers. It is quite possible that several -elated articles were not included in the electronic count reported in this paper, because "information technology" was not included in the list of keywords of those papers. However, the number of such papers is not very high, except for the *ASCE Journal of Computing in Civil Engineering*. The initial count of ICT-related articles published in this journal was unrealistically low (around 5%). To delve deeper, the titles and abstracts of the articles were examined. As a result, the percentage rose to just under 19%. It is quite possible that authors of these articles opted for more appropriate and relevant keywords related to computing or computer applications rather than "information technology" since there is a maximum limit on the number of keywords that can be used for a paper. The findings, shown in Table 1, reveals that only about 5.24% of all articles published in these five leading journals are ICT related.

Table 1: ICT-related journal articles in leading construction journals during the last decade (1996–2006)

Journal title	Total number of articles published	Number of IT-related articles	Percentage of IT-related articles
Journal of Construction Engineering and Management (ASCE)	854	18	2.11%
Journal of Management in Engineering (ASCE)	286	4	1.40%
Journal of Computing in Civil Engineering (ASCE)	353	67	18.98%
Automation in Construction (Elsevier)	606	49	8.09%
Construction Management and Economics (Routledge)	688	8	1.16%
Total	2787	146	5.24%

The conclusion is clear. There are very few ICT-related papers published in the mainstream construction journals. A quick scanning of the titles of these articles substantiates the earlier contention in this paper that most of these papers and research works describe or present a tool or a process rather than the role of ICT in transforming or revolutionizing the process or the organization.

In addition to the journals mentioned above, a journal titled ITCon or Information Technology in Construction debuted in 1995. The publisher was the Royal Institute of Technology (Sweden). ITCon in 2005 combined with IT-AEC journal and since then is being published by the International Council for Research and Innovation in Building and Construction (CIB). The nature of the articles published in this journal (www.itcon.org) is not much different from the most ICT-related papers published in the journals discussed above.

DISCUSSION OF FINDINGS

Taken together, the findings of the two studies suggest that the potential to utilize ICT to bring about fundamental changes in the construction industry remains unrealized. This is disappointing. The challenges facing the academia in CEM are:

- How can ICT and CM/CE be integrated in the course curriculum in colleges and universities?
- How can research be conducted and the results disseminated to both academia and practice on the potential of ACT in altering the practice of CM and CE and do away with archaic rules and regulations?

In the following, these questions are examined in detail.

Potential for ICT in CM

ICT can contribute to CEM discourse at different levels. In the Information Systems literature, it is said that ICT enables one to (a) do things better and (b) do better things. The first is related to increasing efficiency and effectiveness of existing processes in an organization or an industry. The second addresses the basic aspects of these processes and looks at making revolutionary changes by employing innovative processes. These two potentials are discussed below.

Doing things better

In this context, ICT is conceptualized as a tool and a means to support existing processes. There have been some previous attempts in the CEM literature to study this aspect of the role of ICT. Ahmad *et al*. (1995) proposed that the capabilities needed in CEM could be grouped as follows:

- Communications systems – tools or techniques that support project or organizational communication and collaboration like networking and e-business.
- Data accessibility – systems focusing on data capturing, storage, retrieving and transmitting.
- Common systems – systems used for decision making and technical analysis.

In construction, communications or exchange of information is one of the most important functions. The success of this function depends to a large extent on the quality and accessibility of data, as well as on the efficiency and effectiveness of the systems designed to process data. These are basically automation tools and can contribute to increased efficiency. In other words, tasks performed by manual methods if delegated to computer-assisted environments can improve efficiency, particularly in the area of information processing. They do not necessarily enhance effectiveness of the organization.

Doing better things
Here the focus is on the potential of ICT in re-engineering CEM practices. The question addressed is “Can ICT help us examine ways of altering the practice of CEM and do away with archaic rules and regulations?”

This issue has been extensively treated in the management and business literature during the last few decades in the form of business process reengineering (BPR). First popularized in the 1980s by pioneers such as Davenport and Hammer (e.g. Davenport 1993; Hammer and Champy 1993), the essence of BPR is that basic processes and practices in business organizations can be radically changed to increase effectiveness of the organization. These processes can even be totally deleted to be replaced by new processes. The enabler for such re-engineering processes is ICT.

A similar approach can be taken in CEM. Rules and regulations to govern the relationships and contractual obligations of the various entities (owner, contractor, engineer, etc.) have existed for years and continue today. It is time to question whether these practices are still necessary today. Can ICT contribute to changing these rules?

To illustrate, the practice of awarding contracts on the basis of low bids can be considered. The practice is based on the assumption that awarding contracts to the lowest bidder ensures fairness and promotes innovation while keeping the cost to a reasonably low level. The practice implies that the scope of the project is fully defined and hence, the design, drawings and specifications can be fully developed before the project is let out for bidding. This is known as design-bid-build process in which the functions of design and construction are kept separate. The contractor is hired after the design is completed. Project scopes, however, are rarely developed to their fullest extent before bidding. Change orders are inevitable as the owner and the designers usually continue to make changes even after the contract is finalized. The final cost of the project frequently exceeds the contracted price (lowest bid). Now it is a generally accepted notion in the US construction industry that the principle of awarding contracts on the basis of low bids failed to produce its intended results. In the US, even the government sectors that normally adhere to this practice, are increasingly switching to the design-build principle. Under this process, both design and construction are typically carried out by the same entity. The design function does not have to be completed before construction can begin, input from the construction people can be incorporated in the design, and usually coordination between the two (design and construction) functions is greatly improved. It should be noted that under this practice both the designer and the contractor are sharing the project risk, not just the contractors as in the case of design-bid-build principle. The practice of design-build principle can be enhanced by effective use of ICT. An effective and meaningful integration between the two major functions – design and construction – can be achieved by utilizing ICT. In order to achieve meaningful advantages offered by ICT, however, the industry norms and traditions, such as the reliance on design-bid-build principle, must be scrutinized critically. Only then can the real advantage offered by ICT be realized. In this case, ICT plays the role of the enabler for a major paradigm shift from design-bid-build to design-build.

Another fundamental aspect that ICT has the potential to alter is the perspective of the construction project team. Essentially, a project team is a temporary virtual organization (Ahmed and Sein 1997). A variety of organizations and businesses combine to form a project organization whose specific and perhaps only objective is to complete the construction project. The team then disbands. However, even though this team has a relatively short life, it has all the characteristics of an organization. It is a form of "extended enterprise" (Benbasat and DeSanctis 2000). Thus, much can be learned from research on organization theory. The IS literature has a long tradition of examining the role of ICT in effecting organizational structure, form and governance.

Based on the economic theory of organizations, three forms are popular: markets, hierarchy and networks. Traditionally, construction teams are based on markets. Each party, such as a subcontractor independently buy and sell services to other subcontractor or the main contractor on the basis of economic self-interest. These are enforced by legal instruments. However, since all contingencies cannot be covered in a contract, disputes frequently occur. Moreover, as Jarvenpaa *et al*. (2000) point out, it is not a good mechanism for transfer of learning and is susceptible to opportunism by a contractual partner.

A more suitable form for a construction team is a network organization. This is a flexible form and is based on the premise of equality, communication, reciprocity and fair exchange (Jarvenpaa *et al*. 2000). It is also a better form than market for exchange of services whose prices are not easily measured or foreseen, such as in construction. Perhaps the main advantage of a network form is its flexibility. A specific form of networks, especially germane to construction is "production networks" (Powell 1991) where temporary teams are formed for very specific purposes rapidly and then disbanded.

The glue that holds a network organization is building relationships. ICT can play a vital role in this. There is a requirement for common systems that span these diverse partners. Today's technology is teeming with such systems or platforms. Internet technology can be used to ease transfer of information and even data through use of say, XML. Mobile and hand-held devices provide easy ways of accessing common databases and communication.

In essence then, it is not the technology that is missing here; it is the social and human aspects that can be seen as a barrier in exploiting the opportunities offered by ICT. As an example, the concept of virtual organizations, introduced earlier, is dependent on trust. The team participants in a construction project must trust each other and must share the same objectives for the virtual project teams to work effectively. They must be able to overcome the barrier of time and distance by ICT. ICT here satisfies the necessary condition, but is not sufficient. It is not the perfection of technology that can make the concept of virtual teams work perfectly, but the presence of human aspects, such as trust and understanding.

The construction industry is coming to the realization, albeit slowly, that ICT – if viewed as disparate tools – cannot be used effectively (Sawyer 2007). The organizational structures need to be aligned to fit with the ICT infrastructure. Azhar's (2005) research on data warehousing demonstrates that organizational units must be restructured for effective implementation of data warehousing. Thus, it is imperative to understand that ICT cannot be installed in organizations without considering its impacts on interactions among organizational units and on the people working in these units.

These questions have also been addressed by a handful of scholars in construction. For example, Ahmad *et al*. (1995) pointed out three broad areas where construction organizations can focus in order "to do better things". They are:

- Re-engineering (same as BPR, mentioned earlier) – for example, redesigning organizational structure for effective deployment of ICT infrastructure.
- Decentralization of the power of decision making – for example, empowering the middle management with decision making authorities by providing necessary information in a timely manner through ICT.
- Development of integrated information processing systems – for example, sharing of same site data by multiple contractors from an integrated source of information.

Discussion

The twin challenges facing the academia in CEM is to improve the educational offerings related to coverage of ICT and to improve research efforts in this topic. In the following, these two aspects are discussed further.

To improve education

Obviously, the current state-of-affairs in terms of ICT in CEM education needs improvement. To that extent, the following suggestions are made.

- Strengthen existing courses to cover all ICT capabilities and higher knowledge levels.
- Develop new courses, both mandatory and elective, on ICT and construction.
- Develop tracks concentrating on ICT in current CM and CE programmes.
- Develop specialized graduate programmes on ICT in construction.
- Develop industry-wide model curricula that universities can use.

Some initiatives have already been taken or suggested. The curriculum survey reported earlier found some noteworthy course offerings on e-business related areas. For example, Massachusetts Institute of Technology in USA has a course on e-commerce and internet applications in real estate. Carnegie Mellon University, also of USA, has courses on “e-construction” dealing with such subjects as the current status of e-business applications and business models and designing/building Internet-enabled e-construction processes and systems. Ahmad et al. (2006) proposed a course on Data Warehousing for Construction Management that covers not only the ICT capabilities needed in CM, but also knowledge at levels above tools (addressing not only “what?” But also “how?” and “why?”).

To improve research

A key challenge is motivating CEM researchers to carry out research on the role of ICT in CEM. Academics, as any other group, respond to reward system, whether in tangible or intangible form, and have extrinsic or intrinsic motivation. Both aspects are tied up to a great extent on publications. Publication is a key, if not the most important, criterion for tangible and extrinsic rewards such as promotion. They also serve intrinsic motivation and as intangible reward by providing the satisfaction of contributing to the body of knowledge in CEM and, in doing so, gain renown and respect of peers. The onus is therefore on the current “mainstream” CM literature to set a platform for this stream of research. Such is not the case currently, as revealed by the survey reported in this paper.

Chief Editors of prestigious journals in the field, such as the celebrant *Construction Management and Economics*, can encourage submissions on the topic. Special issues on different aspects of ICT can be published. On a more permanent basis, there can be sections on ICT related topics in every issue. Finally, appointing researchers with ICT background to editorial boards can be a motivating factor.

In addition, it appears that there is a widening gap in the way ICT is perceived for application between the practitioners and academia. This issue involves the classical challenge of transferring research results into practice. CEM is in an enviable position of close collaboration between academia and practice. A vast number of academics are also practitioners through consultancy work. The irony is that such academics tend to move away from research. This is disappointing because a research method exists that seems tailor made for CEM. That is action research where the emphasis is on practical problem solving and knowledge creation at the same time. The essence of action research is captured in this definition:

> "Action research simultaneously assists in practical problem-solving and expands scientific knowledge, as well as enhances the competencies of the respective actors, being performed collaboratively in an immediate situation using data feedback in a cyclical process aiming at an increased understanding of change processes in social systems and undertaken within a mutually acceptable ethical framework." (Hult and Lennung 1980)

Thus, action research is building/testing theory within context of solving an immediate practical problem in real setting. It combines theory and practice, researchers and practitioners, and intervention and reflection. Collaboration with practitioners and their learning is vital. It is emphasized strongly that action research is not consulting: it is action, but still research. In essence, it is "research in action."

The IS academic community, stung by long standing criticism about the lack of relevance of research for practice, recently concluded that there is a need to adopt research methods that are "proactive" in nature (Cole *et al*. 2005). Such methods aim at first changing reality and then studying its effects. This is in stark contrast to "reactive" methods that focus on the existing reality (such as surveys and qualitative interpretive case studies). The two methods identified as proactive are design research and action research (Figueiredo and Cunha 2007; Cole *et al*. 2005). Design research is of course what the CEM community does. It is proposed here that the community adopt action research as well.

One can immediately see why action research is perfect for CEM. The close ties between academia and practice and through "practicing academics", the groundwork for mutual informing already exists. All that is needed is to conceptualize all consultancy work as potential action research projects. To that end, this methodology can be taught at the graduate level and workshops and seminars can be arranged at conferences. One conference that has already started these workshops is CITC (Construction in the Twenty-first Century).

CONCLUSIONS

The main message in this paper is that the field of construction is in danger of missing out on the transformational capabilities of ICT. Simply viewing ICT as a tool to support processes in construction is underutilizing the vast potential of this revolutionary technology. Innovative ideas and implementations already exist but these are fragmented and isolated instances. It is essential that these efforts be integrated and become part of the general body of knowledge in construction. This paper is a step in that direction.

A MATRIX FOR SELECTING APPROPRIATE RISK MANAGEMENT TECHNIQUES IN THE BUILT ENVIRONMENT

Doug Forbes[1], Simon Smith[2] and Malcolm Horner[1]

[1]*CMRU, Division of Civil Engineering, University of Dundee, DD1 4HN, UK*
[2]*Institute for Infrastructure and the Environment, School of Engineering, University of Edinburgh, UK*

Within the built environment, there is a discontinuity between risk management techniques used in practice and those developed and researched in academia. Organizations commonly apply a few selected techniques to a range of problems. This could be because of a lack of knowledge and understanding of when a technique can be appropriately used. To overcome this, a risk management matrix is proposed whose purpose is to provide guidance on which technique is appropriate in which context. This characterizes problems by: (1) external and internal risks – defined by a PESTLE Model; (2) the risk owner; and (3) the project stage. A second stage is used to define the data used as fuzzy, incomplete or random. The two-dimensional matrix has been developed from 179 example applications of techniques in the literature. The matrix highlights a focus on techniques for economic issues. It also identifies a lack of examples of techniques applied to political, social, legal and technological risks. The matrix is an effective tool for selecting the appropriate techniques in risk management, but gives no indication of frequency with which techniques have been applied previously. It also highlights further gaps in the current techniques and provides avenues for focusing future research.

Keywords: decision support, risk techniques.

INTRODUCTION

The objective of this work is to create a support tool for selecting appropriate risk management techniques. The construction industry is subject to many risks (Perry and Hayes 1985; Flanagan and Norman 1993) and a wide range of available techniques is identified in the literature. However, very few of these are used in practice. One reason for this could be that there is a lack of knowledge and understanding of when a technique can be applied. To overcome this, a matrix is developed from examples in the literature.

The development of the matrix relies on a common framework to identify problems. This research uses the PESTLE (political, economic, social, technological, legal and environmental) model, which has been previously applied to risk management (HM Treasury 2004), and the FIR (fuzziness, incompleteness and randomness) model from construction systems (Blockley and Godfrey 2000) to create problem characteristics.

[1] d.r.forbes@dundee.ac.uk

RISK MANAGEMENT BACKGROUND

Definitions used in risk management

The construction risk management literature has varied terms for risk management. Definitions have been produced for this research that allow rigour and consistency. Risk can be defined as exposure to a decision that has an uncertain outcome. The outcome and consequence may be favourable or adverse. This definition incorporates the three elements which are considered in risk: (1) likelihood of an event occurring; (2) outcome of an event and (3) duration of an event (Jaafari 2001; Kaplan *et al.* 2001; Hillson 2002; Pate-Cornell 2002; HM Treasury 2004).

The research is concerned with risk management techniques. These techniques are applied at first three stages of the risk management cycle: identification, estimation (analysis stage I) and evaluation (analysis stage II) (Perry and Hayes 1985; Flanagan and Norman 1993; Baker *et al.* 1999). The response and monitoring stages are not considered here, as specific techniques are not applied.

The three stages are defined as: (i) identification is the process by which risks are recognized and recorded; (ii) estimation assessed the magnitude of the risk; and, finally, (iii) evaluation is the process of calculating and defining the combined risk attributes.

Use of risk management techniques

A study carried out by Akintoye and Macleod (1997) reviewed the risk management techniques used in practice by contractors and project management practices. This concluded that the usage rates were very low for all but a few techniques. They found that 77% of contractors and 100% of project management practices used intuition and experienced-based techniques. Subjective probability, Monte Carlo Simulation and sensitivity analysis were used to a limited extent. More ‘complex’ techniques were seldom used, and some were even unknown by the respondents (e.g. Stochastic Dominance). The authors give eight reasons for the lack of use. Most of these relate to a lack of confidence in the techniques, and or their lack of applicability to construction. Similar results were obtained from an Australian study by Bajaj *et al.* (1997) for identification techniques.

These findings have been confirmed over time and a review in 2003 of risk management in UK cost consultants found that probability and consequence was considered by most, as was Monte Carlo Simulation (Wood and Ellis 2003). However, very few carry out a sensitivity analysis and only one out of the 11 consultants sampled used any form of decision, fault or event tree. More ‘complex’ methods were not even considered (e.g. influence diagrams, neural networks).

These studies show a reliance on a small number of techniques. Additionally, these techniques have focussed research away from ‘softer’ risks such as the social and political (Edwards and Bowen 1998). However, the fears of many practitioners that a technique may not be applicable to construction are more likely to be a lack of knowledge of the circumstances for which it can be used. This is perplexing as the literature contains many examples of the ‘complex’ techniques applied to construction problems, demonstrating their applicability and thus there seems to be a problem in transferring this academic knowledge to practitioners.

All of the above studies indicate that there is a lack of knowledge of when to use a particular technique and that no one technique is available for every situation. The lack of a fully integrated decision support technique and the need for a formal framework has been identified in the literature (Dikmen *et al.* 2004; Wang *et al. 2004).*

Available techniques

The literature review identified 36 techniques applied to construction management problems. Some of these 36 exist at more than one of the risk management stages: this gives 16 for identification, 18 for estimation and 18 for evaluation. There are a further 13 techniques that only have one reference in the literature and insufficient details to assess problem characteristics. These have been omitted, and the 52 are used to develop the matrix.

The range of techniques is broad, and they have been grouped into the nine categories shown in Table 1.

Table 1: Risk management categories defined for the matrix

Identification	Estimation	Evaluation
Artificial Intelligence	Artificial Intelligence	Artificial Intelligence
Decomposition	Decomposition	Decomposition
Experiential	Experiential	
Failure ID	Failure ID	
	Other	Other
	Probabilistic	Probabilistic
Sensitivity analysis	Sensitivity analysis	Sensitivity analysis
Support Systems	Support Systems	Support Systems
Trees	Trees	Trees

PROBLEM BREAKDOWN STRUCTURE

To use the matrix, a universal breakdown structure is required. This must be rigorous and allow problems to be categorized. It must also be simple to use to allow selection of risk management techniques. This section outlines a two-stage process for this. The first stage examines the problem characteristics and the second the data.

Existing breakdown structures

There are a range of breakdown structures in the literature. The ‘risk environment’ breakdown divides between external and internal risks. External risks are those “arising from the external environment, not wholly within the organization’s control, but where action can be taken to mitigate the risk” (HM Treasury 2004). Conversely, internal risks are those within the organization’s control, or “risks that have their origin within the project organization or its host, arising from their rules, policies, processes, structures, actions, decisions, behaviours or cultures” (Barber 2005). This is a universal difference and is applicable to all types of risk; therefore, it is used as the highest level of breakdown. The difference between the external and internal nature is the position of the assessing organization. This high level of breakdown is too general for the purposes of selecting appropriate techniques; therefore, a further level of breakdown will be developed.

Stage A: the problem breakdown structure

To ensure that this process was rigorous a method for risk ranking was used (Morgan *et al*. 2000). This sets four objectives: (1) logical consistency; (2) administrative compatibility; (3) equitable; and (4) compatible with cognitive constraints and biases.

The requirements to meet each of these objectives are outlined by Morgan *et al*. (2000) and were all met in developing the Stage A structure.

The first step in developing Stage A was to assess existing generic structures. HM Treasury (2004) use the PESTLE Model to define the external risks associated with a project. PESTLE encompasses political, economic, socio-cultural, technological, legal and environmental aspects (Cabinet Office 2004). It was found that all of the external sources of risks in the literature could be mapped onto PESTLE. This was used for the breakdown of external risks.

The internal risks did not initially map to the PESTLE Model. To overcome this, internal risks identified in the literature (e.g. Edwards and Bowen 1998) were grouped and similarities identified. This forced categories to be created, developed and merged. From this it was possible to describe the internal risks using the PESTLE Model with minor refinements to the definitions.

There are two further parts of Stage A assessment. These are the ‘risk owner’ and the ‘project phase’. The risk owner determines the internal or external nature of a risk. The risk owner is defined as being contractor; client; consultant/designer; financier; facilities management organization or government. These were developed iteratively during the review of the literature. If other organizations had been identified (e.g. subcontractor, supplier), these would have been and can be included as necessary.

Many of the methods for identifying generic project stages were considered too detailed (RIBA 2000, Cooper *et al*. 2005). The stages used in the matrix were defined by reviewing examples in the risk management literature. These cover the whole life cycle of a project and are in line with the RIBA Plan of Work (2000) and whole life costing (Marenjak 2004). The stages are (1) inception/feasibility; (2) design; (3) construction; (4) commissioning; (5) operation; and (6) decommissioning.

Stage B: the data breakdown structure

To this point ,Stage A only defines the nature of the problem. No account is made for the characteristics of the data.

Two structures for uncertainty in construction data were identified. Kishk (2004) developed a framework for whole life cost data including tangibility, availability and randomness. Blockley (1995) included fuzziness, incompleteness and randomness (FIR). This is stated as being the basis of uncertainty in risk and reliability, and has been applied to systems in construction. The model is an established basis for uncertainty for construction systems (Blockley 1995; Blockley and Godfrey 2000). The FIR model was used as the base for the data characterization because it was generic and encompassed the breakdown of Kishk. Iterations were undertaken of the precise definition to ensure that the data in the risk problems are characterized. The definitions outlined below.

FIR model

The first element of the FIR model is fuzziness. Fuzziness is the imprecision of definition (Blockley 1995). For the purposes of defining the nature of data in a problem, fuzziness is present if that which is being assessed is imprecise. This imprecision may stem from a difference in understanding of the terms used, or from a range of possible values in the data itself. For example fuzziness may occur in terms such as high, medium or low; or large and small costs.

The incompleteness aspect of a model is concerned with that which is not known (Blockley and Godfrey 2000). Using this basis, all risk management models are attempting to model incompleteness. Thus, if the technique was being assessed on the ability to manage 'unknowns', all risk management techniques would fall into this category. In light of this, the exact nature of the incompleteness was refined to relate solely to the data that was applied in the model. This provided a better representation of the incompleteness of the data.

The final consideration is that of randomness. Randomness is the lack of a specific pattern in the information (Blockley 1995). This is the uncertainty defined by probability and statistics (Blockley and Godfrey 2000). This has been reviewed for each of the techniques by assessing data with no specific pattern.

Using the revised definitions of the FIR model, the data relating to a given problem could be characterized. This stage of characterization has been called Stage B.

Other considerations
The assessment attempted to include other measures. This was to ensure that all of the characteristics were defined. These included level of detail; consistency; chaotic behaviour and precision. However there are three reasons why the FIR model has been retained. (1) the model is simple to use and easily assessed; (2) the model is widely acknowledged in construction literature and was developed for uncertainty; and (3) the process of assessing examples in the literature demonstrated that data fitted the structure. Thus, the FIR model provides a representation of the data.

The final breakdown structure
The final breakdown structure is shown in Figure 1. This shows the two stages and the ways in which a problem is categorized. The four elements of Stage A and the FIR model of Stage B create a set of characteristics which allow a new problem to be compared to historical problems.

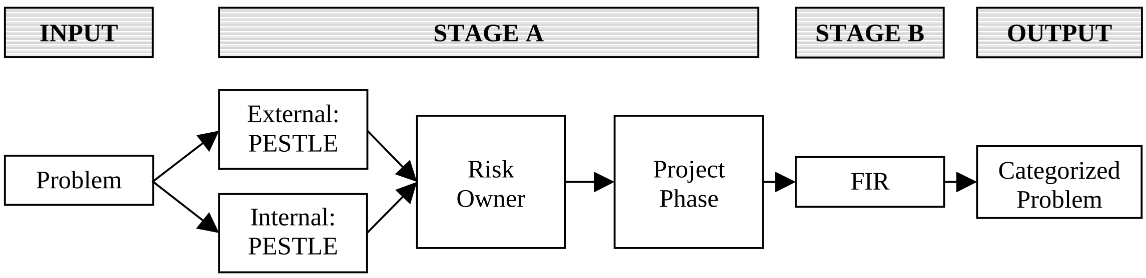

Figure 1: The problem breakdown stages

ANALYSIS OF TECHNIQUES

The historical problems were analysed against the breakdown structure above. Thus, a collection of problem characteristics and corresponding techniques was produced. In total, 179 examples were assessed, collected from 94 references.

During this process, it was noted that not all of the examples were actual applications. Some simply suggested a situation for which a technique should be applied. This was recorded as it was not considered that this should achieve the same merit as if an example were provided.

THE MATRIX

The matrix is two-dimensional, with the categorized problems on the horizontal axis and the techniques on the vertical. The matrix can be used as a decision support technique in selecting risk management techniques for a set of problem characteristics.

The matrix was constructed by assigning each technique to the problem situations it had been applied to. Where a technique was applied to more than one example, the characteristics were aggregated for each technique. This allowed all of types of problems for a given technique to be seen simultaneously. If there were 'suggested' and 'actual' examples, 'actual' took precedence.

There are two matrices: one covering Stage A and the other covering Stage B of the problem characterization. This is due to difficulties in consolidating and reconciling the stages arising from differing natures. This is not a problem, as it allows techniques to be selected on knowledge by either stage. If a technique is required for A&B, a check ensures that it complies with both. An extract of the matrix covering Stage A for identification techniques is given in Figure 2. Estimation and evaluation have been developed in a similar format.

DISCUSSION

The matrix produced is not only a useful tool, but also highlights trends and gaps within the risk management research. This section outlines these points and discusses ways of developing the matrix further.

The first aspect considered is the frequency with which techniques are applied in the matrix. There are 52 techniques available for all the risk management stages. The problem characteristic encompassed by most, both externally and internally, is economic. Forty different techniques have been used to manage internal economic risks. Twenty-nine have been applied to external economic risks. The reasons behind this probably stem from the ease of monetizing values to calculate the risk or the focus within the industry on profit and cost. Additionally, the large number of internal examples may be accounted for by organizations being concerned with the risks they can most readily control. External economic risks, including market and residual value, may be harder to assess and have therefore been avoided.

In the 'risk owner', there is a lack of technique examples that have been applied by government, financiers and facilities management organizations. In contrast, 32 of the techniques have been applied by contractors and 25 for, or on behalf, of clients. However, this may not be because the techniques are not applicable, but because an example has not been assessed covering that area. The relatively high number of examples for clients and designers can be attributed to the Construction (Design & Management) Regulations 1994 (CIRIA 2004a, 2004b). This put a larger onus on the designer and client to assess the risks.

In assessing Stage B, out of 52 techniques, 38 and 24 techniques can deal with incompleteness and randomness respectively; however, only 17 can deal with fuzziness. This is due to the relatively new emergence of fuzzy assessment and will probably increase as techniques grow in acceptance, and fuzzy methods are researched.

The missing values highlight the dynamic nature of the matrix. It has been constructed using 179 examples from the literature. A gap does not necessarily mean that a technique cannot be applied, but that an example has not been located to complete the matrix. However, as it stands the matrix allows valuable judgements to be made in selecting techniques.

A	Actual Example of Tool
S	Suggested Example of Tool

Figure 2: Extract from Stage A of risk management matrix showing identification techniques

Several points relating to the technique groups can be extracted from the matrix:

- Techniques that belong to the tree group, failure identification and sensitivity analysis do not tend to be suited to assessing external risks.
- The support system group does not tend to have examples detailing the owner or phase of the work.
- There is a lack of techniques to evaluate internal political risks. This is true, although to a lesser extent, for internal political and legal risks.
- Fuzzy logic is the most commonly used artificially intelligent technique. The use of neural networks is limited to internal economic risks, and case-based reasoning is 'suggested' as being universally applicable.
- Experiential estimation techniques tend to be non specific regarding the risk owner.

Two major pitfalls can be seen in the matrix. Firstly, no account is made for the frequency with which a technique has been applied in the past. A decision on technique selection has to be made on whether the problem characteristics exist. There is no indication if this is once or several times. For the matrix to be of more use, a means of overcoming this should be addressed.

The second issue is that the position of the risk owner is clouded by the aggregation. It is no longer clear which external and internal risks are associated with a given owner, thus confusion may occur in selecting the appropriate tool.

Further work

One limitation of the matrix is that it can be difficult to use in selecting appropriate risk management tools. To overcome this, options of 3-D and triangular matrices have been considered. However, these were either unworkable or overly complex. A methodology that is designed to use historic examples to make decisions is case-based reasoning (CBR). It is proposed to develop a CBR model based on the data set used in this study. This will make it easier to select appropriate techniques.

It is also suggested that CBR will allow assessments to be made on the past frequency technique examples. This CBR model would also be able to relate the risk owner to each of the internal and external positions, which would overcome the problems caused by the aggregation in the matrix.

CONCLUSIONS

The risk management technique matrix that has been produced from this work is a useful tool in selecting the most appropriate risk management techniques for the built environment. This overcomes the issue of knowing when particular technique can be applied. However, it is still necessary for the user of the technique to gain an understanding of the technique's methodology.

The data structure is constrained by using a standard breakdown. However, it is important that this has a combination of simplicity, while remaining comprehensive. Additional measures beyond the FIR were considered and were found to be difficult to quantify and assess. FIR has been used because it is well established, takes a generic approach to representing uncertainty and is easily understood.

The matrix output has shown that there is a lack of tools available to deal with particular areas. These were the 'softer' risks in: (1) external – technological, legal and political; and (2) internal – political and social. Further research could be carried out into these areas, including the development of fuzzy techniques and the application of techniques for government, financiers and facilities management organizations. A more complete and accurate database could then be established from which to build the matrix.

Bridge management is the decision-making process for selecting and prioritizing actions necessary to maintain a bridge network within acceptable limits without exceeding budget constraints. Decision support systems can help engineers and practitioners in making effective decisions through: (1) improved identification and information of the infrastructure assets; (2) methodologies for needs assessment; and (3) analytical tools for evaluation of alternative solutions. This paper describes a research to choose a decision making technique for an under development bridge deck decision support system. Four quantitative multiple criteria decision making techniques are evaluated. From these, the Analytic Hierarchy Process (AHP) is selected to develop an analytical framework to evaluate and rank alternative bridge rehabilitation strategies. The AHP provides an effective analytical tool to deal with complex decision making and has the following qualities: (1) multi-criteria decision making process; (2) utilize both actual measurements and expert judgment in the decision making process; and (3) the process has a special concern with consistency of judgement and it deals with the departure from consistency.

Keywords: AHP, bridge, decision, rehabilitation.

INTRODUCTION

Aging civil infrastructure has become a major social and economical concern in North America. The concern is due to the fact that satisfactory performance of existing civil infrastructure is essential to maintain economic growth and social development of a modern society. Civil infrastructure facilities and related services can be categorized in groups based on their primary functions and services. The transportation system is one major group of the infrastructure system and includes ground, air, waterways and mass transportation (Hudson *et al*. 1998).

In particular, bridges are important item of the transportation system. Bridges are the most vulnerable element because of their distinct function of joining highways as crucial nodes. In addition, bridges are exposed to aggressive environment and increasing traffic volumes and truck loads (Frangopol and Liu 2005).

Deterioration is a major problem in the operation of a nation's highway bridges. Maintaining, repairing and replacing (MR&R) deteriorating bridges are among the most expensive items for highway agencies.

Managers of municipal infrastructure realize the need for effective tools to manage the vast asset base, and are now demanding decision-support tools to help them in their

[1] saleh_ab@alcor.concordia.ca

work (Vanier 2000). In particular, it is essential to develop rational tools to aid bridge managers in the decision making process.

BRIDGE MANAGEMENT DECISION MAKING

Many bridge management systems currently used base their decision making process on optimizing life cycle cost while enforcing relevant performance constraints. Pontis and Bridgit, among the widely used bridge management systems in the United States, have adopted this methodology (Thompson *et al*. 1998; Hawk and Small 1998). For instance, Pontis utilize dynamic programming to find the optimal long-term policy that minimizes expected life cycle costs while keeping the element out of risk of failure (Thompson *et al*. 1998).

Practical difficulties exist when applying the optimized life cycle cost methodology (Frangopol and Liu 2005). These difficulties arise when the available budget are larger or lower than the minimum life cycle cost. If the available budgets are larger than the computed minimum life cycle cost, the bridge performance can be maintained at a higher level than the level maintained at minimum life cycle cost solution. If the financial resources are not enough to meet the computed minimum life cycle cost, bridge managers have to look for another solution that can improve bridge performance to the highest possible level with the available budget. In addition, more criteria beside cost can participate in the decision making process. Decisions can be governed by multiple criteria and constraints that require the decision maker's knowledge, experience and judgment.

Decision making criteria can evolve in a subjective manner. An example on that is the user cost that is different than the agency cost. The user cost during bridge MR&R projects has several sources and can be either due to delay while the user is using alternative routes or due to accidents while closing the bridge. This cost is not easily estimated in and can evolve in subjective manner to be high for certain MR&R action, medium or low for others.

MULTIPLE-CRITERIA DECISION MAKING

Multiple-criteria decision making is a complex process that requires expert knowledge and judgment to rank and prioritize alternatives. In addition to ranking and prioritizing, the decision making process addresses several issues including clarifying purpose, evaluating alternatives, assessing risks and benefits.

Decision analysis techniques are rational procedures to utilize information, data, and experience in order to facilitate the decision making process in a systematic way. These techniques can aid in the decision making process but are not intended to replace decision makers.

Several decision making techniques have been developed and used in a variety of applications. Few of these techniques are simple qualitative procedures to evaluate the advantages and disadvantages of each alternative and rank the alternatives accordingly. Other techniques are quantitative systematic procedures to utilize data and experience to rank and prioritize a group of alternatives.

Four quantitative decision making techniques proposed in the literature are evaluated in this paper for use in bridge management decision making. These techniques are Analytic Hierarchy Process (AHP), Multi-Attribute Utility Theory (MAUT), Cost Benefit Analysis (C/B) and Kepner-Tregoe Decision Analysis (K-T). Barker *et al*.

(2001) presented comprehensive discussion of these techniques. Table 1 defines the concepts of these techniques.

Table 1: Decision making techniques

Technique	Description
MAUT	Combine dissimilar measures of costs, risks, and benefits, along with individual and stakeholder preferences, into high-level, aggregated preferences
C/B Ratio	Discounting benefits and costs to transform gains and losses occurring in different time periods to a common unit of measurement
K-T	Team of experts numerically scores criteria and alternatives based on individual judgments and assessments
AHP	Pair-wise comparisons of alternatives based on their relative performance against the criteria

The four decision making techniques can be used in bridge management decision making. Table 2 presents advantages and disadvantages associated with each of the four techniques. The AHP is found to have the most advantages and limited disadvantage that can be accounted for. The disadvantage of AHP is the large size of the developed matrices. This can be accounted for by developing computer software to facilitate handling large size matrices.

ANALYTIC HIERARCHY PROCESS (AHP)

The Analytic Hierarchy Process (AHP) is a general theory of measurements developed by Thomas Saaty (1980). The theory presented in this section is based on decision making dependence and feedback authored by Saaty (2001). The AHP provides an effective analytical tool to deal with complex decision making. It is a multi-criteria decision process that utilizes both actual measurements and expert judgment. It has a special concern with departure from consistency and the measurement of this departure.

Two fundamental steps are required to use the AHP methodology. First, a complex system is broken into a hierarchic structure to represent the problem. Second, pairwise comparisons are performed to measure the relative impact of different elements in the hierarchy and to establish relations within the structure.

Fundamental scale of absolute values for representing the strength of judgments has been developed and validated (Saaty 1980, 2001). In this approach, the decision maker expresses his/her opinion about the value of one single pairwise comparison at a time. Usually, the decision maker has to choose an answer among discrete choices. Table 3 presents the scale of relative importance.

The pairwise comparisons lead to dominance matrices from which ratio scales are derived in the form of principal eigenvectors. These matrices are positive and their elements are reciprocal. Thus for any element a_{ij}, the value of elements $a_{ji} = 1/a_{ij}$.

Finally, the judgments are synthesized to determine the overall priorities of the variables and the criteria.

Table 2: Decision making techniques advantages and disadvantages

Technique	Advantages	Disadvantages
MAUT	-Suitable for complex decisions with multiple criteria and many alternatives. -Additional alternatives can be readily added to a MAUT analysis	- Data or judgment must be available to develop the utility functions
C/B Ratio	- Useful to define desirability of government projects or policies	-Suitable only when decision making is based on the monetary cost vs. monetary benefit of the alternatives
K-T	-Simple and requires only basic arithmetic	-Suitable for moderately complex decisions involving few criteria -The scoring system is not well-defined. For example it is that it is not clear how much score “7” is better than score “6” -Scores may be close together, making a clear choice difficult
AHP	-AHP is a useful when there are multiple criteria -AHP is suitable for decisions with both quantitative and qualitative criteria -Break down complex problems into hierarchy structure that provides a structured model of the problem - Facilitate decision making by allowing relative judgment - Define functional utilities based on simple comparisons and provide consistent, meaningful results	- If high number of alternatives and criteria are considered, the number of pairwise comparisons is high. This may foster carelessness among decision makers while performing the pairwise comparisons.

Table 3: Scale of relative importance (Saaty 2001)

Intensity	Definition	Explanation
1	Equal importance	Two activities contribute equally to the objective
3	Weak importance of one over another	Experience and judgment slightly favour one activity over another
5	Essential or strong importance	Experience and judgment strongly favour one activity over another
7	Demonstrated importance	An activity is strongly favoured and its dominance demonstrated in practice
9	Absolute importance	The evidence favouring one activity over another is of the highest possible order of affirmation
2, 4, 6, 8	Intermediate values between the two adjacent judgments	When compromise is needed

AHP METHODOLOGY FOR CHOOSING BRIDGE REHABILITATION STRATEGY

As stated earlier, choosing a rehabilitation strategy can be governed by a group of subjective criteria. AHP methodology can aid decision makers with this task. The AHP methodology application to choose an appropriate rehabilitation action is summarized in the following steps.

Identify alternatives and decision criteria and decompose the problem into a hierarchy

Decision makers can choose a group of rehabilitation strategies R_i (i = 1,2,.....,n) to evaluate for a specific projects. A best strategy is the strategy that meets the multiple criteria established by the decision maker. The criteria are denoted by C_j (j = 1,2…..,m).

Three levels hierarchy structure can be identified. The first level represents the overall objective of choosing best strategy. The second level represents criteria that contribute to the overall goal. The third level represents the candidate alternatives to be evaluated in terms of the criteria on the second level. In this case, the candidates are the rehabilitation strategies. Figure 1 represents the decomposition of the problem into a hierarchy.

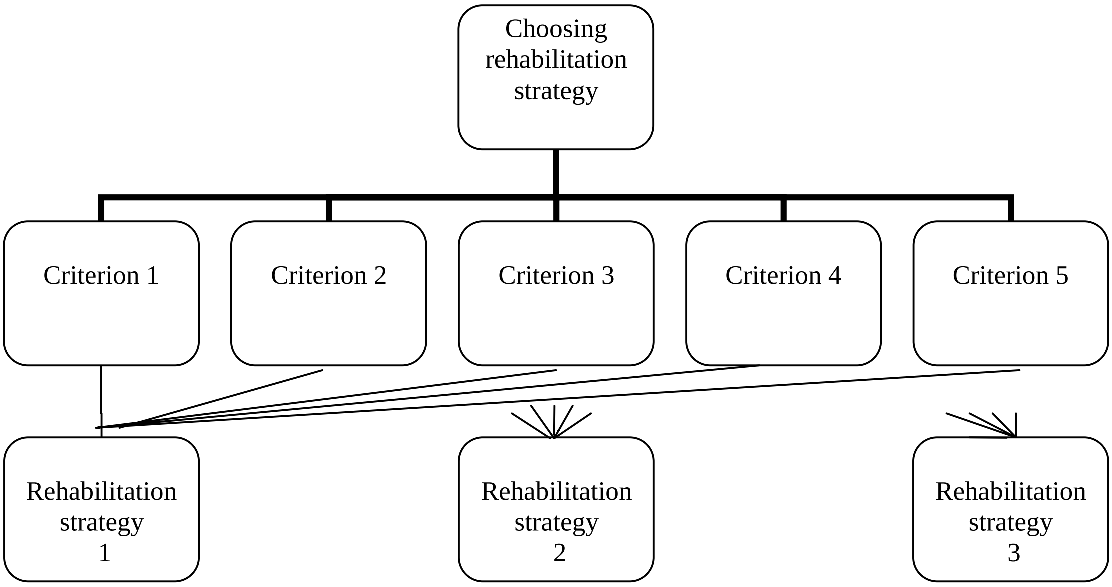

Figure 1: Hierarchy structure for ranking bridge rehabilitation strategies

Perform comparative judgment

At the middle level, a matrix of comparison in the order of (m × m) is derived to relate the relative preferences of the different criteria. This preference is elicited from the expert judgments about the relative importance of the criteria with respect to the overall goal of choosing best rehabilitation strategy. Every two criteria are compared by asking which one is considered more important and how much more important with respect to the overall goal. Scale of relative importance presented in Table 3 is used to give the numeric weights for the linguistic expressions of judgment. If elements in the matrix of comparison satisfy the conditions of $a_{ij} = 1/a_{ji}$ and $a_{ii} = 1$ for all i, then the matrix is a reciprocal one.

$$CM = \begin{bmatrix} 1 & S_{1,2} & S_{1,3} .... S_{1,m} \\ \frac{1}{S_{1,2}} & 1 & S_{2,3} .... S_{2,m} \\ \frac{1}{S_{1,3}} & \frac{1}{S_{2,3}} & 1 .... S_{4,m} \\ . & . & . ... \\ . & . & .... \\ . & . & .... \\ \frac{1}{S_{1,m}} & \frac{1}{S_{2,m}} & .... 1 \end{bmatrix}$$

At the bottom level, pairwise comparisons between different strategies with respect to each criterion are performed. For each criterion, a matrix in the order of (n × n) is developed to represent the relative preference of the different rehabilitation strategies with respect to that particular criterion.

Determine vector of priorities

Vector of priorities is a normalized eigenvector. In absence of large-scale computers to solve the problem, an alternative crude estimate can be used to yield an acceptable approximation for the vector of priorities.

The vector of priorities is estimated in two steps. First, normalize the developed matrices. This is done by computing the sum of each column and dividing each element in a column by the sum of that column. Second, compute the average of each row. The average value of each row represents the priority weight of the corresponding element or criterion.

Determine the eigenvalue and consistency ratio.

One feature of the AHP methodology is checking for consistency. The process allows inconsistency in the pairwise comparisons to a certain extent. If all the comparisons are perfectly consistent, then $w_{ij} = w_{ik}\ w_{kj}$ should always be true for any combination of comparisons taken from the judgment matrices.

A consistency index (CI) can be determined for this purpose. Small value of the CI represents small deviation from consistency which reflects an acceptable consistent judgment.

$$CI = \frac{\lambda_{max} - n}{n - 1}$$

where λ_{max} is an approximation of the maximum eigenvalue. A simple way to obtain λ_{max} is by adding the elements in each column in the judgment matrix and multiplying the resulting vector by the vector of priorities (i.e. the approximated eigenvector) obtained earlier.

In AHP, the pairwise comparisons in a judgment matrix are considered to be adequately consistent if the corresponding consistency ratio (CR) is less than 10% (Saaty 1980). CR is equal to CI/RI where RI is a random consistency index derived from a large sample of randomly generated reciprocal matrices. Table 4 represents values of RI for different matrix size.

A small consistency ratio less than 10% reflects an informed judgment that could be attributed to expert knowledge about the problem under study. If this limit is not achieved, the expert is required to revise the pairwise comparisons to improve consistency.

Table 4: Random index values for different number of elements matrix (Saaty 2001)

Number of elements (n)	R.I.
3	0.52
4	0.89
5	1.11
6	1.25
7	1.35
8	1.40
9	1.45
10	1.49
11	1.51
12	1.54
13	1.56
14	1.57
15	1.58

Synthesize the priorities

Finally, compose global priorities of the different rehabilitation strategies. Lay out local priorities of each strategy with respect to each criterion. Multiply each weight in the resulting vector by the corresponding criterion weight and add across each row to find the overall weight. The resulted vector is the global priority vector of all strategies. The different strategies are ranked according to their overall weights and a strategy with the highest weight represents preferred rehabilitation strategy.

HYPOTHETICAL EXAMPLE

The following is a hypothetical example to demonstrate the AHP as a tool to choose bridge deck rehabilitation strategy. A deteriorating bridge deck is expected to reach the intervention level next year. The decision maker is required to evaluate alternative rehabilitation strategies. The assessment and pairwise comparisons in this example are performed by the authors.

The available strategies are major rehabilitation, minor rehabilitation or increased routine maintenance. These three alternatives should be evaluated using the following criteria: agency cost, user cost, bridge safety, bridge deck useful life and environmental impact.

Figure 2 presents the decomposition of the problem into a hierarchy. The first level is the overall goal of choosing a rehabilitation strategy. The second level represents the five criteria that contribute to the overall goal, and the third level represents the three candidate rehabilitation strategies.

The pairwise judgment matrices shown in Tables 5 and 6 are developed using the authors’ judgment and based on the scale of relative importance presented in Table 3. The matrix in Table 5 is obtained by comparing the set of criteria in pairs with respect to the overall goal. The matrices in Table 6 are obtained by comparing the alternative rehabilitation strategies in pairs with respect to each criterion.

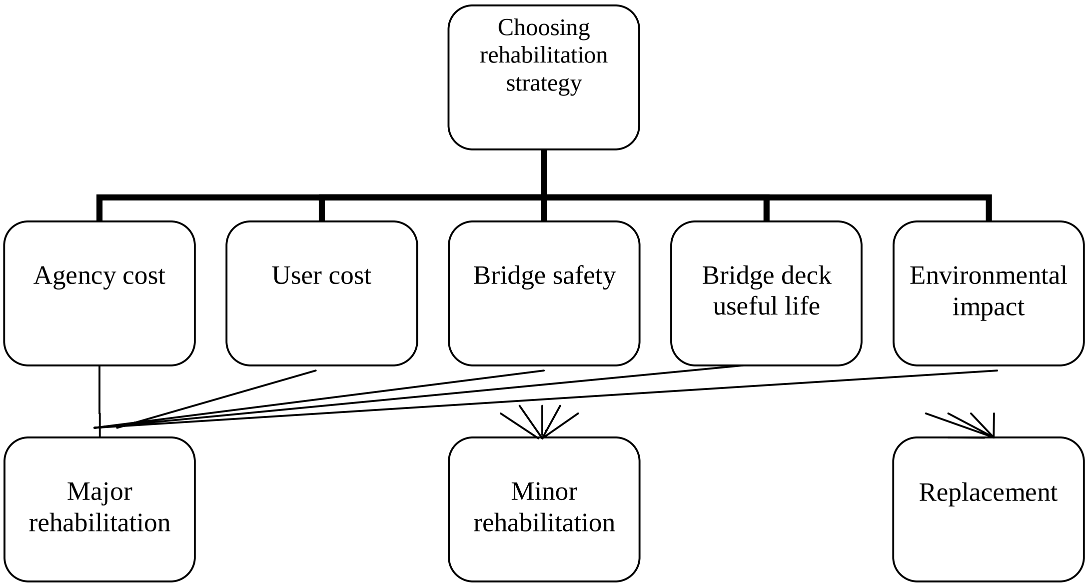

Figure 2: Hierarchy structure for choosing bridge rehabilitation action

Table 5: Comparison of criteria with respect to the overall goal

Criteria	Agency cost	User cost	Bridge safety	Useful life	Environmental impact	Priority vector
Agency cost	1	2	1/6	1	1	0.121
User cost	1/2	1	1/3	1/2	1/2	0.088
Bridge safety	6	3	1	6	6	0.548
Useful life	1	2	1/6	1	1	0.121
Environmental	1	2	1/6	1	1	0.121

λ_{max} = 5.342, C.I. = 0.085, R.I. = 1.11, C.R. = 0.076

Estimated consistency ratios for the judgment matrices are less than 10% which reflect an informed consistent judgment.

Finally, global priorities of the different rehabilitation actions are as follow:

Major rehabilitation = 0.58

Minor rehabilitation = 0.28

Increased routine maintenance = 0.24

The analysis prefers a major rehabilitation and gives approximately the same weight for minor rehabilitation and increased routine maintenance.

Table 6: Comparison of alternatives with respect to each criterion

Agency Cost	Major	Minor	Routine	**Priority**
Major	1	1/3	1/6	0.093
Minor	3	1	1/4	0.221
Routine	6	4	1	0.685

λ_{max} = 3.085, C.I. = 0.042, C.R. = 0.081

User Cost	**Major**	**Minor**	**Routine**	**Priority**
Major	1	1/ 4	1/ 6	0.089
Minor	4	1	1/2	0.323
Routine	6	2	1	0.587

λ_{max} = 3.012, C.I. = 0.006, C.R. = 0.011

	Environmental Major Minor Routine	Priority
Major	1 2 4	0.571
Minor	1/2 1 2	0.286
Routine	1/4 1/2 1	0.143

λ_{max} = 3, C.I. = 0, C.R. = 0

	Bridge Safety Major Minor Routine	Priority
Major	1 2 4	0.571
Minor	1/2 1 2	0.286
Routine	1/4 1/2 1	0.143

λ_{max} = 3, C.I. = 0, C.R. = 0

	Useful Life Major Minor Routine	Priority
Major	1 3 8	0.669
Minor	1/3 1 4	0.257
Routine	1/8 1/4 1	0.074

λ_{max} = 3.028, C.I. = 0.014, C.R. = 0.026

CONCLUSION

This paper reviews bridge management decision making regarding maintenance and rehabilitation. In addition, it discusses four quantitative decision making techniques that can be used for bridge rehabilitation decision making. The AHP methodology is further discussed for its suitability for this purpose. A hypothetical example is presented to demonstrate the use of AHP to choose bridge deck rehabilitation strategy.

The AHP is a valuable tool for evaluating alternatives using multiple criteria while incorporating expert judgment. It facilitates complex decisions and makes them intuitive and rational.

The process benefits from the various advantages of using hierarchy structures and establishes the weights of attributes in a systematic and robust manner. The hierarchy structures' advantages include the following: (1) they describe how changes in upper levels affect elements in the lower level; (2) hierarchy structures assemble natural systems more efficiently than assembling systems as a whole; and (3) they are flexible allowing for adding new elements without disturbing the performance.

One important advantage of the AHP for the selection bridge rehabilitation strategy lies in its capacity to enable the process of rank reversal. Rank reversal involves a change in rank among a list of ranked alternatives, when a new alternative is added or deleted. This feature is the strength of the AHP since rank reversals do occur in practice. For example, if a high-quality rehabilitation strategy is added to the list of alternatives, rank reversal should take place to prioritize the new attractive alternative.

Another advantage is that the AHP allows the decision maker to check the consistency of the judgment regarding the relative importance among the involved criteria and among the alternatives. The decision maker can revise the relative importance to enhance the consistency and perform more informed judgment.

The AHP is normally based on expert judgment. The process might be associated with difficulties if large number of alternative and criteria are involved. Performing many pairwise comparisons may foster carelessness among the decision makers while doing the comparisons. In addition, reviewing large size matrices to enhance consistency can be a difficult task. However, for the purposes of choosing a bridge rehabilitation strategy, the alternatives and criteria involved are limited and the decision makers will not face this problem

For the features discussed above, the AHP has been adopted as a decision making process for a bridge deck decision support system under development.

IDENTIFICATION OF KEY PERFORMANCE INDICATORS TO ESTABLISH THE VALUE OF 4D PLANNING IN UK CONSTRUCTION INDUSTRY

Nashwan Dawood[1] and Sushant Sikka

Centre for Construction Innovation and Research, School of Science and Technology, University of Teesside, Middlesbrough, TS1 3BA, UK

Performance measurement has received considerable attention by both academic researchers and industry over a past number of years. Researchers have considered time, cost and quality as the predominant criteria for measuring project performance. In response to the Latham and Egan reports to improve the performance of construction processes, the UK construction industry has identified a set of non-financial Key Performance Indicators (KPIs). A literature review reveals that a standard measurement framework to evaluate the value of Information Technology (IT) both at quantitative and qualitative levels does not exist. Following an increased utilization of IT-based technology in the construction industry and in particular 4D (3D+time) planning, there is a great need to evaluate the value of such tools in the construction industry. There is great need to develop IT-based KPIs to promote its value. The aim of this ongoing research is to develop a suitable measurement framework to identify and analyse key performance indicators for 4D applications. Two major issues have been addressed in this research: an absence of a standardized set of 4D-based KPIs and lack of existing data for performance evaluation. This paper reports on the first stage of the research study carried out to identify the 4D performance measures on the basis of semi-structured interviews and questionnaire.

Keywords: 4D planning, information technology, scheduling, value, visualization.

INTRODUCTION

Applications of Information Technologies (IT) are progressing at a pace and their influence on working practice can be noticed in almost every aspect of the industry. The potential of IT applications is significant in terms of improving organization performance, management practices, communication and overall productivity. The evaluation and justification of investment in IT infrastructure and tools is crucial to rationalize the high capital cost involved in it. The thrust for improved construction planning efficiency and visualization methodology has resulted into the development of 4D planning.

4D is a planning process to link the construction activities represented in programmes with 3D CAD data to develop a real-time graphical simulation of planned construction schedules. In current practice, a planner has to first interpret what has to be constructed on the basis of available information (design documents, 2D CAD drawings and 3D model). Planner then identifies a list of activities required to construct the project. Finally, on the basis of construction method and based on available resources, the planner creates sequential relationship among the activities

[1] n.n.dawood@tees.ac.uk

and calculates activity and project duration to generate schedule. The traditional planning approach does not assist planners to consider the constructability issues during the advanced development of schedules. As a result, such issues are left for later decisions on the site. In 4D planning, project participants can effectively visualize, analyse and communicate problems regarding sequential, spatial and temporal aspects of construction schedules, and thereby rehearse construction progress in 3D at any time during the construction process. Consequently, much more robust schedules can be generated to reduce rework and improve productivity. According to Dawood *et al.* (2002), 4D planning allows participants in the project to effectively visualize and analyse the problems since the sequencing of space and temporal aspects of the project are considered by visualizing and communicating the project schedule. The industry based Key Performance Indicators (KPIs) that have been developed by the Department of Trade and Industry (DTI) sponsored construction best practice program (CBPP) are too generic and do not reflect the value of deploying IT system for construction planning and in particularly 4D planning. The key objective of this research study is to overcome the presence of a generalized set of KPIs by developing a set of 4D-based KPIs at a project level and in particular site operations.

A major research work was carried out by Construction Industry Institute (CII) to investigate the use of three-dimensional computer models in the industrial process and commercial power sector of AEC (architectural, engineering and construction) from 1993 to 1995 (Griffis *et al.* 1995). The study of CII concluded that the application of 3D computer model has the potential to reduce interference problems, improve visualization, reduce rework, enhancement in engineering accuracy and improve jobsite communications. Songer (1998) carried out a study to demonstrate the use of 3D CAD technology during the project planning phase. The study focuses on the impact of using 2D and 3D technologies in the project schedule review. Songer's experimental results demonstrated that the use of 3D-CAD technologies during planning stage on a construction project could assist in enhancing the scheduling process by reducing the number of missing activities and relationships between various activities as well as invalid relationships in the schedule and resource fluctuations for complex construction processes.

The Centre for Integrated Facility Engineering (CIFE) at Stanford University has demonstrated and reported the benefits of 3D and 4D modelling using various case study approaches (Koo and Fischer 1998; Haymaker and Fischer 2001; Staub-French and Fischer 2001). The application of the Product Model and Fourth Dimension (PM4D) approach at Helsinki University of Technology Auditorium Hall 600 (HUT-600) project in Finland has also demonstrated the benefits of 4D modelling approach in achieving higher efficiency; better design quality and the early generation of a reliable budget on the project (Kam *et al*. 2003).

Various research efforts had been undertaken in an attempt to capture current construction planning techniques. Researcher (Songer *et al*. 2001; Messner and Horman 2003; Haymaker and Fischer 2001) evaluated the effectiveness of computer visualization (4D CAD) to demonstrate the potential of 4D CAD visualization techniques compared to traditional planning approaches during the planning review process. The whole basis of using 4D planning is to identify logical and effective sequencing of the construction activities in construction projects prior to its execution. A rehearsal of the construction processes over time will identify and assist in overcoming spatial and resource conflicts for example, workspace conflicts, constructability, workflow etc., which cannot be represented by using conventional planning techniques. The above studies lack a well-established performance metrics that would allow the quantification of 4D planning at site process level. In the absence of well-defined measures at site process level, the priority of this research project is to establish a set of key performance indicators that will reflect the influence of 4D applications. This will assist in justification of investment in 4D planning in the industry. The remainder of the paper discusses the research methodology adopted for selection of 4D KPIs, ranking of KPIs, statistical analysis and findings of interviews.

RESEARCH METHODOLOGY

The ultimate objective of this research is to deliver project based 4D performance measures and to identify whether project performance can be improved by the utilization of 4D planning. This research has followed a well-defined methodology for the identification of 4D-based key performance indicators (KPIs). The methodology compromises of following three interrelated phases:

1. Identification of performance measures (4D perspective) through literature review.
2. Collection and analysis of interview survey data from various stakeholders (client, construction managers, general contractors, project managers and planners) viewpoint who are involved in the construction project.
3. Quantifying the performance measures for three construction projects.

This paper focuses on the process of identification and development of 4D performance measures by considering the above two phases of the research methodology (i.e. I & II).

Identification and selection of KPIs

The first step in the development of the KPIs was to identify the performance measures that can be utilized for performance assessment later. This was done by the development of a performance measure list that has considered the performance measure characterized by Rethinking Construction, the construction best practice program that launched industry wide KPIs for measuring the performance of construction companies (CBPP-KPI 2004). The Construction Best Practice Program identified a framework for establishing a comprehensive measurement system within both the organization and project level. Other literature includes Kaplan and Norton (1992), Li *et al*. (2000); Chan *et al*. (2002), Cox *et al*. (2003), Albert and Ada (2004), Bassioni *et al*. (2004) were used for the identification of performance measures.

A questionnaire was designed to confirm the performance measure that can be used to validate the value of 4D planning. The reason behind the development of questionnaire was to collect the specific information on identification of 4D performance measures, how to collect the required data and in identifying the methods to measure construction processes in detail. The questionnaire includes both open and closed questions to gain a broad perspective on actual and perceived benefits of 4D planning. To minimize the risk of collecting irrelevant data, a snowball sampling method was devised. A semi-structured interviewing technique was used to elicit information from various stakeholders to identify the key performance indicators at project level. The data and information obtained from semi-structured interviews was analysed using the Delphi technique. This technique was chosen since it is ideal for modelling real world phenomena that involve a range of viewpoints and for which there is little established quantitative evidence (Hanks and McNay 1999).

Three major construction projects in London (currently under construction with a combined value of £230 million) were selected for the research study and data collection. Initially, 42 industry decision-makers with experience in using 4D planning on construction projects were contacted and invited to take part in the research. Twenty-one respondents have accepted the invitation and have taken part in the interviews, resulting in a 50% response rate. Due consideration has been given in the selection of interviewee by selecting respondents (client, construction managers, general contractors, project managers and planners) with various roles and responsibilities on a construction project. In a sample size of 21 interviewees that took part in this study two (10%) were clients, three (14%) were general contractors, four (19%) were construction managers, five (24%) were planners, and seven (33%) were project managers on commercial projects in and around the city of London. They assisted in sharing the information on identification of 4D performance measures, how to collect the required data and in identifying the methods to measure construction processes in detail. The limitation of the study was its small interviewee sample size. The analysis of semi-structured interviews resulted in the development of following 4D-based KPIs as represented in Table 1.

Table 1: Definition of the identified performance measures

Measure	**Definition**
Time	It can be defined as percentage number of times projects is delivered on / ahead of schedule. The timely completion of a project measures performance according to schedule duration and is often incorporated to better understand the current construction performance
Safety	It can be defined as a measure of the effectiveness of safety policy and training of the personnel engaged in activities carried out on site. Safety is a major concern for every construction company, regardless of the type of work performed. Safety is normally measured quantitatively by Time lost as a result of accidents per 1000 man hrs worked and number of accidents per 1000 man hrs worked
Client satisfaction	Client satisfaction can be defined as how satisfied the client was with the product/facility. Usually measured weekly/monthly or shortly after completion and handover
Planning Efficiency	Planning efficiency has been represented in terms of Hit Rate percentage (%). Hit rate percent indicates the percentage (%) reliability of the commencement date for each activity or package(s) by comparing the planned programme against the actual programme
Communication Efficiency	Information exchange between members using the prescribed manner and terminology. The use of a 4D interface allows the project team to explore the schedule alternatives easily and assist in deploying 4D approach. Communication can be quantified in terms of number of meetings per week and time spent on meetings (Hrs) per week
Rework Efficiency	Rework efficiency can be defined as the activities that have to be done more than once in the project or activities which remove work previously done as a part of the project. By reducing the amount of rework in the pre-construction and construction stages, the profits associated with the specific task can be increased. Rework can be represented in terms of number of client changes, number of errors (drawing/design), number of corrections (drawing/design), number of requests for information to be generated, number of claims and number of process clashes spotted due to sequencing of activities
Cost	Percentage number of times projects is delivered on/under budget
Team Performance	Ability to direct and co-ordinate the activities of other team members in terms of their performance, tasks, motivation and the creation of a positive environment
Productivity Performance	This method measures the number of completed units put in place per individual man-hour of work. Some of the identified productivity performance measures are; number of piles driven/day, number of piles caps fixed / day, tonnes of concrete used / day/m^3 and pieces of steel used per day or week

First task for the interviewee were to identify and rank the performance measures using a four-point Likert Scale. The second task was to identify the data required to quantify each performance measure. Their input was considered to be critical in the success of this research. The potential reason behind conducting the semi-structured interviews were to evaluate how project and planning managers perceive the importance of performance measures; this will assist in the development of performance measures that can be used to quantify the value of 4D planning.

RANKING OF KPIS

Interviewees were asked to rank the identified KPIs. The ranking of the KPIs was done by using a four-point Likert Scale. For the prioritization process, each KPI was graded on a Likert scale of 1 to 4 (where 1= Not important, 2 = fairly important, 3 = Important and 4 = Very important) to measure the importance of each performance measure. The quantification of performance measure will be done on the basis of prioritized KPIs. The performance measures will be further classified in qualitative terms (rating on a scale) and quantitative terms (measurement units).Using responses from a four-point Likert Scale; the average weighted percentage for each performance measure was calculated. Figure 1 represents the weighted (%) ranking of the performance measures on the basis of the views of the respondents. The performance measures perceived as being highly important by the respondents are: *time, safety, client satisfaction, rework efficiency* and *communication efficiency.* As shown in Figure 1, time and safety has scored the top ranking as compared to other performance measures.

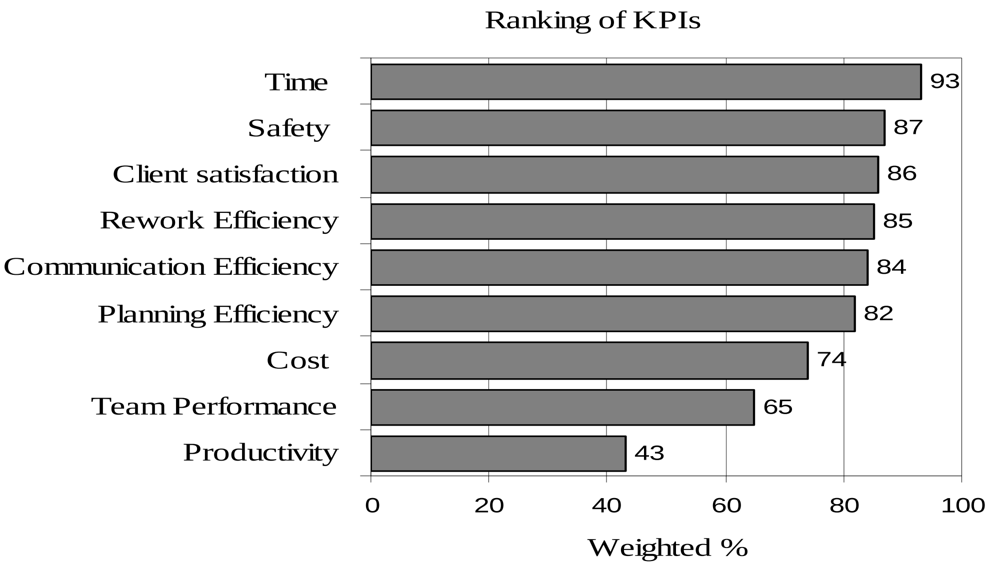

Figure 1: Ranking of KPIs

Table 2 represents the ways to quantify the prioritize 4D KPIs at the different stages of a construction project. For example, 'Time' has been ranked (93%) as top KPI by the respondents and we propose to use 'Schedule Performance Index' to measure it. Schedule performance index (Schedule efficiency) can be defined as the ratio of the earned value created to the amount of value planned to be created at a point in time on the project. Similarly, each of the KPIs will be quantified on the basis of set of performance measures as shown in Table 2.

Table 2: Ranking of 4D KPIs in order of priority

Ranking	KPIs	Performance measures	Stages of construction
1	Time	(i) Schedule Performance	Pre-construction & Construction
2	Safety	(i) Number of accidents per 1000 man hrs worked (ii) Time lost in accidents per 1000 man hrs worked	Construction
3	Client Satisfaction	(i) Number of client change order (ii) Number of client queries (iii) Satisfaction questionnaire (iv) Number of claims (time/cost)	Construction & Post-Construction
4	Planning Efficiency	(i) Percentage of activities started & completed on time (Hit Rate %)	Construction
5	Communication Efficiency	(i) Number of meetings per week (ii) Time spent on meetings per week (iii) Number of request for information responded	Pre-construction & Construction
6	Rework Efficiency	(i) Number of errors (Drawing) (ii) Number of corrections (Drawing/Design) (iii) Number of claims (Quality) (iv) Number of sequence clashes.	Pre-construction & Construction
7	Cost	(i) Cost Performance	Pre-construction & Construction
8	Team Performance	(i) Personnel turnover & productivity (ii) Timeliness of information from team	Pre-construction & Construction
9	Productivity	(i) Tonnes of concrete used per day / m^3 (ii) Pieces of steel used /day or week (iii) Number of piles driven / day (iv) Number of pile caps fixed / day	Construction

STATISTICAL ANALYSIS

The purpose of implementing statistical analysis techniques (correlation and multiple linear regression analysis) on this survey is to determine how time variable considered as a dependent variable influence by independent variables (safety, customer satisfaction, rework efficiency, communication efficiency, planning efficiency, cost, team performance and productivity). The method of data analysis adopted depends upon the complexity of the research problem. In this study, Spearman's correlation method and multiple linear regression analysis statistical tools were used for analysing the performance measures. Spearman's rank correlation is considered most suitable to test the association between any two variables and to show the probability of the association. Multiple regression is used to indicate the relative effects of independent variables on a dependent variable and the strength of relationships between the variables. SPSS software (Statistical Package for the Social Sciences) was used as the statistical tool for analysis.

Correlation analysis and multicollinearity

Correlation coefficient is a measure of the strength of any linear association between a pair of random variables. It measures how closely a change in one variable is tied to the change in another variable, and vice versa. Using SPSS tool, the correlation coefficient matrix obtained by the Pearson's correlation analysis is shown in Table 3. The first observation in Table 3 is that almost all the independent variables are correlated with the dependent variable (Time Y), i.e., there is a *dependence* of Y on X_1,

X_2,.... X_K. The correlation results indicate that Time variable is significantly and positively associated with rework efficiency (r=0.7, p<.01), communication efficiency (r=0.6, p<.01) and planning efficiency (r=0.6, p<.01). No significant relation was found between safety, customer satisfaction and productivity. This confirms that the independent variables which affect performance have been correctly identified. A better planning and communication of information can lead to decrease the amount of rework needed on a construction project. This will ultimately assist project management team to complete the project on time.

Table 3: Correlation matrix for performance measures

Performance measures	Time	Safety	CS	RE	CE	PE	Cost	TP	Productivity
Time	1.0								
Safety	0.2	1.0							
Customer Satisfaction (CE)	0.3	-0.1	1.0						
Rework Efficiency (RE)	0.7	0.5	0.2	1.0					
Communication Efficiency (CE)	0.6	-0.1	0.8	0.4	1.0				
Planning Efficiency (PE)	0.6	0.2	0.5	0.6	0.6	1.0			
Cost	0.5	0.7	0.0	0.6	0.1	0.4	1.0		
Team Performance (TP)	0.6	0.3	0.6	0.5	0.8	0.6	0.5	1.0	
Productivity	0.3	0.6	0.2	0.5	0.3	0.4	0.7	0.5	1.0

The correlation matrix is further used to check multicollinearity in the regression model. The severity of multicollinearity presence may usually be identified by inspection of the correlation matrix and the effect on the regression coefficients and their standard errors as a result of changing the mix of independent variables. The three variables i.e. client satisfaction, communication efficiency & team performance are highly correlated with each other. One possibility to solve multicollinearity is to drop from the regression analysis, variables which are a source of the multicollinearity *(Cooper and Weekes 1983).* If variable client satisfaction is dropped from the model, the adjusted R^2 reduces from 0.708 to 0.68 and similarly if variable communication efficiency and team performance is dropped from the model, the adjusted R^2 reduces from 0.708 to 0.67 & 0.70. Based on this reason, client satisfaction, communication efficiency and team performance is not excluded from the model, despite the presence of multicollinearity. The evaluation of the interview results indicates that the visualization of the model improves the understanding of the work package and scope of the work to both the client and team members. Consequently, they are able to communicate better with each other and increase the performance of the team.

Regression analysis

The details of the rating done by 21 respondents were in-put into the SPSS software and regression model was produced (Table 4). The predictive power of the model is judged through the statistical measurement coefficient of determination (R^2), which is a measure of the goodness of fit for the model. R^2 is used to measure the strength of the correlation when more than two variables are being analysed. The R^2 gives the proportion of the variance of Y, which is explained by the independent variables, reflecting the overall accuracy of the predictions. However, when the number of independent variables is introduced into the model, R^2 also increases. A better estimate of the model goodness of fit is indicated by *adjusted* R^2. Unlike R^2, it does not inevitably increase as the number of included explanatory/independent variables increases. Model uses eight independent variables (productivity, customer satisfaction, rework efficiency, planning efficiency, safety, team performance, cost and communication efficiency) and has an R^2 of 0.708. The regression results indicate that Time variable is positively associated with project performance variables (productivity, customer satisfaction, rework efficiency, planning efficiency, safety, team performance, cost and communication efficiency). As generally interpreted, this (R^2) value indicates that 71% of project performance can be explained by the independent variable. It is worth noting different research traditions have different interpretations of acceptable value for R^2. While engineering models seek a high degree of explanatory power for use in design, social science models are more necessarily limited. A time-series models tend to have a high R^2 of 0.5 to 0.7 (*Kennedy – 1998)*. The standard error is a measurement of the dispersion for the regression model's prediction power. The standard error of estimate is 0.52071, which is low.

Table 4: Summary table for regression analysis

R	R Square	Adjusted R Square	Std. Error of the Estimate
.841(a)	.708	.513	.52071

FINDINGS OF INTERVIEWS

Analysis of the information gathered through interviews has assisted in understanding how project and planning managers perceived the benefits of 4D planning, how it could be improved and what are the barriers in the implementation of 4D planning within the industry. A majority of the project managers felt that the use of 4D planning has assisted them in risk reduction in schedule programme, decreasing the amount of rework and reduction in overall project duration. Following are the benefits of using 4D planning on the basis of information collected from the interviews:

- Risk reduction in a programme.
- Detecting sequence clashes
- Improves visualization.
- Assist in reducing overall project duration
- Enhanced client satisfaction
- Assists in reducing the amount of rework required to be done.

Project managers felt that work force attitude (lack of awareness), lack of sufficient IT skilled people, resistance to change by general contractors were cited as the major concerns for successful implementation of 4D planning. The major impediments in the implementation of 4D planning in construction are:

- Lack of sufficient IT skilled people with the required knowledge of 4D.
- Time and money involved in training to upgrade the skills of work force.
- Resistance to change within the industry and to go through a new learning curve.
- Construction companies are not eager to invest in research and development.
- A lack of system compatibility, standardization and willingness of user to adopt this technology.

A due consideration should be given to the parameters like cost of the project, complexity of the project, risk involved and level of details required before developing the 4D models. There is a great need of improvement required to link the knowledge based system with the 4D models to analyse the feasibility of schedules from cost, safety, and other performance metrics viewpoint.

CONCLUSIONS

Findings of the interviews indicates that the industry is making less effort to reap the benefits of 4D planning and to improve the working practices at site level. Industry is still considering 4D as a demonstrative tool rather than a planning tool. To fully exploit the benefits of 4D technology, stakeholders are required to develop a new set of skills and implement organizational changes. There is a great need and demand to bring project team together at an early stage of the project. Designers are required to focus more on overall design and coordination of design tasks to avoid conflicts at construction stage. General Contractors are required to work more closely with designers from the design development stage to provide their valuable input at early stages of designing to capitalize the benefits of 4D planning. This will assists in addressing buildability and coordination issues during an early design stage of a construction project. As a consequences site efficiency can be improved by reducing the amount of errors, rework and waste involved during construction stage.

While there were some differences existed between owners and contractors relative to their views about 4D planning and its benefits, but there were common opinions among all stakeholders relative to the following points:

- All respondents felt that 4D planning is an effective project control tool for monitoring, planning and executing a project.
- Majority of the respondents felt that 4D planning is a beneficial in risk management applications.
- All respondents felt that 4D is an effective interpretative and communicative tool compared to 2D drawing approach.
- 4D facilitates in communicating the issues relating to construction of the interrelated works between the stakeholders and especially with suppliers.

This study has identified five key performance indicators consistently perceived as being highly significant at site process level are: time, safety, client satisfaction, rework efficiency and communication efficiency.

Future research activities

The future research activities will include:

- Continuing the interview process to further confirm the 4D-based KPIs.
- Collating and analysing the site data and to quantify the KPIs for three construction projects.
- Benchmarking the KPIs with industry norms and identifying the improvements in construction processes resulted due to the application of 4D planning.
- Conducting cost/benefit analysis.

SIMULATION AIDED PROJECT DECISION MAKING

Abdulsalam A. Al-Sudairi[1]

Associate Professor, Architectural Management Program, College of Architecture & Planning, King Faisal University, PO Box 2397, Dammam, 31451, Saudi Arabia

One important role of project managers is to make decisions before, during and after the project execution. Most of the time, these decisions are neither straightforward nor easy to take and therefore, they require careful analysis and evaluation, which might require a tool such as simulation. In order to assess the right decisions simulation perhaps is the most sophisticated tool for project managers. This paper demonstrates the potentiality of object-oriented simulation models in making hard decisions on a complicated construction project. The project is located in King Faisal University campus in Dammam, Saudi Arabia. By analysing its structural system and its architectural components, this building can be divided into smaller segments. Thus, there are different ways of sequencing the construction of this building. Making a decision on the optimum sequence is very crucial. Simulating the construction process of the aforementioned building required careful data collection through field observations and interviews. The purpose of this data was to describe the logic and the inputs to the construction process that are necessary for model verification and validation. With a verified and validated model one can evaluate the different ways of sequencing the construction activities of this case study. Object-oriented simulation models are absolutely essential in simulating construction processes because they fit the nature and the requirements of such processes. Building a sound simulation model starts with careful understanding of objects, their classes and how they are interrelated with each other.

Keywords: modelling, object-oriented, process, simulation.

INTRODUCTION

Management is about making decisions. In construction projects decisions are made on a daily basis where most of them are programmed. Programmed decisions are those that are made in accordance with some habit, rule or procedure. Stoner and Wankel (1986) pointed out that every organization has written or unwritten policies that simplify decision making in recurring situations by limiting or excluding alternatives. Unfortunately, not all decisions can be programmed because there are compound variables that may lead to different alternatives where each one has both advantages and disadvantages. Which alternative is the best remains a very difficult question to answer especially in large projects. To assess these solutions and to make the right decision, managers are advised to use sophisticated tools like object-oriented modelling. In fact, using traditional tools like CPM and PERT may lead to some disadvantages, such as time delays due to extended reviews (Bhuiyan and Thomson 1999; Wei *et al*. 2002). Besides, these tools are not dynamic and very difficult to perform what-if analysis.

[1] aalsudairi@kfu.edu.sa

This study demonstrates the use of object-oriented modelling in a relatively large construction project in order to determine the best sequence in constructing it. The construction project of the college of architecture and planning building in King Faisal University campus in Dammam, Saudi Arabia, was chosen as a case study and modelled in Extend+BPR®, which is an object-oriented simulation package. The simulation model focused on the construction process of the structure of the aforementioned project.

This case study concerns a three-storey building with almost 7000 m^2 per floor. Rethinking the work structuring of this project, one may come up with numerous ways of sequencing its progress. Such a case study could be constructed floor by floor or each floor may be divided into smaller segments so that construction progresses from one segment to another. Furthermore, segmentation of the project could be done according to its physical characteristics (e.g. structural/architectural) that may lead to a difficult situation of the work structuring of this project.

Different work structuring may affect the size of the work-in-progress (WIP). This is because work structuring breaks down a project into smaller production chunks that move in the value stream until they become the completed work (Tsao *et al*. 2000). The size of WIP, on the other hand, may increase or reduce cycle time of a production system. According to Little's law, the following formula for the relation of cycle time and work in progress in any production system can be derived (Koskela 1999):

$$\text{Cycle time} = \text{work-in-progress}/\text{throughput}$$

Thus, by reducing WIP, the cycle time is reduced, provided that throughput (throughput is the rate of, or interval between, finished products) remains constant.

Moreover, simulating construction processes requires careful examination of its flow units (which are known as *objects* in simulation terminologies), operations and their logic, inputs and outputs to these operations and so forth. Recognition of such issues is crucial in building a sound simulation model.

Thus, the main objective of this study is to investigate the potentiality of simulation in solving complicated problems that are almost impossible to solve with traditional methods. To construct a simulation model for the aforementioned case study, data collection and field surveys were conducted to identify model inputs and logic that are necessary for verification, validation and analysis.

THE NEED FOR SIMULATION IN CONSTRUCTION PROCESSES

Simulation is defined by Pritsker (1995) as the process of designing a mathematical model of a real world system and experimenting with the model on a computer. Simulation uses a computer program to actually mimic causal events and the consequent actions in a system (Harrel and Tumay 1997). Simulation is a management tool that does not typically generate an optimum solution to a problem (Moore *et al.* 1993). In fact, it is a solution evaluator; it directs one towards the best workable solution (Harrell and Tumay 1997).

The use of simulation for modelling construction activities enables the modeller to test almost all possible changes to a construction process and hence give a clearer picture of the optimum solution (Slaughter and Eraso 1997). In fact, Martinez and

Ioannou (1997) stated that simulation-based methods are almost universally accepted as the most effective because of their modelling versatility and power.

Utilizing simulation in construction processes needs thorough investigation. Each construction process is almost unique because of factors such as weather, site conditions and resources availability. The type of construction materials is also a critical model input. The delivery and unloading methods, the type and size of resources and the construction methods are all dependent on the type of material flowing in a process.

Halpin and Riggs (1992) developed four steps in model formulation. These steps are (1) flow unit identification (a flow unit could be a physical item of descriptive work); (2) development of flow unit cycles; (3) integration of flow unit cycles; and (4) flow unit initialization. One may notice that the flow unit is a key word in these four steps. This is because the selection of the flow unit dictates the degree of modelling detail incorporated into the simulation model (Halpin and Riggs 1992). For instance, identifying a material flow unit in a block-laying process could be laying a section of blocks or laying one block. In this case, the latter assumption would be more accurate than the former assumption because it almost mimics the real system. Fortunately, today’s simulation packages give the opportunity to go into such detail with relative ease.

The structure of the case study is mainly constructed from cast-in-place concrete. Because of that, a cubic metre of concrete is assumed to be the flow unit in the simulation model. To be more specific, each cubic metre was further identified according to its structural elements. The structural elements are footings, columns and slabs. The reason behind such detailing is that each element has certain requirements that may vary enormously. For example, the time to place a cubic metre of concrete for a footing is not like placing the same amount of concrete to a column.

With features offered in object-oriented simulation packages, going into such detail become very easy and more importantly suits the nature of construction processes. To be specific, modelling with object-oriented simulation packages is even more effective and easy when compared with other simulation packages (Al-Sudairi 2007; Cheng *et al*. 2006; Farrar *et al*. 2004). The remaining sections will discuss these issues in more detail.

What is object-oriented modelling?

Though it is not clear what makes certain software object-oriented many programmers, software professionals and end-user applications proclaim products that are object-oriented (McGregor and Sykes 1992). In addition, information technology experts do not agree about what actually constitutes an object-oriented simulation package. This study adopts the definition of McGregor and Sykes (1992), who claim that a software system supports three concepts namely *objects*, *classes* and *inheritance* to be considered object-oriented.

An object-oriented program is a software system whose components are *objects*. Each object is characterized by its own set of attributes and by a set of operations that it can perform (McGregor and Sykes 1992). Bank transactions, temperature degree in a room and processing a design/construction permit are all examples of objects. A cubic metre of concrete of a footing, a column or a slab is the basic object in the simulation model of the construction process. A combination of several cubic metres of concrete, which is the basic object, forms another specific object that could be the footing, column or slab.

A *class* is a set of objects that share a common conceptual basis. All objects in a given class have matching attributes and operations. For example, a column, which is one of the objects in the simulation model, has many classes according to its location and structural properties. As there are 144 columns per floor this has become very crucial in modelling the concrete structural process of this case study. Similarly, using an object-oriented simulation model made the identification of this large number of columns very easy. In general, object-oriented simulation packages support a graphical environment that makes the process of building a simulation model easier. In fact, the users do not have to access lower-level programming language details as well (Cheng *et al*. 2006; Laguna and Marklund 2005).

Inheritance is a technique for using existing definitions as the basis for new definitions (Law and Kelton 2000; McGregor and Sykes 1992). Here, *inheritance* means that if one defines a new object type (sometimes called a *child*) in terms of an existing object type (the *parent*), then the child type inherits all the characteristics of the parent (Law and Kelton 2000). Optionally, certain characteristics of the child can be changed or new ones can be added. As mentioned earlier, a cubic metre of concrete is the basic object and many cubic metres of concrete would generate almost new objects such as footings, columns or slabs. Figure 1 shows the inheritance concept of the simulation model of the case study where an *object* starts from a cubic metre of concrete to a part of the whole building. Here, the simulation run will be terminated once the building is completed.

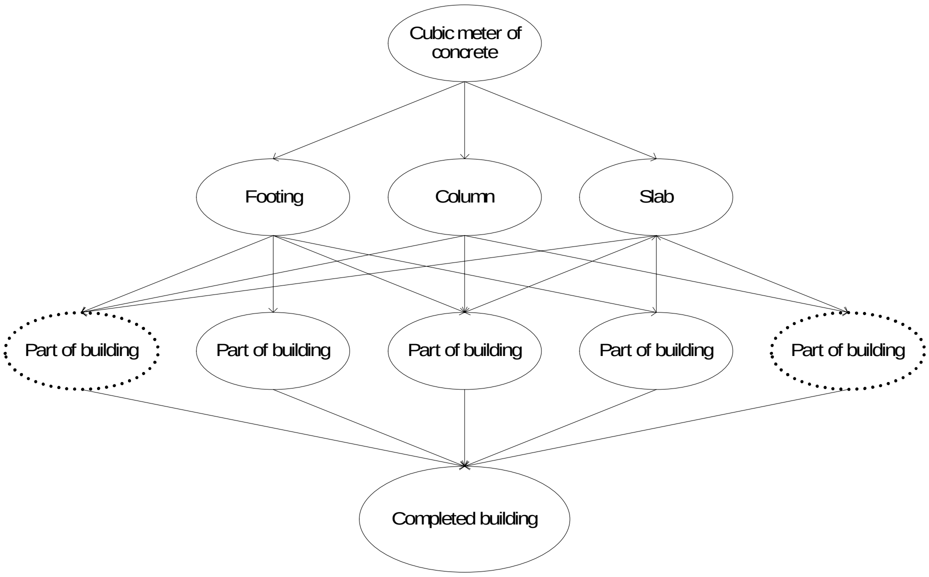

Figure 1: A hypothetical representation of the model objects

The logic of the model for this study was set to sequence construction activities of the footings, the columns and finally the slabs. It is true that there were similarities as well as differences among these specific objects. For instance, the time taken to strip the formwork of slabs was longer than those activities involved in both footings and columns.

In this study Extend+BPR® was selected because of its simplicity of use and its adaptability in modelling lengthy complex processes (Al-Sudairi 2007).

The most important parts of any Extend+BPR model are the *blocks*, the libraries where blocks are stored, the dialogues associated with each block, the connectors on each *block*, and the connections between blocks. A *block* specifies an action or process; it is used to represent a portion of a model. Some blocks may simply represent sources of information. Others may modify information as it passes through them. In other words, a block is a high-level modelling element for building simulations without programming (Extend 2002). Information comes into the block and is processed by the program that is embodied in the block. The block then transmits information to the next block in the simulation through connectors as shown in Figure 2.

Almost all blocks in Extend+BPR have input and output connectors, the small squares attached to the sides of a block. Input and output connectors are usually predefined and their function is known in advance. Connection lines are used to hook blocks together; they show the flow of information from one block to another through the model (Extend 2002). Figure 2 presents a small portion of the simulation model. In this study there were almost 100 blocks used for the construction process.

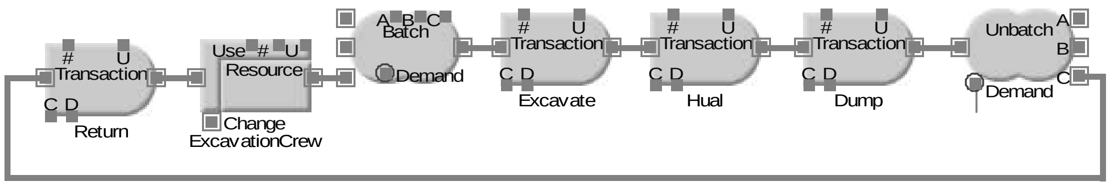

Figure 2: A small portion of Extend+BPR model that simulates excavation activities

CASE STUDY AND MODEL BUILDING

An empirical study is designed to demonstrate the potentiality of object-oriented modelling as a tool in managing construction processes. This study focuses only on the construction process of the skeleton; i.e. the model simulates excavation, backfilling, and all concreting activities of foundations, columns and slabs for all floors. Concreting activities included steel reinforcement, formwork, placing concrete and curing. Building a sound simulation model requires the following steps, which are basically the research methodology:

1. Data collection of the aforementioned activities (e.g. time and resources required to set formwork for a column) describes the logic of the model and its inputs. The sources of the collected data included drawings, bill of quantities performed by the general contractor, resources and their productivity rates, and a CPM schedule for the major phases in constructing the building. Certain cost data were gathered from the construction cost index manual prepared by Projacs (Projacs 2002).

   Figure 3 shows a typical floor plan of the case study. It is a rectangular floor plan with 110m in length and 64m in width. There is an atrium along the building dividing into two independent zones. Also, there are two expansion joints across the building dividing it into three independent areas in each floor (see Figure 3). With the atrium and the two expansion joints, each floor can be divided into six independent sections. Thus, there are four ways of structuring the work of this building which are (1) by levels (which is the actual/as-is case); (2) by zones; (3) by areas; or (4) by sections. Figure 4 conceptually illustrates these four scenarios.

The main structure of the building is a two-way concrete slab cast in place. The actual sequence of this building was done floor by floor and the construction took 360 working days to complete its skeleton.

The building is procured in a traditional design-bid-build with lump sum contract. The construction of the building began in September 1997 and was completed in October 2000.

2. Interviews with those involved in the design and construction of the case study are another source of information that serves two purposes. First, to get more data and confirm other data gathered in step one (e.g., the total time required to finish the whole skeleton, size and type of construction crew for certain activities, etc.). Secondly, to identify key experts for model verification and validation.

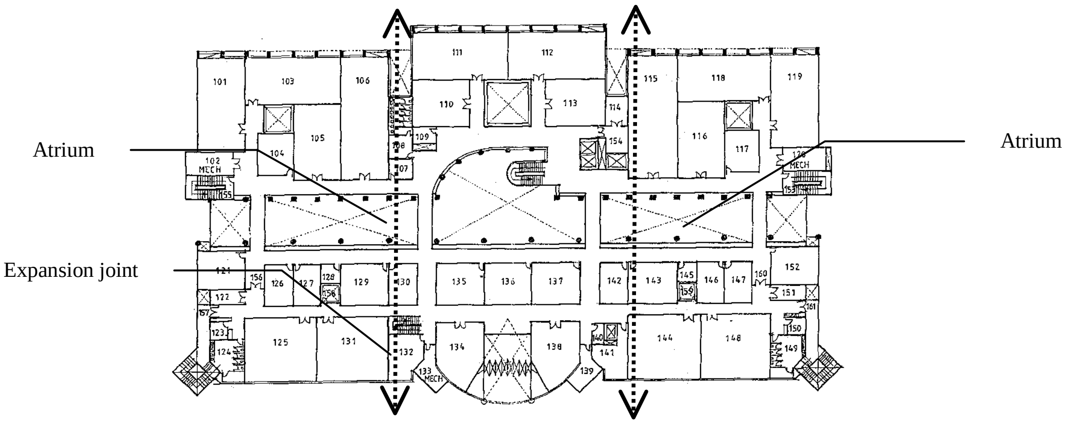

Figure 3: Showing the typical floor plan of the case study with its atrium and the two expansion joints

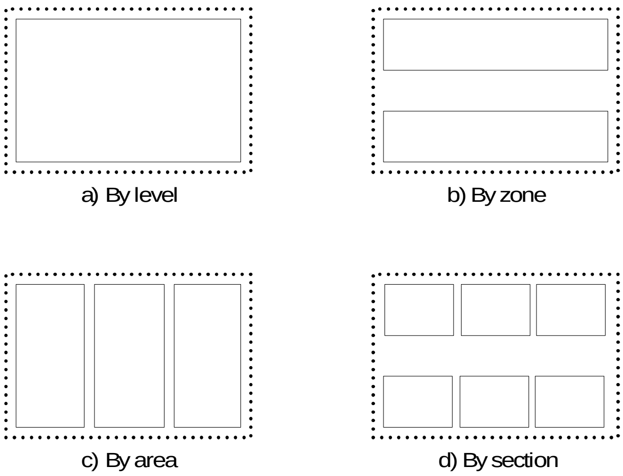

Figure 4: Showing the four possible scenarios in sequencing the construction process

3. Construct an initial model by simulating a small portion of the case study. In doing so, it is easier to verify the logic of the model. A complete model for the whole construction process of the skeleton was then constructed. The model simulates underground activities and overground activities. Underground activities include excavation, foundation and backfilling. Overground activities include column and slab activities for all floors.

Simulating the construction process of the aforementioned building required careful attributing of its objects (i.e. footing, columns and slabs). Each object in the model was identified by its structural function that varies from footings, columns or slabs and by its horizontal and vertical location. For instance, the model was designed to differentiate between two columns located on one level with different locations on the same level. This is accomplished by coding each column by its level, zone, area and section. In doing so, the model will not mix columns of section 1 with those in section 2 of the same level. Likewise, objects are identified vertically so that the model will not release objects of level 2 until all objects in level 1 are completed.

Table 1 shows a small portion of data input to the model that was utilized in order to differentiate between model objects and to be able to select any sequence of the four scenarios. The first column in Table 1 gives a code number to each column, which is a unique number so that the model can recognize each column individually. The remaining columns in Table 1 are set to identify each column according to its location. For example, column 72 is located in section 3 of area 2 of zone 1 on level 1, whereas column 73 is located in section 4 of area 2 of zone 2 on level 1. The same thing applies to footing and slab objects. It is worth mentioning that slabs in reality are not as clear as in columns or footings. For simulation purposes, the whole slab for each level in the case study was divided into smaller slabs according to columns carrying them. For example, a slab for a room with four columns will be divided into four slabs.

Table 1: A small portion of data input to the simulation model

Column	**Level**	**Zone**	**Area**	**Section**
71	1	1	2	3
72	1	1	2	3
73	1	2	2	4
74	1	2	2	4

4. Model verification is to ensure that every portion of the model operates as expected. Using features offered in Extend+BPR, such as animation, the author reached a confidence level that the model is functioning properly. Verifying a model does not mean the model is completed. One needs to make sure that the model is mimicking the real system.
5. Model validation means that the model is reflecting the actual system. The purpose of validation is to confirm the robustness of the simulation system by testing the simulation results for closeness to the actual system (Cheng *et al*. 2006). For instance, a project completion time of 330 days based on six working days per week and an eight-hour shift per day was obtained from the simulation model. This result was validated by comparing it to the actual completion time of major milestones as shown in Table 2.

Table 2: Comparing completion times of simulation results to actual data

Project milestones	**Simulation**	**Actual**
Substructure including excavation & backfilling	79 (day)	81 (day)
Ground floor	81	83
First floor	85	86
Second floor	85	85

Total		330	335

6. Model adjustment is carried out by looking into different scenarios with different work structuring that reflects the physical components of the case study as mentioned in step 1.
7. The results of the different scenarios of the valid model are compared with each other to reveal certain issues with respect to managing construction processes.

DISCUSSIONS OF MODEL COMPARISONS

For the sake of the research, the only change introduced to the 'as-is' model was the size of work that a construction crew can start with. The simulation model treated the size of WIP as the number of columns/slabs that vary according to the work structure, which could be by level (144 columns/slabs), by zone (72 columns/slabs), by area (48 columns/slabs) or by section (24 columns/slabs) as mentioned in step 1 of the previous section.

The second column in Table 3 shows the effect of reducing WIP to project cycle time, which is generally positive. There is a significant improvement in cycle time reduction, which is almost 17%, and better utilization; there is almost 30% improvement in crew utilization. When work structuring goes by 'area', there are enough workable activities on different segments of the building. That is, one crew could be working on foundations in one area while another crew is working on columns in another area. This means that work structuring led to a better synchronization and alignment of the construction activities where construction crews are kept productive most of the time.

Table 3: Comparing results of all scenarios

	Cycle time	**Total cost**	**Productivity**	**Utilization**
Level (as-is)	330 (days)	$296075	0.76 (M^2/hour)	61 %
Zone	277	$252852	0.97	71
Area	275	$250709	0.99	72
Section	318	$290850	0.82	62

However, the effect of reducing WIP to cycle time is not always exact, i.e. less WIP does not necessarily mean less cycle time. The least WIP (i.e. at 24 columns/slabs) reduced cycle time marginally as opposed to moderate WIP (i.e. at 48 columns/slabs) that reduced cycle time significantly (see Table 3).

Comparing the previous results to Little's formula, one notices a contradiction. This is because one condition of Little's formula is to have minimal waiting time between sub-processes. In construction projects, especially in cast-in-place concrete processes waiting time is inevitable. The waiting time in this case study ranged from two to three weeks that led to multiple stops and hence poor production. In fact, Santos *et al*. emphasized the role of technological innovation to reduce decoupling between processes so that they can start earlier (Santos *et al.* 2000). That is, one way of reducing waiting time in concreting processes is by adding certain admixtures to concrete so that it can set faster leading, to less waiting time.

Another lesson learned from simulation is that there could be more than one good solution with different ramifications as shown in Table 3, which is also consistent with the results of Al-Sudairi *et al*. (2000). The cost measure in Table 3 was only obtained from the direct labour expenses in constructing the building. The utilization measure is the percentage of time that a construction crew is actually engaged in primary work. Table 3 summarizes simulation results where the only change was the WIP. Other issues such as manpower and material availability, weather and learning curves are not considered in this model. Considering these issues would definitely lead to multiple scenarios with different results. For instance, taking into account concrete formwork would add another difficulty to the decision-making process. That is, the least WIP would require less formwork with multiple usages that may require getting extra formwork. However, the largest WIP would require larger formwork with few usages that might not require any extras. Having said that, it is difficult to analyse a problem of this nature with traditional tools; indeed, simulation is one of the right tools that gives the opportunity to explore and evaluate multi-dimensional problems.

Again, object-oriented modelling gives us the opportunity to examine the impact of waiting time between concreting activities to the total cycle time of the construction process. To test the impact of waiting time to WIP, a hypothesized waiting time was introduced to the model. Results presented in Table 4 are based on a hypothetical waiting time between sub-processes, which ranged from one day to seven days, just to show the importance of overcoming decoupling between processes and making them flow continuously. When waiting time is one day Little's formula became absolutely true. The least WIP led to the highest reduction in cycle time.

Table 4: The impact of waiting time to the total process cycle time (days)

Waiting time	Level	Zone	Area	Section
One day	248	216	210	204
Two days	260	218	212	206
Seven days	272	223	217	216

It is apparent from the findings presented in this paper that simulation is indeed a powerful and flexible tool. It is powerful because it enables the modeller not only to consider many factors but also to measure the impact of each factor to the simulated system. Likewise, simulation is flexible tool because it can accommodate multiple scenarios in one model. The simulation model of this study was set so that it can mimic the four scenarios with little changes. Moreover, questions like: what things management should give up in the current practice; what are the consequences of adopting certain changes; what is the most effective scenario, and so forth can be answered easily. These features are very difficult to obtain when using other tools.

The three concepts (*object*, *class* and *inheritance*) associated with object-oriented modelling are absolutely essential in simulating construction processes because they fit the nature and the requirements of such processes. Building a sound simulation model starts with careful understanding of objects, their classes and how they interrelate with each other. In construction projects, objects vary from one process to another, which poses another difficulty in modelling them. Simulating a block-laying process is not like simulating a steel erection process. Therefore, the objects in the later process, which are steel members, are not as interchangeable as the objects, which are blocks, in the former one. Appreciation of this fact is the first step towards sound simulation models because it enables the modeller to be as close as possible to the real construction process.

One may argue that modelling with simulation takes time and effort and is also very difficult to verify and validate. This is truly a misconception as modern simulation packages are object-oriented and usually associated with graphical environments that do not need a sophisticated programming background. Equally it is very easy to construct, and also flexible for changes if necessary.

CONCLUSIONS

This study advocates the use of object-oriented simulation modelling as an essential tool for analysing and evaluating construction processes. The construction process for architecture and planning for building presented in this study is very difficult to analyse and to reach an optimum solution with traditional tools. Indeed, simulation is a superior tool due to its numerous advantages as being dynamic, flexible and beneficial through all project phases.

Identifying objects and systems that usually govern them is crucial in simulating construction processes using object-oriented modelling tools. The complicated case study presented in this paper was easily evaluated by using this tool.

One great lesson that can be learned from simulation is that there could be more than one good solution with different ramifications. The best solution may be hindered by traditional practices such as bad process design. In addition, factors like material and labour availability were not considered in the simulation model that would definitely add another dimension to this study.

The improvement gained by reducing the size of work-in-progress is mainly limited by waiting time and decoupling between processes. Reduction of WIP requires smooth flow in the value stream that in turn leads to cycle time reduction and better crew utilization. This means great savings in effort, time and cost that are fundamental in managing construction projects.

IMPROVING CONSTRUCTION AS AN ECONOMIC SECTOR: SOME REFLECTIONS

Francis T. Edum-Fotwe[1] and Ronald McCaffer

Department of Civil and Building Engineering, Loughborough University, LE11 3TU, UK

The drive for continuous and significant improvements and productivity gains in the construction sector has received attention from different stakeholders associated with the sector. Much of the initiative to improve construction was prompted by similar gains that attended the manufacturing sector after the latter sector had undergone a transition from a craft-based to a process orientation, with many of the processes being automated. The significant improvement in the manufacturing sector prompted the adoption of a programme in the 1990s to reform the construction sector in the UK to reflect a more manufacturing outlook for its operations and business activities. While this initiative produced several notable developments, there have been queries raised in recent times on how the sector's performance can be improved on a sustainable basis. For any sustainable improvement scheme to work effectively, it has to be accompanied by a shift in the cultural perspectives for improvement in construction. Within the paper the authors explore the general concepts of improvement and innovation as well as the nature of innovation in the construction sector. They address the apparent slow rate of innovation that has been associated with construction for several decades. They also make the case that much of the transformation which the sector would have to undergo to enable construction to attain the same levels of improvement and innovation as obtains in the manufacturing sector would have to be a cultural reorientation to make innovation the norm, rather than the exception. A framework to support the formal execution of continuous innovation is presented.

Keywords: construction, culture, improvement, innovation, systems.

INTRODUCTION

The 1990s saw unprecedented efforts by the UK to transform its construction sector from its traditional approach to delivering projects to become more of a manufacturing process (M4i 2000). This was conducted under the flagship Innovative Manufacturing Initiative, aimed at stimulating innovation across different industrial sectors within the UK (Graves *et al*. 1998). Construction's programme under the Innovative Manufacturing Initiative scheme was captioned under a theme of construction as a manufacturing process. The rationale of 'Construction as a Manufacturing Process' was to encourage construction to adopt and emulate the process orientation widely reflected by the manufacturing sector. The aspiration of Construction as a Manufacturing Process was to stimulate similar levels of productivity gains and operational improvements that attended the transition from functional to process orientation by the manufacturing sector (McCaffer and Edum-Fotwe 2003; Winch 2003).

[1] f.t.edum-fotwe@lboro.ac.uk

Within this paper, the authors explore the general concept of innovation and the nature of innovation in the construction and other sectors. The authors give attention to the apparent slow rate of innovation that has been associated with construction for several decades. They argue within this paper that a root and branch examination of the various systems that make up construction would have to be performed to enable construction to attain the same levels of innovation as obtains in the manufacturing sector. Fundamental to the transformation that the sector would have to undergo is a cultural reorientation to make innovation the norm, rather than the exception at all levels within construction. A framework to support the formal execution of continuous innovation is presented.

DRIVE FOR IMPROVEMENT IN CONSTRUCTION

Concern for improvement of the construction sector has been shared over the years, with several reports commissioned to address various issues that were considered as relevant to construction performance (Langford and Murray 2003). The Technology Foresight Panel (1995) for example, provided a catalyst for construction to see its processes from this business perspective. Subsequent developments, such as Egan (1998) and its forerunner, Latham (1994), adopted the view of a *customer or client is king* focus, with recommendations for improvement in the value that clients gain from implementing projects. The closer focus on the requirements of the client advocated by Egan (1998) was also a response to domestic competition and emerging economic realities from increasing globalization. The arrival of various benchmarking schemes including the European Construction Institute Performance and Process Benchmarking Initiative provided channels for attaining the business and organizational improvement implicit in such a client orientation. The related key performance indicators from the Construction Best Practice Programme, and the Movement for Innovation (M4i 2000) were aimed at spearheading a nationwide improvement in the sector. The impact of these initiatives, along with developments that have continued from the new initiatives, has been a new way of doing business in construction (Egan 2002). For example, new forms of contract, such as two-stage design and construct, contract management, private finance initiatives (and public–private partnerships) are fostering a new business climate for the sector (HM Treasury 2000).

These changes are contributing to a re-definition of the roles and positions of key stakeholders within the sector. For example, there has been a gradual shift observed in the role of the architect, which had hitherto been a *lead* for the project team in the building sub-sector of construction to *concept guardian*, with the managerial leadership subsumed by other professionals (Edum-Fotwe and Thorpe 2002). Equally observable is the growth of supply chain principles in the sector, spurred on by a need to bring about better alignment of the various supplier organizations that provide inputs to the project. The initial efforts on supply chain improvement addressed the physical logistics. Later developments saw the inclusion of information resources in improving logistics. To be able to put some these improvements achieved through the efforts of Construction as a Manufacturing Process agenda, it is important to place such achievements in the light of what constitutes innovation and how it may be stimulated in construction.

INNOVATION AS KEY TO IMPROVEMENT

The concept of innovation addresses both incremental and radical changes to processes, services and products of a company or an industrial sector. According to Christensen *et al*. (2004), the primary goal of innovation is often to solve a problem by bringing to life ideas generated through creative talent. The nature of the problem could range from the very technical such as addressing operational inefficiency or correction of design error, to the more subtle business requirement, such as the need for market growth. As such, the motivation for, and scope of innovation undertaken by, an organization could vary extensively in scope and often would involve considerations that transcend one single discipline (European Commission 2006). Figure 1 illustrates different categories of improvement that a construction organization may have to confront and identifies these as seven primary types of innovation. The next sections address each category of innovation briefly.

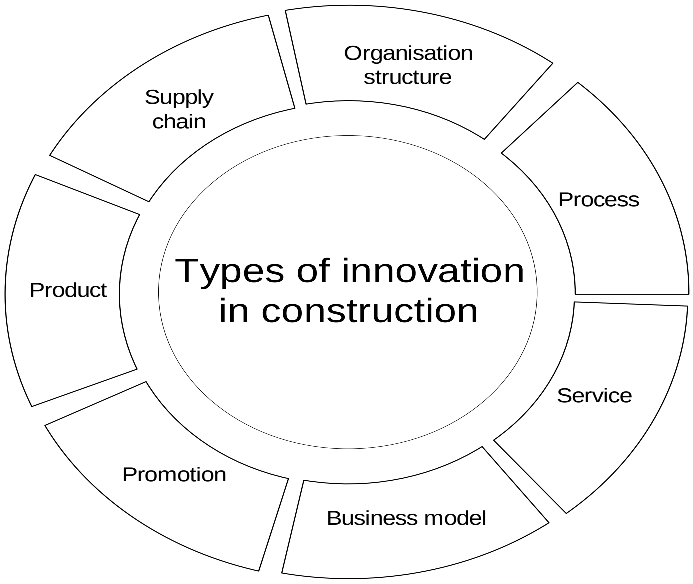

Figure 1: Innovation categories for construction organizations

NATURE OF CONSTRUCTION INNOVATION

There are two modes by which a construction company can implement innovation. These are incremental mode and radical innovation mode. The two modes are not mutually exclusive and one mode can be used to support the other in a programme for company or industry improvement. The incremental mode involves improvements whereby small changes are made to existing processes, products and practices, without altering the essential nature of the company's activities. The radical mode on the other hand entails a substantial overhaul of the organization's systems. It questions the raison d'être of each part of the organization, and often will result in a significant change in the purpose and basis for conducting the activities of a company (Tucker 2002; Turner 2006).

Figure 2 illustrates progress in performance improvement for two organizations, A and B. Organization A's incremental innovation efforts over time would result in a performance gap of $P_{b1} - P_{a1}$, which will widen over time.

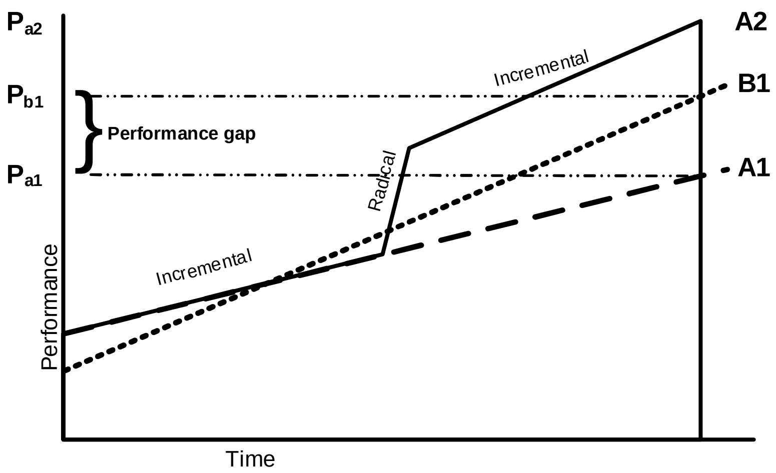

Figure 2: Nature of innovation in construction

The only means for addressing the performance gap is for Organization A to undergo a transition through radical innovation for a majority of the innovation categories outlined in the earlier sections of this paper.

The timing of radical innovation by a construction company is crucial as it enables an organization to inject a new pace into its activities and prevent the onset of obsolescence (Senge *et al*. 1999). Incremental innovation on the other hand is required all the time. Identifying what aspects organizations should earmark for incremental innovation and the frequency of conducting radical improvement is a capability that is essential for maintaining competitive advantage (Oke 2001).

While construction can boast of exemplar cases of leading edge developments, such exemplar developments are not widely shared across the whole of the industries making up the construction sector. This is due to the time constraint faced by most companies as well as the heightened levels of competition that characterize construction (Gregory and Deasley 2002). Typically therefore, a greater proportion of the effort of most construction executives is devoted to achieving and addressing the efficiency of the tasks they undertake rather than exploring radical alternatives for more effective solutions. Any improvements and innovations are therefore conceived within the limits that enable construction executives to maintain the same degree of control of the procedures involved in the tasks they undertake. Construction's posture on innovation as a result tends to reflect an incremental mode, whereby executives contemplate only small changes that do not dramatically alter their current operations and business. While the pursuit of such an incremental mode for innovation may be good in its own right, any organization that adopts only that posture potentially runs the risk of being overtaken by the competition.

SECTOR-WIDE DIMENSION OF INNOVATION

While it is easy to identify isolated cases of innovation by individual organizations at company or project level, the extent to which these isolated innovations are shared across the sector is more difficult to classify. Figure 3 presents a profile of innovation effort within construction at the organizational level and how the individual efforts are reflected through the whole sector. The essential argument that is presented in Figure 3 is that construction's innovation and improvement efforts tend to reflect the technical/technology and/or society and community driven factors. Notable in the technology stream of factors is the use of ICT, and similarly for society and the community is the reputation of the company and the sector as a whole. While the economic aspects of the sector receive much attention, there is relatively little or no effort in innovation or radical improvement in productivity that attends the economic considerations (Latham 1994; Egan 1998 and 2002). This is in part due to the context of economics within construction. Traditionally, economics in construction has focused predominantly on the optimization of onsite tasks and functional activities (Edum-Fotwe 2000). A fuller discussion of the sub-categories of technical, economic and society factors has been provided as part of the SUE-MoT project funded by the Research Council in the UK.

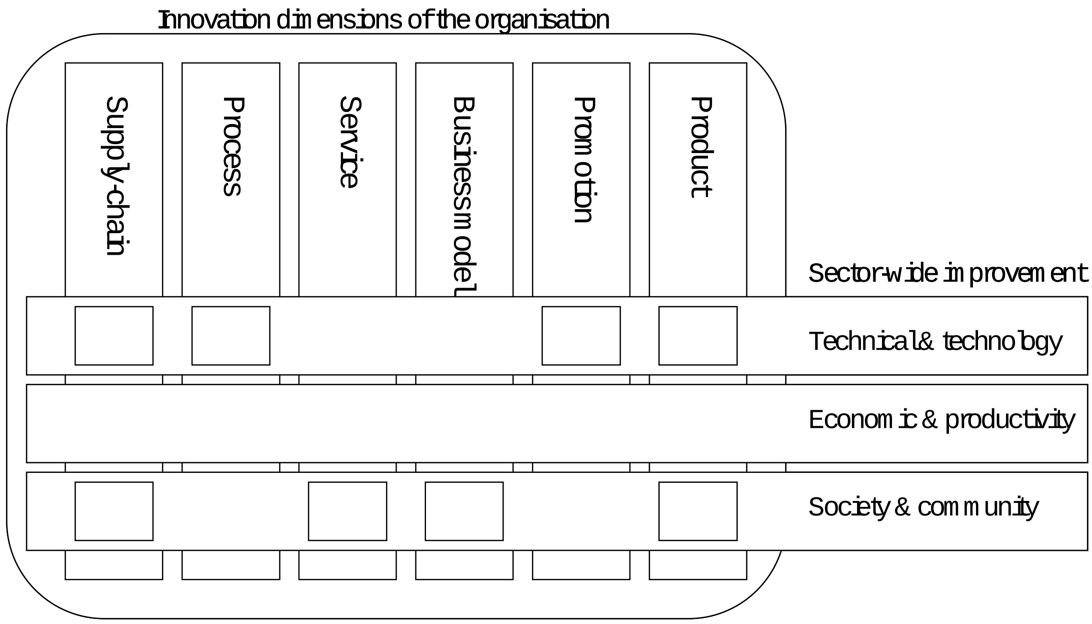

Figure 3: Innovation efforts across different dimensions in construction

The absence of or limited effort in economic innovation has contributed to a situation whereby the economic motivations of the construction sector appear to lag behind that of other sectors. The nature of economic realities that led to the development of the concepts of business and economic activities for the construction industry have undergone significant changes (Flanagan *et al*. 1998). It therefore calls for a revisit to the fundamentals of what constitutes the construction economy – its scope and areas of activity, as well as how it can be made to address present realities and potential changes likely to impact on the sector. This can be achieved by giving attention to the theoretical foundations that give rise to the activities of the industry along the current applied orientation for its research and professional practice.

Construction economics – its scope and development

Construction economics broadly addresses the use of economic concepts for the operations and activities of the construction industry. It involves the application of the principles and know-how of economics to the business and production processes of the construction industry. This includes economic options of design solutions comprising design economy and cost planning, economic considerations for translating design solutions into physical facilities to meet defined requirements, and methodologies for cost estimating and control. It also involves the economic functioning of firms within the construction sector as well as the relationship of the sector to national and international economies.

The need for a wider scope

The outlined areas of focus for construction economics within the industry's activities clearly reflect the Adam Smith concept of 'how scarce resources are allocated among the alternative users' as in general economics. It can be argued therefore that construction economics is no different from general economics or, for that matter, economics for any other sector of production. Ofori (1994) however, has suggested that construction economics developed as an outcome of the unique nature of the construction industry, which is characterized by large and expensive physical products, a complex industry structure and production processes, and a distinctive method of price determination. This underlying character of construction means that some of the generic principles from mainstream economics need to be fine-tuned to ensure their applicability to the industry's context. Equally, it calls for an appreciation of the underlying theories that drive the economic activities of the industry and its associated processes aside from the general principles of economics. In practice however, the development of construction economics has largely been influenced by its relationship to the industry and professional institutions associated with quantity surveying, commercial management, engineering economics, development economics, and investment and finance. The rationale for this strong influence is that construction economics is an applied subject and as a consequence its research focuses on the applied to the exclusion of the broader understanding of the theories that characterize construction activities. Commenting on this Betts and Wood-Harper (1994) suggested that the subject area appears to be developing in an evolutionary way based on the culture of industry practices, and largely unaffected by mainstream economic concepts and theories. This lack of strong foundation within mainstream economics and management for construction economics might be accounted for by the fact that construction has always seen itself as part of engineering. As such its principles of economy are predominantly based on and influenced by engineering concepts. Therefore, in order that such theories from mainstream economics can have a place in construction economics, research effort needs to be devoted to the demonstration of the applicability of these theories to the construction context.

According to Bon (1989) construction economics has focused on forecasting the economic consequences of a building decision on the basis of ever more extensive historical data about individual buildings and their components. However, the key task of building economics is to assist the decision makers concerned with building economy in their day-to-day operations involving the entire real property holdings at their disposal. Bon (1989) goes on to argue that the problem with the old focus of the field is twofold. On the one hand, the economic history of building activity is an important area of study in its own right, but the practical significance of building economics hinges on the field's sensitivity to the anticipation of continual economic change facing decision makers. This necessitates a viewpoint much broader than a prediction of the potential impact of the decisions relating to a single project. In addition Bon (1989) describes the record for the use of economic forecasting within the construction sector as not convincing over the extended periods of time associated with the building life cycle. To address this apparent shortcoming of construction economics, Bon (1989) advocates that the focus of the subject should be shifted away from investment decisions to decisions concerning the use of capital. His more significant argument was the view that such an active orientation on capital decisions for the problems of construction economy would require investigations of the theoretical underpinnings for economic activities within construction.

Modern economies are no longer based on the simplistic concept of mass production and consumption of goods and services (Green 1998). There is ample evidence to suggest that in very many instances, producing more in the current changing environment, however efficiently, is not necessarily better in terms of the strategic goals for every business. While lessons on this can be readily drawn from the IT sector, some vivid analysis can be established with the housing sector. This is perhaps epitomized by the trend towards downsizing and repositioning to focus on core business for several major construction organizations to increase productivity in the short term. However, downsized organizations often have to face a future that suffers from low financial performance if their first and repeat business is dependent on labour-intensive operations, which is the case for construction (Edum-Fotwe 1995). Its operations and processes are dominated by a high labour content. The picture here is that the sector is changing, and therefore the economics concepts and theories need not only to respond to such changes, but also to understand the dynamics of the new and evolving form of economy. This paper argues that it is not just economies that are changing. Economic theory is itself responding to the challenge of rapidly moving events. Construction economics therefore ought to take a look at new approaches as well as the established orthodoxy, and systematically build up an understanding of economic theorizing so as to offer opportunities and ideas to practitioners for application to real problems.

IMPROVING THE CONSTRUCTION ECONOMIC SECTOR

Clearly, there is a role for research in engendering the new agenda of a broader scope for the subject and responding to changing economics as advocated in the previous sections. Within the CIB, the work of the various task groups and working commissions already reflects some of the aspects of a broadened scope for the subject (Bröchner 2003). These need to be integrated to give construction economics a more defined role so that areas of economics not so represented can be addressed. Research in construction economics should be able to reflect adequately the sum total of economic activity within the construction sector. Also such a broadened scope could give attention to the new and emerging economics required for the sector, and its relationship to national and international economies.

THE WAY FORWARD

To overcome some of the weaknesses discussed in the foregoing sections of this paper it is expedient to have a generic framework for implementing innovation that can be employed at both organization and sector level. Such a solution will help to make construction's efforts to become innovative on a sustainable basis a formal activity that could lend itself to better planning and management. Figure 4 presents a flow process for the generic framework for implementing and managing innovation. The framework results in an innovation system that is implemented at either organization or sector level. The additional system inputs reflect unmanaged and managed environments. The unmanaged environment is represented as leadership, ideas bank, individual initiative, imposed innovation and unintended innovation.

The managed environment consists of structural changes, resources and enabling technologies, sub-processes and procedures, and a supportive culture that nurtures innovation. The persistent use of the framework should help to engender a culture of incremental and radical innovation in balanced proportions and make innovation the norm for construction (Drayton 2006).

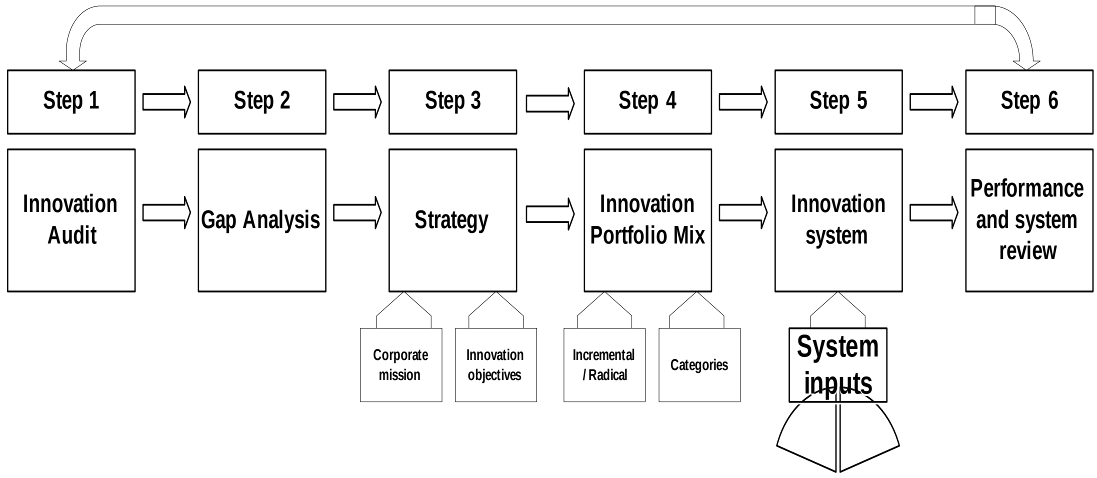

Figure 4: Framework for implementing innovation in construction

Additional to the implementation of the framework, there are other issues such as professional development programmes, education and training and possible regulatory instruments to foster innovation that will need to be in place. Some of the changes implicit in addressing each of these issues will be influenced by budgetary allocation. However, much of the change that will have to be advanced to make innovation a norm in construction will have to be cultural. An example will be a shift in professional boundaries to eliminate the *silo mentality* that prevails within the sector, to enable innovations that straddle different professions to be contemplated. Of equal relevance will be the alternatives put forward by Bröchner *et al*. (2005) and Winch (2006).

CONCLUSION

Within this paper the authors have explored the nature of innovation and the extent to which it pervades across construction as a sector. In an era when clients no longer demand the same price as the last project, but want reduced prices consistent with maturation of each process and product, it is important for construction to accelerate its innovation capability. The review of innovation efforts in construction indicates that construction operates at a sub-optimal level. The sub-optimality is accounted for in part by the focus of innovation within the sector. The focus of innovation within construction reflects technical and society factors, and less so economic ones. As such the causes of the sub-optimal levels of innovation can be traced to the nature and structures of the sector, as well as the arrangements for delivering its projects. In addition, the cultural posture within construction at both sector and company level inadvertently militates against the adoption of innovation. As a consequence, innovation effort in construction is predominantly informal, and often happens through serendipity. A framework to overcome the present informality as well as providing a systematic method for implementing innovation has been presented. The use of the framework at organization and sector level should enable construction companies to become more innovative.

LEARNING TO KNOW AND KNOWING TO LEARN: DISCURSIVE PRACTICE AS KNOWLEDGE ENABLER

Christine Räisänen[1] and Sven Gunnarson

Building Economics and Management, Chalmers University of Technology, Sven Hultins gt 8, Gothenburg, SE-412 96, Sweden

An important challenge for the construction industry is the capture and sharing of enacted, context-specific knowledge and experience. Such knowledge is made up of both technical components and components dealing with communication, motivation and social interaction. To manage this ensemble, a new professional praxis needs to be developed. Drawing on learning theories, this paper focuses on a particular activity, the dialogue seminar, which supports collective meaning making. The cornerstones of a dialogue seminar are the modalities of reading, reflecting, writing and dialogue. Based on empirical examples from our research on dialogue seminars and on our own application of the approach in a continuation course for the construction industry, this paper argues that collective learning needs a structured praxis and a legitimate place and time in the organization.

Keywords: collective learning, construction industry, dialogue, professional knowledge, reflection.

INTRODUCTION

Today, new practices, increasingly sophisticated and demanding customers, growing competition and more complex product differentiation are putting pressure on construction companies to pay attention to learning and knowledge dissemination within and between building projects. Although the complex issues of knowledge management and learning have been widely researched over the past two decades, much of this research has been concentrated on developing comprehensive information technology repositories to ensure that knowledge is codified and disseminated, e.g. standards, regulations, governing principles and prescribed practices. This explicit knowledge forms the governing accounts of how the organization works, and in due course become ingrained into the organization’s structures, making it difficult to question and contest (Gabriel 2000).

However, while formal structures do serve as viable repositories for the accumulation and transfer of explicit knowledge, they cannot capture the enacted, context-specific practices of a workplace, nor can they ensure that the experiences acquired from one project may be used as a basis for judgement in future projects. While these formal repositories are valuable for novices, who are struggling to learn the organizational routines, they are less effective for the capture and sharing of new knowledge in the making and lessons learned among practitioners. Moreover, actors in construction projects, at least in Sweden, prefer verbal to written communication and are more

[1] christine.raisanen@chalmers.se

likely to seek information from co-workers than from written documents or the intranet (e.g. Gluch 2006; Styrhe *et al*. 2004). They consider their day-to-day activities as mainly consisting of immediate, situated solving of emergent problems and rely on their close co-workers as knowledge resources (Knauseder *et al*. forthcoming).

There is a lack of mechanisms to enable distributed construction organizations to collectively capture the dynamic professional know-how created through the ongoing discursive interplay between people involved in situated action in local contexts (Lave and Wenger 1991; Scollon 1996). This implicit or 'tacit' knowledge cannot be articulated or codified since it is intimately linked to individuals or group practices in the workplace (Nicolini *et al*. 2003; Gherardi 2001; Nonaka *et al*. 2001). Rather it is disseminated through communication such as the exchanges of 'war stories' between members of a community of practice (Fong 2005; Orr 1996). Explicit knowledge is supported by tacit knowledge, and it is this tacit underpinning that guides the user in situations where judgements need to be made. Tacit knowledge 'is the understanding that enables us to produce behaviour without thinking about it' (Isaacs 1999: 51). Learning does not only mean acquiring knowledge content, i.e. knowing that, but also understanding the contexts in which that knowledge applies e.g. knowing how, why and when. Answers to the latter questions are usually embedded in organizational routines, norms and ideologies, and are the main causes of organizational inertia manifested in the 'not invented here' syndrome.

Narratives and stories are effective vehicles for sharing experiences and highlighting contradictions. They can be a means of creating a common platform for communication and collective thinking (e.g. Boyce 1996; Gabriel 2000; James and Minnis 2004; Weick 1996). A variety of more or less structured methods have been developed to collect and disseminate organizational narratives, storytelling workshops (Abma 2003), the learning history (Jeffries *et al*.) and conversations (Isaacs 1999). Most of these methods concentrate on the modality of speech; the stories are retrospective reconstructions of situations (Weick 1996), which are then shared and discussed among participants. Although such reconstructions are valuable for making sense of organizational discourses and activities as well as for triggering new ideas, the modality of speech remains elusive.

The purpose of this paper is to explore the possibilities of a structured collective knowledge-creating and sharing praxis in which several modalities come into play – reading, reflecting, writing and conversing – and where several minds and voices are dialogically engaged. The method, called dialogue seminar, was collaboratively developed in-house by researchers and the managerial players of a complex systems-development firm (Göranzon *et al*. 2006). The first author of this paper studied the development process and the praxis to assess its potential for other fields. We have then adapted and tested the method on a number of continuation courses for managers and in-house project management courses (Räisänen and Gunnarson 2006) in the construction industry. We first briefly discuss some inherent contradictions that hinder collective learning. We then describe the dialogue seminar praxis in its original context. We then show how we adapted the praxis to an educational context. The paper ends with a discussion of the windows of opportunity that the dialogue seminar opens for collective meaning making in organizations.

ORGANIZATIONAL CONTRADICTIONS

Although knowledge management and learning are recognized as important issues at the strategic level of an organization, there remains an inherent resistance to deal with the underlying psycho-social and cultural factors that influence learning. The strong positivistic belief in measurement and the transparency of the data tends to result in a reductionist definition of knowledge, equating it with information; hence the over-belief in information technology as the solution. A realistic description of organizations in general – which we think also applies in construction organizations – is that depicted by Claxton (1999), which he calls the implementation mindset. These organizations are driven by technocratic views of rational efficiency grounded in ideologies of rationality, quick-wittedness, decisiveness, and being articulate and well informed. However, research in cognitive psychology, neuroscience and learning, among others, are suggesting evidence to the contrary, namely that creative thought processes are not linear, quick, logical and articulate, but rather hesitant, meandering, subject to multiple revisions and inner deliberations before being expressed (e.g. Claxton 1999). Thought processes are dynamic social phenomena. They are context-specific, drawing on individuals' past knowledge and experience, their assumptions and prejudices, and their assessment of the situation. In other words the nature of creative thinking is a 'soft' process that takes place on a tacit plane fed by social interaction and discourse.

Action and discourse are inherently interweaved and every discourse is linked to 'an entrenched action-net of alliances that facilitate translation and mobilization of knowledge and modes of knowing' (Gherardi and Nicolini (2003: 214). The analogies, metaphors and examples embedded in the discourses trigger associations, which enable interlocutors to conceptualize and articulate tacit knowledge. This in turn makes it easier to internalize and memorize the information for future use. Therefore, codified knowledge (e.g. data) will not produce action on its own; it has to be interpreted, internalized and enacted by people in situated practice (e.g. Lave and Wenger 1991). In our view, one of the main problems with collective and organizational learning is not a lack of capability at the individual or group level, but rather the lack of learning practices that enable the sharing of tacit knowledge and make learning relevant, stimulating and worthwhile. Fong (2005) showed how dialogue, such as feedback and storytelling across disciplinary borders in cross-disciplinary construction project teams created mutual understanding and enhanced the sharing of tacit knowledge.

Learning across organizational borders, disciplines or spheres of society is to-date neither much practised nor much researched. Yet, this kind of learning can provide a totally new and enlightening perspective on in-house problems. By telling the story of a systems development firm's transformation into a learning organization, we provide such an example and suggest how we may use some of the lessons learnt to enhance communication and learning in construction firms.

THE DEVELOPMENT OF A DIALOGIC PRAXIS

The setting

CS is a knowledge-intensive, project-based firm that develops integrated hardware and software solutions for embedded real-time systems. Within this area, the work tasks are varied, spanning several disciplines and specializations, such as systems design, software development, electronic engineering, process optimization and staff training. The company was founded in 1992 as an independent branch of a large corporation. Since then it has expanded rapidly (from six employees in 1992) to over 300 consultants in 2003 at 12 locations throughout Sweden. About 80% of the business is generated outside the corporate group, with clients from R&D departments in large and medium-size enterprises within automotive engineering, aerospace, defence, medicine, telecommunications and multimedia.

The background

With the rise of the information society, the market for complex systems design grew dramatically putting pressure on knowledge firms such as CS to seek a competitive edge through effective management of their intellectual capital. For CS it also became imperative to prevent their experts from being recruited by competing or client companies. Moreover, to maximize their knowledge capital, CS needed to ensure that individual knowledge and experience within the company were shared and used to generate new insights and knowledge.

Providing staff with explicit knowledge – knowing that – during their first few years in the company did not pose a problem; however, to stimulate and incite knowledge workers to engage in productive inquiry (Cook and Brown 2002) e.g. reflection about methods, tools and meanings used in their practice, was far more difficult. Management lacked the competence and experience to develop a method for productive inquiry that would encompass the whole company. The largest challenge was to change the deeply ingrained implementation mindset of the engineers. In a retrospective reflection on the company's struggle towards this end, the CEO commented:

> We realized [then] we needed to improve, but did not know what direction to take. Our questions kept circling around professional knowledge: What is it, how can it be developed and how is it transferred? […]

In a joint venture with researchers, CS embarked on a pilot project to explore the nature of experiential learning in a professional context; more specifically they wanted to understand the relationship obtaining between individual and organizational knowledge. The objective was to enhance knowledge in the firm by developing an institutionalized practice for intersubjective reflection concerning the nature of knowledge and the role of language in meaning making; in short the objective was to become a learning organization both in words and in deeds (Fock 2006).

The view that the researchers had of professional knowledge is that it is a complex interweaving of technical expertise, intuitive judgement and communicative sensitivity. These qualities are acquired through collaborative engagement that goes beyond the use of work descriptions and methods. To foster these qualities at CS, a prevalent and reductionist definition of knowledge – knowledge is equal to information, is acontextual, explicit and codifiable – had to be challenged. Moreover, the governing view that knowledge can be transferred by means of generalized rules, models and standards also needed to be questioned.

The endeavour

A pilot project was initiated in 1997 by a group of nine senior executives including the CEO and led by two researchers of work science. The goal of the project from the researchers' perspective was to shift the participants' inherently scientific epistemology of possession (individuals possess knowledge) towards an epistemology of practice (knowledge is generated through action in professional groups: Cook and

Brown 2002). The assumption was that to achieve this epistemological shift, scientific discourses and genres needed to be challenged and in part replaced by new constitutive meaning carriers generated through collective dialogue.

What CS wanted was to implement a method that would enhance the organization's collective knowledge, promote a holistic view of systems development, foster individual and group know-how and sense of judgement, encourage variation and creativity, and give the company a strong competitive edge. CS's ambition was to use the method in their interaction with their clients.

The pivot of the pilot project was language. Drawing on Wittgenstein's notion of language games (1983) and the dynamic, dialogic plasticity of meanings (Bakhtin 1986), the researchers strove to sensitize the group of nine to the intricate interrelationships between words and action, i.e. to enable the CS technical experts to internalize a wide variety of language games and understand the linkages between language, action and knowledge.

The method developed at CS was called the *dialogue seminar*. As the name indicates, the method is dialogic, relying on the active use of several genres and modalities: close reading, reflecting, personalizing, writing, listening, talking, performing and publishing. The dialogue seminar creates legitimate time and space for personalizing and sharing conversations, voicing alternative or contradictory stories, scrutinizing and discussing diverse meanings and perspectives on technical and social aspects of the organization's practices. It is a means 'thinking together' (Isaacs 1999). As one of the group of nine expresses it:

> A dialogue seminar is an environment for thought. [It] must foster the element of surprise and the unexpected, and allow diversity and disparate perspectives to fuel reflection and generate new, common, knowledge.

In the following section we briefly describe the method as designed for the purposes of CS.

The method

A typical dialogue seminar at CS is divided into three parts: pre-seminar, seminar and post-seminar. Each seminar is led by a senior knowledge worker well versed in the practice. He or she chooses a set of texts to base the seminar conversations on. These texts may concern specific problems within the area of systems development, but they may also be from entirely different fields. The chosen texts have different functions. They may be thematic, relating directly to the theme and problem area that the seminar has in focus; they may be analogous, describing other practices or problems in entirely different fields in order to create perspective; and they may be epistemological, conveying fundamental understanding, historical and epistemological, of a situation or practice.

Prior to the seminar the participants have to read the texts and are instructed to annotate as they read: i.e. to have a dialogue with the text. The associations, examples, analogies and contrasts triggered by the texts should then be personalized in individual narratives (essays). The participants are specifically asked to relate events and phenomena in the texts to their own experiences. In this preparatory part, the participants are engaged in three important activities: close reading, critical reflection and tapping into their own experience to bring forth what they did not know they knew.

In the dialogue seminar, each individual narrative is 'published'; it is read out loud by the author while the rest of the participants listen. Participants then reflect on what they have heard, first individually and then collectively. In this way, each reading generates reflection and dialogue on the action described. In this intersubjective exchange, different points of view confront each other and are merged, creating a powerful collective energy.

In the post-seminar phase, the records of all the new meanings (analogies and metaphors) generated in the collective dialogue and documented by the recorder are circulated and annotated by the seminar participants. The revised record and all the personal narratives are then made available to all CS employees, serving as organizational memory, consisting of novel associations and meanings specifically relevant to the CS context. These collectively generated new meanings serve to sharpen systems developers' sense of judgement by providing them with a reference for what the community of practice views as appropriate for a given situation.

The outcome

The primary task of the group of nine was to question the underlying assumptions built into established rules and models and to develop an architecture for systems design that consisted of tools and methods that were collectively created, supporting creative thought processes and facilitating communication and collaboration. In the pilot project, the group laid the groundwork for the continued change process within the organization by rewriting the organization and spreading their story in a jointly published anthology (Hoberg 1998) recording their transformation and their reflections. Since its publication, this text has been used as reading material in the first dialogue seminar attended by novices. It initiates them into the discursive practices of the organization through learning-by-doing rather than through top-down prescription. The concepts that are highlighted in this and the other texts read by novices are associated with social interaction, communication and collective meaning making for systems developers. In these texts examples, analogies and metaphors are widely used as mediating tools for productive enquiry as the following example demonstrates:

> We have to have a dialogue with the tool/technology. What can it achieve and what are its limitations? When it comes to new tools and methods we must have the possibility to practise before we start using them in real situations. We at CS often compare our practice to that in the theatre, with the staging of a performance. There is a huge difference; actors **practise – rehearse –** before they perform. Imagine how wonderful it would be if we could do the same thing in a system-development project. The project manager would be the director, who would not allow the programmers to work with 'real' coding until they have mastered all the tools and the method. We could run micro-increments of the project in order to practise and test the development model. (Essay by novice attending his first dialogue seminar)

In this short extract, we see how the novice struggles to appropriate the mediating tools of his profession as he reflects over the crucial importance of understanding the prescribed tools and the role of the manager. This reflection gave rise to several insights and illustrative oral stories from more experienced systems developers concerning the limitations of tools and methods, the qualities of leadership, the time constraints in projects, and the possibilities of building learning loops into work models.

The CS story is a good illustration of Cook and Brown's (2002) notion of knowing in action. The whiteboard becomes a metaphor for the dialogue seminar and at the same time its primary mediating tool. It consists of an empty landscape where individual and group knowledge, both tacit and explicit merge in the social action of generating a new genre: to whiteboard!

It took the group of nine a year to create the architecture for the new CS: they called this trial period 'the year of the architecture'. Since then, the dialogue seminar has become an institutionalized method for productive inquiry throughout the organization. All the new recruits are socialized into the method and it is also used as a tool for negotiating with clients. It is not within the scope of this paper to discuss CS's work with the dialogue seminar in greater detail, but it serves as an example of a successful attempt to change the mindset of an organization.

DIALOGUE SEMINARS FOR CONSTRUCTION

We have adapted the dialogue seminar in a variety of courses for actors involved in different sectors of the construction industry. Here we discuss the viability of the dialogue seminar to enhance collective thinking and learning for the industry. Since we used the same approach and procedure described above, we now focus on the outcome and possibilities provided by the approach.

Background and endeavour

The course entitled 'Effective knowledge management and project development' was divided into two parts. Each part consisted of three two-day modules, run as seminars rather than lectures. The modules in the first part, as the following titles describe, concern how to exploit intangible assets and resources in construction projects, i.e. M1: Balanced project psychology; M2: Situated communicative practice; and M3: Effective knowledge-management. The authors of this paper developed and ran modules two and three, the third as a dialogue seminar. (The last three modules deal with tangible assets, such as measurement tools, performance and profitability.) The course was the outcome of a joint initiative by industry and the university to provide practitioners with the opportunity for continued education. We have completed two full courses with 13 and 12 participants, respectively.

The purpose of the dialogue seminar was threefold: to test the method in a context of heterogeneous participants, to enable the synthesis and externalization of new knowledge acquired in the two previous modules, and to allow the participants to experience a new praxis through doing it. Reflecting on practice, as mentioned earlier, does not come naturally, especially not for practitioners schooled in an epistemology of technological determinism, and there is seldom sufficient time or space for reflection built into organizational and project work models. There is therefore a need to raise practitioners' awareness of the potential benefits from collective reflection during, as well as after, a project. We saw the dialogue seminar as a way of fostering participants both with method and tools, as well as the experience of moving from the implementation mindset to a processual mindset.

We chose one of each of the text types described above. The thematic text argued for the value of reflective writing as a tool for individual and collective reflection. The analogous text was a type of allegory describing the dilemma of the leader of a shipwrecked polar expedition consisting of Eskimos and Germans. The epistemological text probed the inherent contradictions between creativity and routine. They were given the same instructions as for the CS seminars. After the seminars, we collected all the stories and our own follow-up notes in a memory-book, which we then distributed to the participants.

All the participants, although reserved and sceptical of the writing task prior to the seminar, completed their essays and participated in the seminar. During the dialogue seminars, the participants never wanted for discussion topics. Each essay reading resulted in engrossing discussions and candid revelations. Some of the essays were personal; others depicted generic problems encountered in project management. The topics that the essays gave rise to differed in the two seminars owing to the different configurations of participants. In the first seminar, where the participants were all senior managers with similar disciplinary backgrounds, the topics clustered around four practical areas: the need for a change of attitude within the construction industry, the need for improved leadership development, the need for a holistic view of the building process, and the sector-specific problems such as certification and salaries. In this group, the energy in the discussions was generated by the participants' need to externalize their concerns and frustrations in terms of the future. The mutual recognition and sharing of these feelings as well as the identification of some of the causes created an understanding across professional borders, which hitherto seemed to be lacking.

The second group was composed of several participants from very different educational backgrounds, e.g. economists, engineers, lawyers, architects and from widely different professional spheres within construction e.g. academics, municipal officials and private sector managers. There were also relatively more women in this group than in the previous one and a wider age distribution. Another difference between the two groups was that group two was extremely verbal, which is fairly unusual in a Swedish context. In this group the topics clustered around abstract concepts such as the value of ideal representations (utopias), the multifaceted nature of listening, the advantages and disadvantages of knowledge and information, and types of learning and their effects. Although these topics may seem abstract, they were generated from some very concrete stories of personal adversities and gave rise to a variety of interesting insights into the whys and wherefores of some organizational norms and practices. Here the essays probed the causes and effects of individual actions and the nature of the lessons learned from these stories. The added perspectives from their peers contributed to a richer understanding in the group.

Illustrative examples

The distributed texts and previous modules were the springboard to help participants tap into their own stores of experience. The openings of some of the essays reflect this process:

> Sitting here and reading the texts many words buzzed around me: knowledge, openness, goal, purpose, definitions, limitations, client, complexity – and all the while the question why? Why do things function or why don't they function? We seek solutions and we create complex methods in order to make things work better the next time around. Even though we may know somehow, that with common sense we can go far. What is common sense?

Rhetorical questions were often used to introduce the topic and organize the argument, especially in the less personalized essays. Examples of some of these questions were: How much do project members need to know? or Who is the client? or What factors make some projects successful and others failures? or How and why do misunderstandings and misinterpretations arise? These questions may seem rather broad – and they are. The point is that they are seldom ventilated in the workplace. Instead they lie under the surface – as the causes of many problems – but are not sufficiently probed when solutions are suggested. These broad questions became the starting point for focused and personal opinions.

Although the essays were very different in terms of content, form and style, they all touched upon fundamental issues that were uppermost in the minds of the participants at this point in time. No one trivialized the task or the resulting conversations, and all the essays, probably because of their differences, elicited reactions. It is interesting to note here that everyone contributed to the conversations. Either they reflected in general terms on specific statements or they identified with examples in the texts, relating them to their own general experiences of projects or they countered with a personal example as corroboration or contrast.

Typically, personal essays could start like this.

> Once a long time ago … when *my world* was about to change. It happened in 1978 during my first week as team leader. I had just graduated as an engineer and was proud to be part of the building of one of the county's largest hospitals. I felt confident since I possessed experience from many summers' traineeship on building sites and felt I knew quite a lot about how things were done. My older brother, an experienced site manager, advised me: 'don't think you know everything about a building site; wait 10 years or so.' Yea, yea, I thought. *But what had he really said?!*

The essay goes on to describe how the young team leader provokes a head-on conflict with an older and experienced carpenter by criticizing him in public and giving him an order. The carpenter, known as the *golden hammer*, was the chosen leader of the carpentry group on site. He reacted violently to being insulted in front his 'guys'. He retaliated with a long and loud invective, ending by commanding the novice to: 'disappear into your office and shuffle your papers, and never appear on the site again!' The author was crestfallen and at a loss since he did not understand what had gone wrong. After all he had just been following the rules. When he later phoned his brother and told him that he was going to quit, his brother exclaimed: 'Had you already forgotten my advice or did you not understand what I meant?' The story ends with the author's reflections on the social dimensions and meanings of the word 'communication', a word that is broadly used and likewise broadly misused. This story and many like it gave rise to very intense discussions concerning emotions, attitudes and facing threats in the workplace. These are again issues that are seldom addressed other than behind closed doors.

The reading and writing exercises aimed at providing the participants with new ways of using these tools for thinking. Normally reading in the workplace is focused on content, which is then taken at face value. Likewise, writing in the workplace is a routine chore, where templates rule over both purpose and content. Reading the texts out loud aimed at demonstrating how differently we perceive a text when we read it silently to ourselves and when it is read out loud by the author, whose intonation, stance, tone and emphases bring life to even a seemingly boring text. Furthermore, this kind of reading is more likely to stick in a listener's memory. One common reflection from the participants was their surprise at the variation of styles and interpretations. The writers used different strategies to get their stories across. The following are a few examples.

Metaphors or images are effective ways of illustrating a point. Two metaphors, which became mottos for the groups were the ‘journey’ toward a goal and the ‘choice of path’. There was unanimous agreement that the project journey, process, was more important for learning than was the product. The choice of path became emblematic in many discussion concerning organizational changes and career paths within the construction industry.

Another strategy that was used in the essays was irony. For example one participant described the perfect meeting. This utopia exposed all the inadequacies of current meeting cultures and gave rise to a think-tank on what each individual’s responsibility could entail and how we could contribute to small changes in our own organizations.

Similes or analogies were probably the most common strategy, for example drawing on current sports events to discuss leadership and organizing. Moreover, many tapped into the analogy of the shipwrecked polar expedition to compare with their own chaotic situations. Another strategy is to draw on philosophical or theoretical examples. One such example was the use of Darwin’s evolution theory, which was used to show what happens when evolution is forced or rushed without preparation for change or time for adaptation.

The reactions from both groups during the follow-up were overwhelmingly positive. Besides being impressed by the stories and amazed that two pages of writing could contain so much of interest, they thought that the discussions were the richest learning activities. When we probed the reasons for this, they concluded that it was because the lessons learned were linked to specific individuals and situations. Moreover the discussion topics were generated by the groups and therefore felt to be far more relevant to any topics we would have imposed.

An interesting reflection was that the dialogue seminar enabled the participants to acquire knowledge and experience in a short time. This is an important insight since one of the arguments against using dialogue seminars in the workplace could be that it is far too time and resource consuming. This short-term perspective is thus overridden by the long-term benefits experienced by the participant. Several of them decided to try and adapt the approach to e.g. project planning or kick-off meetings. The most important reaction for us, which has further encouraged us to use the method in all our courses as well as in our research, is that the participants without exception were intellectually stimulated by the activity and genuinely enjoyed the activity.

CONCLUSIONS

In this paper we have shown that using a structured dialogical methodology, incorporating both oral and written modalities stimulates as well as facilitates a shift in mindset and attitude towards change in an organization. In our courses, we found that the dialogue seminar was a powerful tool to inspire participants to engage honestly in conversations and to share their personal views and experiences. The use of several modalities stimulated several senses simultaneously, which we feel resulted in an analytical rather than a cataloguing stance to the texts, their essays and the ensuing dialogues.

The different modalities also facilitated the externalization of tacit knowledge in the groups. The readings led to personal reflections and associations to personal experience of similar or contrasting events. The writing allowed the participants to visualize their ideas, examine and evaluate them. In the dialogue seminar, the sharing of individual narratives by the group generated innovative ways of dealing with common problems. On the social plane, the sharing of stories created coherence in the group as well as solidarity. Together, the group developed a common mode of communication that was in tune with the interests and affinities of that particular group. Each group shaped the implicit norms and sense of judgement, which could be called up as examples in future situations of uncertainty. The seminar thus provides a space for the orchestration of voices and sense making within a collective in an organization.

THE FINANCING ISSUE: THE CASE OF INNOVATIVE FIRMS FROM THE BUILDING AND CONSTRUCTION INDUSTRY

Frederic Bougrain[1]

Département économie et sciences humaines, Centre Scientifique et Technique du Bâtiment (CSTB), 4, avenue du Recteur Poincaré, 75782 Paris CEDEX 16, France

Entrepreneurs who innovate are supposed to face financial constraints. The aim of the paper is to check this assertion for innovative building and construction firms. The analysis draws upon statistical data and case studies made of about 50 firms less than five years old that have been highlighted by the French weekly construction magazine "*Le Moniteur*". It shows that entrepreneurs face some financial constraints when they intend to launch innovations. It also indicates that new innovative firms are able to benefit from the support of private investors and large companies.

Keywords: innovation, newly created firms, financing, SMEs.

INTRODUCTION

According to the European Commission, "access to finance remains a major concern for businesses, including innovative SMEs. Innovative and R&D-intensive businesses often have difficulties in obtaining finance in the stages between demonstrating a new technology, process, product or service and exploiting it commercially. Compared with its main competitors, the market for finances for-innovative companies from the pre-seed to expansion stages in Europe is still underdeveloped. Better access to equity and quasi-equity for more mature innovative SMEs is also needed for 'follow-on' investment to help businesses reach their full potential, bring their products and services to the market, and continue funding their research" (European Commission 2005: 12).

This conclusion is confirmed by the data collected for the fourth Community Innovation Survey by the statistical service of the French Department of Industry. (The fourth Community Innovation Survey (CIS4) was launched in France in 2005. Collected information concerned corporate innovative behaviour during the period 2002–2004. About 25,000 French firms employing more than 10 employees received the postal survey.)

A total of 41% of French innovating firms quoted the lack of appropriate forms of finance and the costs of innovation as the main barrier to innovation (SESSI 2006). The lack of adequate knowledge (qualified employees, knowledge about technology and markets, difficulties to find cooperative partners) was ranked second and considered as a barrier by 26% innovative firms.

The study also demonstrates that firms employing less than 250 people are more financially constrained than larger ones. Similar results were found by Harhoff (1998)

[1]f.bougrain@cstb.fr

in Germany. Lack of bank loans and equity capital was the main obstacle to innovation. Similarly in the USA, Himmelberg and Petersen (1994) noticed that self-financing was the main resources invested in R&D by the 179 high-tech SMEs from their sample. Finally, in the Netherlands, the lack of financial funds was the main criterion that differentiates SMEs from their larger counterparts.

The financial issue appears even more important for newly created companies. These firms also lack self-financing capacity, but they cannot cushion the risk associated with the development of the innovation whereas established firms can rely on their day-to-day businesses.

The building and construction industry is often perceived as a laggard for innovation compared with other industries. The fragmentation of the industry, the procurement process mainly based on tendered price, the high number of small firms and the conservatism of employees of the building site are often put forward to explain this situation. Paradoxically, the financial issue is rarely presented as a constraint in the empirical literature.

The innovation research field in the building and construction industry has lead to a growing number of articles during the last few years. However, there is a lack of empirical studies in the field of financing of innovation. Therefore, the aim of this paper is to focus on the financing issue. The analysis will be restricted to newly created companies.

The goal will be twofold: the first is to examine whether entrepreneurs who created a new company based on an innovation project, encountered financial difficulties in the first years following their creation. The second is to identify which financial sources (internal resources, debt and external equity) companies tend to favour to develop their business.

The first part is based on a literature survey. It intends to provide arguments to answer the following questions: To what extent are innovative projects constrained by financial obstacles? The second part examines the characteristics of the innovation process along the supply chain of production. The aim is to establish a link between the financing issues, the actors and the nature of the innovation process. The third part draws upon case studies made of about 50 firms less than five years old that have been highlighted by the French weekly construction magazine “*Le Moniteur*”. Information was published every week between 2002 and 2005. It concerns the business sector of the firm, its capital structure, its year of creation, the number of employees and the background of the founder(s) (usually the manager(s) and owner(s)) of the firm. This part details which financial source is favoured and how the lack of financial funds hinders the development of the firms.

INNOVATION AND FINANCING: SOME THEORITICAL ELEMENTS

Uncertainty and innovation

“Innovation is a quest into the unknown. It involves searching and the probing and reprobing of technological as well as market opportunities” (Teece 1996: 194).

Innovation projects have to deal with three types of uncertainty (Freeman 1989):

1. Technical uncertainty is linked to “problem-solving feature of innovative activities” (Dosi 1990: 303). The solutions of innovation-related problems are

always challenged and the set of solutions is never known in advance. New technical states are discovered during the innovation process and vary according to opportunities and incentives. In some sectors such as pharmacy, it is even necessary to invest large sum of money before being able to assess the value of the initial idea. Therefore, delays and lags are not perfectly mastered. Associated costs may increase and jeopardise the project. This uncertainty, which is very high at the beginning of the life cycle of a product, can be reduced through tests and trials. But the feasibility of a project is just one element of a success. The innovation has also to be viable at a marketing level.

2. Market uncertainty refers to the commercial achievement of a viable product or process. Potential uses and demand are often highly unpredictable and the firm has almost no ability to control these elements. Moreover, external elements may modify the initial conditions that prevailed when the project was launched. New competitors may appear; consumers' tastes may evolve.
3. Uncertainty is also linked to business cycles. "In a mature, established industry the risk of the firm's assets is very likely determined by the fundamental riskiness of the firm's line of business" (Wedig 1990: 297). According to Wedig, the systematic risk attached to R&D projects is higher for small firm than for large ones. It is reasonable to assume that newly created companies face even greater risks. Most of these firms rely on a single product; they have no track record and cannot provide collateral to investors.

The uncertainty decreases when a project moves downstream and is close to final launch while the need for fresh money increases. The commercialisation stage requires investing much more financial and human resources than the development programme. For high tech sectors, it is often assumed that for every euro spent at the R&D level, ten will be necessary to bring the product into production and about 100 will be required to bring it to the market (Chabbal 1995).

The uncertainty is even reinforced by asymmetric information and moral hazard problems.

Asymmetric information and innovation

In the financing of innovation, the asymmetric information problem refers to the fact that managers usually have better information about the characteristics of their innovative projects than private investors. Consequently, lenders who cannot distinguish good and bad projects will propose a high-risk premium to all potential investors to compensate for risk default. Therefore, firms with sound projects will not stay on the market.

Reducing information asymmetry is quite problematic when one deals with innovation. Indeed firms may have interest not to disclose the characteristics of their projects for strategic reasons (Kay 1988). By revealing their innovative ideas, entrepreneurs face the risk that potential competitors benefit from their project. This problem is enhanced when inventor-entrepreneurs cannot rely on strong property rights to protect invention from imitation: "While this problem is somewhat softened when there is good patent protection, most non-industrial providers of funds are going to need technical experts to evaluate the technology, in which the risk of leakage remains" (Teece 1996: 210).

Asymmetric information problems are stronger for small businesses (Ang 1991). They are not forced to produce verifiable information. Therefore, it is more expensive for potential investors to collect information and to monitor the firm. Moreover, small businesses may have greater difficulties to send credible signs to the financing market.

These difficulties for private investors to appreciate the quality of innovative projects are enlarged by moral hazard problems.

Moral hazard and innovation
Potential investors have not only to appreciate the quality of innovative projects; they also have to monitor the behaviour of the entrepreneurs once the loan is afforded. Moral hazard problem refers to the fact that managers usually control the allocation of the funds while the investment effort is unobservable to the investor. Entrepreneurs have a tendency to put their venture's interests first during the first years following the creation of the firm. Investors are likely to have lower optimism. To avoid shirking behaviour and ex-post opportunism investors, they may require greater protection that will increase both direct and indirect costs of borrowing: "Direct costs of borrowing include such items as interests rate and monitoring costs; indirect costs include restrictive covenants, personal guarantees, and equity participation" (Brophy and Shulman 1993: 66).

Because of asymmetric information and moral hazard problems, risk adverse investors such as bank are likely to be reluctant to finance innovative projects with uncertain outcomes.

The financial constraints may even be much stronger for newly created businesses. Most of them rely on a single product. They also have a high debt-equity ratio and they are not able to provide strong collateral to minimise the risks taken by investors.

INNOVATION IN THE CONSTRUCTION SECTOR: THE FINANCING ISSUE

Some characteristics of the innovation process in the construction industry
The construction sector is too heterogeneous to be lumped into a single category. Firms' positions along the value-added supply chain affect their innovative strategy. Material suppliers, manufacturers of equipment, contractors, facility managers, etc., are likely to follow different patterns of innovation (the analysis is limited to these four actors that are among the most important in the industry).

Pavitt (1984), who was the first to put ahead the existence of sectoral patterns of technical change, categorised general contractors as "suppliers dominated firms". Firms from this category devote few resources to R&D. They focus their innovative activities on processes. "Most innovations come from suppliers of equipment and materials, although in some cases large customers and government-financed research and extension services also make a contribution" (Pavitt 1984: 356).

Material suppliers belong either to "large scale producers" (these firms are scale-intensive and devote a very high proportion of their resources to cost-reducing process innovation) or to "science-based firms" (internal R&D and scientific developments carried out in public research centres and universities, constitute their main sources of innovation. These firms do not limit their innovative activities to their sector of origin since they produce a very strong proportion of innovations used in other sectors).

Special foundations contractors, manufacturers of building components and equipments can be considered as "specialised suppliers". Their competitiveness rests on their specific know-how and their capacity to develop reliable products and to respond continuously to users' needs. Opportunities for innovation do not result only from in-house R&D but from close and complementary relationship established with customers.

Firms involved in the management and maintenance of the buildings tend to follow the pattern of services companies described by Sunbo (1998) and Djellal and Gallouj (1999). Most of the time innovative services do not come from an R&D department but from marketing department and transversal project groups. Innovations are also often co-produced with the end user.

Innovation and the financial constraint in the construction sector

Articles dedicated to innovation in the building and construction industry have benefited from a growing interest in the last few years. Paradoxically the field of financing of innovation has rarely been examined. Most studies focused on the financing of projects, which appear to be one of the main issues for the industry.

Elements from the empirical and theoretical literature speak for a financial constraint while some others do not.

Most innovations developed by contractors are made at the job site and do not require a high amount of financial resources. They are often developed in the course of a construction project. A dominant part concerns the organisation. They "are emphatically not 'R&D projects' in any formal sense" (Slaughter 1993: 87). In these cases, financing is not an issue.

Most material suppliers that spend a high amount of R&D are owned by large groups quoted on the stock exchange. They have access to international financial markets. Financing, *per se*, is not an issue. Because of their broad portfolio of businesses, the unpredictable results of innovative projects are mitigated. Therefore, private investors are not discouraged to support these firms. Then financing innovation may become an issue within the firm and between competing business units.

The building and construction industry is often perceived as a mature industry with a reputation for resistance to innovation and change. An empirical study focusing on the financial behaviour of craftsmen revealed that banks usually consider that the industry is less risky than others (Observatoire des PME 2005). The growth of the sector for the last five years is perceived as positive.

However, several arguments also indicate that the building and construction industry do not depart from the general trend and is financially constrained.

The fourth Community Innovation Survey (SESSI 2006) indicates that financial factors were considered as a barrier by about 43.6% of French innovative construction companies (39.4% of the firms surveyed declared that they were innovative between 2002 and 2004 (new products, process, organisation and market). Innovative products represented about 12% of the turnover of these firms in 2004; 27% of them modified the organisation of their activity; 54.8% carried out R&D between 2002 and 2004). The lack of competences, marketing factors and the lack of incentives respectively only concerns 31%, 30.3% and 13.3% of the firms. Moreover, 19% of non-innovative firms did not innovate because of the financial constraints.

This lack of appropriate forms of finance is stronger for small firms than for larger ones: 46.5% of small firms considered it as a barrier while there were only 16.6% of firms with more than 250 employees. These difficulties lead firms either to seriously delay their innovative projects (28.3% of the innovative firms of the sample) or to abandon them (16.2% of the firms). Larger companies are also affected (24.7% of them abandoned at least one innovative project between 2002 and 2004; 34.5% had to delay at least one project over the same period).

However, one of the limits of this national enquiry is to present construction as a homogeneous activity. As presented before, innovation patterns and constraints strongly differ among the actors of the value-added supply chain.

An ongoing research project indicates that contractors devote fewer resources to R&D and innovative activities than manufacturers. However, in some cases, when innovations are turned to commercial products, processes or services, funding might become an issue for contractors.

Manufacturers of building components and equipments do not need to rely on the most recent scientific knowledge. Their size is quite small compare with material suppliers. They have small R&D laboratory and design office to deal with the development of new products/processes. Therefore, they are still subject to lags and uncertainty, which are a source of financial constraints.

Newly created companies of the building and construction industry that mostly base their activities on a single innovative project probably do not follow the general pattern of innovation. To examine this case, the paper ends with an empirical study that draws upon case studies made of about 50 firms from the building and construction industry with less than five years old.

THE FINANCIAL CONSTRAINT OF NEWLY CREATED FIRMS FROM THE BUILDING AND CONSTRUCTION INDUSTRY

Between 2001 and 2006, the French weekly construction magazine “Le Moniteur” published detailed information about 80 newly created companies (the empirical study is limited to 50 cases. The next version of the paper will integrate all business stories. Moreover, some interviews will be carried out to get more qualitative information). These companies were less than five years old at the time of the publication. Their creation was based on a certain innovation.

Most information was published in 2003 and 2004 (more than 55 cases). Each article with about 450 words provided details on the business sector, the capital structure of the firm, the year of creation, the number of employees and the background of the founder(s) (usually the manager(s) and owner(s)) of the firm.

For the purpose of this study, it was necessary to classify each article in a common framework. Five categories were identified:

1. Contractors.
2. Manufacturer.
3. Consultant (companies that sell their specific know-how – e.g. a company selling diagnosis for asbestos, lead, etc.).
4. New services based on information and communication technologies.
5. Civil engineering.

Information concerning the number of employees and the source of finance for innovation were also retained to categorise each newly created company.

Three sources of finance were identified:

1. Public subsidies (such as zero interest loans, public grants, etc.).
2. Support of an investment fund: In this case, the private investor owns a minority part of the equity of the firm.
3. Support of a large firm.

Table 1 exposed the sources of finance according to the activity of the firms.

Table 1: Sources of finance according to the activity of new created firms

Activity	**Number of employees**			**Public subsidies**		**Support of an investment fund**		**Support of a large company**	
	<10	**10–19**	**20–25**	**Yes**	**No**	**Yes**	**No**	**Yes**	**No**
Construction techniques	3	1	0	1	3	0	4	0	4
Contractor (site process)	8	0	2	1	9	0	10	0	10
Manufacturer	4	2	0	1	5	2	4	2	4
Consultant	5	2	0	1	6	0	7	1	6
ICT	10	2	0	4	8	2	10	2	10
Civil engineering	10	1	0	4	7	1	10	3	8
Total	40	8	2	12	38	5	45	8	42

All these companies are very small: 80% employ less than 10 employees.

The manager is the majority shareholder in 48 cases. In 24% of the cases, firms have received some kinds of public subsidies (e.g. financial aids, free rent). This indicates that the public institutional framework dedicated to support innovation and business creators is quite well organised.

Investment funds are involved in only 10% of the projects. They tend to focus their investment in ICT and civil engineering projects.

This may result either from the strategy of the creator or from the attitude of the private investors:

- Creators usually look for the independence of their company. Most of them do not intend to attract private investors who may latter on take the control of the firm. The entrepreneurs' own resources and those of friends and family often constitute the starting equity.
- Private investors such as venture capital financiers tend to focus their investments on a limited number of sectors (Hall 2005). Venture capital investors usually target their investment in industry with high growth perspectives. They also intend to monitor the creator and to provide advice based on their experiences. They expect capital gains at the time of exit. These elements are supposed to reduce asymmetric information and moral hazard problems.

  The building and construction industry does not belong to the sectors that attract most of the investors. In 2005, building and construction attracted only 6% of the funds invested by private capital investors. It represented 2% of the files (AFIC 2005). (Biotechnology and the medical sector received 7% of the funds (16% of the files); the computer industry, 8% but 23% of the files;

telecommunication, 12% and 7% of the files; industrial goods and services, 18% of the funds and 10% of the files.)

Large companies appear as one of the main support of new firms (e.g. as a client or as an investor). The eight cases mainly concerned promising innovation. SMEs are characterised as being flexible and respond more quickly than large firms to external changing circumstances (Rizzoni 1994). By promoting new ventures, large firms that are considered more bureaucratic and tend to favour exploitation over exploration have access to complementary expertise. They also keep an eye open for new technology and equipment. The investments of large firms are a form of trade: funds and/or access to market against technical expertise. ("I am inclined to regard the early stage innovative disabilities of large size as serious and propose the following hypothesis : An efficient procedure by which to introduce new products is for the initial development and market testing to be performed by independent investors and small firms (perhaps new entrants) in an industry, the successful developments then to be acquired, possibly through licensing or merger, for subsequent marketing by a large multidivision enterprise…Put differently, a division of effort between the new product innovation process on the one hand, and the management of proven resources on the other may well be efficient" (Williamson 1975: 205–6).)

Among the firm of this sample, one considered that the lack of financial funds hindered its development. Two other were looking for private investors who had knowledge about the industry. This result appears quite contradictory with the national survey (uncertainty is supposed to be much stronger for newly created and innovative firms). Some reasons may explain this result:

- Many new firms that are working in services do not need as much financial resources as manufacturers.
- Entrepreneurs who start a business have the ability to receive several subsidies during their first year of activity. Moreover, for the first three years, they do not pay taxes.
- There is also probably a selection bias: most firms selected by the weekly magazine were among the leading start-ups in their field.

CONCLUSION

The financing issue for newly created firms and innovation has benefited from a limited attention of researchers working in the field of building and construction. The arguments developed in this paper intend to present this issue.

The study indicates that innovative firms from the industry do not depart from other sectors. They also perceive the financial factor as the main barrier to innovation.

Newly created companies that present growth prospects seem to receive more support from private investors or large firms than traditional firms (such as contractors).

This study also shows that the reputation of the building and construction industry, which is often perceived as a laggard for innovation compare with other industries, is not justified.

COMPETING ON INNOVATION IN A LOCATION CENTRIC SECTOR: A STUDY OF MALAYSIAN HOUSING DEVELOPERS IN INDIA, CAMBODIA AND SOUTH AFRICA

Ahmed Awil[1], Abdul Aziz and Abdul Rashid

School of Housing, Building and Planning, Universiti Sains Malaysia,Penang 11800, Malaysia

We report on the internationalization activities of Malaysian housing developers in three countries: India, Cambodia and South Africa. Activities associated with housing development have generally been locally centred, with production, design and consumption all being undertaken locally. Therefore housing developers have generally been engaged in location-bound competition. Competition among developers has generally been between local firms based on the location-specific practices. Such practices limited the activities of housing development firms to engage such activities within a certain geographic spread, with most firms competing locally, a few firms nationally and in some rare cases internationally. Yet, recent changes characterized by economic liberalization, housing reforms and increasing urbanization rates have transformed the housing development sector. This study reports on the way Malaysian housing developers have leveraged their activities in Malaysia into foreign locations through the leveraging of their competitive advantages. Housing development activities by developers from one country with financing from another country coupled with a contractor from another country and the purchase by non-local residents have characterized such changes. This study found that Malaysian housing developers were competitive in the development of integrated townships, golf resorts and high-end condominiums projects. Additionally innovation-based design, introduction of an industrialized and time-bound construction process and innovative marketing and financing deals were the other important features that differentiated Malaysian housing developers from their local competitors.

Keywords: housing development, innovation, internationalization, Malaysia.

INTRODUCTION

Like construction, housing is an immobile product that is undertaken for local consumption and is susceptible to the vagaries of the general economic environment. The notion of housing development we will assume to constitute the development of housing projects by business organizations for profit and, following the laws of supply and demand, the production may exceed or meet the needs of the market depending on the suitability of the project to the needs of the local populace (this may include expatriates or if investment laws allow foreign buyers for investment purposes). As such any production will be local in nature while the producers may be either local or foreign depending on the prevailing investment laws of the country.

The housing sector has changed in the past 50 years, during which many of the developing nations gained independence. Since then there have been gradual changes

[1] awil7@yahoo.com

in the laws of the housing industry. In the first period since independence the provision of housing has been considered as an obligation by the state to its citizens, therefore there was a proliferation of state agencies that were entrusted with the provision of housing to the populace. Governments have a strong interest in the performance of the housing sector. Good housing policies lead to better social stability (ODPM 2005) and are also used for managing macroeconomic growth (World Bank 1993). Over a period of time owing to factors like rising population, higher rates of urbanization and stagnant economies there has been reorganization of the housing industry in that private enterprises started participating and in due time were considered as an integral part of the provision of housing. The World Bank in 1993 advised governments to abandon their role as producers of housing and instead act as regulators of the market and adopt enabling policies to facilitate the participation of private sector in the housing sector (World Bank 1993). Since then there has been further reorganization of the local economies brought about by globalization and liberalization with governments realizing the increased need to allow the participation of foreign capital and firms in the local economy.

Most of the literature on international housing development is dominated by two streams of research; those studies dealing with the issues of cross-border portfolio investments (McAllister 1999; Worzala 1994) and those studies of housing sectors and policies for a given number of countries (Walker and McKinnel 1994; Doling 1999). Other studies have also dealt with the engagement of firms in international housing development but are focused on explaining motivations of the management and direct investment in a particular location. Jiang *et al.* (1998) investigated foreign investments in the Chinese real estate industry and found that direct investments into the local firms or outright purchase of real estate was driven by underdeveloped Chinese capital markets and as means of investment in a high growth market that offered above normal rates of return. This paper discusses the internationalization of the housing developers from two perspectives. First, it focuses only on innovation practices introduced into host markets; secondly, the discussion is based on experiences of Malaysian housing developers. The findings presented here are a part of a large study on the internationalization of Malaysian housing developers.

HOUSING DEVELOPMENT SECTOR

The housing sector is crucial in the economies of many countries and contributes to between 2% and 8% of the gross national product; the flow of associated housing services contributes another 5–10% (World Bank 1993). The impact of housing investments can be estimated from a look at the linkages between housing and related industries that is estimated from 269 industries (Karnad 2004) to 600 (Bestani and Klein 2004). The housing sector is also connected to the broader economy through a number of different circuits – the real, fiscal and financial sides of the economy. Investments in housing have long been understood to be an important tool for political stability, economic development and socio-economic up-liftment (Hollander 1963). Housing investments are also used at times to ‘pump prime’ the economy in order to overcome recessions. Davis and Heathcote (2005) in a study of the real estate sector (with data from 1948 to 2001) in the United States found that residential developments lead the economic cycle while non-residential developments lag the economic cycle. Again Green (1997) utilizing data from 1959 to 1992 finds that residential investments cause higher GDP growth rates while non-residential investments are caused by higher GDP rates.

The effects of the housing sector on the economy are at three levels: real effects associated with investment output, employment and prices. Financial effects are those associated with the financing of housing and related residential infrastructure, while fiscal effects are those associated with taxation and subsidization of housing (World Bank 1993: 34). Also institutional arrangements in the housing and mortgage markets play an important role not just in overall economic efficiency but also in managing economic shocks (Catte *et al.* 2004). Similarly, employment in the residential construction industry, which comprises 1–3% of the economically active population in developing countries, is associated with employment in other industries in the same ratios; one additional job in the residential construction sector gives rise to two other jobs (World Bank 1993).

Housing is a non-innovative industry and has a poor record in introducing innovative design and production, with firms not competing on innovation (Ball 1999; Barker 2004). The housing industry is less technologically intensive than many industries (Ball 1999), therefore there is less technological superiority between local and foreign firms and as such there are no ownership advantages that can accrue to housing developers if they seek to undertake internationalization. Yet, there has been an increase in the number of housing developers engaging in internationalization. Innovation as it is understood in this paper is a process of piecemeal improvements in the development by the stakeholders to the process (Ball 1999: 13). The following sections of the paper will detail the reasons why foreign housing developers are able to compete with local developers.

INTERNATIONAL HOUSING DEVELOPMENT

Changes in the dynamics of national economies, liberalization of markets, improvements in transportation and communication and ease of movement of capital have changed the previous assumptions that differentiated markets into domestic and international (Martin 2003). These changes have been evident since the late 1990s in the Asia Pacific region where liberalization of markets and higher rates of urbanization emerged allowing the participation of foreign firms to undertake international housing development initially for consumption by foreign or expatriate personnel and later for the domestic populace. These transformations in economies have mostly been evident in the Asia Pacific region since the early 1990s, and there has been an increasing role for foreign housing developers in those countries that have experienced economic liberalization, high urbanization rates and reforms in the housing sector. These housing developers have been primarily from this region, owing to the fact that the pace of housing development increases with increases in economic development (World Bank 1993).

Not all countries and locations that have had experience in developing a successful housing development sector have had any involvement with international housing developers. This arises due to three interacting features that are continually in a state of flux and determine whether there will be international housing development in a particular country. These three forces may be named as:

1. host government housing policies;
2. local housing industry;
3. international firms' initiatives.

These three factors determine whether there will be participation by international housing developers in a particular location. Taking the first factor of host government polices, this determines the general direction and growth that a particular nation undergoes and whether there will be any foreign direct investment or participation by foreign housing developers in the housing industry. The second factor encapsulates the status of the local housing industry and whether it is of sufficient technological or development advancement. If it is lacking in such critical inputs then there will be possibility of the engagement of international housing developers. The third factor of international firms' initiatives determines whether a particular firm is orientated towards engagement in international housing development. Where there is less concern about opportunities in international markets there will be fewer initiatives and therefore less engagement by the firm. In locations like India, China and Vietnam, and to a large extent Cambodia and South Africa, there has been a large infusion of foreign capital in the form of foreign direct investments. These investments have in turn created a demand, from both the local consumers and foreigners resident there, for new housing developments that meet their requirements, a demand also created by the rising affluence of the local populace. Both nations previously practised centrally planned economies where the workforce received subsidized housing courtesy of their employers. But owing to liberalization in their economies there has been upsurge in the demand and nature of housing that the local developers were unable to satisfy. This in turn called for two types of involvement; first, provision of skills and knowledge of the development process and secondly, the need to input capital into the local housing sector.

Malaysian housing developers have been active in Malaysia since the colonial era. Since then they have grown and their growth has been helped both by increases in population and urbanization. The Malaysian urban population increased from 4.6 million to 12.8 million between 1975 and the year 2000. To accommodate such a large size of population, new townships and extensive infrastructure had to be developed, with the government encouraging private developers to take a lead role. Malaysian housing developers also gained from astute planning and housing policies that enhanced and managed the growth of the housing sector. The housing sector in Malaysia has benefited from this relationship and the result has been Malaysia having some of the highest rates of home ownership in the world (UN Habitat 1998). Malaysian developers have been aided in the undertaking of such large developments by factors such as Malaysia's stable economic environment; provision of affordable loans by the banks; and a mature housing policy in practice in Malaysia which is known as the 'sell and build' concept, whereby housing developers are able to utilize the capital of housing buyers and thereby reduce any risks. Possession of large tracts of land (most developers initially were plantation owners) enabled developers to develop land stage by stage so as to test the viability of the development. These factors thereby increased the capabilities of Malaysian housing developers by enabling them to accumulate resources such as capital, development knowledge and experienced personnel.

Such advantages and level of advancement were not the sole preserve of Malaysian housing developers, but were also experienced by other developers from Singapore and Hong Kong. Owing to the limited land size and population, developers from the city states of Hong Kong and Singapore were motivated to internationalize their activities much earlier than Malaysian developers; in the case of Hong Kong developers extended to China in the mid-1980s and Singaporean developers in the early 1990s. The competitive advantages that these developers had over the local Chinese developers were expertise in the management of the development process, financial prowess and their introduction of advanced construction methods that enabled them to introduce innovative products and reduce the construction time. Yet, developers from Singapore or Hong Kong are not typical developers who have an interest in undertaking development as a viable means of business. Hong Kong developers have an incentive to integrate their activities with Hong Kong, given the fact that Hong Kong is integrated with China, logically allowing them to enhance their activities to a location that has the same cultural and linguistic affinities. Singaporean developers on the other hand are either private entities that are encouraged or led in their internationalization by the state, or the housing development firm is a majority state-owned enterprise, called a ‘government-linked company’. Housing developers like Keppel and Capitaland are examples of government linked companies undertaking internationalization. Doling (1999) discusses the housing sector in the little tiger economies (Singapore, Hong Kong and South Korea) as a state controlling the nature of development (owing to the fact that the majority of the land is state owned in Hong Kong and Singapore and state acquired for residential development in South Korea). Other factors like construction and consumption are market oriented and are within the discretion of the developer.

RESEARCH METHOD

This section presents an overview of the method used for data collection and analysis for this paper. A mixed-method approach was identified as a suitable means of locating the competitive advantages that Malaysian housing developers possessed. This approach was necessitated by the need to collect both quantitative data on the housing developers and a qualitative section that covers the internationalization of housing developers from their initial motives to their experiences. A total of 33 housing developers were identified through a combination of snowballing technique and a review of the publications in business and news media. Of that number eight housing developers responded to the questionnaire section of the study, while six of the eight developers consented to taking part in case studies detailing their internationalization. Subsequent cross-checking with industry professionals confirmed that it is only those eight developers who responded to the questionnaire to have actually undertaken internationalization, while the rest made announcements of their intention to internationalize or signed memoranda of understandings with foreign developers/partners. Data were collected through a questionnaire for the quantitative section and through interviews and site visits to consenting developers coupled with secondary data for the qualitative section. The questionnaire was pre-tested through a pilot study involving academicians, housing development professionals and the president of the housing developers association. Responding developers were asked to rate internationalization factors on a five-point Likert scale. Space limitations preclude us from presenting detailed case studies of the housing developers’ activities. Additionally, confidentiality assured to respondents prevents disclosure of their identities.

RESULTS

We will be presenting below the competitive advantages possessed by Malaysian housing developers vis-à-vis local developers in their internationalization. Further, competitive advantages have been divided into three factors: ownership, locational and internalization advantages (identified from Dunning 1980, 1988). Dunning argued that for firms to internationalize they need to possess superior ownership advantages vis-à-vis local firms (processes or products); to realize these advantages in particular locations; and to organize these through internal firm structures. We report here only on the ownership advantages. Ownership advantages have further been broken down into two: ownership advantages emanating from advantages intrinsic to the firm and advantages accrued due to country ownership of the firm. Country-specific advantages are developed from close interaction between developers, suppliers, government and buyers (Porter 1990). In this paper we will limit reporting to the ownership advantages intrinsic to the housing developers. Firm ownership advantages emanate from resources within control of the firm. Resources are inputs into the firm's production process that include: capital (its borrowing capacity and ability to generate internal funds); equipment (sophistication of its plant and equipment); skills of employees (formal reporting structure, planning, controlling and coordinating systems); and patents (trade marks, copyrights and trade secrets) (Hoskisson *et al.* 2004). Resources that a firm possesses enable it to exercise its ownership advantages in undertaking internationalization. Resources and related activities possessed by a firm have an important influence on the propensity of firms to internationalize (Chatterjee and Wernerfelt 1991; Ramanujam and Varadarajan 1989). However, not all resources controlled and owned by the firm constitute a source of sustained competitive advantage (Porter 1985). Therefore, for resources to be able to provide competitive advantage they must have the following characteristics: they must be valuable, rare, non-substitutable and difficult to imitate by rival firms (Barney 1991).

Table 1: Firm ownership advantages (advantages intrinsic to the firm)

Ownership advantages	N	Mean	Rank	Std. deviation	Level of importance
Understanding foreign market potential	8	4.50	1	0.535	Very imp.
Large financial capital	8	4.25	2	0.463	Imp.
Superior and innovative property development skills	8	4.13	3	0.354	Imp.
HQ–overseas coordination	8	4.00	4	0.535	Imp.
Firm's name and image	8	4.00	4	0.535	Imp.
Relationship with local and central authorities in host country	8	3.88	5	0.835	Imp.
Business relationship with host country firms	8	3.88	5	0.835	Imp.
Extensive experience and capable workforce	8	3.87	6	0.354	Imp.
Part of a larger group	8	3.87	6	1.126	Imp.
Business relationship with Malaysian firms	8	3.63	7	0.518	Imp.
Previous international expertise	8	3.63	7	0.518	Imp.

Notations used: means 1.0 to less than 1.49 = unimportant, 1.5–2.49 = little importance, 2.5–3.49 = moderately important, 3.5–4.49 = important, from 4.5–5.0 = very important.

Housing developers report their top three ownership competencies as their advantages accruing from their understanding of opportunities in foreign markets, their financial capital and their skills in superior and innovative property developments (see Table 1). In the first instance knowledge of housing markets and emerging opportunities is important in aligning a firm's competencies with potential opportunities. The liberalization and reforms in the housing sectors of India, China, Vietnam, Cambodia and South Africa for different reasons created a number of opportunities for foreign housing developers. Malaysian housing developers were the first movers into India, Cambodia and South Africa. Secondly, the possession of significant financial capital is both an important competitive advantage over local developers (more so in discussion) and a legal necessity (in India, foreign developers need to invest in a minimum of US$5 million in a joint venture and US$10 million in a wholly owned subsidiary) in the undertaking of international developments. In the housing development sector, larger developers are able to borrow capital at lower interest rates, spread risks over a wider area and offer different types of developments that cater for different levels of income (Ball 2003). Thirdly, experience and knowledge of innovative housing development activities over local developers helped Malaysian housing developers in their internationalization.

India

India, one of the world's largest countries, has recently undergone a period of economic reform since liberalization of the economy in 1991. Among the changes include the government privatization of most of the state-owned enterprises and increasing participation of the private sector in almost all the sectors of the economy. The pace of liberalization picked up after the initial period and the participation of foreign enterprises in the local scene was allowed gradually. Among the sectors that have benefited from this liberalization is housing development. In the year 2002, during the budget proposal the go ahead was given to the participation by foreign enterprises in the Indian housing sector. This decision stemmed from two roots: first, the need to increase foreign direct investment into India, which was lacking in comparison to China (Jiang *et al.* 1998 report that one-third of all foreign direct investment in China was real estate related); and secondly to raise the expertise level and process knowledge of the local housing sector through collaboration or competition with foreign developers. In India, there has been a recent increase in the announcements of Malaysian housing developers who have an interest in carrying out housing development. When the data collection phase of the study was being carried out in mid-2005, there was only one Malaysian housing developer who was active in India. This developer, Developer A, was the first international housing developer to initiate an integrated township project in India. Developer A is part of larger group that has interests apart from property development in construction, plantation and industries.

Developer A has taken advantage of its previous experience in India as a contractor to diversify into property development. The possession of a construction arm is an important advantage in India. First, the developer is able to ensure better quality of its developments and secondly, the developer is able to assure buyers of the completion date. Indian house buyers were previously let down by both the quality of developments and the delay in handing over properties after the due date. With these promises being made at the initial stages and the highlighting of the housing developer's experience in Malaysia, house buyers were confident of the ability of the developer to deliver on these promises. Other innovative practices delivered to the Indian buyers include concealed utility services and a clubhouse.

Cambodia

Cambodia was plagued by a protracted civil war between 1970 and 1992. The civil war was settled at a peace accord in 1992, followed by general elections supervised by the United Nations. The prolonged civil war in Cambodia caused serious disruption to the local economy. The dire economic situation inhibited the development of local banks and associated financing for domestic mortgages. The local housing developers lacked the professional expertise needed to utilize the development knowledge of foreign developers. The changing political situation created a favourable environment for both domestic and foreign firms. Among the favourable changes is that Cambodia is a member of Association of Southeast Asian Nations (ASEAN) and has a free trade agreement with the United States in the export of textiles. Because of these favourable factors there has been an increase in inward investment in the setting up of textile garment factories for export to the United States. Additionally, there has been a return of Cambodian diaspora to the homeland. The combination of incoming foreign investments and diaspora has necessitated provision of new housing developments for residential or commercial purposes. Two Malaysian developers ventured into Cambodia, the first in 2004 and the second in 2005; Developers B and C.

Developer B's Cambodian development comprises 172 units of two-storey detached villas and 30 townhouses, giving a total of 202 units. Phase one, comprising 70 villas, has recorded 50% sales since its launch (in mid-2005). A prominent marketing strategy of Developer B is to sell to Cambodian house buyers the concept of having an integrated community that is being introduced for the first time into Cambodia. Cambodian housing is dominated by mixed use developments that have office/shop lots on the ground floor with the upper floor used as family accommodation. The image of Malaysia as a country that has developed in economic terms and has a successful housing sector has also helped in the marketing and selling of properties to Cambodian house buyers. The development by the Malaysian developer is both the single largest housing development and also the first integrated development in Cambodia. The development features:

- gated community with perimeter fencing and guardhouse;
- practical and modern design;
- beautiful landscaped park and elegant roads lined with trees;
- family clubhouse facilities.

Among the new features in housing development introduced into the Cambodian market is the concept of 'house without renovation'. This concept originates from the Malaysian developer's attempt to coordinate the needs of the house buyer well before construction (during the design stage) so that the buyer has no need to alter his house after handing over. The negotiation between the buyer and developer for the buyer's design changes are negotiated well in advance so as to incorporate such needs of the buyer into the house design. In Cambodia, the authors observed during field visits that even new houses that have been built are undergoing renovation, which is indicative of either the poor quality of the development or the inadequacy of the design to accommodate the individual needs of the buyers.

Developer C has introduced the concept of mixed development into Cambodia for the first time. Previously, Cambodian developments were divided into residential or commercial developments. Additionally commercial developments were either office blocks or shop lots. The commercial part of the development introduces the concept of versatility to potential buyers, by allowing them to combine office lots, buy one level or combine shop lots with the office lots, providing buyers a multiplicity of choices in a modern setting with facilities that are contemporary in nature. With the introduction of the shop-cum-office lots concept to Cambodia Developer C has accrued the first mover advantage for its development.

South Africa

Since the end of the apartheid era in South Africa there have been marked changes in the political and economic situations. Principally these have been the lifting of sanctions, multi-party elections and economic opportunities for the majority population. Malaysian investors have been among the earliest into South Africa, encouraged by the previous government of Dr Mahathir Mohamed (see Awil and Abdul-Aziz (2005) for a detailed discussion on government role in the internationalization of housing developers). In the post-apartheid era Malaysian investors were the second largest investors in South Africa after the United States.

Three Malaysian housing developers began operating in South Africa in the immediate post-apartheid era. We report here on the activities of one developer, Developer C, who internationalized into South Africa in 1996 and completed the last phase of its development in 2006. This developer has developed a distinct niche in Malaysia as a property developer with innovative practices that focus on developing a country-style living. This developer in partnership with a local developer jointly developed a golf estate, the first in South Africa, in the vicinity of Pretoria (the political capital). Among the earliest innovations undertaken by Developer C included limiting the financial risks that potential house buyers were exposed to by capping the interest rates at 15% for the first two years after house purchase (this was in the period following the apartheid era, a period of high and rising interest rates). This attracted those house buyers for whom interest rates were an inhibiting factor. Additionally, the guarded residential golf estate was the first such estate in South Africa.

CONCLUSION

The housing sector has generally been a sector where foreign capital and foreign developers have played a minimal role. Housing developers from the Asia Pacific region have been experiencing a general increase in their internationalization into countries in the region. The three countries discussed above have different housing sectors, yet the three of them have initiated policies that have attracted foreign developers. The experiences of Malaysian housing developers in three countries have shown that it is possible to compete in location-centric sectors, through the introduction of innovative development practices. Though the local developers are knowledgeable and experienced in the local scene, yet their advantages can be surmounted by the ability of foreign developers to utilize their foreign capital coupled with the introduction of innovative development practices. Malaysian developers were competitive in those types of developments of which they had experience at home such as golf estates, high-end condominiums and integrated townships. As the three countries discussed above are developing countries, the findings are specific to developing countries.

SOCIAL NETWORK ANALYSIS: A ROBUST METHODOLOGY TO EVALUATE KNOWLEDGE CREATION CAPABILITY AND ABSORPTIVE CAPACITY

Era Kurul,[1] Noriko Otsuka and Andrea Colantonio

Real Estate & Construction, Oxford Brookes University, Oxford, OX3 0BP, UK

'Knowledge creation capability' and 'absorptive capacity' are argued to be the main sources of competitive advantage in the UK construction industry. They are inextricably linked with one of the ingredients of 'social capital, i.e. accessibility to resources by individuals. Even so, the current discourse on managing knowledge does not pay due cognisance to these aspects of integrated project teams. This research primarily aimed at exploring the interrelationships between these concepts at the team level and testing the robustness of Social Network Analysis (SNA) as a methodological approach to establishing the structural features of social capital that promote or demote knowledge creation capability and absorptive capacity, mainly by augmenting the accessibility to resources by individuals. Semi-structured interviews with key members of two project teams were interpreted through the combined use of SNA and content analysis. Here the SNA results are discussed. The main practice-related finding is that project managers (PMs) are the knowledge brokers in project teams with unique advantages in accessing external knowledge and controlling knowledge flows within their teams. Methodologically, SNA was shown to have the potential to be developed into a robust tool to assessing accessibility to resources by individuals and to assessing innovation capability of project teams once the methodological approach of this project is developed enough to measuring resources as assets and to evaluating the outcomes of mobilizing these resources.

Keywords: integrated team, knowledge management, methodology, social systems.

INTRODUCTION

The knowledge management (KM) paradigm has evolved considerably since the 1990s when it emerged as a novel thrust in organizational performance research. Its domination by the 'asset capitalization' perspective has been counterbalanced by the acknowledgement of informal knowledge processes, such as the ability to source, transfer and create knowledge, as strategic capabilities for gaining competitive advantage (Fong 2003; Kess and Haapasalo 2002; Roth 2003; Reagans and McEvily 2003; Quintas *et al.* 2003; Sharkie 2003). Within this context, any functional unit's ability to recognize the value of *external* knowledge, to assimilate it and to apply it to commercial ends, i.e. its 'absorptive capacity' (Cohen and Levinthal 1990), has become critical in gaining competitive advantage.

The above evolution has been hand in hand with the emergence of "the second knowledge perspective", which perceives knowledge "as a set of shared beliefs that are constructed through social interactions and embedded within the social contexts in

[1] ekurul@brookes.ac.uk

which they are created" (Fong 2003). New knowledge is created through 'a series of transformations, by which standard resources, which are available in open markets [or contained within the project teams], are used and combined within the organizational context in order to produce [competences and] capabilities' (competences and capabilities (unlike resources) are unique to each organization, and so are the sources of competitive advantage (Grant 1991)) (Ciborra and Andreu 2001; Roth 2003; Lang 2001; Lank 1997)..

Social interactions play an important role in this transformation process, which is generally undertaken by intra-organizational project teams within the UK construction industry. These interactions are contained within the social networks of teams and facilitated by the linkages between their members. As a result, exploring how these linkages influence each member's opportunity to access the resources that are embedded in his/her social network becomes a key step towards understanding a construction firm's role as a knowledge creator.

Bourdieu's (1986) conceptualization of social capital is appropriate for this exploration as it acknowledges both the social structure itself and the networks and the resources that people can access through that structure. Lin (1999) details Bourdieu's concept by introducing the "three ingredients of social capital: resources embedded in a social structure; accessibility to such social resources by individuals; and use or mobilization of such social resources by individuals in purposive actions." These ingredients resonate with Nahapiet and Ghoshal's (1998) three dimensions of social capital: structural, relational and cognitive, and they are inter-related. Among these relationships the structural and positional variations are of special interest in terms of the differential distribution of accessibility between members of a network. Therefore, this paper focuses on the structural dimension. Such a focus would also be instrumental in assessing the robustness of Social Network Analysis (SNA) as a methodological approach to establishing the network features that increase or decrease a member's accessibility to the embedded resources. As a result, it may become possible to use SNA for measuring absorptive capacity.

Structural dimension of social capital is concerned with the network of relations that are embedded in the structure of any social group. It purely relates to 'the configuration of linkages between people or units'. These linkages are the main channels through which knowledge, specifically tacit knowledge, flows within project teams. They play an important part in defining the extent of a team's absorptive capacity, which depends not only on its interface with the external environment but also on the transfer of knowledge within and across project teams (Cohen and Levinthal, 1990; Bresnen *et al*. 2003). Moreover, these linkages create opportunities to exchange and combine existing knowledge. As such, they are the bases of one of the three conditions of knowledge creation (Groshal and Moran 1996).

A DISCUSSION ON METHODOLOGY

This research was undertaken in the context of two qualitative case studies. This approach matched well with the limited amount of existing knowledge in this study area and the consequent exploratory nature of this research. Moreover, it resonated with the context-specificity of knowledge and knowledge processes, which calls for a methodological approach, such as case studies, that would facilitate their study in their real-life context (Yin 1994).

One inter-organizational project team in each of the two industrial partners to this research project provided the context for the field study. Case Study One (CS1) was the project team (PT1) building an office block in the City of London for one of the UK's largest development companies. The project team (PT2) that was refurbishing a laboratory/office facility for a multi-national pharmaceutical company was our second case study (CS2). In both cases, the clients and the main contractors had established working relationships for more than a decade. In both instances, the contractors had single-point responsibility. Thus, the emergent project teams were *integrated*.

A combination of Social Network Analysis (SNA) and content analysis was the main methodology used in this research. Here the discussion only focuses on SNA as content analysis is out of the scope of this paper. At the lowest level of analysis, SNA relies on data on the quantitative features of the relations, e.g. frequency of contact, between the nodes that form a network (Freeman 1992) (nodes can be people, departments or whole institutions. In the context of this research, the nodes of each social network were members of the project teams that were studied). SNA was considered to be a robust methodology as it would facilitate the exploration of the structural features of a social network through the analysis of 'relational data' (Scott 2000), as well as providing a collection of metrics to determine how the project teams used the resources embedded in their networks to source knowledge and advice (Wasserman and Faust 1994). It was considered to be particularly suited to project teams that were studied because they were temporary coalitions bound together by flows of information and materials (Pryke and Pearson 2006; Winch 2002). Furthermore, it was anticipated that SNA would facilitate simple quantitative measures and the visualization of the teams' networks, paving the way to very useful discussions amongst their members. It would thus enable limited deployment of action research. It had been acknowledged that SNA alone would not be adequate to explore the qualitative features of the relationships between the nodes despite these advantages. Therefore, content analysis was used at a later stage of the research project to systematically analyse the textual data on these features, and thus to address "the problem of relational content" (Burt and Schott 1992; please see Data Collection section below for a discussion).

(Some sub-sections of this section are based on Kurul *et al*. (2007).)

Sampling

Both case studies were identified in collaboration with senior staff of industrial partners according to the procurement method, project stage at the time of the first field-study, size, complexity, novelty of the project, and the anticipated levels of collaboration that the client and the project team would demonstrate. Subsequently, the key participants to the research project were selected from both teams in collaboration with the Project Director (or equivalent) as they were in a position to identify the key team members that were critical for knowledge creation at the project level. This approach also enabled the research team to determine the boundaries of the networks that it was going to study based on the "significant" issue under consideration, i.e. criticality for knowledge creation within the team. In this respect, Scott's (2000) "reputational approach" to identifying the network boundary was followed. Despite the inherent potential bias in this selection process, the research team deemed this approach to be necessary to gain the project teams' trust and to secure their full support. Given this, anticipated levels of co-operation at the project level gained prominence over the global representativeness of the deliberately small research sample. However, methodologically acceptable levels of representativeness were achieved in the sampling of the interviewees from the broader project team. Interviewees were selected such that all the stakeholder groups that were involved in the projects were represented.

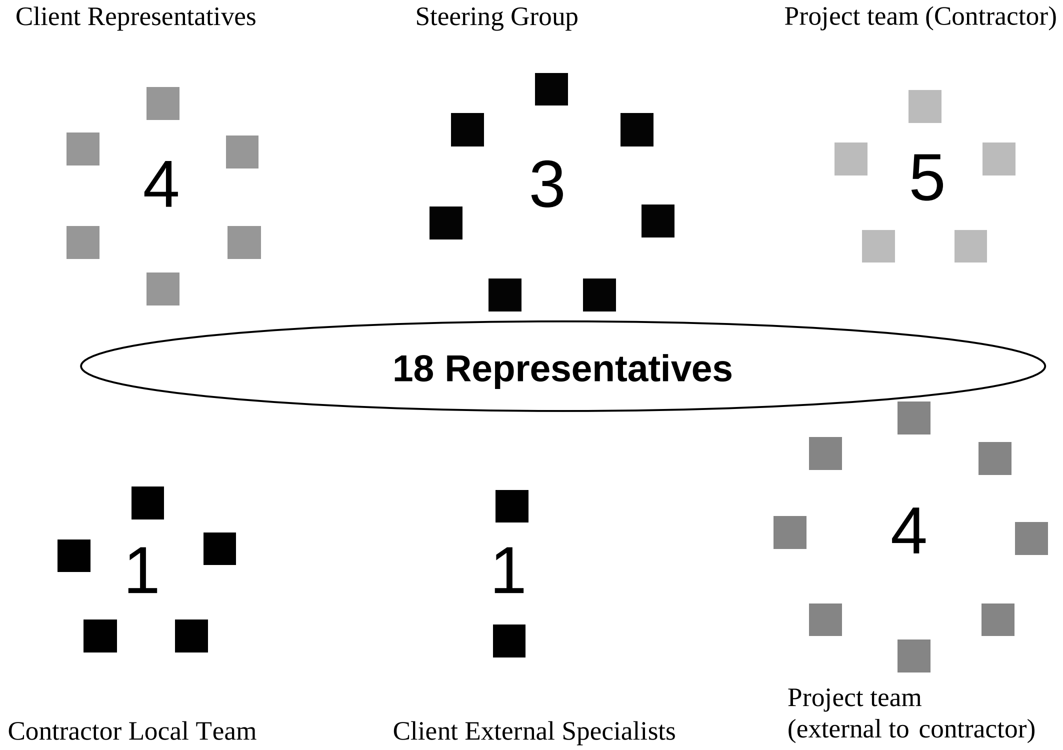

Figure 1: Sampling

Figure 1 illustrates this point. It shows the interviewee sampling for CS2 in terms of the sizes of different groups of stakeholders (represented by the number of boxes in each cluster) and the number of interviewees chosen from each group (integers given at the centre of each cluster). This approach yielded an interviewee sample of 20 and 18 team members respectively for CS1 and CS2.

Data collection

The research project entailed two fieldwork periods during which data was collected through semi-structured interviews with each participant. The questions for the first round of interviews were based on our conceptual framework and ensuing literature review; and were piloted on the Project Directors (PDs) (or equivalent). Similarly, the second round of interview questions were devised after feedback sessions with the teams and tested with both PDs. During the two field study periods, the post-doctoral research assistants (RAs) were based in the project offices in order to observe the interaction between interviewees in their natural working environment and to substantiate, to a limited extent, the validity of the interview data.

The main means of relational data collection were “name generator” questions that the interviewees answered during the first fieldwork (Burt 1997; Lin 1999; Marsden 1990). These questions are given in Table 1. Questions 1 and 2 were mainly concerned with the generic contact made with members of the project team, while Questions 3 and 4 related to sourcing knowledge and advice from colleagues within the team or outside it. These two sets of questions were designed to establish whether different groups of people were contacted for generic issues and for sourcing knowledge and advice. Question 5 further explored this issue, while Question 6 aimed at understanding whether team members were investing in sustaining their social networks at an informal level outside their working environments.

Table 1: Name generator questions

1.	How often do you contact the people within the project team?
2.	Could you map your contact lines on the project team diagram?
3.	Who do you contact first when you have a problem and why that person? In what capacity do you know him (or her)?
4.	Who do you contact first when you want to find out something or need some knowledge/advice? Why do you contact that person? In what capacity do you know him (or her)?
5.	Would you ask for the same advice to someone else? If yes, can you tell me why?
6.	Do you also spend some of your free time with the above people?

The main potential shortcoming of the above list of questions is that they assume a common understanding of what ‘knowledge’ is and that the interviewees can readily distinguish between, for example, knowledge and information. The research design aimed at overcoming this shortcoming by introducing the distinction between knowledge and information during the interviews. However, it is still possible that some of the respondents may have used these terms interchangeably, and thus they may have referred to information sourcing relations instead of knowledge sourcing relationships.

In this context, we also face “the problem of relational content” which represents the context of other activities within which the knowledge interaction between two nodes took place (Burt 1997). One way of overcoming this problem was to ask redundant questions in order to establish whether the interviewees had variable tendencies for their knowledge interactions. This was achieved to a limited extent by including Question 4 as a redundant question for Question 3. Another issue with the relational content was that the interviewees had to decide which of their activities were problem solving activities and what they sought was knowledge. Moreover, social network models that were used assumed that each node interpreted their knowledge interaction activities in the same way as other interviewees did. Once again, the semi-structured interview set up allowed for establishing what a problem-solving activity was. The interpretative differences between interviewees could have been addressed by asking each interviewee to describe the problem-solving activity that s/he was referring to in some detail. Unfortunately, this opportunity was overseen at the time of this study.

Another issue with the data collected is that the interviewees were asked to recall the names of the people that they sourced knowledge and information from. Marsden (1990) points out that recall data is biased towards stronger links. As a result, nodes that form the end of weaker links may have been omitted from the dataset. In the main, such possible omissions could not have had a major influence on the findings “egocentric data” gathered from sampled individuals was analysed, and hence the generated names which fell outside the research sample and data associated with them was not analysed.

Data analysis

Raw relational data was tabulated in databases and analysed through SNA by using InFlow (InFlow is the social network analysis software package that was used in this research). Tabulation was based on the names that emerged in response to the “name generator questions” (see Table 1) and the frequency of the contact for knowledge and advice sourcing that was cited by the interviewees, i.e. daily, weekly, monthly and rarely. Hence, we analysed "egocentric network data" for the ties surrounding the sampled individuals (Marsden 1990).

This tabulated data was used to draw network maps of the project teams and to calculate SNA metrics. One-way and two-way network maps could be drawn but only two-way maps were analysed. One-way maps included all the nodes which were referred to during the interviews, i.e. A, who was in our interviewee sample, referred to a knowledge and advice sourcing relation to X who was not in our sample. Hence, nodes that were not in our interviewee sample became part of the one-way network maps, which demonstrated that the actual boundary of the network goes well beyond that which we identified by using the reputational approach. Conversely, two-way maps only comprised of the nodes that we interviewed. In all cases but one, there were reciprocal links between the nodes, i.e. A referred to B in terms of a knowledge and advice sourcing relation, and B referred to A in the same context.

The decision to analyse only the two-way maps was taken for three main reasons. First, at the subject level, the two-way knowledge and information exchange interactions are regarded to be most critical for finding new ways of doing things, i.e. knowledge creation. Second, in the methodological context, there is "the fundamental need for at least two persons and at least one connection of some special sort between them" (Wallace 1996, quoted in Freeman 1992). The one-way maps indicated that there was a relationship between the nodes but it was not possible to get both nodes to mutually acknowledge the presence of this relationship and to verify its knowledge sourcing nature. This third reason was a barrier, which was a consequence of the resource constraints on this research.

Many different types of SNA metrics could have been produced through the analysis. The SNA metrics given in Table 2 were produced and interpreted for the purposes of this. The choice of these metrics was based on the review of SNA literature (e.g. Mizruchi and Potts 1998; Otte and Rousseau 2002; Reagans and McEvily 2003) and its previous applications (e.g. Loosemore 1998; Pryke 2004). This review enabled the research team to identify *density*, *degree centrality*, *closeness centrality* and *betweeness centrality* as the main metrics to be examined in order to explore the relationship between the structural dimension of social capital, stimulators of absorptive capacity and of knowledge creation. Short definitions of these metrics and a very brief overview of their potential influence on knowledge creation and sharing processes are given in Table 2. Additional factors such as *network reach* were also taken into account in the analysis in the light of their usefulness to understand the relationships between these stimulators and the cognitive and relational dimensions of social capital. The latter were subsequently investigated in greater depth by using content analysis, which is outside the scope of this paper.

Table 2: SNA indices vs. KC capability & AC

Density measures the connectivity of nodes (interviewees) to others in the network. It is a representation of the number of existing connections as a percentage of all theoretically possible connections. Density values above 0.50 (or 50%) indicates that there is risk of communication and/or information overload in the network(Krebs and Holley no date)
Degree Centrality provides an indication of the extent to which a node is connected to its immediate environment. Denotes a node's ability to communicate directly with others in the network, in other words their communication activity (Freeman 1979). Also, it denotes an individual's opportunities to access resources (Sparrowe *et al.* 2001) and is a significant predictor of his/her involvement in innovation (Ibarra 1993)
Closeness Centrality represents "the extent to which an actor can reach a large number of other factors in a small number of steps" (Mizruchi and Potts 1998). Nodes with high closeness centrality have the ability to reach large numbers of nodes while they rely on a minimum number of intermediaries (Freeman 1979). They can avoid the control of others, and are efficient as they can reach all other actors in the shortest number of steps (Nohria and Eccles 1992)
Betweeness Centrality reflects a node's potential to control other nodes by controlling and filtering the information flow between them (Loosemore 1998; Sparrowe *et al*. 2001). Nodes with high betweenness centralities could play 'brokerage' or 'gatekeeper' roles
Network Reach is a measure of the length of information paths between nodes. The key paths in networks are 1 and 2 steps, and on rare occasions 3 steps (Burt 1992, Friedkin 1983). "Horizon of observability" indicates the maximum path length, beyond which people are unlikely to be aware of other people's roles and work (Friedkin 1983)

The results of these analyses were presented to the relevant project team in two workshops. These workshops not only provided the participants an opportunity to express their views on the research findings but also enabled the research team to incorporate some degree of action research as they facilitated discussions within the project teams about their knowledge creation and sharing practices.

MAIN SUBJECT-SPECIFIC RESULTS

A detailed discussion on the interpretation of the above metrics is outside the scope of this paper. Readers interested in such elaboration could refer to Kurul *et al.* (2006, 2007). Below is a brief overview of the main results of this research project.

The main findings suggest that project team configurations have a high level of influence on the network structure, which influences both knowledge creation capability and absorptive capacity of project teams. Within this context, the selection of people to source new knowledge from is grounded on the formal 'chain of command' and the division of roles amongst members of a given team.

Density values of both PT1 (0.32) and PT2 (0.46) indicated network structures potentially facilitating effective communication in that they were both below the 0.50 threshold that Krebs and Holley (no date) identify for the risk of communication and information overload. However, the *degree centrality* results for PT1 showed that the density values should not be taken at face value in terms of effectiveness of communication. Employees of the construction management company in PT1 had a clear advantage over the trade contractors in terms of the exchange opportunities that they accrued from the network structure (see **Table 3**). Such opportunities were probably much more evenly distributed for all members of PT2 almost regardless of their affiliations as evidenced by their *degree centrality* ranking which did not show affiliation-based clustering.

Table 3: Degree centrality results

Project 1			Project 2

A similar affiliation-based observation could also be made on the closeness centrality rankings, which could also be used as an indication of the of the social cohesion around a relationship as it "reflects how close an actor is to the other actors in the network" (Wasserman and Faust 1994). The closeness centrality ranking for PT1 demonstrated that the structure of PT1's network and its 'command chain' relegated members outside the management contracting firm at lower ranks, possibly reducing in turn their enthusiasm to put effort into coming up with new ideas (see **Table 4**). By contrast, PT2 network structure resulted in a much more diversified closeness centrality ranking that possibly fostered opportunities for truly intra-organizational cross-pollination of new ideas.

The *betweeness centrality* results corroborated the PMs' inevitable brokerage roles, as dictated by their 'command chains'. PM1 and PM2 respectively dedicated 29% and

36% of all their communication activity to controlling and filtering information/knowledge transfer between other nodes in their networks.

METHODOLOGICAL KNOW-HOW & LESSONS LEARNT

This section reports on the methodological know-how that the research team accumulated and considers the lessons learnt from applying SNA in the context of knowledge creation and absorptive capacity. This discussion falls into two categories: conceptual and operational.

At the conceptual level, it has been shown that SNA facilitates the exploration of the structural features of the social networks of the studied project teams. This was achieved through the basic interpretation of SNA metrics to determine how the project teams made use of their networks in sourcing knowledge and advice. This basic interpretation should be more advanced by correlating different metrics and interpreting the results of this correlation in order to get a more realistic understanding of how the networks behave.

A similar level of sophistication is also yet to be reached in the comparative analysis of the results of both SNA and content analysis. Once again establishing the correlations between these two different sets of results is the first step forward. As this has not yet been done, it may be possible that this research has just identified the actors who are key in terms of providing knowledge and information but not necessarily key in terms of creating new knowledge (Ashworth and Carley 2006). One way of testing this is to establish the correlation between a node’s position in the network as a knowledge and information provider and his/her knowledge creation capability.

At the operational level, basic utilization of SNA enabled the visualization of the teams’ networks, paving the way to very useful discussions amongst their members and between the research team and the project teams. It thus facilitated limited deployment of action research. This was regarded to be very beneficial by the industrial partners, who also showed a strong interest in having the tools and knowledge necessary to map the networks at different stages of their projects and to compare themselves with benchmarks for measuring knowledge creation capability and absorptive capacity of project teams. This wish raised the issues of the temporal nature of the social networks, the lengthy data collection process and the absence of such benchmarks.

Hence, the research team came to the conclusion that it was necessary to establish a much less time-consuming data collection tool without losing the opportunity to collect rich qualitative data and benchmarks for knowledge creation capability and absorptive capacity. This requires a longitudinal study on a statistically significant number of projects and thus poses an operational challenge. It may be possible to follow Ashworth and Carley’s (2006) approach and use simulation.

Another issue about data collection is the interpretation of knowledge by each interviewee. As we stated above, it is possible that some interviewees considered knowledge and information to be interchangeable. This condition results in the need to develop a strategy to understand whether each node’s interpretation of the knowledge interaction that was referred to in the name generator question(s) (see Table 1) was the same.

CONCLUSIONS

At the subject level, the main findings suggested that project team configurations have a high level of influence on the network structure, the selection of people to source new knowledge from is grounded on the formal ‘chain of command’ and the division of roles amongst members of a given team. It was also identified that there might be a correlation between the exchange opportunities that individuals accrue from the network structure and the roles of their affiliated companies in a project, e.g. construction management.

In the methodological context, this research has corroborated, among others, Lin (1990) and Scott (2000) by applying their principles in the knowledge creation and absorptive capacity context for the first time and thus showing that SNA is instrumental in assessing one of the ingredients of ‘social capital, i.e. accessibility to resources by individuals. It emerged from the discussions with industrial partners to the research project that this potential could be exploited by project teams in the industry, if structural benchmarks to assess knowledge creation capability that is inherent in a given network at a given point in time could be established and an easy-to-use management tool could be developed.

In this context, this research design had two main shortcomings in its deployment of SNA. First, the relational data was possibly biased as it was collected through name generation by recall. It is thus necessary to complement it with other methods such as observations so that the interview data can be triangulated, if this method is to be used in the future. Second, the network maps that were drawn were snap-shots at a point in time. Therefore, SNA has to be periodically repeated if its results are to be used for benchmarking. Given this, semi-structured interviews were not the most appropriate data collection strategies. It is critical that a more effective and less time-consuming data collection strategy is developed.

ACKNOWLEDGEMENTS

This paper is based on the findings of a research project that is funded by the Engineering and Physical Sciences Research Council (EPSRC, project reference: EP/C530160/1).

STAKEHOLDER VALUE DRIVERS OF PUBLIC PRIVATE PARTNERSHIPS IN GREECE

Athena Roumboutsos[1]

Shipping, Trade and Transport, University of the Aegean, 2A Korai str, Chios 82100, Greece

Public Private Partnerships are described as endeavours that seek to achieve value and benefit for both the public and private sector. As the procurement process matures, value drivers crystallize, providing the basic negotiation framework. In countries, such as Greece, where experience is limited, this knowledge is not registered, though, imperative to achieving progress in the sector. The value drivers of PPP projects as perceived by the prime stakeholders of a PPP project, i.e. construction companies, the public authorities and the financial lenders, in Greece are presented herewith. These are derived through a questionnaire survey. The results indicate the varying perceptions between stakeholder groups and are compared to similar studies undertaken and provide insight as to barriers to minimize the pre-contract period of PPP engagements.

Keywords: Public–Private Partnerships, stakeholders, value for money.

INTRODUCTION

A key motive for public authorities' interest in Public Private Partnerships (PPPs), as stated in the green paper, is that PPPs enable governments, constrained by the EU's own fiscal rules, to make more investments in public services. In addition to the need to launch investment programmes, which would not have been possible within the available public-sector budget, within reasonable time (European Investment Bank, 2005), the scheme has been made even more favourable due a recent ruling by Eurostat (the Statistical Office of the EC) in February 2004, according to which the assets involved in a PPP should be classified as non-government assets, and therefore recorded off balance sheet for government, if the private partner bears the construction risk, as well as, either availability or demand risk.

Nonetheless, governments need to demonstrate value for money (VFM). Central to this demonstration is the "comparison" of benefits and costs between the two procurement options (i.e. traditional and PPP), where the allocation of risks and risk premiums combined with discount rates affect the final outcome. Grimsey and Lewis (2005), in a comparison study of methods used in 29 countries, found that the Public Sector Comparator (PSC) was only applied in 6 countries, namely the UK, Australia, The Netherlands, South Africa, Canada and Japan, while the rest used alternative methods.

However, PPPs, if they are to provide value, should not only be about financing of capital investments, but about exploring the full range of private sector management, commercial and creative activities, while securing value for money (VFM) for all

[1] athena@aegean.gr

stakeholders involved. The VFM assessment is not an exact science, the net result being that opinions on and perceptions of VFM vary from stakeholder to stakeholder (Akintoye *et al*. 2003). Problems reported in PPPs, such as high tendering costs, complex negotiations, costs restrains on innovation etc, stem from this very issue of varying stakeholder value drivers (Spackman 2002; Tiong *et al.* 1992).

The issues surrounding VFM are threefold: the identification of value for money drivers; the estimation of their importance and relation to success factors; and, finally, the investigation of the varying importance among stakeholder groups.

To the end, the first issue has been extensively covered by many researchers, academia and practitioners (Akintoye *et al*. 2003; Ball *et al*. 2003; Edwards and Shaoul 2002; Grimsey and Lewis 2005; Leiringer 2006; Nisar 2007; Pitt *et al*. 2006 etc.. Many of these are similar to the “VFM drivers” identified in the report “Value for money drivers in the private finance initiative” (Arthur Andersen and Enterprise LSE 2000). Li *et al*. (2004), addressing the second issue, after extensively reviewing the literature on value for money drivers looked into their relative importance to critical success factors for PPP/PFI construction projects in the UK. Finally, the fact that perceived VFM varies between stakeholders, i.e. the third issue, has, to date, received little attention by researchers.

To this end, research presented herewith investigates the perceptions on value of PPPs by the prime stakeholders, through a questionnaire survey in Greece. Findings are compared to similar studies undertaken in the UK.

BACKGROUND

A review of informed literature on PPPs would indicate that a variety of the characteristics of the PPP are promoted as key to the creation of VFM and, consequently, lead to the success of the endeavour, thus, constituting key success factors. The aspects of the PPP procurement process most frequently mentioned from attributed sources are listed below.

Table 1: Summary of critical success factors for PPPs (source: Li *et al*. 2005)

Critical success factor	**Source**
Strong private consortium	Jefferies *et al.* (2002), Tiong (1996), Birnie (1999);
Appropriate risk allocation and risk sharing	Qiao *et al.* (2001), Grant (1996)
Competitive procurement process	Jefferies *et al.* (2002), Kopp (1997), Gentry and Fernandez (1997)
Commitment/responsibility of public/private sectors	Stonehouse *et al.* (1996), Kanter (1999), NAO (2001b)
Thorough and realistic cost/benefit assessment	Qiao *et al.* (2001), Brodie (1995), Hambros (1999)
Project technical feasibility	Qiao *et al.* (2001), Tiong (1996), Zantke and Mangels (1999)
Transparency in the procurement process	Jefferies *et al.* (2002), Kopp (1997), Gentry and Fernandez (1997)
Good governance	Qiao *et al.* (2001), Frilet (1997), Badshah (1998)
Favourable legal framework	Bennett (1998), Boyfield (1992), Stein (1995), Jones *et al.* (1996)
Available financial market	Qiao *et al.* (2001), Jefferies *et al.* (2002), McCarthy and Tiong (1991), Akintoye *et al.* (2001b)
Political support	Qiao *et al.* (2001), Zhang *et al.* (1998)
Multi-benefit objectives	Grant (1996)
Government involvement by providing guarantees	Stonehouse *et al.* (1996), Kanter (1999), Qiao *et al.* (2001), Zhang *et al.* (1998)
Sound economic policy	EIB (2000)
Stable macro-economic environment	Qiao *et al.* (2001), Dailami and Klein (1997)

Well-organized public agency	Boyfield (1992), Stein (1995), Jones *et al.* (1996) Finnerty (1996)
Shared authority between public and private sectors	Stonehouse *et al.* (1996), Kanter (1999)
Social support	Frilet, 1997
Technology transfer	Qiao *et al.* (2001)

The Arthur Andersen and Enterprise LSE report (2000) identified 18 value-for-money drivers for the UK and distinguished them as primary and secondary depending on the average score they obtain through interviews with PPP/PFI participants. Li *et al*. (2005) through an extensive literature review identified 19 critical success factors (Table 1), 18 of which were ranked in through their research.

In Table 2, this ranking is compared to that of the Arthur Andersen and Enterprise LSE report (2000). It is evident that success factors and VFM drivers "coincide" in many cases, while differing in importance. This may be due to the evolution of perceptions realized between the two studies as the market matured through the undertaking of more projects.

Table 2: Comparison of literature ranking

Li *et al*. (2005) Critical Success Factors	**Rank**	**Anderson and Enterprise LSE (2000) VFM Drivers**	**Rank**
Appropriate risk allocation and risk sharing	2	Risk transfer	1
Transparency in the procurement process	10	Transparency of process	12
Competitive procurement process	12	Competition	5
Commitment/responsibility of public/private sectors	4	Long term nature of contracts	3
Thorough and realistic cost/benefit assessment	5	Public sector comparator	10
Well-organized public agency	7	Public sector project development skills	9
Good governance	8	Private sector management skills	6
Shared authority between public and private sectors	17	Alignment of interest of authority and contractor	8
Multi-benefit objectives	14	Project bundling	17
		Innovation	7
Project technical feasibility	6	Output based specifications	2
Strong private consortium	1		
Available financial market	3		
		Cost of capital	13
		Deal flow	14
Favourable legal framework	9		
		Performance measurement and incentives	4
		Involvement of third party financiers	18
Political support	11		
Government involvement by providing guarantees	16		
Sound economic policy	13		
Stable macro-economic environment	15		
Social support	18		
		Public Sector implementation	15
		Release of hidden asset value	16
		Quality of advice to public sector and bidders	11

The research undertaken in Greece focused on the "common" factors identified in Table 2, as well as factors identified as important in the local market. The principal aim was to identify the relative importance of these factors for the Greek market. In addition, it was equally important to identify a possible maturing process. More specifically, the factors presented herewith are:

1. Risk allocation – optimal allocation and valuation of risk.
2. Competition.
3. Contract duration and scope.
4. Innovation.
5. Borrowing costs – financing of the project.
6. Private sector versus Public sector management skills.
7. Performance measurement and incentive.

The above do not respond to all factors investigated but only to those on which each category of stakeholders had more consolidated views.

RESEARCH SURVEY DESCRIPTION

The current survey is part of a questionnaire survey conducted to register risk allocation preferences, partnering and value-for-money drivers of private and public entities interested in Greek PPP projects. In particular, the stakeholders addressed were: construction companies, financiers (banks), ministries interested in promoting PPP infrastructure within their scope of activities and associations with a stake in PPP procurement. Table 3 presents the numerical figures of the survey. The description of the participants follows herewith.

Table 3: Survey respondents

	Construction Companies	Banks	Ministries	Associations	Total
Respondents N	19	5	5	2	31
% Total	61.3	16.1	16.1	6.5	100
Universe	42	5	5	8	60
Response rate	45%	100%	100%	25%	52%

Construction companies

Construction companies selected for the survey were companies eligible to undertake PPP projects, i.e. those classified as classes 6 and 7 by the Greek Ministry of Public Works, thus, those companies having the respective construction experience and financial background. It should be noted that, in Greece, there are seven classes and a newly established construction company with no experience enters the register at class 1 and is “allowed” to undertake low budget, and consequently (in most cases) low technical difficulty works. Questionnaires were addressed directly to the company heads and followed by interviews for additional information and clarification. The objective was to register “company” rather than individual opinions.

The survey was conducted in the winter of 2004–2005, in a very turbulent business environment of recession for the construction industry following the Athens 2004 Olympic Games. Of the 61 companies classified under the 6^{th} and 7^{th} construction class in the 2004 Ministry register, only 42 (universe population) were found to remain in operation. This was due to a number of mergers that took place immediately after, or just before the completion of works between consortium members. 19 construction companies responded to the questionnaire, i.e. a response rate of 45%. The respondents are presented in Table 4. The respondent companies were all highly reputable in Greece (two are included in the top 100 European Companies listing) and active in most infrastructure sectors. The stated field of expertise included buildings, ports, transportation, power and energy, water and sanitary.

As depicted, the majority of the respondent companies have been established before 1990. A total of 41% have an annual turnover of more than 40 million Euro, while 72% of the companies interviewed claim that more than 60% of their turnover is generated through public contracts. Thirteen companies have more than 100 employees; 68% of the companies surveyed had participated in a PPP procurement procedure. Half of these companies (54% in total) were involved in a completed PPP project. All, but one, companies expressed interest in participating in a PPP project.

Table 4: Respondent construction companies' profile

Property	Description	Frequency	%
Year of establishment	Before 1970	5	31
	1970–1990	7	35
	1990–2002	7	35
Number of employees	<100	6	31
	101–500	9	47
	>500	4	21
Average annual turnover in MEuro	6–40	11	58
	41–100	3	16
	101–250	2	10
	>250	3	16
% of turnover originated from public sector	0–40%	3	16
	41–60%	2	10
	61–80%	7	37
	81–100%	7	37

Financing institutions
Not all Greek based banks were interested in PPPs and, thus, were not included in the survey. The ones interested were "The National Bank of Greece", "The Commercial Bank", "Alpha Bank" and "Eurobank". The European Investment Bank (EIB), due to the bank's great involvement in PPP projects, was also included in the survey focusing on the Greek market. Thus, concerning the financing institutions, the survey covered all potential players and while the number of respondents is small (five), it constitutes a response rate of 100%.

Public sector
The identification of key persons in position to respond to the questionnaire in the Greek public sector was a task of considerable difficulty. One major problem stemmed from the fact that the government was preparing the Greek legislation concerning PPP projects and most government officials and key advisors to ministers were reluctant to express opinions which might not have been in line with the final outcome. Major ministries were targeted intensely, i.e. the Ministry of Finance and Economics and specifically members of the PPP taskforce, the Ministry of Public Health, the Ministry of Education, the Ministry of Internal Affairs, the Ministry of Public Works.

Associations
A number of associations and NGOs influenced by the PPP procurement method were targeted. However, only two were in a position to report their positions as authorities while the rest only personal positions and, thus, were excluded from the sample. The

two that responded were the Technical Chamber of Greece and the Association of Designers and Planners.

PRESENTATION OF SURVEY RESULTS AND DISCUSSION

The importance of value drivers identified in the literature was explored by means of a Likert scale rating questions, i.e. statements for which participants were requested to state their level of agreement on a 1 to 5 scale (Table 5). A number of these question-statements were followed by multiple-choice questions aiming to verify the reason of agreement stated (Tables 6, 7 and 8). For example, long-term contracts may be equally important for all participants but for different underlining reasons.

Likert scale rating questions were structured in both positive and negative patterns in order to verify the unbiased of the responses and the administered questionnaires had questions ordered differently, in random, so as to avoid distortion of responses due to fatigue.

Table 5: Cross tabulation of mean scores (1 = extremely important to 5 = not important)

		Construction Companies		Banks		Ministries		Associations		Total

10	Public sector's level of experience in PPPs **	3.94	0.73	3.25	0.96	4.25	0.50	3.50	0.71	3.86	0.76
11	Project Mng *not* core business for the public sector Authority**	2.06	1.21	2.25	1.89	3.00	1.63	1.50	0.71	2.18	1.33

Note: *Sd = standard deviation, ** Likert scale rating: 1 = extremely high to 5 = inadequate

Survey responses were analysed using the SPSS statistical package. Only descriptive analysis was carried out due to the limited number of responses, regardless of the significant response rate. Table 5 presents the results by stakeholder category and in total. It is noted that totals are presented for reasons of completeness rather than significance. The calculated standard deviation (noted as sd in the table) denotes the value of the mean response for each item on the table.

Risk allocation – optimal allocation and valuation of risk

From a financial perspective, it is reasonable to suggest that the required rate of return on an investment increases as the amount of risk in the investment increases (Brigham 1985). Thus, the theory and practice that in PPPs risk should be borne on the basis of the principle that the party best able to control or manage a risk should take responsibility for the risk in order to achieve the optimum (lowest) cost is sound (Loosemore 2007). The allocation of risk is seen by many as the most crucial element in a PPP being able to achieve VFM. Nonetheless, Lam (1999), in his sectoral review of risks associated with major infrastructure projects implemented all over the world, concluded that optimum risk allocation is not easy to obtain as much depends on the relative bargaining power of the parties and the potentiality of the reward for taking the risks.

Risk allocation (item No. 5 in Table 5) was expected to figure as “extremely important” (mean = 1) for all stakeholder groups. However, this was not identified in the survey. As noted in Table 5, mean values were 2.11 and 2.50 for construction companies and the public sector, respectively and only the banks and the associations (mean 1.50 and 1.00, respectively) gave risk allocation the expected relative importance.

This response may be due to the fact that while less than optimum allocation of risks has been identified in the first PPP projects in Greece (Roumboutsos and Striagka 2004), their perceived end value was not reduced.

Finally, findings are comparable to those reported by Li *et al*. (2005). An interesting point is the fact that in both cases the public sector placed less importance on risk allocation than the private.

Competition

A PPP project, like a conventional project, has to go through the tendering process. Where a PPP has been won in open tender, it makes the argument for VFM easier to substantiate. The element of competition has additional benefits to the public client during negotiations. However, this needs to be balanced against the bidding costs as these will more than likely be recovered elsewhere.

Transparency in the tendering procedures (item No. 1 in Table 5) and a *favourable legal framework* are elements (item No. 9 in Table 5) that reinforce competition. As depicted in Table 5, *transparency in the tendering procedures* was identified as the most important item across all stakeholder groups, while the *legal framework* was estimated as marginally important though under discussion during the survey. This may be due to the fact that experience with PPPs to the date of the survey was not connected to specific legislation and that the majority of stakeholders view a legal framework as *safety in the bidding procedure* (see Table 6).

In addition to the above, as shown in Table 6, the majority of stakeholders (60%, 75% and 100% of the banks, public clients and associations) consider price-lead competition a benefit for the public sector, while construction companies (56%) express scepticism concerning the possibility of poor deals that will ultimately affect the public sector.

A minority of respondents registered their fear of the creation of oligopoly market conditions, which in effect has been identified in recent PPP contracts. This is really the antithesis of competition. The barriers to entry of new competitors to PPP procurement are high. The absence of competition from the procurement process can only result in a loss of credibility, and potentially VFM, for PPP procurement. Bid costs can therefore be seen as having a negative and real impact upon PPP and VFM, particularly so when the number of bidders is reduced to one.

The importance of *more PPP tenders* in order to balance the costs, figured with a relative significance (see Table 5, item No. 8).

Table 6: Views related to competition issues

	Construction Companies	Banks	Ministries	Associations	Total
Price – lead competition					
Benefit to public sector	33%	60%	75%	100%	46%
Poor deals for private sector and impact on public sector	56%	0%	25%	0%	39%
Oligopoly market conditions	6%	20%	0%	0%	7%
Other	6%	20%	0%	0%	7%
Legal framework					
Safety to the bidding procedure	94%	100%	75%	100%	93%
Other	6%	0%	25%	0%	7%

Contract duration and scope

The duration of the contract and the scope of the contract works are very closely linked. The long duration of PPP contracts and the inclusion of the facilities management function allow the consortium to consider properly whole life costing issues in order to minimize the contract period costs. Additionally, value cannot be achieved unless, during initial procurement, bidders grasp the opportunity to integrate design, construction and facilities management issues to minimize life cycle costs and optimize operational efficiency (Spackman 2002; HM Treasury 2003). Furthermore, the manner in which PPPs are usually structured requires the consortium to construct the asset(s) before it can receive payments. This very often results in the consortium investing more in the initial stages of the contract than would be done under standard procurement arrangements to hasten the completion of the building relative to "traditional" construction.

This view was challenged by Leiringer (2006) – as though a logical conclusion, it has not been empirically verified. The survey findings (Table 7) support this view. Life cycle planning is not the primary objective of the private sector supplier, who, in the majority, views long-term contracts as a means to secure ROE.

Indisputably, from the contractor's point of view, there is benefit in life cycle planning *in the event the contract is won*. Otherwise, it is an additional loss. Consequently, contractors will view long-term contracts as a means to secure ROE, as operational costs (since no or minimum life cycle planning was involved) would most likely reduce profits from revenues. This perception is in total contrast with the interests of banks and public sector, since these parties would be interested in an overall reduction in project risks that is connected to the minimization of operational costs and the overall quality of the project, which would, possibly in addition, secure revenues.

Finally, the view presented by the contractors is in line with their view concerning price-lead competition (i.e. poor deals for the private sector with ultimate impact on the public).

Table 7: Views on contract duration

	Construction Companies	Banks	Ministries	Associations	Total
Long-term contracts					
Required for high investment projects	44%	20%	25%	100%	41%
Invoke life cycle planning	28%	80%	50%	0%	38%
Alternative approaches to investment and service delivery	28%	00%	25%	0%	21%
Length of contract depends					
Expected project life cycle	0%	20%	25%	0%	7%
ROE	94%	40%	25%	100%	76%
Public sector requirements	0%	0%	50%	0%	7%
Other	0%	40%	0%	0%	7%

Innovation

The ability to innovate is directly related to the quality of the output specification and the element of competition during the initial stages. This has been exemplified in successive rounds of PPP prison procurement that showed that a combination of innovation and competition led to reductions in costs at each stage (HM Treasury 2003). The *aspect of innovation* figured as the second most important factor in the survey (see Table 5, item 2) across all stakeholder groups with a strong convergence depicted by the small standard deviation (sd) figures, ranging from 0.50 to 0.82.

Borrowing costs – financing of the project

The fact that the government can borrow more cheaply than the private sector is an accepted fact. It is assumed by many that the differential in the cost of capital between the public and private sectors means that the consortium's higher cost of capital will have a negative impact on the VFM case, but, it is argued, determining VFM is not simply about comparing interest rates. This is not correct when the cost of the project is the same regardless of the procurement route (Grout 1997). Thus, if the cost of capital is to be considered, it should be on the difference between the cost of purchasing the asset traditionally and through PPP. Therefore, the cost of capital has a smaller role to play in the VFM argument than many may first appreciate.

The importance of establishing a *thorough cost/benefit assessment*, as indicated in the survey, is more important for the construction companies and the associations than it is for the banks and the public sector (see Table 5, item 5). On the other hand, *combined procurement of financier and constructor* seem important for all stakeholders except construction companies (see Table 5, item 6).

Table 8: Impact on public funding

	Construction Companies	Banks	Ministries	Associations	Total
Availability of public funds	50%	0%	50%	100%	45%
Flexibility of Public funds	39%	60%	25%	0%	38%
Commitment of public funds	11%	20%	25%	0%	14%
Other	0%	20%	0%	0%	3%

Finally, there is always the assumption made that the government would be able to raise the capital if the project were not to proceed as a PPP. Table 8 illustrates the stakeholder perceptions on *the effect PPPs have on public funds*. It is evident that there is no converging view both within and among stakeholder groups.

Private sector vs. public sector management skills
For a variety of reasons that no one appears to be able to put their finger on, management skills are viewed as essential. Whether or not there is a real difference between management skills of the private sector and the public sector is open to debate. However, there is a real difference between the systems and procedures required within the public sector when compared to the private. It could be argued that the levels of accountability, less in the private sector, and delegation of authority, more in the private sector, allow "things to happen faster" and, thus, the perceived value of "private sector management skills".

In any case, PPPs are a complex task and one that places a very high demand on the capability of the public sector. Additionally, it would also appear to be common sense that the overall project success is to a very large determined by the ability of the public sector client to adopt and sustain the best value regimes through out the project life (Akintoye *et al.* 2003).

This aspect has been registered in the survey in concerning the *public sector level of experience in PPPs*, which was rated very low by all participants, and the essentiality of *project management carried out by the public sector*, which was equally considered outside the core responsibilities of the public sector (see Table 5, items 10 and 11 respectively).

However, PPPs are viewed by all stakeholders as an *alignment of private and public interests* in such as way as to establish better overall management (see Table 5, item 3).

Consequently, the assumption concerning private and public sector management skills holds true for the Greek PPP stakeholders.

Performance measurement and incentives
Performance measurements and incentives of themselves do not materially affect the empirical argument for or against VFM. However, they will increase the confidence of the client if they are set and apportioned correctly. Recent commentary has stated that the simplistic assumption that there is a necessary and direct relationship between project incentives and performance outcomes is doubtful (Bresnen and Marshall 2000).

Survey findings (Table 5, item 4) indicated that the possibility of *additional entrepreneurial activities during the asset life cycle* was viewed as positive by the construction companies and the ministries (mean = 1.94 and 2.00, respectively), while the other stakeholders were very negative (mean 4.25, and 3.00 for banks and associations).

Comparison with other findings
Table 9 below compares the ranking of some of the value drivers for PPPs as identified in the literature and the present research.

It is evident that ranking changes over time and between countries as the importance of value drivers as depicted by the stakeholders seem to be dependent on the particular market environment.

Transparency in the process seems to be of prime interest in Greece, while of lesser importance in the UK, where risk allocation is of essence.

Table 9: Comparison of findings

Li *et al*. (2005) Critical Success Factors	**Rank**	**Anderson and Enterprise LSE (2000) VFM Drivers**	**Rank**	**Present Findings**	**Rank**
Appropriate risk allocation and risk sharing	2	Risk Transfer	1	Risk Transfer	5
Transparency in the procurement process	10	Transparency of process	12	Transparency of process	1
Thorough and realistic cost/benefit assessment	5	Public sector comparator	10	Cost/benefit Assessment	6
Shared authority between public and private sectors	17	Alignment of interest of authority and contractor	8	Alignment of interest of authority and contractor	3
Multi-benefit objectives	14	Project bundling	17	Additional entrepreneurial activities	8
		Innovation	7	Innovation	2
Favourable legal framework	9			Favourable legal framework	9

CONCLUSIONS

A questionnaire survey was undertaken in the Greek PPP market among stakeholder groups in order to identify key value drivers. These were found to be country specific when compared to respective findings carried out in the UK. On a number of factors, stakeholder groups varied significantly as to the importance attributed. Three of which –risk allocation, competition and contract length – are considered to have an impact on the pre-contract bidding and negotiation process, as parties have contrasting views as to the targeted benefit and many potential bidders are discouraged.

A maturing process was not identified, as perceptions are considered to be due, principally, to the prevailing market environment and the local experience.

Additionally, it was found that the gross distinction between private and public stakeholders is not substantiated as financing institutes differ considerably to the private sector clients (construction companies).

Further research should be undertaken as to the varying perceptions on value drivers of PPP stakeholders.

DIFFERENCES IN IMPLEMENTATION AND EFFECTS OF THE PUBLIC PROCUREMENT ACT IN THE EU CONSTRUCTION SECTOR.

Stefan Olander and Kristian Widén[1]

Construction Management, Lund University, PO Box SE 221 00, Lund, Sweden

All member countries in the EU must follow the given directive for public procurement that has been decided upon. The purpose of the directive is to ensure sufficient public procurement and sound use of public resources. However, knowledge about the implementation and effects of the directive is limited. One clear indication is that the effects vary between different countries in the EU. A preliminary study of the implementation of the public procurement act in Sweden and Denmark for the construction sector has been conducted, with the aim of obtaining knowledge of how and why implementation and effects vary. One distinction is that the number of appeals concerning public procurement is higher in Sweden than in Denmark that might depend on a different implementation of the directive, mainly because Sweden has added amendments to the directive while Denmark has not. The variation of implementing the directive between member countries may have a negative impact on the opportunities of obtaining the best possible service and technical solution in the public procurement process.

Keywords: construction sector, European law, public sector, procurement.

INTRODUCTION

The public sector is a highly influential participant in the construction industry, as it exercises a major role in several ways. It is, for example, policy-maker, legislator and client (Andersson 2003) and, in some cases, performs services directly (Andersson 2004). The public sector, as client, can influence and motivate other actors to a significant extent (Edquist *et al*. 2000). Public policies, laws and programmes are other ways in which governments can influence innovation in the industry (Manseau and Seaden 2001).

The European public procurement directive has both positive and negative effects (e.g. NOU 1998; Ramsey 2006). Positive effects are that public procurement across Europe has the same basic prerequisites and, thus, can generate a clearer competition among suppliers. A negative effect is cost driving and time-consuming bureaucratic routines. Other issues that have been highlighted, especially by parties in the construction sector, are difficulties of adopting new forms of cooperation, innovative solutions and implementation of environmental targets in the procurement process. The new directive (Dir 2004/18/EC) is stricter, but also opens up for more collaborative forms of cooperation, such as partnering and PFIs, through, for example, the use of competitive dialogue (Finansdepartementet 2006; Ramsey 2006). In particular, the 'competitive dialogue' procedure would allow early dialogue with

[1] stefan.olander@bekon.lth.se

industry and provide information on what the public sector wants to buy. This would guide and stimulate the creation of new ways of working and ideas (Manchester Business School 2006).

The purpose of the research presented here is to obtain a preliminary view of how a difference in the implementation of EU public procurement directives will affect the construction industry. Two countries, Denmark and Sweden, act as examples of this phenomenon. The research should be seen as a baseline for further studies about how the public procurement process acts as an enabler or barrier for change and development for the construction sector and if national legislations have an effect on this.

The research presented here should be seen as a preliminary study of public procurement within the European Union. Sweden has taken the approach of adding amendments to the EU directive whilst other member countries, e.g. Denmark, have adopted the EU directive as is. The data gathered consists mainly of official documents and public investigations concerning the implementation and effects of the public procurement act within the European Union in general and Sweden in particular. In addition, the views of construction sector clients have been obtained through an informed dialogue with a representative of the Swedish construction client organisation; additionally, a representative from the Danish construction client organisation has been contacted in a similar way to obtain information of relevant differences between Sweden and Denmark in the implementation of the public procurement act.

PUBLIC PROCUREMENT

All member states in the EC have to follow the EU regulation on public procurement. The purpose of the regulation is to enhance competitiveness and to eliminate non-tariff barriers to intra-community trade (Bovis 2006), and to promote transparency and prevent corruption (Sanderson 1998). The rationale behind the open market is that for many sectors, for example the financial sector, business across the globe was already harmonising procedures and specifications – and as a sharp-edged tool, not because of bureaucratic obsession for its own sake (MacGillycuddy 1988). Public authorities are significant market players as buyers of goods and services. Before the creation of the Internal Market, national, regional and local authorities favoured domestic suppliers. This was not only incompatible with the Treaty provisions requiring the creation of a single Internal Market but also had negative macro and microeconomic implications for the European economy (Commission of the EU 2004). Furthermore, there are indications that proper use of the directives is far from common practice. The non-compliance of the directives from public authorities is a major issue (Gelderman *et al*. 2006).

Public procurement has evolved from a primary mission of acquisition goods, supplies and services to enable public employees to successfully discharge their responsibilities into a process of facilitating the delivery of core government services by independent contractors (Wendell and Lawrence 2005). Under these arrangements, the (fragmented) public sector procures services from the private sector, including the use of the underlying assets, rather than directly providing them. Governments and their agencies are in effect becoming the producer and regulator of services rather than the provider (Shaoul 2002), which increases the number of partnerships when procuring these services. Public procurement partnerships take government procurement and contracting professions out of their comfort zones and require a great deal of individual discretion. The ability to exercise discretion is a commodity that is not shared equally by all governments and by all government procurement systems (Wendell and Lawrence 2005).

An essential aspect of public procurement partnerships is the implicit understanding that the choice of partners and the specific boundaries of the partnership relationship must be negotiated. A movement away from regulating process in favour of jointly agreed upon goals or outcomes require new and different public procurement approaches (Wendell and Lawrence 2005). Nielsen and Hansen (2001) found that the introduction of the "competitive dialogue" would be a step in the right direction of supporting rationally grounded buyer-seller relations within technically complex procurement processes. The new competitive dialogue procedure, which will be "based on" the general principles of transparency and equal treatment, will be spelt out in the directive alongside the conditions for its use (Arrowsmith 1999). This implies that the expressed rules applying to this procedure will be more detailed than those governing the competitive negotiated procedure. Provided that the new rules are themselves limited to reasonably general concepts, this could be advantageous (Arrowsmith 1999).

The introduction of a new "competitive dialogue" procedure are important in the context of public private partnerships to ensure that all award procedures for such complex contracts can be conducted in an effective manner (Arrowsmith 1999). However, due to the uncertainty in both hierarchical position in respect to other procedures and internal structure, the "competitive dialogue" may create opportunities for fraudulent post-tender negotiations and unduly reduce competition in a market (Curtol *et al*. 2006). Competitive dialogue is potentially available not merely for the sort of complex public private partnership that prompted this adoption, but also for other non-standard procurements. However, there remains some doubt over its precise application because of the uncertainties connected with the procedure of competitive dialogue (Arrowsmith 2004).

The concepts of transparency and accountability are nowhere more significant in public administration than in procurement (Schapper *et al*. 2006). Opening of public procurement national markets to the EU competition implies a series of economic and social reforms. The principal of openness, fairness and transparency are basic elements of an effective public sector, which intends to align with the mechanism of a free market (Mardas 2005) The effects of the Public Procurement Directives have been questioned ever since first adopted in the 1970s (Gelderman *et al*. 2006). Some argue that empirical evidence is consistent with the *ex-ante* expectation that the EU single market programme should have increased competition and consequently reduced market power, especially for firms operating in industries where non-tariff barriers were perceived to be high (Bottasso and Sembenelli 2001). The commission argues that an increase in cross-boarder contracts will be an indication of a well-functioning public procurement market (Sanderson 1998). Several studies, for example Cox and Furlong (1997), of possible increases of cross-border contracts in the early 1990s did not show the expected results. The reason for this is said to be faulty application of the regulations by the member states. The solution of this problem was to make member states to implement the regulation as correct, clear and easy as possible in the national context (European Commission 1996). The public sector has to recognise that an effective public procurement system implies the openness of public contracts to foreign competitors (Mardas 2005). The existence of preferential public procurement policies is a well-known fact in many countries. Favouritism in the awarding of public contracts can result from an explicit “buy local policy” when the government offers a specified preference for domestic suppliers (Mougeot and Naegelen 2005). However, if a domestic product performs well in terms of industrial and trade structures, then it can also perform well within an open non-discriminatory public procurement market against foreign bidders (Mardas 2005). The cost of not encouraging intra-EU competition is substantial. The public sector pays more than it should for goods, supplies and services it buys and, in doing so, supports sub-optimal enterprises in the European Union (Martin *et al*. 1999).

There are several reasons why the EU legislation might have failed to open-up public procurement markets to international competition (Martin *et al*. 1999). First, purchaser might be splitting up large contracts so that the value of each falls below the threshold stipulated in the procurement legislation. Second, purchasers might simply not advertise their prospective purchases even where a contract falls within the remit of the legislation. Finally, the Commission relies on others to bring cases of malpractice to its attention and plays no pro-active role in this process. Gelderman *et al*. (2006) found that educating and training public purchasers will be an effective tool for increasing the familiarity with the rules and thus the compliance with the directives.

The procurement regulation builds on neo-liberal theories, which assume that public supply efficiency is best achieved through competitive and open tendering procedures (Cox and Furlong 1997; Bovis 2006). This, for certain types of procurements and products, is apposed to other theories – see for example the first paragraph in this section. The neo-liberal theories were particularly clear in the early versions of the regulations; changes in the later versions made it possible to choose more collaborative approaches to public procurement (Bovis 2006).

National institutions, measured in terms of both quality and similarity, along with instruments of foreign trade policy, have a strong and significant impact on trade between European countries (Cheptea 2007). How the national governments choose to implement the regulations at the national level is largely decided by the political system and the prevailing business system (Bovis 2006). Three different business systems have been identified in the European Union (Winch 2000):

- Anglo-Saxon (i.e. the UK).
- Corporatist (i.e. Germany and the Netherlands).
- Étatique (i.e. France and Italy).

Sweden and Denmark would be closest to the corporatist system. The corporate system there is generally a greater willingness to intervene in the market to protect social values (Winch 2000).

There are many different strategies public agencies can adopt in order to promote competitive markets, for example, managing markets via individual contracts and transactions, managing key suppliers in strategic markets, changing capability requirements for purchasing personnel (Caldwell *et al*. 2005). Public procurement can aid the development of a sector and innovation (Edquist *et al*. 2000). Arguments for its use as an innovation policy instrument refer to its use of the market power and technological competence of large public sector organisations to reduce risks, provide incentives, articulate demand, and assure markets for producers who would otherwise hesitate to develop innovative solutions and products (Geroski 1990). Moreover, public procurement can also play a vital role in the diffusion of innovations, where the spread of a new product or system to new markets or market segments typically requires further development work in order to adapt it to these new contexts (Edquist and Hommen 2000). The distinction between ‘direct’ and ‘catalytic’ public procurement (the latter being carried out on behalf of other eventual end-users) is also highly relevant for the diffusion of innovations. With the perspective of public procurement affecting the development of a sector, a national innovation system perspective may also be used to categorise different national approaches. Four different categories have been identified (Manseau and Seaden 2001) and three of the four are present within the European Union:

- Market-driven (i.e. the UK).
- Government-led (i.e. France and Germany).
- Social-democratic (i.e. Denmark and Sweden).
- Meso-corporatist (i.e. Japan, this category is not present in Europe).

In Sweden, many clients are considered to be weak, lacking a level of knowledge that would classify them as ‘informed clients’ (NAO 2005). Uninformed clients lacks a basic familiarity with the rules, which according to Gelderman *et al*. (2006) was a major reason for the non-compliance of the directives. The design professions, in the conception stage, are also considered to have a weaker position when compared with other countries, while the contractors, at least the larger ones, are considered to have a strong position within the Swedish construction business and innovation system (Bröchner *et al*. 2002). In Denmark, it is very much the other way around, the client and the design professions, especially the architect, are considered to be strong, while the contractors are considered to be relatively weaker. According to a study made by Manchester Business School (2006), the strongest voices against current procedures for public procurement tended to focus on the distinctive characteristics of national implementations of those Directives, rather than the Directives themselves. In Sweden, the implementation was seen as particularly onerous. Industry representatives commented that much more documentation was now required, and there was a noticeably greater tendency to use lowest price as a tender selection criterion. While some viewed the greater transparency of the process as a benefit, this had led to increased costs in bid preparation, less emphasis on quality issues, and, most notably, an explosion of formal contests of the outcome of bids. These had grown from 113 to 1124 in five years (Manchester Business School 2006). This would indicate that national variations in public procurement legislations will have an effect on the efficiency of the public procurement process.

There is an identified need for developed forms of procurement and contracting allowing for an increase in innovation and development of the construction industry and its products (Latham 1994; Egan 1998; Näringsdepartementet 2000). The scope for the construction sector to continuously develop and innovate would greatly be enhanced by appropriate procurement strategies by the clients. The advantages of (a) a specific product focus, (b) an alignment of motivation and (c) a drawing on lessons from other industries are confirmed (Kumaraswamy and Dulami 2001). Something that procuring on the lowest price does not encourage.

It is the client that makes the initial decision to procure construction works and the way in which procurement takes place. This in turn influences the degree of supply chain integration and ultimately the overall success of the project (Briscoe *et al*. 2004). In construction, where there are usually many parties taking part in the project for different periods of time and with different assignments, it is not only the project areas that need to be integrated but also the parties (Moore and Dainty 2001). The client is the most significant factor in the success of supply chain integration and the client must develop practices that facilitate such integration if the construction process is to be improved. Frequent changes in the forms and terms of contract and the preference for competitive price tendering are detrimental to supply chain relationships. Practices such as the use of negotiation to secure suppliers and the development of open-book accounting practices assist in building better relationships and integration (Briscoe *et al*. 2004).

EFFECTS OF THE IMPLEMENTATION OF THE PUBLIC PROCUREMENT ACT

From the perspective of construction clients, there are some major concerns about the implementation and effects of the public procurement act. One part of the public procurement regulation is that an unsuccessful bidder may challenge the procurement process of a contract. This makes it possible to get a neutral validation of whether the procurement procedures have been correct, but it adds to the cost driving and time consuming features of the public procurement process. A study on the competitiveness of the construction sector in various countries within the EC (Manchester Business School 2006) indicates that Sweden has by far the highest number, as well as the largest increase, of contested public procurements within the EC. In Denmark, which basically has the same national business system as Sweden, there are no indications of this dramatic increase of contested public tender awards.

There are indications that both the Swedish and the Danish public agencies are more cautious in their interpretation of what is possible to do within the EU directive framework than public agencies in other EC countries (e.g. the UK), with the difference that Swedish legislators have adopted a slightly more defensive position by adding national rules. From the perspective of the public construction client, it was found that they find it difficult to follow the regulations, in both Sweden and Denmark, due to insecurity of how to interpret the benefits that exists within the directive. Thus, there is a focus on the limitations rather than on the possible benefits. In a Swedish study (NOU 1998), 50% of the clients answered that they cannot follow the regulations completely and according to the suppliers the agencies can not even follow their own evaluation models, which may be one cause for the many challenged of public tender awards in Sweden. A possible explanation for these challenges is the additional rules made in the Swedish legislation, which differs from many other EC countries (e.g. Denmark and the UK), where the EU directive has been adopted without additional legislation and rules. There is a criticism of this implementation of the public procurement directive by the Swedish client organisation as being too complex, bureaucratic and unbalanced in favour of the supplier and contractor in relation to the client. The imbalance between contractor and client can further be explained by the fact the contractors in Sweden have traditionally a stronger position than the client, which is not the case in Denmark. This imbalance in strength between the client and the supplier/contractor can result in both a higher possibility and a willingness to appeal procurement decisions in Sweden. However, in Denmark the clients have a stronger position and a majority in the board of appeals for public procurement that might have a mitigating effect on the number of challenges.

Additional national rules can further have the effect that legislation becomes too detailed and, thus, acts as a barrier for different forms of cooperation, e.g. partnering and private finance initiatives because of the belief that this kind of cooperation is not compatible with the Swedish public procurement act. This is clearly not the case in other EU countries (e.g. the UK) where this kind of cooperation between client and supplier/contractor are commonly adopted. However, in Denmark, which does not have this additional legislation to the directive, there is also some reluctance from public clients to adopt this kind of cooperation. Another aspect of too detailed public procurement rules is that the unaccustomed clients base procurement decision on price alone and do not value soft parameters in these decisions. There is a tendency for Swedish and Danish clients to make an increased effort in valuing soft parameters in the tendering process, although price still weighs heavy in the decision and evaluation process. The uncertainty in the evaluation process of soft parameters has probably added to the number of appeals. This can have the effect that if this, in general positive, development is punished with a higher degree of appeals there is a risk that clients choose the safe option of deciding on price alone.

CONCLUSIONS

Manchester Business School (2006) concluded that governmental bodies constituted an essential part in the process of change for the construction industry. As a major client in construction, governments play a key role in the use of procurement techniques, in which:

- Quality is as important as price.
- Life-cycle costing is applied to safeguard the future.
- Professional designers and consultants are properly used and selected.
- Training is ensured.
- Innovation is encouraged.
- Only properly qualified and regisetred firms and individuals are employed.
- Fair pricing and contract terms are applied.

A public procurement process and the legislation surrounding it needs to enable procurement techniques or at least not act as a barrier. The only reason for a member state to add rules and legislation to the EU directive is if it will enable a more effective and positive development of procurement techniques.

Despite similarities in their national business systems, Sweden and Denmark have adopted the EU public procurement directive differently. There are some indications from the representatives of the client organisations in Sweden and Denmark that this may have an effect on the outcome of public procurement within these countries. However, there are still perceptions in both countries of similar problems with public procurement. The main difference is the number of challenges of the public tender awards. Thus, the question is if the difference in implementation is the cause of the difference in the number of challenges.

Further studies are needed to gain knowledge of the effects of added national rules to the EU directive in relation to the transparency and effectiveness of public procurement. Does the implementation of added national legislations and rules act as barrier or as an enabler? From a client perspective, the need for further research is to map the strength and weaknesses of the public procurement in different EU countries in order to evaluate how national variations in the legislation will affect the public procurement process.

PERFORMANCE MEASUREMENT OF THE MAJOR PROCUREMENT ROUTES IN FINLAND

Adekunle Sabitu Oyegoke[1]

Department of Construction Economics and Management, Helsinki University of Technology, PO Box 2100, 02015 HUT, Finland

The aim of the study is to compare procurement performance in Finland based on key project performance variables. The study is based on empirical case-questionnaire studies. Construction project performance is measured via a rating system through key variables of time, budget, quality, satisfaction, contracting system, and the effectiveness of design management along procurement types. The measurement is carried out along design and construction phases. The procurement methods are categorized in accordance with the major (prevalent) routes in Finland: design and build, consulting CM, contracting CM, general contract – traditional, general contracting – separate trades. The results show that the performance attributes are shared between different routes, for instance, the design and build ranked first in responsibilities/risk distribution, design management and meeting of the project target while the contracting CM is better in completion time, quality level and equal general contracting (separate trades) in technical quality level. Conversely, the consulting CM and general contracting – separate trade ranked better in interrelationships than most routes in design and construction phases owing to their flexibilities in apportioning responsibilities to different consultants and trade (specialist) contractors.

Keywords: construction, Finland, measurement, performance evaluation, procurement.

INTRODUCTION

The performance of a procurement route depends on many organization variables as procurement route defines project organization set-up. Love *et al*. (1998) define procurement as an organizational system that assigns specific responsibilities and authorities to the people and organizations, and defines the relationships of the various elements in the construction of a project. In other words, project procurement establishes the contractual framework that determines the nature of relationship between the project team within the duration of their interactions. Different measurement methods have been used to measure project performance. Konchar and Sanvido (1998) measure quality on the basis of building element performance and Yng *et al*. (2002) use a Likert scale to measure the owner's satisfaction and administrative burden. Extensive work has been done by Samelson and Levitt (1982), Kaka and Price (1991), Russell *et al*. (1992), Kumaraswamy and Chan (1995) and Chua *et al*. (1999) on different factors that influence project performance.

The aim of this study is to compare project performance along procurement routes within Finnish practice, in order to measure their efficiency and effectiveness in relation to cost, time, quality, satisfaction, stakeholders' relationships, etc. The

[1] aoyegoke@cc.hut.fi

procurement route is categorized into five in accordance with their share and value of contract in Finland. The scope of this paper is procurement performance measurement within the selected performance variables and is limited to Finnish practice.

RESEARCH METHOD

This study is carried out by empirical studies via a case-questionnaire survey. The empirical study is carried out via a case-questionnaire to probe some recent cases of different procurement routes and to make an assessment of project performance as a whole. A self-completion case-questionnaire is used to collect both qualitative and quantitative data from experienced industry practitioners. The method adopted in this paper is to measure the identified performance variables in project procurement performance by a rating scale of 1–5 points. This is to obtain both factual and attitudinal information and understanding from different players. All the investigated projects in this study are based in Finland covering both private and public projects.

Conduct of the project case survey

The aim was to reveal the organizational set-ups and the involved parties' task-level performance in the project cases, ex post, along the five prevailing procurement routes (general contracting – traditional, general contracting – separate trades, CM contracting, CM consulting and design-and-build contracting) and the perceptions of the key project parties in the building sector in Finland. The contents of responses are analysed and authenticated through unstructured interviews. The analysis of the rating questions is done through descriptive data analysis. The aim is to have a broader view of analysing the data since a subjective-quantitative rating system is used. Out of maximum of 5 on the rating scale, 3.75 is assumed to be a reasonable performance level amounting to 75% of performance level. Variables along procurement routes are then categorized as 'measured high or low' depending on the means rating.

The project case-questionnaires were distributed to 51 professionals. Forty-two professionals responded before the closing date. Owing to the insufficiency of the data, seven questionnaires were discarded from the analysis. In other words, 35 (69%) project case-specific questionnaires were eligible that were executed between the year 1999 and the year 2005. In Table 1, the combined distribution of 35 project cases is shown by the gross floor area and the procurement route type. There are one to four projects in each category except in GC-st in (3001–6000), GC-t (6001–10 000), D-and-B contractor (10 001–15 000) and all the routes in category >15 000 except in CM contractor.

Table 1: Distribution of the projects by building size and procurement route (n = 35)

		Gross floor area (sqm)				
Route	**No.**	**< 3000**	**3001–6000**	**6001–10 000**	**10 001–15 000**	**> 15 000**
General contractor – t	8 (23%)	4	2	0	2	0
General contractor – st	6 (17%)	4	0	1	1	0
CM consultant	8 (23%)	1	3	2	2	0
CM contractor	7 (20%)	2	2	1	1	1
D-and-B contractor	6 (17%)	1	2	3	0	0
Total	35 (100%)	12	9	7	6	1

OVERALL PROJECT MANAGEMENT AMONG PROJECT CASES

The overall project management performance consists of nine variables. These variables are randomly selected by the FinSUKE research team and the author after due consideration. This group comprises experienced industry practitioners from both contracting and consulting practices as well as experienced academics. These projects are not randomly selected (selected by the respondents) but cover main procurement routes used in Finland.

- The upper-level choice of the procurement route and its effectiveness/consequences for other variables associated with the project organization set-ups.
- Early clarity in the allocation of risks and the distribution of responsibilities is one measure for high-level responsibility/risk management.
- Overall project target attainment is high level if it meets the project objectives after completion.
- Overall client satisfaction is measured high level depending on the client perception during the construction processes and completed project outcome.
- The attainment of a client's budget is measured high level if the budget is within the set targets.
- Design management is measured high level if the design is well coordinated and adds value to the processes.
- High-level technical quality of the finished products.
- Well-managed project quality as stipulated in the contract documents.
- On-time project completion attainment.

In Table 2, the overall project performance rating is shown in terms of nine variables, in descending order among the projects (n = 35). The overall mean ranking is at the level of 3.95. The mean ranking varied between 3.60 and 4.21. The rating varied between 3 and 5 points among the six variables and between 2 and 5 among the three remaining variables, i.e. budget attainment, design management and responsibility/risk management. On average, the respondents were most satisfied with the selected procurement routes (with the mean of 4.21). Project target attainment, good schedule management and client budget attainment ranked also high. Design management performance was ranked as the lowest (with the mean of 3.60) due to the late design, the insufficiency of (detailed) design documents.

Table 2: Overall project performance rating

Performance variables	Mean	1	2	3	4	5
Procurement route	4.21	–	–	4	19	12
Project target attainment	4.15	–	–	4	22	9
Completion time	4.10	–	–	6	19	10
Client budget attainment	4.06	–	2	7	13	13
Client's satisfaction	4.00	–	–	8	18	9
Quality	3.88	–	–	8	22	4
Technical quality	3.82	–	–	9	22	3

Responsibility/risk	3.76	–	1	12	15	6
Design management	3.60	–	2	13	17	3

In Table 3, the overall project performance rating is shown for each of five prevailing procurement routes among the 35 projects. The choice of the procurement route used rated best with the highest total mean value, followed by target attainment, completion time, budget attainment and client satisfaction. These are followed by quality assurance, level of technical quality, allocation of responsibilities and risks and lastly design management. The standard errors measure of uncertainty and the sample variance of the data are low. The standard deviation low results show the realiability of the ratings because the data points are close to the mean.

There are no dominant routes among the routes under survey. For instance, the design-and-build contracting system ranks first in target attainment, responsibility distribution and risk allocation and in design management. The CM consulting route is rated higher than other routes in procurement choice and overall client satisfaction but rated last in quality assurances. The separate trade traditional general contracting is rated best in technical qualities but rated last in a choice of procurement, budget attainment and client satisfaction. The CM contracting route is ranked best in completion on time, quality assurances and technical quality, but last in responsibilities/risks allocation. The general contracting route ranked better than other routes in budget attainment, but last in completion on time, quality assurances, technical quality and design management. In overall performance the design and build ranked first followed by CM-contracting, general contracting-st, CM-consulting and lastly general contracting-t.

Table 3: Comparison of the overall project performance rating along variables and procurement routes among the projects cases in terms of means (n = 35)

Performance variables	**Total mean**	**D-and-B contracting**	**CM consulting**	**General contracting-st**	**CM contracting**	**General contracting-t**
Procurement route	4.21	4.17	4.38	4.08	4.14	4.13
Project target attainment	4.15	4.50	4.00	4.33	4.00	4.00
Completion time	4.10	4.08	4.38	3.83	4.43	3.75
Client budget attainment	4.06	4.00	4.13	3.50	4.14	4.38
Overall client satisfaction	4.00	3.92	4.31	3.83	4.00	3.88
Quality assurance	3.88	4.00	3.75	3.83	4.14	3.75
Technical quality	3.82	3.80	3.75	4.00	4.00	3.63
Responsibilities/risks	3.76	4.00	3.88	3.83	3.57	3.63
Design management	3.60	4.33	3.38	3.50	3.86	3.25
Overall performance	3.95	4.09	3.99	3.86	4.03	3.82

Responsibility distribution and risk allocation management in project cases
In Figure 1, the rating of the responsibility/risk distribution varies 3.6–4.0 among the five procurement routes. The D-and-B contracting was ranked first based on the integration of the design management with the other responsibilities and the clear risk distribution among the project parties. In the GC contracting with separate trades and CM consulting, the contractors are selected after the completed design phase and the contractors are coordinated and supervised by the general contractor or the CM consultant, respectively. CM consulting allows trade contractors to have direct contracts with a client.

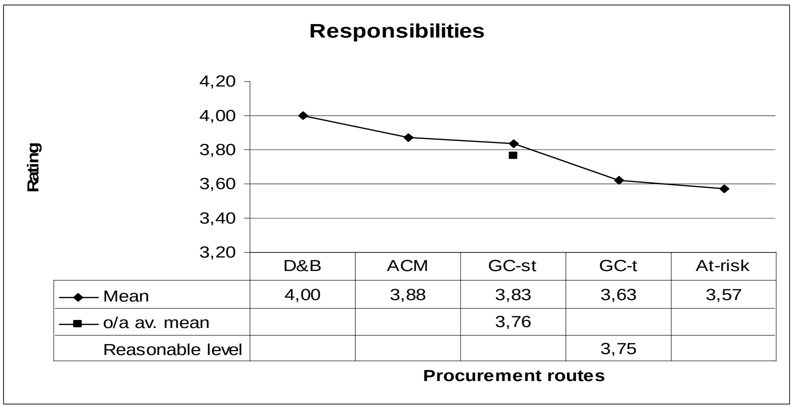

Figure 1: Risk and responsibility distribution rating by procurement routes among the projects (n = 35)

The risk-taking CM contracting was ranked the lowest route because of a lack of adequate checks and balances when a CM contractor assumes the dual role of designer and contractor during different project phases. In addition, a CM contractor carries out preconstruction management services. Uncertainty is inherent in a client's final choice between the independent contracting firm or CM contractor in the construction stage.

Many project cases were executed under an uncoordinated task approach or under a subcontracting approach with a back-to-back form of risk allocation. In such cases, the specialist contractors were responsible for their detailed mechanical and electrical drawings that were checked by the design team before the incorporation into overall design. A specialist M&E contractor is responsible for the technical risks. In practice, only a few changes and claims emerged. In addition, FM services were subcontracted to specialist contractors.

Overall client satisfaction management among project cases
In Figure 2, the overall mean of the client/owner satisfaction is shown to be ranked at the high level of 4.0. The satisfaction varied 3.8–4.3 among the five procurement routes. The CM consulting was ranked best (4.3) based on the various reasons such as the direct contractual relationships between the client/owner and the trade contractors, the reduction of the project cost owing to the elimination of the main contractors' profit and the effective competition between the trade contractors.

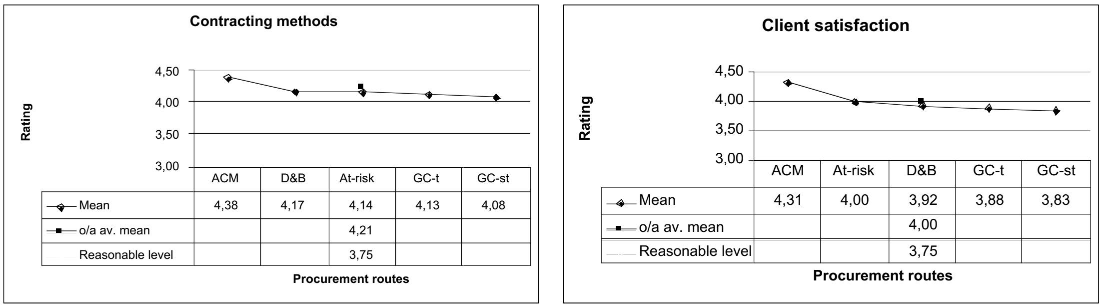

Figure 2: Contracting methods and client satisfaction rating by the procurement routes among the projects (n = 35)

In Figure 3, the overall mean of the client's/owner's budget attainment is shown to be ranked at the high level of 4.1. The budget attainment varied 3.5–4.4 among the five procurement routes. The traditional general contracting (GC-t) was ranked best (4.4) primarily due to the completeness of the documents before the actual construction works begin. Figure 3 also presents the overall mean of the client's/owner's project target attainment is shown to be ranked at the level of 4.2. The target attainment varied 4.0–4.5 among the five procurement routes. The D-and-B contracting was ranked best (4.5) followed by the general contracting with separate trades (4.3). The single point of the D-and-B contractor's performance responsibility as well as the D-and-B contractor's and the GC-st contractor's inputs in value management/engineering were mentioned to be key factors behind the high degree of project target attainment.

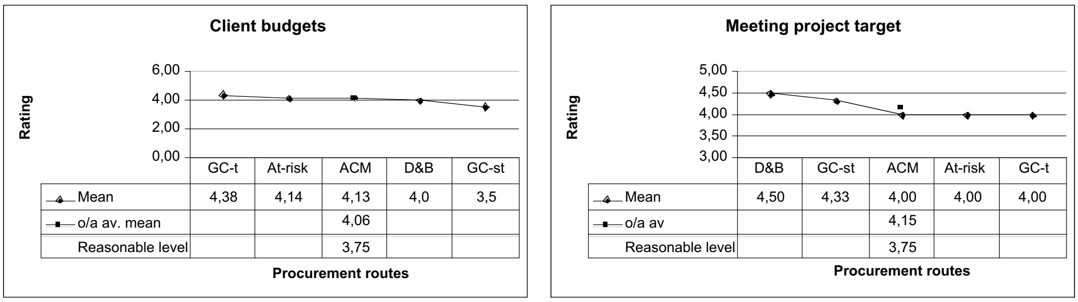

Figure 3: Client's/owner's budget and project target attainment rating by the procurement routes among the projects (n = 35)

Building design and technical quality management among project cases

In Figure 4, the overall mean of the building design management is shown to be ranked at the fairly low level of 3.6. The level of the design management varied 3.3–4.3 among the five procurement routes. The poor design management was witnessed in the case of the traditional general contracting (3.3) and CM consulting (3.4) below the overall mean and reasonable level of performance 3.75. This was due to the fact that the contractor was not involved in the design process, the overall design led to many design changes, the design documents were not ready on time and the lack of the responsibilities/penalty in the case of design mismanagement.

In four project cases, the specialist contractors or the subcontractors were acting in the capacity of the multiple prime contractors engaged in the design and construction of their section of the contracts (e.g. the structural shell, the HVAC systems). These contractors were involved early to work with the design team so that their component or work could be fully integrated with the main works. The design team provided them with the information on the functionality, the specifications and the usage of the building. The dual tendering involved the subcontractors to compete on the price, the schedule and the quality as well as on the life cycle value management as part of the FM services and the renewal. In all the four cases, the main contractor coordinated the construction works and the design team provided project management and administration services.

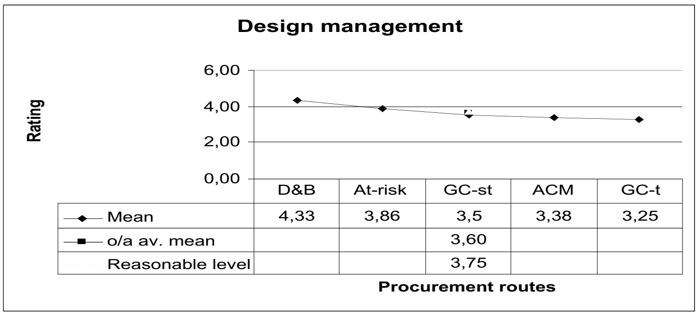

Figure 4: Design management rating by the procurement routes among the projects (n = 35)

In Figure 5, the overall mean of the project quality assurance is shown to be ranked at the fairly low level of 3.9. The level of the quality assurance varied 3.8–4.1 among the five procurement routes. The risk-carrying CM contracting was ranked best (4.1) followed by the D-and-B contracting (4.0), owing to the both contractor's involvement in the preconstruction phase and the value engineering management. Also in Figure 5, the overall mean of the technical quality level is shown to be ranked at the fairly high level of 3.8. The level of the technical quality varied 3.6–4.0 among the five procurement routes. The general contracting with separate trades (GC-st) and the risk-carrying CM contracting were ranked better (4.0) than the other routes in managing the technical quality. In the former case, the separate trade contractors contributed markedly already in the design phase (some of them even carried out the design work).

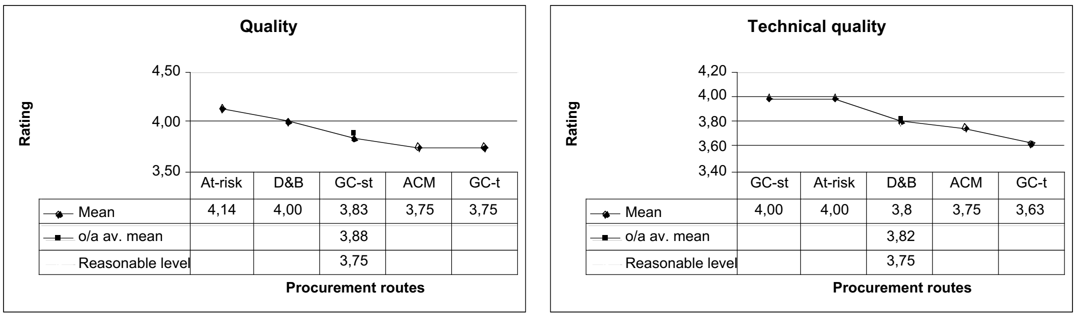

Figure 5: Project quality assurances and technical quality rating by the procurement routes among the projects (n = 35)

Schedule management among project cases

In Figure 6, the overall mean of the project schedule management is shown to be ranked at the high level of 4.1. The level of the schedule management varied 3.8–4.4

among the five procurement routes. The risk-carrying CM contracting was ranked best (4.4) because of the involvement of the CM contractor in the preconstruction and construction phases adding more value in the constructability, the early construction decision making and the trust among the other project parties.

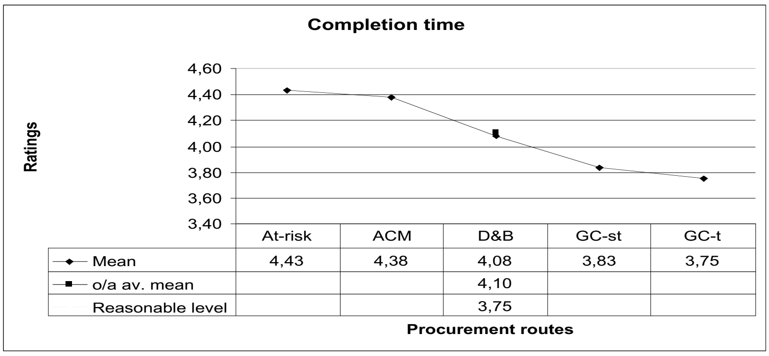

Figure 6: Completion time rating by procurement routes among the project cases (n = 35)

RESULTS SUPPORTING THE PREVALENT PROCUREMENT ROUTES

In procurement routes, the variance between the highest and the lowest is 0.30 points. The CM consulting route has 4.38 points, with the lowest point of 4.08 for general contracting. The variance in project target attainment is 0.50 points, with the highest in the design-and-build route (4.50) and the lowest in CM consulting, CM contracting and GC-t. The CM contracting rated higher than the other routes in completion on time (4.43) while the GC-t has 3.75 points. The GC-t has a higher rating in budget attainment (4.38) while GC-st has lowest rating (3.50). The clients are more satisfied with CM consulting route (4.31) but less satisfied with GC-t (3.88). Project quality assurance is more pronounced in CM contracting (4.14) but less in CM consulting and GC-t (3.75). The GC-st and CM contracting are higher in technical quality (4.00) while CM consulting is lower (3.75). Both performance risks and project responsibilities are well defined in the design-and-build route (4.00) but less defined in CM contracting (3.57). In design management, the design-and-build route has 4.33 points while GC-t has 3.25 points. In overall performances, the design-and-build is better than the other routes (4.09) followed by CM contracting, CM consulting, GC-st and finally GC-t.

The results of the survey indicate the fact that each procurement route has its strengths and weaknesses in such terms as the nine project management variables. This supports the previous notion that there is no single procurement route that suits best to all kinds of building projects:

- The D-and-B contracting was evaluated to be best in design management, responsibility and risk distribution and project target attainment.
- The CM consulting was evaluated to be best as procurement route and in achieving high client satisfaction.
- The general contracting with separate trades (GC-st) was evaluated to be best in managing high technical quality.

- The risk-carrying CM contracting was evaluated to be best in the tight project schedule management, high project quality assurance and equal GC-st in technical quality level.
- The traditional general contracting (GC-t) was evaluated to be best in attaining the client budget.
- In overall performance, the design-and-build ranked first followed by CM-contracting, general contracting with separate trades (GC-st), CM-consulting and lastly traditional general contracting (GC-t).

Table 4 presents results supporting the prevalent procurement routes. In overall project performance the prevalent routes are above reasonable level of performance of 3.75 in most of the variables.

Table 4: Results of the project cases survey supporting the prevailing routes at above 3.75 performance level

Variables	Results supporting the other procurement routes
Overall project performance management	Target attainment, completion on time, budget attainment, quality control and management, technical quality attainment, proper distribution of responsibilities and risks, and better design management
Responsibilities/ risks allocation	D-and-B (4.00) Single point of performance responsibilities and risk on non-performance
Relationship management	Direct contract with the owner as in the CM consulting, single point of responsibility as in D-and-B, and with a separate trade contractor, and multiple points in implementation as in CM consulting
Overall client satisfaction	CM consulting (4.31) The direct contractual relationships between the client/owner and the trade contractors as well as the cost reduction due to elimination of a layer of profit
Client target attainment	D-and-B (4.50) Clarity in defining owner's requirement through project performance specifications
Client budget attainment	GC-t (4.38) Larger contingency amount that covers design and the completion of the working documents before the construction works begins
Building design management	D-and-B (4.33) Single point of design and construction responsibilities and performance risks
Project quality assurance	CM contracting (4.14) The contractor's involvement in the preconstruction phase and the value engineering management
Technical quality management	GC-st and CM contracting (4.00) Specialist involvement via competition in design and construction works
Project schedule management	CM contracting (4.43) based on the integrative involvement of the CM contractor

Table 5 shows some of the areas where there are problems in prevalent routes: unclear definition of responsibilities as in GC-st, non-involvement in design as in GC-t contractors, clash of interest as a consultant and contractor as in CM contracting.

Table 5: Results of the project cases survey below reasonable level of performance 3.75

Variables	Prevalent routes below reasonable level of 3.75
Client budget attainment	The GC-st route has a rating of 3.50 because of unclear responsibilities (prime and subcontractor) leading to management problems between the main contractor and separate trade contractor
Technical quality	The GC-t has a rating point of 3.63 because of the main contractor's non-involvement in design and blame shifting between the designers
Responsibility/risks	The CM contracting has a lowest rating point of 3.57 owing to its clash of

management	interest as a consultant and contractor. The GC-t has a rating point of 3.63 owing to uncertainty associated with the design and construction works (value engineering and management)
Design management	The three variables (GC-t 3.25, CM consulting 3.38, GC-st 3.50) suffer from lack of involvement in design process (except separate trades contractors), insufficiency of design and lack of value engineering and management

In the area of responsibility distribution and risk allocation among project parties, many project cases were executed under an uncoordinated task approach or under a subcontracting approach with a back-to-back form of risk allocation. Across the separate trade contracts, the separate trade contractors were responsible for their detailed drawings and technical risks. This gave encouragement to innovate and to raise the quality standards. For example, one specialist contractor in one of the cases suggested the adoption of a self-supporting glass wall that reduced the external wall area markedly. In the area of project party relationship management, the relationships between the client/owner and the designers as well as between the client/owner and the contractors were managed best in the design phases under CM consulting. In turn, the relationships between the client/owner and the contractors were managed best in the construction phases under D-and-B contracting. Multiple direct contracts with a client/owner seem to be free of conflicts and, thus, beneficial to the whole building process. In turn, the two GC contracting routes were ranked best in managing the relationships between the contractor and the subcontractors.

In the area of overall client satisfaction, the CM consulting was ranked best based in part on the direct contractual relationships between the client/owner and the trade contractors as well as the cost reduction. In the area of client budget attainment, the traditional general contracting was ranked best in attaining the client's budget because the working documents are completed before the construction works begin. In the area of building design management, many separate trade contractors and subcontractors acted as the multiple prime contractors engaged in the design and construction of their section of the contracts. The main contractor in some of the cases coordinated the construction works and the design team provided project management and administration. This is more evident in the design-and-build route because of the single point of design and construction responsibilities and risks. There were no major strains between the stakeholders in communication, cooperation and coordination throughout all the project phases.

In the area of technical quality management, the general contracting with separate trade contractors contributed markedly to the design phases (some of them even carried out the design work). In the area of project quality assurance, the CM contracting and the D-and-B contracting were ranked best because of the contractor's involvement in the preconstruction phase and the value engineering management. In the area of project schedule management, the CM contracting was ranked best based on the integrative involvement of the CM contractor.

CONCLUSIONS

Most of the measured variables performed above the reasonable performance level. The ranking order of the variables along procurement routes shows that there is no dominant route, as best performances are shared between different routes. This finding supports the influence of the relationship between management and environmental factors as a major contributor to the success of a procurement route. The study shows the weakness of four project management performance variables that are measured below the reasonable performance level in some of the procurement routes: the client target attainment, the attainment of technical quality, the distribution and allocation responsibility and risk, and the design management.

In ranking order of the means, the design-and-build route performed better than other routes because of its integrated nature of performance and design management attributes. The CM consulting ranked second because of its fragmented nature of execution process and direct contractual link with the client. The combination/improvement of these attributes from integrated and fragmented procurement spectrum could be used to re-engineer contracting processes either in the form of modification of the existing routes or by development of a newer route. This should take into account the fragmentation of the process through the involvement of many first-tier specialist contractors. Each of the specialist first-tier contractors will then utilize the integration process by carrying out design through to construction of their specialist trade (facility management optional). This will potentially prevent insufficiency of design, unclear responsibilities and lack of value engineering and management as shown in ‘low’ measured results.

GOVERNANCE OF PERFORMANCE OF BUILDING SERVICES DESIGNERS IN DESIGN AND BUILD CONTRACTS

Francis W.H. Yik[1] and Joseph H.K. Lai

Department of Building Services Engineering, The Hong Kong Polytechnic University, Hunghom, Kowloon, Hong Kong SAR, China

The work reported in the paper is a preliminary study for informing a conceived study that aims to enhance performance of building services design professionals in Hong Kong. The reasons for conducting such a study and for basing the study on design and build (DB) projects are explained in the paper. The preliminary findings suggest that factors that are conducive to better performance of building services designers in DB projects include: DB contractors' demand for high standards in schematic design for winning contracts by bidding; DB contractors' willingness to pay higher design fees; more stringent design-checking procedures; any design-related rework at the expense of contractor; higher level of design liability beyond reasonable skill and care; and more active participation by contractors in design management and services coordination. However, there are obstacles to wider adoption of DB in the Hong Kong construction industry, especially the regulatory control in force.

Keywords: building services designer, design and build, Hong Kong, liability, performance governance.

INTRODUCTION

When contractors are under pressure to finish a construction project within a specified timeframe and at an agreed price, work quality could be sacrificed (Chini and Valdez 2003). However, contractors are not the only party to be blamed for project time and budget overruns and poor construction quality. Research has revealed that many such problems can be traced back to the problem of the quality of design, such as errors, incompleteness and lack of constructability, and to poor contract administration and lax supervision by design consultants (Tan and Lu 1995). Love and Li (2000) found that design-related rework accounted for 72% of the total rework costs in two building projects. A similar finding is reported in Koskela *et al*. (2002), together with the deficiencies in design management, including the deficiencies in client's brief, frequent design changes and lack of planning of design consultants.

For building projects, architects are often held responsible for productivity and quality problems owing to their lack of construction knowledge (Fox *et al*. 2002). As to building services installations, which are commonly regarded as specialist works and procured through subcontracting, many contractual and in-use performance problems are due to flawed designs, fuzzy demarcation of responsibilities between services designers and subcontractors (Parsloe 1997), and lack of adequate consideration given to testing and commissioning and operation and maintenance during design (Mantai

[1] bewhyik@polyu.edu.hk

2006). The consequences of unsatisfactory performance of building design professionals (including architectural, structural and building services consultants), such as latent defects, can incur huge economic losses, not only to building owners, contractors and subcontractors but also to themselves in case they are held liable for negligence and the damage exceeds the protection they have through professional indemnity insurance (Bateson and Mak 2000).

Many building construction projects procured using the traditional design–bid–build (DBB) procurement system are plagued with the above-mentioned problems. Since the 1980s, the design and build (DB) system, including its various variants (Akintoye 1994; Ng and Skitmore 2002), is increasingly used for procurement of construction projects in many parts of the world for both private and public sector projects (Akintoye 1994; Ndekugri and Turner 1994; Songer and Molenaar 1996; Molenaar *et al*. 1999), including in Hong Kong (Chan 2000). This trend is expected to continue (Yates 1995; Lam *et al*. 2004).

Historical reviews (Agostini 1996; Songer and Molenaar 1996; Konchar and Sanvido 1998; Pietroforte and Miller 2002) show that the resurgence of DB (ancient master builders being the original design/builders) was mainly due to project clients' dissatisfaction with the DBB procurement system (the dominant system since the early 20th century), especially in respect of frequent occurrence of claims owing to incomplete, belated and erroneous designs, and conflict and disputes among contract parties, which may entail costly litigation (Yates 1995). Under a DB contract, not only the design/builder assumes single-point responsibility, the liability of both the designer and the builder increases (Ndekugri and Turner 1994; Agostini 1996; Chan and Yu 2005), which is one of the major reasons for clients to choose DB contracts (Scriven 1996).

Research studies on the performance of DB projects reveal that DB is effective in reducing project time and cost, variation orders owing to incomplete/erroneous designs, administrative task of owners, and in minimizing legal entanglements (Akintoye 1994; Yates 1995). Research findings on the impact of DB on work quality, however, are inconclusive; some showed that DB can lead to improved construction quality (e.g. Konchar and Sanvido 1998; Molenaar *et al*. 1999) while some others showed that it cannot (e.g. Akintoye 1994). Nonetheless, there is evidence that DB can be used for most sizes of project provided the client is experienced (Ndekugri and Turner 1994), and clients' experience with DB projects was generally positive (Molenaar *et al*. 1999).

Besides DB, other measures for enhancing construction project performance have been used, such as the requirements for designers and contractors to be ISO 9000 certified (Chini and Valdez 2003) and for buildability assessment (Fox *et al*. 2002); alternative dispute resolution methods (Cheng *et al*. 2004); partnering (Latham 1994); etc. More recently, measures such as design quality indicator (DQI) for measuring design quality (Gann *et al*. 2003) and post-occupancy evaluation and 'soft landings' for providing feedback to design (Way and Bordass 2005) are being advocated.

THE NEED FOR STRENGTHENING GOVERNANCE OF PERFORMANCE OF BUILDING SERVICES DESIGNERS

Although numerous research studies that aimed to enhance the processes and outcomes of construction projects can be found in the literature, very few embraced or dealt specifically with building services, apart from treating services works generally as specialist subcontract works (e.g. Hughes *et al*. 1997). Experience of assessing energy performance of new and existing buildings under the environmental assessment scheme HK-BEAM (Burnett *et al*. 2004), building energy audit and plant performance evaluation studies (e.g. Yik *et al*. 1998), and studies on specialist subcontracting practices in Hong Kong (Yik *et al*. 2006) showed that, for building developments that adopt the traditional DBB procurement system:

- At the stage of tendering, building services system designs may remain incomplete, which is a characteristic nature of specialist works (Yik *et al*. 2006). This is inevitable if the design is dependent on the characteristics of components and equipment, which will become known only after subcontractors are appointed and their offers are confirmed. For example, discharge pressures of chilled water pumps cannot be ascertained until pressure drops across chillers, air-handling units, valves and pipe fittings are known. Some building services consultants hold that tender specifications and drawings are meant to provide subcontractors with an indication of the scope of work and the performance required of the subcontract works; subcontractors are required to 'complete' the design while preparing shop drawings and other submissions for their approval (Yik *et al*. 2006). This, however, blurs the demarcation of design liability between the consultant and the subcontractor (Parsloe 1997), and is thus prone to dispute.
- Design work is often done within a limited time, based on assumed design parameters and rules of thumb, which the designer may not have time to come back and verify. Few designers are well equipped with knowledge and skills for detailed building performance simulation for in-depth design evaluations. Hence, design mistakes and omissions, and oversized plants can often be found (Yik *et al*. 1999). The introduction of building environmental performance assessment should have encouraged greater use of simulation tools in design, e.g. building energy modelling, but observations made in HK-BEAM assessments are similar to the finding of Mantai (2006) for projects assessed under the US LEED scheme: 'what we typically see is that the design choices are completed first, then the energy modelling is completed merely to document the number of LEED points'.
- All-embracing clauses like: 'the subcontractor shall supply and install …, as stipulated in the Specification and shown on the Drawings, including any additional … as are required to complete the work to the satisfaction of the Architect', 'in the event of anything … which is omitted from the Specification, the Contractor shall execute and provide all such works and things according to the direction of the Engineer or his representative', etc. are often used in contract documents, to hold subcontractors responsible for design omissions/mistakes and contingent situations, and thus to transfer design liability to subcontractors (Yik *et al*. 2006).
- Participation of design consultants in site coordination and testing and commissioning (T&C) of services systems is often inadequate while T&C skills of subcontractors are generally weak.

Clearly, besides the knowledge and skills of building services designers (and subcontractors), there is a need to enhance the existing mechanisms, including institutional, contractual and management measures, for better governance of the performance of building services design engineers (and perhaps other building design professionals as well).

THE APPROACH

With the intention of identifying effective measures for better governance of the performance of building services design professionals in Hong Kong, it is anticipated that some could be found by examining the ways in which clients and contractors of DB projects ensure designers would perform adequately. This is on the premises that:

- The client is keen to ensure that the schematic design on the basis of which the contract is awarded, and for which the amount of money to be paid has been committed, is adequately developed and the construction works for its realization are adequately executed such that he will eventually get an end-product that fits his intended purpose.
- As a DB contractor has overall responsibility for both design and construction of the entire project, he has the contractual obligation as well as financial incentive to ensure building services systems are adequately designed, coordinated, installed, and tested and commissioned to meet the client's requirements, and will be completed on time and within budget.
- Therefore, both the client and the DB contractor will make efforts to monitor the progress and quality of design works, which collectively should be more stringent than what a project client will do in the case of a DBB project.

It is reasonable to expect that a DB contractor will closely monitor the performance of his designers because he has to shoulder the design liability as well as the extra liability arising from combining design and construction under a single contract. In the case of a traditional DBB project, the contractor is liable only if his performance deviates from project plans and specifications or from the standards of good workmanship (Agostini 1996), while the liability of the client's design consultants is limited to 'reasonable skill and care' (Songer and Molenaar 1996; Gaafar and Perry 1998). A DB contractor, however, is liable for defective project-related conditions irrespective of whether the project was designed in accordance with industry standards or whether the work was performed in accordance with the plans and specifications (Agostini 1996), i.e. he is liable for 'fitness for purpose' (Ndekugri and Turner 1994), although this term is not legally well defined (Gaafar and Perry 1998; Chan and Yu 2005). Liabilities may also be implied by relevant statutory provisions, such as the Sale and Supply of Goods Act in the UK (Scriven 1996; Gaafar and Perry 1998). In Hong Kong, the relevant legislative provisions are the Sale of Goods Ordinance (Cap 26) and the Supply of Services (Implied Terms) Ordinance (Cap 457) (Cheng *et al*. 2004).

Whereas a higher level of design liability is a strong driving force for adequate performance, there is a practicality problem in that insurance to cover design liability for 'fitness-for-purpose' can hardly be obtained (Ndekugri and Turner 1994; Gaafar and Perry 1998; Chan and Yu 2005). It is therefore important to have the liability of a DB contractor clearly defined in the contract to reflect the intention of the contract parties (Scriven 1996), taking into account that there is in fact a spectrum of liability between 'reasonable skill and care' and 'fitness for purpose' (Gaafar and Perry 1998). However, even the DB contractor's liability for design problems is laid down as the 'average level of skill and care' standard, as Friedlander (1998) pointed out: 'it is rare for the standard of care to permit a design that does not achieve its intended results, … it is difficult to maintain any distinction between a design that is negligent and one that simply fails to function properly after other possible causes of the failure, such as improper construction or improper operations, are ruled out'.

THE STUDY METHOD

Apart from building services works, many aspects of DB projects in Hong Kong have already been extensively studied by local researchers. They found that in Hong Kong, DB projects are dominated by public sector projects (Chan 2000; Chan *et al*. 2001, 2002; Lam *et al*. 2004; Chan and Yu 2005) (see further discussion below). For public building projects (other than public housing projects), the Architectural Services Department (ArchSD) is the major agency that acts as the project client on behalf of the government. All such public building projects use the same general conditions of contract which are publicly available (HKG 1999a; Chan 2000; Chan and Yu 2005) and are managed by the client in a similar manner.

Given the extensive work already done by local researchers, the major information gap to be filled is the role and practices of building services consultants in the schematic design, design development and approval, and work execution stages of DB projects, which is an area where little research has been done. By focusing on public DB building projects commissioned by ArchSD, which represent the dominant type of DB building projects in Hong Kong and are managed by a single client organization following more or less standardized procedures, representative information can be obtained through in-depth discussions with an experienced building services consultant. For this purpose, meetings were held with a practising consulting engineer, who is director of a leading local building services consulting firm, and from whom sufficient information to meet the objective of the preliminary study was obtained.

The findings of the preliminary study, reported in the forthcoming section, were consolidated from an extensive literature review and desktop studies; the investigators' collective experience with the local construction industry gained from professional practices and through other relevant research studies; and in-depth discussions with the practising consulting engineer. Before the meetings for 'brainstorming' and 'information mining' were held, a list of questions on the following issues, which were regarded as critical factors influencing services designers' performance, was prepared to guide the discussions:

- objective, scope and programme of work of building services consultant;
- procedures used by DB contractor/client for vetting and acceptance of designs;
- consultancy fees;
- subcontracting, supervision and coordination of services works;
- design changes and variation orders;
- consultant's liabilities for design and installed works.

For each of these issues, how it would differ if the traditional DBB procurement system was used instead was discussed. Two rounds of meetings were held; each lasted for about three hours. The meetings were recorded such that the investigators would not be distracted by the need to jot down notes, while no important information would be lost. After each meeting, notes were prepared based on the audio record and distributed to all participants to ensure correctness of the notes and to allow each participant to provide supplements.

SERVICES DESIGN DEVELOPMENT AND WORK EXECUTION IN DB PROJECTS IN HONG KONG

Variants of DB system

Depending on the client's intention, his experience with the project nature, complexity of the project and workload on the client's in-house design team, the client may use his own design staff or commission a services consultant to produce schematic designs and prepare the relevant client's requirements for various trades of services works (such as heating, ventilating and air-conditioning, electrical, fire, lift and escalator, and plumbing and drainage installations). The services design completed at the tender stage may vary from a minimal level, in which case there will be comprehensive specifications of provisions and functional requirements for the DB contractor to fulfil (close to pure design–build), to about one-third of the whole design work (basically develop and construct). The latter case is often found in special projects that have to meet complex and highly specific end-user requirements (e.g. hospitals (Chan 2000)). If a consultant is appointed for schematic design, he will also be commissioned to evaluate tender submissions, but will not be allowed to team up with a DB contractor to bid for the project.

A certain amount of double-handling of design work exists (by the client's and the tenderer's designers); the more so the more design work is completed prior to tendering. Novation of consultants, which can avoid such abortive work, had been used before (e.g. in the HK$1.8 billion Sheung Shui Slaughter House project completed in 1999) but it is rarely used now, probably because of the awareness of the potential problems with novation (Ng and Skitmore 2002).

Contract requirements

Subcontracting the design element of the works under a DB contract is expressly permitted (HKG 1999a). Where an independent design consultant is appointed, the independent consultant shall execute under seal and provide to the client a warranty of his performance. There is an optional provision in the General Conditions of Contract for Design and Build Contracts (HKG 1999a) which requires the DB contractor to appoint, at his own expense and subject to the client's approval, an independent design checker who has the responsibility to check the designs developed after contract award against the tender offer and the client's requirements, and to certify compliance. For building services works, the checker will typically be a separate building services consulting firm. Furthermore, the design checker has to execute under seal and provide to the client a warranty of his performance. As part of the design-checking procedures, the DB contractor has to obtain the client's consent before commencement of any part of the works.

In the case of a traditional DBB contract, the contractor is not responsible for the design of the permanent work or any temporary work designed by the architect, except as may be provided for in the contract (HKG 1999b). Under the General Conditions of Contract for Design and Build Contracts (HKG 1999a), the contractor shall be liable for any defect or insufficiency in the design of the works as would an appropriate professional designer (i.e. for reasonable skill and care), and shall not be obliged to ensure the design is fit for the purpose intended by the contract. However, it is also provided that: ‘where the Employer has relied upon the Contractor to select Plant and materials required by the design to be incorporated in the Works, the Contractor shall ensure that all such Plant and materials are reasonably fit for the purpose intended by the Contract’. For building services systems, selection of plant and materials is part of the design work. Furthermore, it is hard to conceive any services system equipment and components which the client does not rely on the DB contractor to select. It follows that although the design liability to be shouldered jointly by the DB contractor and his services consultant may not be strictly up to ‘fitness for purpose’, it is higher than what the designer and the contractor would be liable for individually in the case of a traditional DBB project.

Tendering and bidding

The tendering method and procedures (pre-qualification, two envelopes for separate technical and price submissions, and bid evaluation based on overall score of technical proposal and price) have already been reported by others (e.g. Chan and Yu 2005). Increasingly, greater emphasis is put in tender assessment on innovative and/or unconventional design features that can enhance building energy and environmental performance. In this respect, the building services consultant has a key role to play. As achieving a high score in the technical assessment may allow a contractor to win the contract even if his tender price is not the lowest, DB contractors will prefer to appoint services consultants who are better equipped to embrace such design objectives in their design. Consequently, the fees that services consultants can get for DB projects are generally higher than for traditional DBB projects of comparable sizes.

DB contractors in Hong Kong are basically general building contractors and hardly any of them have a full-fledged in-house design team. When they bid for a DB project, they will call upon their preferred architectural, structural, building services and other consulting firms to form a design team, and will demand exclusivity from the consultants, but may not select services subcontractors at this stage. DB contractors will take an active role in sourcing for major services components and equipment while the services consultants will adapt their schematic designs to suit the selected components and equipment. The services consultant will be required to explore various alternative designs, for striking an optimal balance between fulfilment of specific requirements of the client (e.g. functional requirements and those on energy efficiency, environmental performance, etc.), impacts on architectural and structural designs, constructability and cost. DB contractors will pay the consultants a fee even if they lose in the bidding, although the fee may be insufficient to fully compensate for the costs incurred to the consultants. The conditions of appointment for subsequent stages of design work are often negotiated, but a firm agreement may not be made until the DB contract is awarded.

Design development and work execution

After contract award, the DB contractor will work out a master programme for the project for the client’s approval, which will lay down the milestone dates for completion of the design development works by the consultants, compliance checks and certification by the independent design checker and for achieving client’s approval in principle (AIP) and detailed design approval (DDA). The DB contractor will also negotiate and make contracts with subcontractors. Compared to a traditional DBB project, services works tend to be subdivided into smaller packages; the DB contractor will handle purchases of major services components and equipment (e.g.

chillers) from vendors direct while services subcontracts will cover on top of the installation work, supply of other materials.

During the design development stage, the DB contractor may require the services consultant to conduct further alternative design evaluation studies but, at this stage, the major objective will be for cost minimization or enhancing constructability. In this stage, the client should provide and confirm detailed requirements on services provisions for the consultant to incorporate such requirements in the detailed designs.

Subsequent to obtaining DDA, construction work may proceed and the client will refrain from making further requirement changes, unless absolutely needed. The consultant's workload will drop whereas subcontractors will start preparing shop drawings and proceed with installation works. During the construction stage, the DB contractor will assume an active role in coordination of building construction and services installation works, but will call upon the consultant to check and certify works completed (for payment claim purpose) as well as testing and commission procedures and results.

COMPARISON OF DB WITH DBB

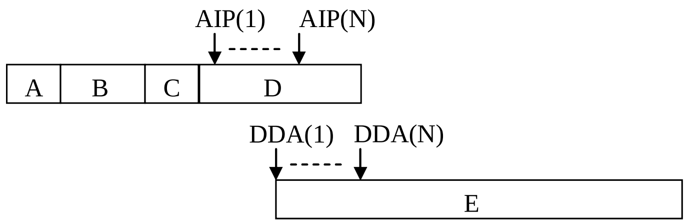
In DB projects, the design consultants work towards two different design objectives during the bidding and the post-contract-award stages. In the bidding stage, the objective of the schematic design is to achieve high standards so as to increase the DB contractor's chance of winning. Once the contract is awarded, realizing the proposed designs becomes a contractual obligation of the DB contractor. The involvement of an independent design checker helps ensure this will happen. However, after contract award, cost minimization becomes one of the key design objectives. This explains why work quality of DB projects can be better or no better than traditional DBB projects, which depends on the client's requirements, the weight given to the technical assessment relative to the weight for tender price in assessing tenders, and the rigour of the design checking and approval procedures and site inspections.

Figure 1 shows a comparison of the time span of various stages of a DB project against a traditional DBB project. Compared to a DBB project, consultants are, generally, given less time (in total) for completing the schematic design and, after contract award, also the detail design for a DB project, while the total amount of design work could be more. Owing to the different work styles required of design engineers for DB and DBB projects, some consultancy practices have set up a dedicated division for handling DB projects. The construction programme may be shortened through using DB mainly because of the better integration of designs with plant and equipment and construction/installation methods from the outset, and the earlier work commencement permitted by overlapping detailed design with construction work execution.

In a DB project, the client will not pay nor will grant extension of time for any extra works that are due to incomplete design or design errors, which is a strong driving force for the DB contractor, and a pressure on the consultant, to ensure such design deficiencies are minimized. Errors and omissions may also be identified by the independent design checker. There will be much fewer variation orders due to changes in clients' requirements after detailed design approval is granted, because such changes will incur more serious impacts on project time and cost. Also, there are fewer coordination problems, owing to the much greater involvement of the DB contractor in the process. All these factors are conducive to completion of the project on time and within budget.

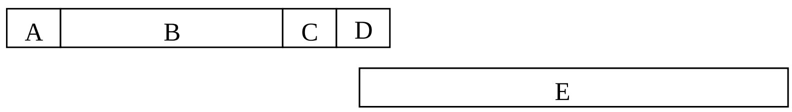
In summary, the incentive for building services designers to turn out quality designs and the measures for governing their performance may both be stronger in DB projects than in conventional DBB projects. Nevertheless, inexperienced clients, an unclear brief, insufficient time allowance for schematic design and detailed design development, and the attempt by contract to minimize cost after contract award are unfavourable factors that could undermine design quality.

(a) **Design and build project**



A – Project inception, tender documents, pre-qualification
B – Tendering, schematic design (≈3 months)
C – Tender evaluation and contract award
D – Design development (≈6 months)
E – Shop drawings and construction/installation
AIP – Approval in principle; entire works broken down into N parts in the process
DDA – Detailed design approval

(b) **Traditional design-bid-build project**



A – Project inception, selection of consultants
B – Scheme design, design development and tender documents (≥12 months)
C – Tendering, tender evaluation and contract award
D – Shop drawings and permission for commencement of works
E – Construction

Figure 1: Project programme for building development: (a) design and build project; and (b) traditional design–bid–build project

LIMITED USE OF DB IN PRIVATE SECTOR IN HONG KONG

The limited use of DB by private sector clients in Hong Kong may be ascribed to the following reasons:

1. The Building Regulations (Cap 123) in force in Hong Kong, which evolved around the traditional DBB procurement system, are hindering adoption of DB in private sector projects. The Regulations provide that construction work may commence only if all the required consents have been obtained, which require submission of a full set of building plans, structural and drainage design drawings and calculations. Hence, the benefit of overlapping the design and construction processes for shortening project duration, which is one of the major advantages of DB, is not attainable. Furthermore, the ‘authorized person’ (typically the architect or structural engineer), who is responsible for

dealing with the Building Authority on matters regulated by the Building Regulations as well as for supervising, checking and sanctioning the contractor's work, will have difficulties in discharging his statutory duties when he is employed by the DB contractor as his design consultant (Chan and Yu 2005). Public work projects, however, are exempt from this legislative control, which explains why public work projects dominate among buildings that are procured using DB contracts (Chan 2000).

2. It is a common perception that the DB procurement system tends to turn out unimpressive buildings with just average construction quality, notwithstanding that this has been shown to be not necessarily true (Ndekugri and Turner 1994; Chan *et al*. 2002). For removal of this obstacle, contractors who have good experience and skills in undertaking DB projects and wish to expand their DB business have to demonstrate to potential clients the benefits that clients can get by adopting DB. This, however, will be possible only if the Building Regulations are amended to remove the above-mentioned hurdles.

CONCLUSION

The preliminary findings suggest that factors that are conducive to better performance of building services designers in DB projects include: DB contractor's demand for high standards in schematic design for winning contracts by bidding; DB contractor's willingness to pay higher design fees; more stringent design-checking procedures; any design-related rework at the expense of contractor; higher level of design liability beyond reasonable skill and care; and contractor's more active participation in design management and services coordination. However, there are obstacles to wider adoption of DB in the Hong Kong construction industry, especially the regulatory control in force. Despite the fact that there are factors that may adversely affect design quality in DB projects, the work provided prima facie evidence that researching into DB projects will be worthwhile and should form a significant part for an in-depth study that aims to find out how performance of building services designers can be enhanced.

ACKNOWLEDGEMENT

The authors are indebted to the interviewee who shared his knowledge and experience with them, which was crucial to this study.

FACILITIES ASSET MANAGEMENT: CHALLENGES AND OPPORTUNITIES

William W. Badger[1] and Michael J. Garvin[2]

At the request of the Federal Facilities Council, the US National Research Council appointed a committee of experts to determine what organizational and individual competencies are necessary to 'help ensure effective federal facilities asset management (FAM) in the next fifteen years'. The collective wisdom of the committee is synthesized and presented as 'Ten Insights' about this evolving organizational function and professional discipline. The facilities asset management profession has gained new significance since the cost to adequately expand, modernize, repair and maintain enterprise assets and real property has begun to dominate budgets. Moreover, organizational leaders have recognized that the environments that facilities provide are mission enablers and require a significant investment of resources. These insights represent several significant outputs of the committee's work and are central to the development and growth of this discipline. The presentation is intended to provoke discussion and debate among the international community about the topic.

Keywords: asset management, facilities management, facilities performance, human resources management, real property management.

INTRODUCTION

The United States government owns more than 500 000 buildings, facilities and their associated infrastructure worldwide. These assets are valued in excess of $328 bn (FFC 2001). At least 30 individual federal agencies are involved with facilities acquisition and management, spending upwards of US$20 bn annually to acquire new facilities and renovate existing ones. Federal owners are increasingly recognizing the magnitude of the management challenge posed by such a portfolio. Moreover, they have begun to realize that facilities asset management is important to the future of the federal enterprise. At the bequest of the Federal Facilities Council, the US National Research Council appointed a committee of experts to determine what organizational and individual competencies are necessary to 'help ensure effective federal facilities asset management (FAM) in the next fifteen years'. The committee met on several occasions over the course of 1.5 years to study this topic and make its recommendations. The collective wisdom of the committee is synthesized and presented as 'Ten Insights' about this evolving organizational function and professional discipline. These insights represent the most significant outputs of the committee's work and are central to the development and growth of this discipline. The intent of this presentation is to provoke discussion and debate among the international community about the opportunities that facilities asset management will

[1] bill.badger@asu.edu

provide for construction management professionals and academics in the US. More than likely, the capital and effort expended in facilities asset management will soon match that expended in new construction.

TITLES AND NAMES

Over time the title and name for the ‘facilities asset manager’ and the profession of ‘facilities asset management’ has evolved. In reviewing the literature on the description and the development of facilities asset management, a variety of names and descriptions were uncovered. In some parts of the world, the word ‘facility’ instead of ‘facilities’ management is used. Atkin and Brooks’ (2004) definition truly captures the essentials of facilities management.

> Facilities management has traditionally been regarded as the poorer relation within the real estate, architecture, engineering, and construction professions. This is because it was seen in the old-fashioned sense of care taking, cleaning, repair, and maintenance. Nowadays, it covers real estate management, financial management, change management, human resources management, health and safety, and contract management, in addition to building and engineering services maintenance, domestic service and utility supplies. These last three responsibilities are the most viable. The others are subtler, although of no less importance. For facilities asset management to be effective, both the ‘hard’ issues, such as financial regulations, and the ‘soft’ issues, such as managing people have to be considered.

The International Facility Management Association (www.ifma.org) defines facility management as ‘a profession that encompasses multiple disciplines to ensure functionality of the built environment by integrating people, place, process, and technology’. This definition clearly illustrates the holistic nature of the discipline and the interdependence of multiple factors in its success.

Elsewhere, the British Institute of Facilities Management (www.bifm.org.uk) promotes the development of facilities management as a critical, professional and strategic business discipline.

According to Lincoln (1968), Knight (1978), and Hilmes (1985), over the past 40 years the managers of installations and facilities for the US Army went through a number of name changes: post engineer, facility engineer, director of engineering and housing, and currently the director of public works. In the private US sector titles like plant engineer, building manager, physical plant manager, asset manager, and director of facilities emerged.

Throughout the committee’s investigation, much discussion regarding the titles to utilize was heard. The committee decided upon the moniker ‘facilities’, as is the case in the UK, versus ‘facility’, which is the current preference in the US. An additional consideration was the term ‘asset management’, which implies a focus upon asset and real property preservation to many whereas the term ‘facilities management’ connotes alignment of the property portfolio with the enterprise. The combination of the two into ‘facilities asset management’ suggests this discipline is charged with both requirements. Accordingly, the profession is titled ‘facilities asset management’ and the professional’s title is ‘facilities asset manager’.

SIGNIFICANCE

As the 21st century progresses, the facilities asset management function will gain unprecedented significance. Even today, the US federal government has already recognized the importance of this discipline for the ways that the federal government conducts its business. Various forces are driving the profession towards a different future:

- Within the US federal government, not the least of these is the *changing global landscape*. Real and perceived threats to national security as well as evolving global political and economic power balances have very tangible implications for federal facilities.
- As the baby boomer generation moves on, an *ageing workforce* presents the real possibility of workforce shortages in the near future. Moreover, the transition of this generation of workers could spell the loss of significant institutional memory and experience.
- The *workforce of the next generation* has very different expectations of the work environment and the nature of work. This generation is unquestionably the most ‘connected’ that the world has ever seen. Multi-tasking with various mediums of communication and information exchange is the norm. The workplace of the future must accommodate these types of workers and the style that accompanies them.
- *Rapid changes in information technology* are having remarkable impacts upon the ways that we live, work and interact. Indeed, links between people and organizations as well as connections to data, information and knowledge are changing society. The influence of IT upon facilities and facilities asset management is also quite pronounced. Today, IT is an inherent part of the work environment, where an enterprise’s information infrastructure is as important as its physical infrastructure. Moreover, IT is changing the physical infrastructure itself as well as the methods for its development and management.
- *Outsourcing* is no longer a novel trend since its presence as an organizational strategy now spans decades; however, the challenge for any enterprise, and particularly the facilities asset management function is to determine what activities or services are core to the enterprise’s mission and which ones are not.
- The *sustainability movement* has pushed society towards greater sensitivity of the environment. As more and more enterprises seek to minimize their environmental ‘footprints’, facilities are being correctly viewed as a tangible representation of an enterprise’s commitment to the environment.

These drivers of change have very tangible implications for FAM. First, future work environments are likely to be more diverse. One can imagine a situation where the workforce is remotely distributed and the organization’s space is only needed to facilitate face-to-face interaction periodically. Certainly, one can imagine many plausible future states. Regardless of what ultimately happens, the fundamental purpose of facilities asset management is to provide the enterprise with the appropriate environment or workplace for the conduct of its mission and business. Second, a world-class workplace will be necessary to attract a world-class workforce. The workplace is often an overlooked determinant in workforce recruitment and retention, and the workforce of tomorrow will have particular expectations for the work environment. Thus, the 'configuration' of the existing workplace will need to evolve. This will present a tremendous challenge as facilities asset managers search for ways to economically modify existing plant assets and expand the asset portfolio to meet the enterprise's new workplace needs. Third, 'smart' buildings will be more common in the future with legacy structures having been retrofitted with infrastructures that support both 'intelligent' and 'smart' work environments.

As budgetary pressures rise and as the coupling of the enterprise with the facility portfolio tightens, dollars allocated to facilities will increasingly be viewed as investments as opposed to costs. Return on investment (ROI) will become more and more a factor in property asset management, making life cycle planning more prevalent and visible.

Today, the facilities asset management function has grown from one that was focused upon operating and maintaining a single facility to one that is more strategic and has a broader perspective. To meet the challenges of tomorrow, facilities asset management must continue to evolve and it must do so quickly. Facilities asset managers must step beyond their traditional comfort zones of project-level management and field-level decision making towards programme management and executive-level decision making.

Tomorrow, facilities will have become very important elements of the federal mission and objectives. They will be strategic assets to the organization, assets which have the capacity to dramatically shape federal government's services, workforce, finances and environmental performance. But this potential value does not come without risks. Failure to improve and modernize facilities can degrade government performance as easily as success can empower it. Antiquated and obsolete facilities constrain business processes, hinder workforce productivity and recruitment, and cost the organization too much economically and environmentally. Indeed, when facilities are considered strategic assets, they occupy a different place in the government's value and risk equation. Any resource that has the potential to influence effective and accountable government must receive appropriate organizational attention.

UNIQUENESS

The roles and responsibilities of the facilities asset manager are unique among managers in the life cycle management system. The horizontal nature of the organization increases the challenge of efficient information flow. It creates a condition where a wider range of core competencies and professional development is needed. The 'facilities asset managers' must educate and train the facilities asset management workforce.

The facilities asset manager is a 'connected integrator' of multiple functions. The roles and responsibilities for this class of manager are unique among managers in the capital life cycle project system. This manager must be connected, empowered to integrate, and able to influence multiple functional areas. The graph in Figure 1 below shows the involvements of the stakeholders (owners, clients, designers, constructors and facilities asset managers) throughout the life cycle.

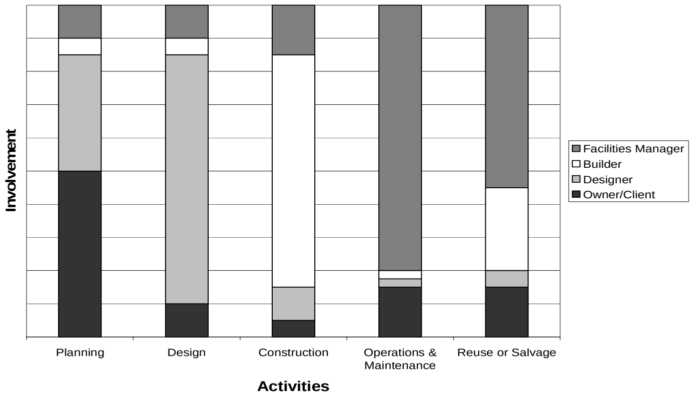

Figure 1: FM role in the project life cycle

Of all the various parties involved in a project's life cycle, the facilities asset manager is the only one involved throughout the life cycle serving as the dominant player throughout the operations and maintenance phase, which constitutes over 90% of the life cycle work.

INTERFACE WITH THE ENTERPRISE

Enterprises must empower this leader to integrate and to influence multiple functional areas. The graph in Figure 1 illustrates the 'relative' involvement of the stakeholders (owners/clients, designers, builders and facilities asset managers) throughout the life cycle of a typical facility. Granted, the amount of involvement can differ for particular circumstances, but the point is that facilities asset managers have significant roles from the start and their responsibilities only increase. Moreover, the facilities asset manager is the dominant player during the operations and maintenance phase, which can constitute the vast majority of the facility's service life – particularly for institutional-type owners.

Clearly, the leader of the facilities asset management function has an unparalleled perspective of an enterprise's real assets. To leverage the potential of these assets to enhance productivity, improve employee health and safety, increase the bottom line and better the environment, an enterprise must empower the facilities asset management function with appropriate resources and authority. A 'chief facility officer' who has the same stature as a chief operating officer or a chief financial officer is necessary to guarantee proper visibility of these resources. In fact, facilities cannot become an organizational multiplier if they are not part of top level discussions about strategic issues such as long-range planning and resource allocation. To become more than an afterthought, the senior facility manager must be part of the organization's executive team.

LEADERSHIP

Facilities asset managers will need increased leadership skill sets to be able to lead the workforce instead of being just a practising manager without necessary leadership skills. Facilities asset management organizations must implement a leadership transformation model to change to a more focused leadership organization.

Core competencies should be structured to ensure that leader development efforts are focused on the attainment of high levels of individual and organizational performance. They can also be structured to be enduring even as resources diminish, demands increase, and priorities and strategies shift. Competencies provide a basis and a common language for discussing educational publications, doctrinal manuals, assessment and feedback tools, and ways to access distance and distributed learning programmes for self-development and lifelong learning. Figure 2 shows the balance between skills during career progression.

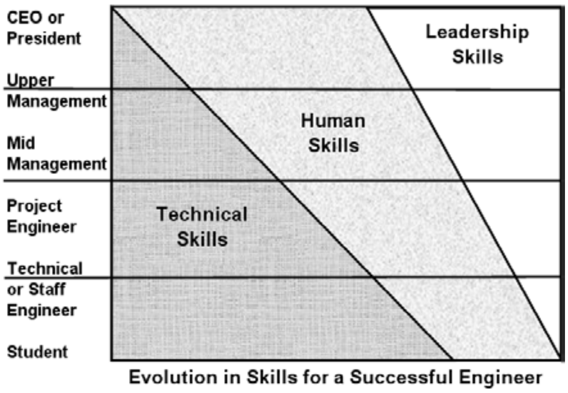

Figure 2: Leadership developments for engineering managers (Farr *et al.* 1997)

Leadership transformational model

According to Badger and Garvin (2007) executives in architecture, engineering and construction (AEC) initially receive their education and degrees in areas of study with a technical focus. These graduates are then required to learn new skills in FAM if they are to progress within their respective career fields.

In the Badger *et al.* (2007) papers, researchers are using a framework for the leadership transformational programme that could guide companies or organizations to a leadership model and promote the education and training required to enhance the organization's leadership skills. A modification of the steps found in the US Marine Corps (2006) training model was considered the most useful. The resulting research would allow a company to introduce new knowledge, implement this knowledge, and change the culture to address the seven leadership steps described below:

1. Leading and knowing self.
2. Preparing to lead by gaining leadership skill awareness.
3. Lead the workforce by implementing leadership skills.
4. Lead subordinate leaders while practising leadership.
5. Develop subordinate leaders' teams.
6. Develop leadership climate by empowering and developing.
7. Lead changes of the processes by implementing best value for the organization.

NEW CORE COMPETENCIES

Figure 3 illustrates a new framework for the facilities asset management function. This framework is a bit of a departure from the traditional view of this function as one that only plans, acquires and tends to constructed facilities. The leaders of this function must adopt the governing mindset of a smart owner. The term 'smart owner' is used in the commercial design, engineering, and construction industry to designate a business entity that has the skill base – usually a staff with the professional qualifications and authority – necessary to plan, guide and evaluate the facility acquisition and management process. A smart owner focuses on the relationship of a specific facility to the successful accomplishment of an organization's business or overall mission (FFC 2000). The governing behaviour of the FAM function is focused upon strategic decision making that emphasizes a life cycle management approach and continuous improvement. Core competencies for facilities asset management teams have evolved and require *integration* (of facilities services), *alignment* (with the agency mission), and ongoing *innovation* (to address future needs and opportunities). Organizational capabilities that support these core competencies are *business management*, *professional* (technical) *competence*, and *behavioural skills*. The FAM function also requires people with a diverse array of individual skills who can truly leverage enterprise knowledge to enable it to achieve its objectives.

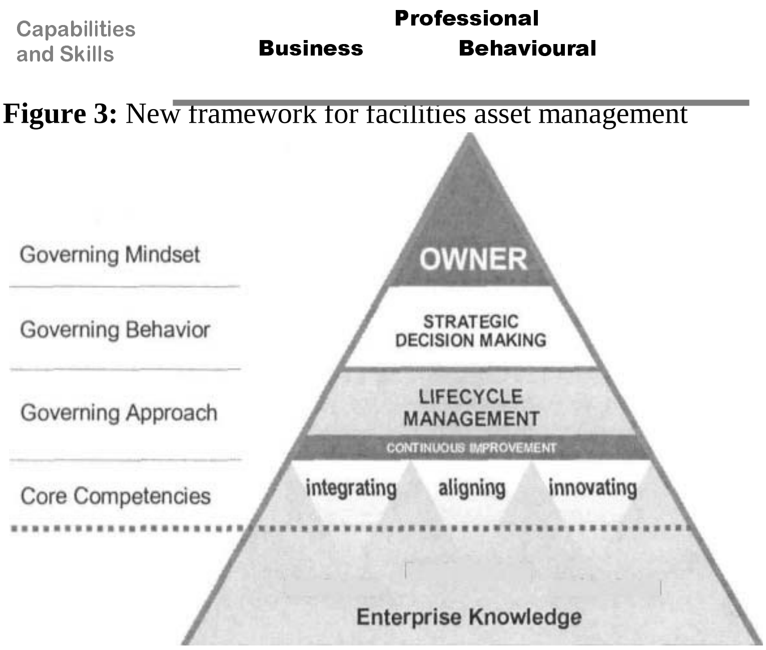

Figure 3: New framework for facilities asset management

Governing mindset – owner

Every professional in facilities asset management must take ownership of the organization's facilities. This is more than a cliché. Each professional must treat each workspace, each meeting room and each division's headquarters as if it were his/her own. This perspective allows facilities to respond to the agency's needs appropriately. To appreciate how important an ownership mentality is, compare the basic behaviour of the home renter versus the home owner. Moreover, the owner envisions the space as it ‘might be’.

Key behaviour – strategic decision making

Facility operational decisions and the associated management of the respective facility assets directly impact on enterprise service as well as financial and environmental performance. Therefore, enterprise or corporate leaders must understand and appreciate the impact of facilities and facilities asset managers on the enterprise. Hence, one of the most important responsibilities of the facilities asset management function is to ensure the appropriate information is evaluated for decision making. Within the facilities management community, many refer to this notion as ‘informing the client function’. Essentially, this is a strategic decision-making process that leads to configuring or adapting the facilities portfolio to suit the organization and its mission. To achieve this, senior leaders must: (1) understand how facilities impact on the mission; (2) establish appropriate policies for facility acquisition, management and disposal; (3) allocate adequate resources to support facility policies and management; and (4) evaluate facilities services systematically to determine the ‘fitness’ of the facilities portfolio.

Approach – life cycle management

Facilities asset managers of the future must take into consideration the entire life cycle of buildings and facilities portfolios. Since 85–90% of a building’s life cycle costs are post-construction, taking a total asset management perspective and understanding the concepts of total cost of ownership for facilities are vital. Proper stewardship of facilities requires an understanding of the importance of the interrelationships among these costs, thus enabling the development of cost-effective maintenance management plans.

Total asset management and total cost of ownership approaches consider the overall life cycle of facilities, from planning/design/construction through operations and maintenance to capital asset management and facility renewal or disposal. The importance of implementing a facility asset management approach that integrates facility operation and maintenance considerations with facility capital investments cannot be overstated.

Core competencies – integration, alignment, innovation

C*ore competencies* are knowledge, skills and abilities identified within a specific organization to enable successful performance of planned objectives. Core competencies need to be re-examined on a regular basis, often as part of the overall planning and budgeting process, to ensure they align with the organization’s needs. If the core competencies and the organization’s mission are unaligned, inefficiencies resulting from this mismatch (at the individual, team and/or organizational level) may exist, potentially leading to failure in meeting planned objectives.

Many professions are typically involved in the development and management of real assets. These include real estate, architecture, engineering, construction and facilities management. Of these, facilities asset managers are the only professionals fully engaged on a day-to-day basis, throughout the asset life cycle.

Integrating the various stages, activities, and players; *aligning* the diverse teams and tasks to one mission; and *innovating* across traditional functional lines to enable strategic decision making and achievement of objectives are the core competencies that the facilities asset management function must demonstrate to add value and contribute to enterprise/mission success. These competencies represent the future of this discipline. Indeed, the more traditional skills (related to planning, acquisition, management and disposal) are necessary; however, if both physical and virtual spaces are to act as one to facilitate organizational success, then a new skill set is vital for the leaders of the FAM function.

FUTURE WORKFORCE

It is essential that the facilities asset management organization has the ability to attract and recruit high quality employees to achieve world-class status. The marketing and selling of the new facilities asset management career field will be required and the education and training of the new workforce is needed. The development of the workforce will need continuous attention and investment.

A professional with a honed set of leadership and management skills will continue to progress whereas one who is lacking such skills will likely reach a point of career stagnation. One effective approach to ensure access to a pool of FAM talent is for universities and colleges to provide education, certifications and degrees in this field. In some corners of academia, scrutiny and serious consideration are being given to this new field of endeavour in higher education. However, the pipeline for new degrees in facilities asset management likely will not be producing such talent in the near future. This will require facilities asset management organizations to continuously educate and train the existing workforce.

Figure 4 illustrates the typical profile of academic disciplines for many universities and colleges in the US. It highlights the fact that few departments, schools or colleges are currently addressing the FAM field of university educated professionals. This lack of university graduates in the FAM field necessitates recruiting entry level BS graduates from other disciplines. This also requires better marketing of career opportunities to attract recruits and the need for increased facilities asset management image building.

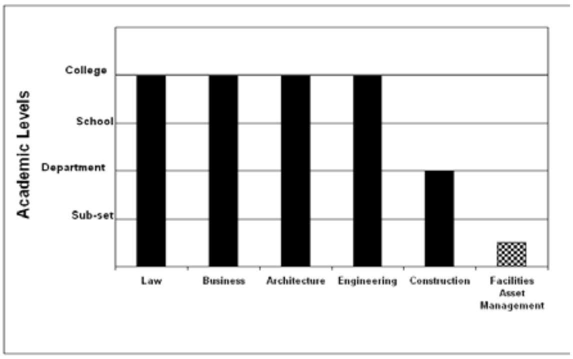

Figure 4: Typical profile of academic disciplines

A comprehensive workforce development programme should include both new and current employees. The establishment of such a programme will require the creation and adoption of a recognized education philosophy, and a core set of values that underlie all of the respective development components. It is vital that support be sustained with annual budgets, focusing on the development of the agency's core competencies.

RESEARCH

Research (knowledge development) is the cutting edge area of any growing field or discipline. The knowledge developed from research activities serves not only the immediate professional community but also those who are served by that community. For facilities asset management to become a true profession, knowledge development must play a significant and extensive role, with the results implemented in an effective manner. The knowledge development process will provide a continuous improvement environment for corporations, professional organizations and individual professionals themselves. Formal programmes ensuring such an environment need to be established.

The most immediate, applicable form of knowledge development is that which is internally generated. It is likely to have the most immediate impact. If an enterprise does not have adequate internal resources to conduct extensive research, engaging an outside source of expertise can serve this purpose. Such studies may come from academia, professional societies or from private consultants. Outside organizational utilization in conducting research, in addition to providing personnel and expertise, can also provide the 'independent voice' needed for credibility. Most 'breakthrough' contributions come from such sources because of the 'risky' nature of such endeavours. Involvement of enterprise human resources is still desirable and needed to ensure proper guidance of the research efforts. This involvement will also provide added benefit for the individual's experiential growth and will increase the potential for implementation of study results. Involvement usually enhances buy-in, promotes implementation and facilitates cultural change.

Unfortunately, US universities intending to develop and grow facilities asset management research areas and to add new areas of discovery and investigation are starting with little recognition or support. A monumental task awaits the US institution or the individual desiring to embark upon a path of discovery in the facilities asset management field. Despite the fact that research and educational outcomes have the potential to change the business practices and technologies of facilities owners worldwide, who collectively hold physical asset portfolios valued in trillions of dollars, the critical mass needed to launch FAM research is missing.

INVESTMENT IN EDUCATION AND TRAINING

One step in building a comprehensive workforce development programme is to identify educational needs, available training sources, and potential alliance partners from professional societies and organizations. Another step is to create innovation, new knowledge (research), and new product knowledge transfer mechanism to import ideas, technologies and knowledge into facilities asset management organizations. This model will capitalize on the capabilities of professional societies with an extensive knowledge and expertise base in facilities asset management. To accomplish the above educational, training and research programmes will require annual funding. According to Rose and Nicholl (2002) implementation of an effective development program will require both personnel and financial resources, in the range of 2–5% of an agency's personnel budget. Effective education and training that yields the right level of professional development have become recognized as not only valuable, but also necessary in maintaining an effective executive work force. Some examples of budget allocations targeted for professional development include:

- Motorola University, budgeting 3.6% of its payroll on training, some $120m p.a.;

- Saturn Corp – with its emphasis on debating shared values, cooperative decision making, teamwork, setting the expectation that every employee will undertake 100 hours a year of formal education;
- General Electric, placing 13 000 employees on a two-day thinking skills/problem-solving course;
- Fel Pro, reimbursing tuition costs for employees and paying bonuses to people who earn degrees;
- The Arup Partnership, allowing 10% of all employee time to be devoted to continuing education.

THE FUTURE

The forces of change are already at work. In particular, the demands to do more with less will not wane and the push towards more environmentally sustainable practices will prompt more frequent use of a remote workforce as enterprises attempt to minimize costs and conserve energy. Meanwhile, advances in IT will make the utilization of a remote workforce more feasible and effective. People will be more mobile and even more connected. Information technology will help to redefine the conduct, place and products of work. Current technologies already make it possible to generate documents that are designed for paperless reading, to obtain music without visiting a record store, and to plan and execute work without the benefit of office space. These trends will continue as the ‘digital’ world becomes more and more prevalent. The workforce and workplace of the future will not resemble that of today.

As this happens, the facilities asset management function and the facilities asset manager will evolve and become better recognized and established. This ‘evolution’ will occur regardless of whether an enterprise recognizes it or not. Those that do will have a competitive edge since they will realize that this discipline will become a core organizational function that: (1) provides an enterprise with the work environment necessary for its mission by integrating people, place, processes and technology; and (2) maximizes both the financial and environmental value of facilities throughout their life cycles.

CONCLUSION

This paper has discussed a number of challenges about the changing environment of the facilities asset management profession and the authors have identified some key (10) issues that need attention and innovative solutions:

1. *The title and name*: Over time the title and name for the ‘facilities asset manager’ and the profession of ‘facilities asset management’ has evolved and the recent NRC study recommends the above title and name.
2. *The significance*: The facilities asset management profession has gained new importance because of increasing budgetary pressures. The cost to adequately expand, modernize, repair and maintain an enterprise’s assets and real property has begun to dominate budgets. Moreover, organizational leaders have recognized that properly utilized and well-maintained facilities are mission enablers and require significant investment of resources.
3. *The uniqueness*: The roles and responsibilities of the facilities asset manager are unique among managers in the life cycle management system. The horizontal

nature of the organization increases the challenge of efficient information flow. It creates a condition where a wider range of core competencies and professional development is needed. The facilities asset managers must educate and train the facilities asset management workforce.

4. *The interface*: The recognition of the facilities asset manager's position as a senior executive is paramount for agencies/organizations/companies to accomplish their mission in an efficient and economical fashion. The facilities asset manager should be an active member of the agency's executive decision making leadership group.
5. *Leadership*: Facilities asset managers need increased leadership skill sets to be able to lead the workforce instead of being just a practising manager without the new leadership skills. The facilities asset management organizations need to implement a new leadership transformation model to change to a leadership organization.
6. *New core competencies*: The new facilities asset management function must adopt: (1) a smart owner's mindset; (2) a governing behaviour of strategic decision making; (3) a governing approach of life cycle management; (4) core competencies of integrating, aligning and innovating; and (5) key capabilities and skills in business, behavioural, enterprise knowledge and professionalism.
7. *New workforce*: It is essential that the facilities asset management organization has the ability to attract and recruit high quality employees to achieve world-class status. Marketing and selling of the new facilities asset management career field are required and the education and training of the new workforce is needed. Development of the workforce will need continuous attention and investment.
8. *Research*: Little university and private research information exists in the field of facilities asset management and even less research funding is being introduced or implemented. Facilities asset managers need to invest in developing new research in facilities asset management processes to improve overall performances.
9. *The investment*: Facilities asset management organizations need to invest 2% of their salary budgets on education and training of their workforce and research in process innovations.
10. *The future*: The facilities asset manager career field and the facilities asset management profession will become recognized and established as each matures and investments are made.

THE BEST CRITERIA FOR THE SELECTION OF CONTRACTORS IN THE DUTCH CONSTRUCTION INDUSTRY!

Ruben Favié[1], Ger Mass and Gaby Abdalla

School of Construction Management and Engineering, Technische Universiteit Eindhoven, Den Dolech 2 Vertigo 08.09 Eindhoven Noord Brabant 5600 MB, The Netherlands

Selecting contractors in the Netherlands is often done by the criterion of lowest price. This leads to a lack of innovation and a loss of quality in the construction industry. From the field of purchasing and procurement, we learn that there are several theories and processes for finding the best contractor for the execution of a work. One of the steps in those processes is the assessment of the contractors on the basis of specific criteria. Which criteria have to be used depends on the wishes of the client. But what are, in general, the best criteria to use? Assessment is on the basis of which criterion or combination of criteria really says something about the quality of the cooperation and the final product. In this research, a comparison is made between the criteria that were found in literature with the criteria that were found during a study on the Dutch construction industry. The aim of this research is to find the best criteria for the selection of contractors in the Dutch construction industry.

Keywords: client, criteria, government, innovation, procurement, tendering.

INTRODUCTION

The Dutch building industry is changing. Like in other countries, there are big programmes initiated by the government to improve the industry as a whole. One of the most important aspects of these programmes is the way that clients select and weigh up their partners. The partner, in this case is the contractor.

Building projects are getting more complex. Because of that, the contractors that build these projects have to meet specific demands. Nowadays, the most important criterion for tendering in the Dutch construction industry is price. This means that the contractor that offers the lowest price gets the work. In the Enquete Bouwnijverheid, performed by the Dutch Government in 2003, the disadvantages of this way of tendering are mentioned (Parlementaire Enquetecommissie Bouwnijverheid 2003). The research points out that the criterion of lowest price does not stimulate and augment the quality of the work and innovation in the building industry.

Also, because of the lowest price tendering, all contractors have to do exactly the same thing. Because of this, there are hardly any contractors with a particular expertise. This is very bad for innovation in the industry. This way of tendering also leads to highly divided responsibilities and in a lot of cases bad relationships between

[1] r.favie@bwk.tue.nl

contractor and client. These bad relationships are a result of the fact that contractors try to come up with the lowest possible price. When they have the lowest price in the tender, they are allowed to build the project. During the project, the contractor tries to earn as much extra money as possible. When, for example, the client wants to make a little change in the design, the contractor will ask a lot of money for that. Most of the time he will ask for more money than he really needs to fulfil that job. This will lead to distrust, unpleasant situations and negative energy.

To conclude we can say that lowest price tendering might not be the best way to select a contractor. It would be better to select a contractor and build in a team where the participants can trust each other, and work for the same goal. That will lead to better working situations and more value for every partner in the team.

The question is then: which criteria have to be used to select a contractor in order to reach your aim and create the best value for your organization? In this paper, an overview of existing literature in the field of criteria for supplier selection is compared with a study that was done on the Dutch construction industry. The findings of this research result in recommendations for Dutch clients: which are the best criteria to use in the contractor selection process?

THE CONTRACTOR SELECTION

One of the most important steps in every production process is the selection of a supplier. In the construction industry, very difficult, unique products have to be developed. In the construction industry, one of the suppliers is the contractor. He is responsible for the execution of the work.

Although there are a lot of differences between the construction industry and other industries, the principle of selecting suppliers is the same: a client buys a product from a supplier. The whole process of supplier selection has been discussed in literature for several years. Van Weele has developed a purchasing model that includes the following steps:

1. Determining specification
2. Selecting supplier
3. Contracting
4. Ordering
5. Expediting and evaluation
6. Follow-up and evaluation

Another model for contractor selection is developed by Momme and Hvolby (2002) and is called the outsourcing framework. It contains the following steps:

1. Competence analysis
2. Assessment and approval
3. Contract negotiation
4. Project execution and transfer
5. Managing relationship
6. Contract termination

In each second step of these processes respectively ‘Selecting supplier’ and ‘Assessment and approval’, the determination of criteria for the selection is a very important issue. The problem here is that neither Van Weele nor Momme give the best criteria. In the next paragraph, an overview is given of the literature that handles the right criteria for supplier selection.

THE CRITERIA

In the past 40 years, a lot of research has been done on the issue of criteria for supplier selection. One of the first authors to write on this topic was Dickson (1966). He indicated 23 supplier selection criteria. According to Dickson, cost, quality and delivery performance are the most important criteria. More recent research, done by Choy *et al*. (2003), identifies 18 criteria that were divided into seven groups. Jain *et al*. (2007) formulated groups with six main categories:

1. Cost
2. Quality
3. Cycle time
4. Service
5. Relationship
6. Organizational profile

In this research these groups and the criteria that are in these groups will be used.

METHODOLOGY

Step 1: expert panel
The first step in this research was a workshop in which 15 experts from the construction industry were asked to share their most important criteria for selecting a supplier in construction. The workshop was held as part of a congress at the University of Eindhoven on 2 June 2005. The 15 experts were asked to write down their most important criteria for the selection of a supplier. Doing this, a list of criteria was collected that was completed and refined by a monologue by each of the experts in which the expert was able to explain what his most important values in the process of selecting a supplier were. This collection of 51 criteria is grouped conformable to the categories of Jain *et al*. (2007).

Step 2: survey
The list of criteria that was collected by the expert panel of step 1 was the input for a big survey that was held among over 100 respondents from the Dutch construction industry. This survey was held during a congress at the University of Eindhoven on 8 June 2006. In this survey, the respondents, all professionals from the building industry and students, were asked to rank the criteria on a scale from 1 to 4 (not important – reasonably important – important – highly important). There were 111 respondents, of which 25 were students. Because of their lack of experience in the industry, their responses were not used. So, at the end, the responses of 86 respondents were used.

The survey included 12 criteria. These criteria were filtered out of the list that was the result of step 1 by comparing the supplier selection criteria of Jain *et al*. with the list of the expert panel.

RESULTS

Step 1: expert panel

The criteria that were collected during the workshop with the expert panel can be seen in Table 1. The criteria are compared to the criteria that Jain *et al*. determined. From this comparison, 12 criteria are chosen for the next step in the research, the survey. These 12 criteria are a direct match between the criteria of Jain *et al*. and the criteria from the expert panel. For the criterion of 'Cycle time' that Jain *et al.* collected, no match was found, therefore that criterion was not taken into account for the survey. The criterion of financial stability that was found by Jain has not been named by the expert panel, but because of its importance in the process of selection, that criterion was added to the survey.

Table 1: Comparison of the criteria from Jain and the criteria from the expert panel

Jain *et al.* (2007)	**Expert panel grouped by Jain**
Cost	Cost
Price	*Price/quality ratio*
Logistics costs (transportation, inventory, administration, Customs, risk and damage, handling and packing)	
Operating costs	
After sales service costs	
Relationship	Relationship
Visitation to supplier facilities	Accessibility
Trust and partnership	*Trust*
Compatibility across levels and functions of buyer and supplier firms	*Match*
Business references	Respect
Supplier's customer base	Personal cooperation
Financial stability	
Strategic contribution	Fun
Reliability	*Reliability*
Expectation of continuity	*Reciprocity*
Dependability	*We are not able to do it on our own*
Need identification ability	Good feeling
Cultural similarity	Going for the same goal
Negotiable ability	No nonsense approach
Amount of past business	Enthusiasm
Ability to maintain commercial relations	Culture
Supplier availability	Damage risk
Industrial relations	Dependence
Risks	Returns
	Openness
	Partner must be able to complement me
	Partner has to do one's best
	The project and the objectives must fit the company's values
	Added value: win-win

	Synergy
	Open communication
	Ethics
	Cooperation on the basis of equivalence
	Not being corrupt
	Long-term relationships
	Mutual dependence
	Loyalty
	Mutual interests
	Communication
	No frustrations
	Expectancy
Quality	Quality
Quality performance (e.g. ISO 9000 accreditation)	*Quality*
Marketability	good processes
Durability

Technological capabilities	Cooperation: the content
Innovativeness	Innovation
EDI capability	
Service	Service
Reaction to demand	*Cooperation: organizational*
Ability to modify product	Appointments
Supply variety	
Technical support	
After sales services (e.g. warranties and claims policies)	
Flexibility (payment, freight, price reduction, order frequency & amount)	
Delivery frequency	
Cycle time	Cycle time
Speed to market	

Delivery lead time
Development speed
On time delivery
Fill rate

Step 2: survey

The comparison of step 1 (Table1) results in 12 criteria that were the subject of a survey. In Table 2, these criteria are shown. In the survey, 86 professionals from the Dutch construction industry could rank these criteria on a scale of 1 to 4. The results of this survey can be seen in Table 3.

Table 2: The criteria for survey 1

- Price
- Quality
- Good cooperation
- Creditworthiness
- No nonsense
- A good match
- A partner is able to do something that we can not do
- Trust
- Experience
- Reciprocity
- Image of a partner
- Reliability

The results in Table 3 give an insight into the way the Dutch professionals think about these criteria. The range of the answers is very wide. Because of that, it was only possible to determine the mean of all the rankings.

Table 3: The results of survey 1

	Modus		**Mean**			
Criterion	**All participants**	**All participants (111)**	**Contractors (22)**	**Consultants (41)**	**Real estate developers (11)**	**Public clients (12)**
Price	Important	2,92	2,86	2,95	3,00	3,00
Quality	Highly important	3,74	3,68	3,76	3,82	3,75
a good cooperation	Important	3,17	3,09	3,15	3,09	3,00
Credit-worthiness	Important	2,85	2,95	3,05	3,09	3,00
No nonsense	Important	2,74	2,68	2,66	2,45	2,5
A good match	Important	3,36	3,32	3,39	3,36	3,33
A partner is able to do something that we can not do	Important	3,17	3,23	3,17	3,36	3,42
Trust	Highly important	3,8	3,86	3,83	4	4,00
Experience (references)	Reasonably important	2,4	2,23	2,27	2,55	2,50

Image of a partner	Reasonably important	2,49	2,41	2,37	2,64	2,58

Reliability	Highly important	3,8	3,82	3,85	3,91	3,83

DISCUSSION

In the field of procurement and purchasing, a lot of models are being developed that can help businesses with the selection of suppliers. In most of those models, the criteria for selection play an important role. In this study, a comparison is made of some existing literature from the field of supplier selection with research that has been done in the Dutch construction industry. The criteria that were found in literature for selecting a supplier have been compared with the criteria that were found in Dutch construction for selecting a contractor. From this comparison it can be said that there are a lot of similarities. The ranking of the criteria, however, was very difficult. Probably, the reason for that was the fact that the 86 respondents who ranked the criteria were not working in the same projects and in the same companies. For every new project, the client has to rank the criteria again, because every project has its own characteristics. Because of the similarities between the existing literature on the criteria for selecting suppliers, it can be said these criteria are very useful for selecting contractors in the Netherlands.

NON-CONFORMITIES IN FLEXIBLE PAVEMENTS: A THEORETICAL AND EXPERIMENTAL STUDY ON PAY ADJUSTMENT

Filippo G Pratico[1]

University Mediterranea of Reggio Calabria, Via Graziella Feo di Vito, Reggio Calabria, 89100, Italy

Highway pavements are multi-layered and complex systems. Inspection, sampling and testing are necessary to determine the degree of compliance of the as-constructed pavement with the as-designed pavement (i.e. contract requirements). This phase is called acceptance and a pay adjustment system is finally required in order to assign pay factors and contractors' liabilities. In particular, conditions may occur in which the friction course is a premium material and performs very well, while in the binder course many defects are detected and thus the milling of both the binder and the surface course is required. In such cases, a method to identify liability, estimate pay adjustment and contribute to dispute resolution is needed in order to divide responsibilities and penalties among different subjects and layers. Such a method is proposed. A model, based on life cycle cost analysis (LCCA) of the flexible pavement has been formalized and an experimental application (case history) is presented. Results demonstrate that acceptance criteria based on pavement experimental investigation and LCCA can give a reliable solution for pay adjustment quantification and subdivision.

Keywords: quality assurance, cost, roads, contract administration, life cycle.

OBJECTIVES AND SCOPE

The main objective of this paper is to propose a methodology for solving the issues of detection, analysis and acceptance of a multi-layered pavement in which defects in inside layers are detected. Flexible pavements are considered. In order to pursue the above-mentioned objective, construction, economical and juridical issues have been analysed and discussed; given that premise, an acceptance criterion has been formalized and applied to a real case history.

METHODOLOGY: PART I – ANALYSIS OF FAILURE, CONSTRUCTION ISSUES

In this section, construction issues pertaining nonconformities of inside layers of a multilayered road pavement are analysed; the structure of the problem in terms of acceptance criteria is investigated as key factor for dispute resolution. Premature non-conformities are usually detected "*de visu*" as surface distress.

Surface distress is "Any indication of poor or unfavourable pavement performance or signs of impending failure; any unsatisfactory performance of a pavement short of failure" (Highway Research Board 1970). Surface distress modes can be broadly classified into the following three groups: (a) *fracture* (cracking resulting from

[1] filippo.pratico@unirc.it

excessive loading, fatigue, thermal changes, moisture damage, slippage, etc.); (b) *distortion (*rutting, corrugation and shoving, which can result from such things as excessive loading, creep, densification, consolidation, swelling, or frost action); and (c) *disintegration* (stripping, ravelling, which can result from such things as loss of bonding, chemical reactivity, traffic abrasion, aggregate degradation, poor consolidation/compaction or binder aging, etc.). Thus, in general, surface distress can be related to the structural integrity of pavement.

Surface cracking can result from the overall performance of the multilayer system (pavement); the balance among the mechanical properties of the different layers rules (under given load conditions) where and when cracks will appear and how they will propagate thorough the multi-layered pavement system.

So there is the possibility to detect surface distress substantially related to the failure of inside layers; a class of typical premature, impulsive degradation phenomena originates from the breakage of the link between asphalt binder and aggregates. Separation or removal of asphalt binder from aggregate surface due primarily to the action of moisture and/or moisture vapour is generally termed stripping.

The following factors can be useful in detecting and analysing phenomena, acceptance criteria and liabilities (Kandhal and Richards 2001; Schaus and Tighe 2007; Long and Ioannides 2007):

1. Physio-chemical incompatibility of the asphalt system is a key factor. Aggregate prone to stripping (e.g. siliceous aggregates), particular asphalt binders and traffic can be important factors.
2. Interaction between different hot mix asphalt (HMA) courses (including Open – Graded Friction Courses, OGFC, or porous european mixes (PME)) can be relevant. As a mater of fact, according to some authors, there are numerous examples of stripping that occurred in dense graded HMA followed by an OGFC overlay.
3. Stripping phenomena often occur within 6–18 months from the construction, and either a moisture surplus area or sufficient diurnal temperature range is necessary to start the “heat pump” and get moisture movement within the road (Emery 2006).
4. Extensive milling can be needed.
5. Stripping is influenced from aggregate selection, asphalt binder selection, pavement design, mixture design, construction, drainage and additives (Lavin 2002).
6. Besides high air void content (Turochy and Parker 2007), three essential factors seem to promote stripping: the presence of water, high stress, high temperature range. In particular, dusty or dirty aggregates can affect stripping susceptibility.
7. The following main theories on stripping mechanism can be listed: detachment (i.e. microscopic separation of the asphalt film from the aggregate), displacement (i.e. breaking of the film), emulsification (in presence of water), film rupture (ruptured asphalt films at sharp aggregate surfaces or due to dust), hydraulic scouring (scouring of the asphalt film through the action of traffic and water), pH instability, pore pressure (air voids becoming saturated with

water), etc.; each of them can greatly contribute to understand and attribute causes and liabilities.

In the case of few layers in bridge deck surfacing, the following additional key-points must be considered for dispute resolution (Castro 2004):

- Bridge asphalt pavement must provide good evenness, skid resistance and protection of the deck from the action of traffic, atmospheric agents, de-icing salts; a deck protection (waterproofing layer) is often used.
- Asphalt pavement on concrete bridges may suffer the following particular types of damage: waterproofing blisters, courses reciprocal flow (waterproofing-deck, waterproofing-pavement, etc.), slippage, fatigue cracking, rutting, bleeding, scabbing, surface degradation, etc.
- In the hypothesis of null bond (between deck and pavement), the larger the modulus (of asphalt concrete), the smaller the traction strains (in the bottom of the mix); therefore, Porous European Mixes, having low moduli, can have conspicuous traction strain.
- In the hypothesis of total bond (between deck and pavement), due to the large difference in modulus between deck and pavement, high shear stresses develop and there is a high risk that this bond will disappear over the time.

In the light of above-mentioned facts the following analysis procedure can be outlined:

1. Assess friction course condition.
2. Assess binder course condition.
3. Assess the condition of the other layers.
4. Assess the condition of the tack coats between layers and of the membrane over the bridge deck.
5. Check for the drainage of water from the bridge deck.

Typical testing procedures make use of coring and trenching.

METHODOLOGY - PART II - JURIDICAL AND ECONOMIC STRUCTURE OF THE PROBLEM

In this section, economic and juridical issues related to defects in inside layers are analysed. Note that, in this case, a special issue pertains the chain of liability among the different subjects of the construction process (agency, agency engineer, contractor), especially if the i-th course must be milled and so also the courses laying above (friction course, etc.). Moreover, these features are becoming increasingly important due to the growing importance of wearing courses (long life pavements) and to the fact that friction courses on bridge decks are often considerably more expensive than conventional asphalt concrete pavements.

The key-points of the Italian juridical structure in this field are reported below:

- Art. 1664 of the Civil Code (c.c.): fair pay adjustment for unforeseeable causes. Two related principles: invariance of the contractor performance and invariance of the payment.

- Art. 10 of the Italian Bid/Contract general provisions (DMLLPP n.145 del 19.04.00: fair pay adjustment in case of substantial modification of work quantities).
- Art. 1667c.c.: contractor must warranty for defects (nonconformities and/or insufficiencies with regard to the state-of-the-art). Two types of defects are defined: defects that do not threaten stability "*non inficiano la stabilità*" and defects that threaten stability. In the first case (do not threaten stability), there are two possibilities: (a) pay adjustment and (b) removal of the defect. In the second case (do threaten stability), there is only one possibility: contract resolution with pay adjustment. The warranty for defects continues also after the acceptance (in general, for two years) but only for hidden defects.

On the basis of the above-reported factors and of the state of the art, the following hypotheses have been here outlined (see Figure 1):

(a) First layer involved – milling not needed
The *1st layer* is defective but milling is not needed; Pay adjustment is estimated on the basis of given (if any in the contract) methods or on the basis of life cycle cost analysis, LCCA – see next section). Consideration of both functional and mechanical properties is needed.

(b) First layer involved– milling needed
The *first layer* is defective and milling and reconstruction is needed; the contractor has this liability.

(c) Inside layer involved - milling needed and detectable defect undetected by the agency engineer. Joint liability.
The *i-th (i≠1) layer* is defective and milling and reconstruction of all the above pavement structure is needed; the contractor (of the i-th layer) singularly pays for milling and reconstruction of only the i-th layer; the milling and reconstruction of the above layers is an issue of joint liability with the agency engineer because the defect has been detected too late;

(d) Inside layer involved - milling needed and hidden defect undetected (defectiveness known or unknown by the contractor). Contractor has the liability for all.
The i-th (i≠1) layer is defective and milling and reconstruction of all the above pavement structure is needed; the contractor (of the i-th layer) pays for milling and reconstruction. In particular, it is assessed the liability of the contractor for having placed a course that it knew was defective; it is the case, e.g., of high RAP percentages contained in the mixture, without the necessary mix design.

(e) Inside layer involved - milling not needed- empirical formula for PA estimation suggested in the contract.
The *i-th (i≠1) layer* is defective but milling is not needed; pay adjustment (PA) is estimated on the basis of given methods (usually empirical) set out in the contract; in his case there is the issue of the real representativeness of such methods (is the estimated PA really the quantification of the of the money loss from the agency (and the users)?

(f) Milling not needed- empirical formula for PA estimation not suggested in the contract formula of PA

The *i-th (i≠1) layer* is defective but milling is not needed; PA is estimated on the basis of the LCCA, applied to the pavement (all the layers must be considered).

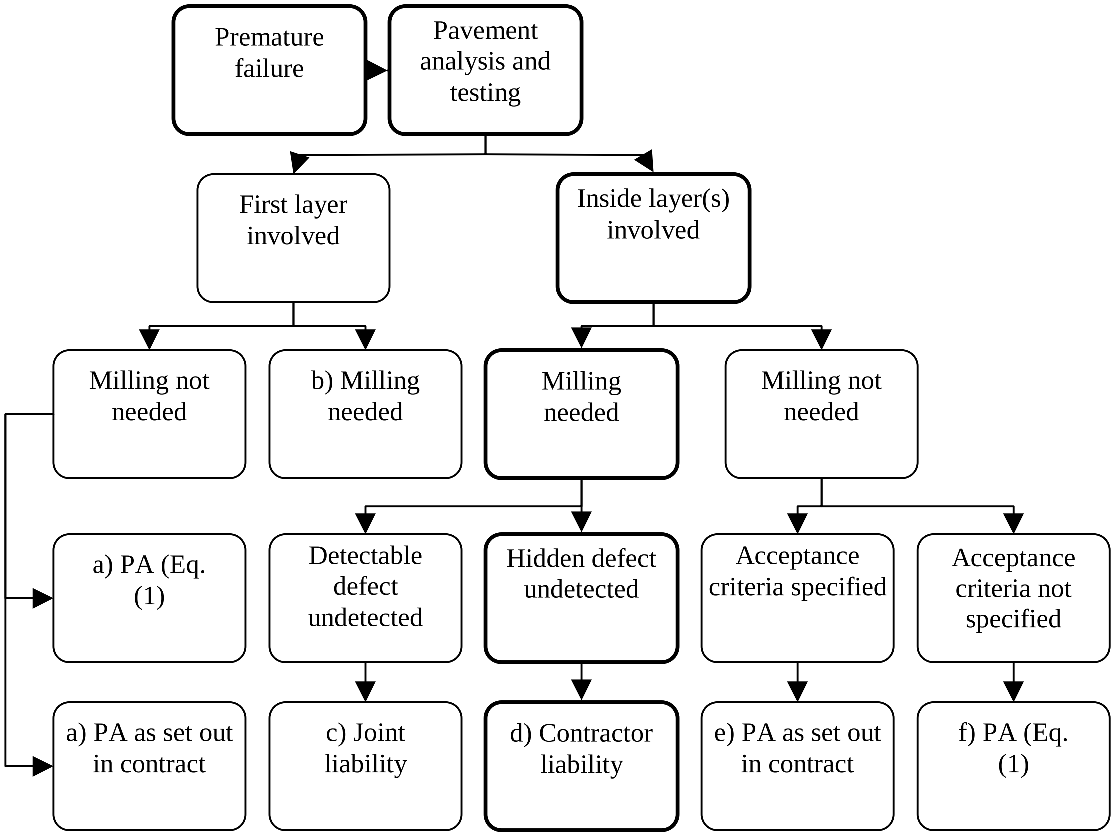

Figure 1: Simplified tree of liabilities and pay adjustment

METHODOLOGY - PART III - ALGORITHMS FOR PAY ADJUSTMENT AND LIABILITIES

This section deals with the proposal of a method for considering the above-mentioned cases in terms of PA. In order to pursue the above-mentioned targets, the algorithm should take into account:

- Surface and volumetric parameters for the friction course; only volumetric parameters for the other courses (in order to consider friction, drainability and similar surface performance).
- As-designed and as-constructed pavement (as a starting point in order to apply LCCA).
- The six cases above summarized and other occurrences if needed;
- The possibility of time delays.

The idea behind the following algorithm is that PA should compare all the costs incurred during the period over which as-designed (DP) and as-constructed pavement (CP) has been compared.

Under these hypotheses there is the possibility to assign to the as-constructed and the as-designed pavement the expected life and the effective work delay (see Table 1 and Figure 2); these factors (D, EB, ODP, ES, OCP) are the inputs of the algorithm below described, while the obtained output is the Pay Adjustment for each layer. In order to achieve this goal, Life-Cycle Cost Analysis (LCCA) is applied (Walls and Smith 1998). As is well known, LCCA is an analysis technique for evaluating the total economic worth of a usable project segment by considering initial cost and discounted future cost, such as maintenance, user, reconstruction, rehabilitation, restoring, resurfacing cost, over the life of the project segment.

For an engineering-economic approach to the problem, the following key-points are important:

- The initial cost of wearing courses ranges from 3 to 15 US$ per square metre, in relation to country, typology, thickness, etc.
- Wearing courses expected life ranges from 7 to 15 years, depending on traffic, climate, etc.
- Maintenance strategy includes crack seal, surface seal, mill and replace, patch and costs vary from 1000 to 30000 US$ for lane-Km.
- As road conditions become better, road administration costs prevail on road user costs, which become negligible; note that routine annual maintenance costs and user delay costs are often negligible if compared to agency costs; anyhow, this assumption must be checked for the single case.
- Discount rate (which depends on the difference between interest and inflation rate) fluctuate from 3.5% to 8% for the different states (OECD 2005); f) typical long-term values for interest and inflation rates are 0.08 and 0.04, respectively.

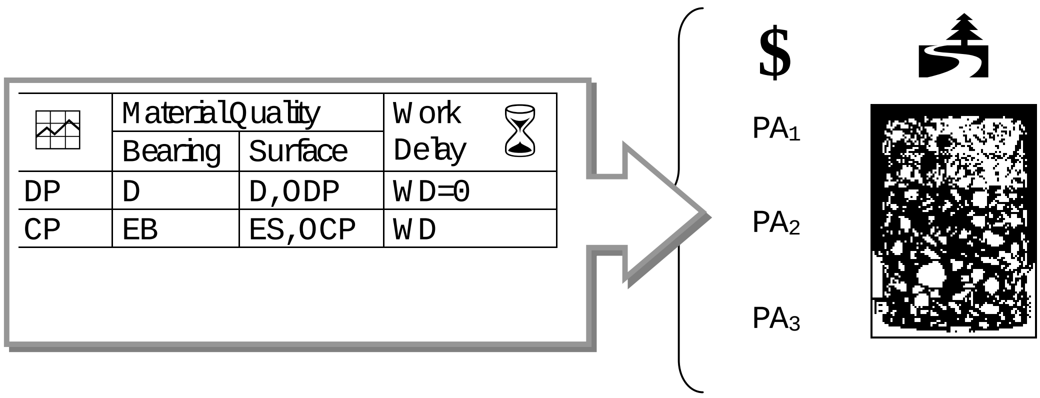

Figure 2: From material quality and work delay to the i-th pay adjustment (see Table 1)

In the light of above facts, the algorithm here proposed for the general case is (Praticò 2007, see figure 2):

$$PA=C_B\cdot[(R^D)\cdot(1-R^{ODP})^{-1}-(R^{EB})\cdot(1-R^{OCP})^{-1}]+C_S\cdot(R^D)\cdot R^{ODP}\cdot(1-R^{ODP})^{-1}+$$

$$-C_S(R^{EB})\cdot R^{OCP}\cdot(1-R^{OCP})^{-1}+C_S\cdot(-R^{ES}+R^D)- PC\cdot C_{DP}\cdot SD^{-1}\cdot W_D \quad (1)$$

where symbols and acronyms are below explained (see Table 1). Equation (1) is based on LCCA of road pavement; two conditions are compared: DP (as-Designed Pavement) and CP (as-Constructed Pavement, see Table 1). Both Bearing (B) and

Supplementary (S) properties are taken into account. Timeliness issues are considered through the factor W_D (Work Delay, days), The output of Equation (1) has the same units as the costs (C_B, C_S, e.g. €). When many layers and contractors are involved, a procedure for the estimation of factors liability is needed. In order to purse this objective, the following procedure has been here formalized (see Figure 3):

Step 1) assessing, for the i-th parameter, the importance I_i (tentative value=1/n, where i=1, 2, …, n):

$$0 \le I_i \le 1 \tag{2}$$

and

$$\Sigma I_i = 1 \tag{3}$$

Step2) calculating the Percentage of Defects PDi, for the i-th factor, where

$$0 \le PD_i \le 100 \tag{4}$$

step 3) calculating the Relative Liability L_{BRi} (where B stands for Bearing properties, R for Relative and i for i-th layer):

$$L_{BRi} = PD_i \cdot I_i \tag{5}$$

Step 4) derivating the liability L_{Bi}, where

$$L_{Bi} = L_{BRi} \cdot 100/\ (\Sigma L_{BRi}), \tag{6}$$

And

$$PA_{Bi} = PA_B \cdot L_{Bi}/100. \tag{7}$$

Note that it results:

$$\Sigma L_{Bi} = 100. \tag{8}$$

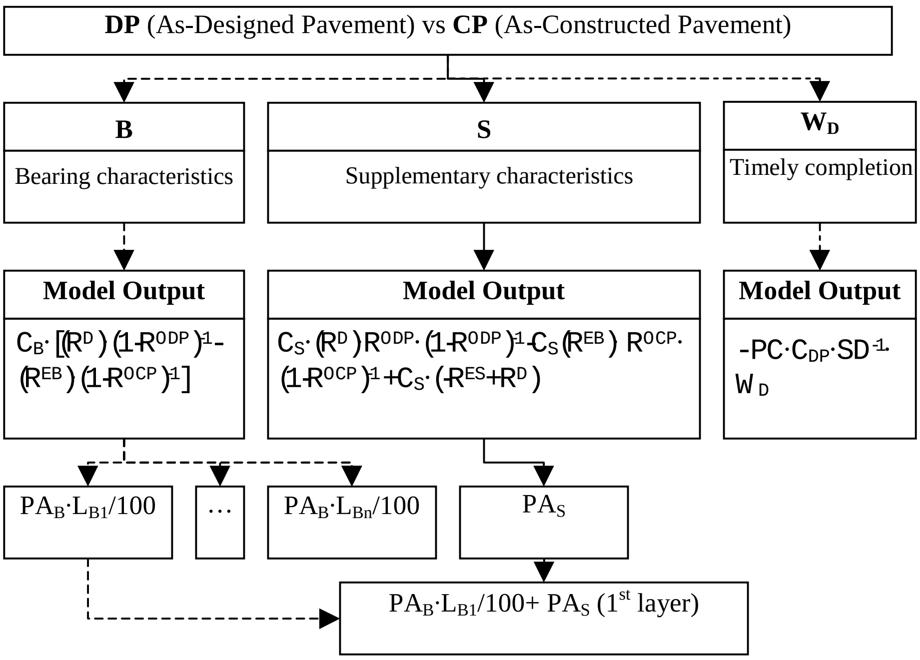

Figure 3: Pay adjustment and liabilities (see Table 1 and Equations 1–8)

Table 1: List of symbols and acronyms

B	"bearing" component of the pavement
C_B, C_S	Present Costs, referred to "B" characteristics or to "S" ones
CP	As-Constructed Pavement, actual pavement constructed by the contractor
D	Design life of the as-Designed Pavement; also called initial design life, it is the amount of time for which the chosen pavement design is expected to carry the traffic loads without the application of a global rehabilitation.
DP	As-Designed Pavement; desired pavement, as defined by the agency (buyer)
E, EB, ES	Expected life of the CP, general, for only B component, for only S component, respectively
I_i	Importance of the i-th parameter
INF, INT, R	Inflation rate, interest rate, $R=(1+INF)\cdot(1+INT)^{-1}$.
L_{Bi}	Liability
L_{BRi}	Relative Liability (i-th layer)
O, ODP, OCP	Expected life of successive resurfacing/reconstruction, general, of DP, of CP, respectively
PA	Pay Adjustment
PC	Project Criticality (dimensionless, default value=1)
PDi,	Percentage of defects for the i-th factor
S	Supplementary component of the pavement. It hasn't bearing properties.
SD	Scheduled Duration of the work (days)
W_D	Work Delay expressed in days (positive for late completion, negative for early completion)

EXPERIMENTAL APPLICATION: A CASE-HISTORY

A premature failure has been detected on a motorway in southern Italy. The following pavement structure has been detected:

1. First layer: PEM.
2. Second layer: HMA binder course .
3. Third layer: HMA base course; condition: good.
4. Fourth layer: granular base; condition: good.
5. Fifth layer: subgrade; condition: good.

Pavement surface condition was assessed thorough the procedure above formalized:

- Visual surface inspection (surface cracks rating in terms of frequency, surface area, shape, etc., see Figure 2).
- Visual inspection after coring and trenching (see Figures 4 to 9).
- In-lab testing.

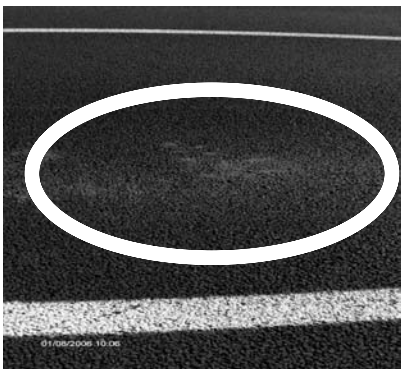

Figure 4: Surface condition: rutting, cracks (in the wheelpaths), water and fines bleeding

Figure 5: Slab extraction: PEM cracked, binder course strongly damaged

The slabs (1st and 2nd layer) extracted from the wheel path resulted significantly defective (binder course) in terms of mix consistency, aggregate grading, asphalt binder percent; a very irregular bridge deck was observed and monitored.

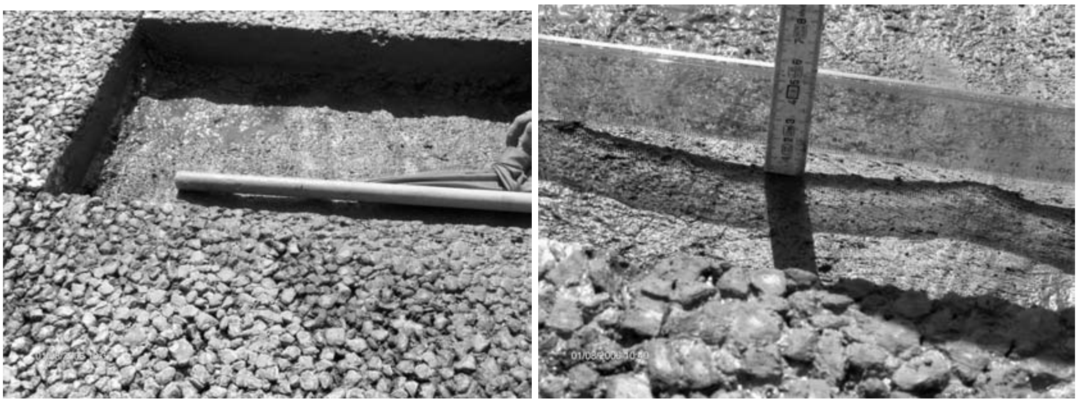

Figure 6: Evidence of a bridge deck rough and irregular

The cores (1st and 2nd layer), extracted in the shoulders, resulted in good conditions; on the contrary, the cores extracted in the wheel path resulted significantly damaged (especially for the binder course).

By referring to the binder course, all the cores presented air void contents greater than 8% and permeability greater than 0,0013cm/s.

Figure 7: Cores 1 and 2 extracted from the shoulders

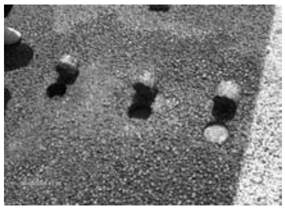

Figure 8: Cores 3 (right), 4, and 5 (left)

Moreover, some non-conformities in the methodology of applying the tack coat membrane to the bridge deck have been detected.

Figure 9: Slab and state of the bridge deck

On the basis of the in-lab experiments, the following additional findings have been found: (i) the PEM was always conforming; (ii) the binder course had a conspicuous moisture content; (iii) the membrane (on the deck) was always in good conditions; (iv) the bond between the membrane and the deck was mainly insufficient, with a very rough bridge deck and recurrent water patches; and (v) pavement condition all around the wheel path area was cracked with an incipient state of potholes formation.

According to the analysis above performed (Methodology – part II), in order to scan the possible causes the following main factors have been considered:

- Surface water drainage: water ponding was detected near transverse joints (in correspondence of bridge pillars). Vertical pipes on shoulders or joint cutting in the shoulders have been suggested.
- Bridge deck roughness: the roughness of the bridge deck has been charged in joint liability due to the practical impossibility to have a sufficient bond between membrane and deck.
- Bond between bridge deck and membrane: the condition of the membrane (thickness: 0.8cm) resulted satisfactory, but the bond between the bridge deck and the membrane resulted to be not fully conforming; the following main causes have been hypothesized: imperfect hot sealing, roughness of the bridge deck, traffic of heavy vehicles during construction, great difference in terms of stiffness between the membrane and the other layers. Nonconformities have been detected in the technique used for overlapping.
- Binder course and tack coat: on the basis of the tests performed on cores and slabs, three different classes of air void contents have been detected in the three lanes: first lane, AV>14%; second lane: AV>13%; third lane (opposite direction) AV>8%.
- A strong correlation has been detected between air void content (of the binder course) and surface distress (in the friction course).
- The following factors may have interacted with the high air void content: (a) the percolation of water through the PEM in the direction of the binder course; (b) the reduction of the modulus of the binder course, due to the high void content (when air voids increase from 5% to 11%, then relative modulus decreases from *circa* 1 to 0.6); and (c) related processes of stripping and therefore progressive disintegration of the binder course with consequences for the PEM.
- Friction course (PEM): rutting has been monitored (about 1cm on wheel path); the friction course appeared cracked in the wheel path. Water seepage out of cracks (water bleeding) has been detected and water and fine material appeared ejected from underlying layers through cracks in the HMA layer under moving loads (water pumping). According to the investigation above performed (Methodology – part III), water bleeding and pumping have been associated to a decreased skid resistance and structural support. Among the possible causes, several including poor drainage, underlaying failure and fines excess and dusty aggregates have been hypothesized. Though the presence, only in the wheel path, of bleeding of fines and water and cracks, tests on the friction course (PEM) resulted always conforming to the specifications set out in the contract.
- Multilayer design consistency: in the specifications set out in contract, the necessity of a tack coat has been clearly stated both for the sections on the bridge deck and the others. Design has been successfully checked for consistency.
- Anomalies in load conditions: operational speeds and load spectrum have been surveyed and resulted conforming to the road class and the design hypotheses.

- Weather conditions during construction: agency engineer did not report rain after the construction of the binder course and before the construction of the friction course.
- Other causes: other possible causes have been detected but their influence resulted unquestionably minor.

Table 2 summarizes the influence of the parameters above considered on the premature failure of the pavement (the procedure above formalized has been used, see equations (2) to 8). Only the relevant factors have been considered.

Table 2: Estimation of the influence of each cause on the premature failure of the pavement

Non-conformity	**I_i**	**PD_i**	**Relative Liability L_{BRi}**	**Liability percentage (L_{Bi}, rounded)**	**Liability**
a) Surface water drainage	0.1	34.5	3.5	10	Contractor
b) Roughness of the bridge deck	0.1	35.2	3.5	10	Contractor
c) Bond between membrane and bridge deck	0.1	69.6	7.0	20	Contractor
d) Binder course and tack coat between binder course and friction course	0.3	69.5	20.9	60	Contractor
e) Friction course	0.4	0.0	0.0	0	
Total	1.0	208.8	34.8	100	

Given the compelling schedule, the technical occurrence of stripping phenomena has been considered as the main support for the assessment of the hidden defects (cfr. the case f above described in Figure 1).

On the other hand, tests proved that reclaimed asphalt pavement have been used in the binder course, so violating contract specifications and *a fortiori* supporting for contractor liability.

In the light of above, the contractor was charged of milling and reconstruction of membrane, binder course, tack coat and friction course.

The following interventions have been concerted:

- Pipes in proximity of transverse joints, in order to facilitate the drainage and to mitigate the local barrier effect due to the joints.
- Milling of the existing pavement and full depth reconstruction.
- Use of anti-stripping additives also in the binder course.
- Minimizing air void content in the binder course.
- More accurate quality controls, especially for the bridge deck membrane and for the tack coat between layers.

MAIN FINDINGS

This paper outlines a model that aims to evaluate the real economic worth by performing a complex estimation of costs based on LCCA, and by assigning single liabilities based on the percentage of defects. On the basis of the performed study and according to the relative experimental validations, the following main conclusions can be drawn: (i) in acceptance procedures, defects and anomalies can be related to construction problems and are very difficult to be detected without specific disruptive investigation thorough cores and trenches. Analyses and testing can proceed *layer-by-layer* ; (ii) from a juridical and economical point of view two key-factors must be identified: who is liable of what and how much does he pay in the case a pay adjustment is needed; (iii) the first issue depends on the potential to detect the defects before laying the above layer(s); and (iv) the second subject can be solved by using empirical formulas or by recurring to a better estimate of the real cost for the agency through the concept of life cycle cost both for surface and volumetric defects. A model has been here formalized and validated. More research is needed into model optimization and validation.

INNOVATIVE REVENUE-SHARING SCHEME FOR PUBLIC–PRIVATE PARTNERSHIPS IN INFRASTRUCTURE PROJECTS

One of the most important issues in developing a balanced relationship between the government and private concessionaire is establishment of a fair revenue-sharing scheme. In practice, there are several conventional types of revenue-sharing schemes and each type has its advantages and disadvantages. Appling a suitable revenue-sharing scheme for the multiple-operator system (where there are a number of private concessionaires) will enhance system fairness and management efficiency. Using the scheme for every private operator in the system, however, may not be appropriate, as each operator may have different financial configurations such as investment cost, operation & maintenance cost (OMC) and expected revenue. The objective of this paper is to discuss the conventional approaches of the revenue-sharing scheme and to recommend an innovative and appropriate one to reduce risk burden and maintain the incentive of the private concessionaires to improve efficiency and service quality of project.

Keywords: infrastructure, public–private partnership, revenue-sharing scheme.

INTRODUCTION

Revenue sharing schemes between public authority and private concessionaire are one of the most critical issues in developing a balanced relationship between government and private investors in public-private-partnership (PPP) infrastructure development project. In practice, a public authority (governmental agency) awards a concession to operate a large-scale infrastructure normally to a single or limited number of private companies. This situation creates a monopoly condition where the opportunity to seek for excessive profit is given to a private concessionaire. The "excessive profit" means the portion of earning in excess of the minimum amount needed to attract investors to a project. In economics, it is referred as "rent", which will disturb the overall efficiency of the project (Milgrom and Roberts 1992). Therefore, the revenue-sharing scheme must be provided in order to take the excessive portion of profit back to public.

On the other hand, private sector's biggest concern over the infrastructure project is the risk it needs to take, especially demand risk. Risk in infrastructure development project is complex and huge (Flybjerg *et al*. 2003). No private investor would like to

[1] santi.cha@kmutt.ac.th

join an infrastructure project without any mitigation mechanism or support from government (Fishbein and Babbar 1996).

In Thailand, the government has recently been considering investments in several packages of infrastructure projects, such as a network of intercity toll ways and a mass transit network. During 2005–2009, the government planned to invest approximately 42.5 billion US dollars in such mega-projects. In specific, mass transit network in Bangkok needs 12.5 billion US dollars. To develop these projects, the government has two options for investment: public investment or PPP.

Both options have some pros and cons. With public investment, the government entirely invests in the projects using government budget (taxes) or borrowing from lending agencies such as the World Bank, ADB, JBIC and so on. The key advantage of public investment is that the government can take control of the direction of project, because the government is the sole owner and no private concessionaire is involved. However, the problem is that the amount of investment is quite large: using government budget would draw too much amount of money out of a very limited financial resource (the government budget size is approximately 30–35 billion US dollars yearly), while borrowing would increase public debt up to a critical level that would affect the country’s fiscal stability.

PPP has several advantages. With PPP, a private concessionaire invests at least partially in projects. For example, in a mass transit project, a private concessionaire would invest in “rolling stock”, while the government typically invests in civil works. Therefore, the government is freed from a financial burden. Furthermore, major investment and operational risks are transferred to private concessionaires. However, the major drawback of PPP is the contractual issues including responsibility sharing, risk allocation, government support schemes and revenue-sharing schemes between government and private concessionaires. These contractual issues need to be carefully designed to fit the investment environment such as project financial conditions, socio-political conditions and economic conditions.

A revenue-sharing scheme is one of the most important elements in the design of a PPP contract. The design of revenue-sharing schemes affects several important issues of infrastructure operation, namely financial return of government and private concessionaire, incentive to improve quality of service by private concessionaires and incentive to improve operational efficiency by private concessionaires.

This paper intends to clarify the existing revenue-sharing schemes typically used in projects around the world. Each model has its own advantages and disadvantages. Concepts and mechanisms of the mostly used models are discussed: the Percentage-of-Revenue model, Rate-of-Return-Cap model and Revenue-Cap model. Then an innovative revenue-sharing scheme is proposed with an underlying concept and mechanism.

REVIEWS OF REVENUE-SHARING SCHEMES

There are three typical models of revenue-sharing schemes being used in infrastructure development projects around the world: Percentage-of-Revenue, Rate-of-Return-Cap and Revenue-Cap (Alexander *et al*. 1996; Estache and De Rus 2000; Kerf *et al*. 1998; ETA 1988).

Percentage-of-Revenue model

With this model, a certain percentage of a project's revenue is returned to the public authority. The remaining portion will be given to a private concessionaire. For example, 30% of the total service fee collected is returned to the public authority. The authority may use this money to compensate for the construction cost already invested or for operation and maintenance. The money can be also used to invest in future extension of the infrastructure.

Disadvantage of this model is that revenue stream of the project is directly disturbed by the sharing mechanism. For example, 30% (which is substantial) of the total revenue is extracted from the private concessionaire's pocket. This obviously increases the break-even point and thus increases the financial risk of the project. In response, private concessionaire may increase the cost of risk in the project's financial appraisal. The additional cost of risk is eventually added into the service fee paid by users as compensation for the risk. If the fee is fixed by the authority and cannot be raised for the compensation, the project becomes unattractive to the private sector. In such a case, there would be little or no private companies willing to join the project. This condition worsens the competitive environment necessary for the bidding process.

This model is suitable for a project with low financial risk. An example is the extension of an existing transportation project. In such case, user demand can be determined without much uncertainty by using historical data from the existing project. Therefore, risk associated with financial return is very low. This model has been used in several infrastructure projects, for example, the Second Stage Expressway System in Greater Bangkok (extension from the First Stage Expressway).

Rate-of-Return-Cap model

The mechanism of this model is to limit the ceiling of the financial rate of return. If the rate of return is in excess of the specified level, the excessive portion must be given to the public authority. This mechanism directly addresses the "excessive profit" of the private concessionaire due to monopoly conditions created by the concession.

This model has a critical disadvantage. It potentially discourages private concessionaires from improving the operational efficiency of a project, for example, using better technology with a lower operation cost. For example, the concession contract may specify Rate-of-Return Cap for private concessionaire at 15% (Internal Rate of Return – IRR). If the IRR of a project is at a level equal or near to 15%, the private concessionaire would have no incentive to work more efficiently, because the additional return from improving efficiency would be finally given to the public authority.

Furthermore, the Rate-of-Return-Cap mechanism may create an incentive for the private concessionaire to behave opportunistically, for example, spending on unnecessarily expensive equipment in a way that could reduce the exceeding IRR down to the limit. In practice, such "opportunistic behavior" cannot be detected easily by the public authority.

Many infrastructure projects are using this scheme: the Mass Transit System in Bangkok is an example.

Revenue-Cap Model

With the Revenue-Cap model, the return for private concessionaires (before expenses) is limited to a ceiling value specified in concession contract. If the amount of user fee collected goes beyond the ceiling value, the exceeding portion will be returned to the public authority. This scheme intends to address the issue of private concessionaires' excessive profits.

The important disadvantage of this scheme is that it may lessen the incentive to improve the private concessionaire's quality of service, in such as cleanliness, speed of service and system security. An increase in service quality may grow user demand and result in additional revenue, but it comes with an additional cost. If project return is approaching or exceeding the revenue-cap ceiling, there is no point for the private concessionaire to invest in improving service quality without eligibility to take the additional return.

INNOVATIVE REVENUE-SHARING SCHEME

Motivation of this research is initiated from the idea that there should be a new revenue-sharing scheme that can minimize disadvantages of the revenue-sharing schemes explained above. Specifically, a revenue-sharing scheme that can maintain the incentive to improve operational efficiency and service quality without imposing excessive risk burden on the private concessionaire should be constructed. Most importantly, the new scheme must have the ability to regulate excessive profit of the private concessionaire, which is the original objective of revenue-sharing scheme.

Another important objective of this initiative is to build a revenue-sharing scheme that can be used effectively for the project with multiple operators responsible for multiple subsystems, such as a mass transit system where there is number of transit lines to be operated by different operator. Each subsystem has a unique financial configuration, such as amount of capital investment needed, financial structure, operational cost and revenue, etc. Furthermore, each subsystem may have different level of user demand. However, the usage fee for all subsystems may need to be the same rate for management purposes. These constraints often occur in some type of infrastructure such as a mass transit system. Therefore, subsystems with different financial configurations may match different revenue-sharing schemes, depending on the risk profile attached to it. Choosing any conventional revenue-sharing schemes and using it for all subsystems may not be appropriate. However, using different schemes for different subsystems may instead create problems over fairness among operators. Therefore, having a new revenue sharing scheme that can accommodate the explained conditions would be the solution.

Mechanism

From the objective requirements stated above, a new revenue-sharing scheme has been designed and constructed, as shown in Figure 1.

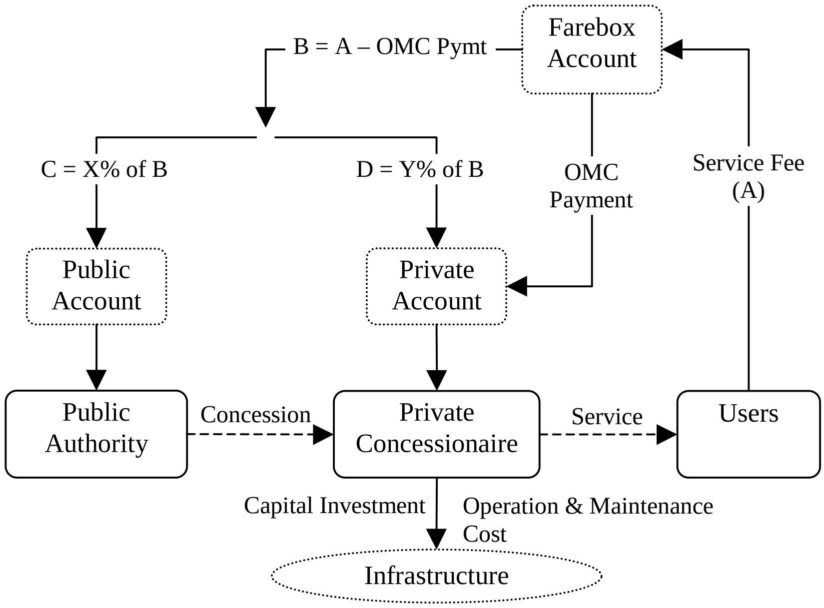

Figure 1: Mechanism for the new revenue-sharing scheme

The mechanism in Figure 1 works as follows:

1 Public authority awards a concession to operate the project to a private company called "private concessionaire". The concession normally specifies operational details, such as the right to collect a service fee, operation, expiry, etc.

2 The concessionaire makes a capital investment for construction/installation of the infrastructure.

3 After operation has commenced, the concessionaire begins to provide a service to users in exchange for a service fee. The fee collected from users will be transferred to different accounts along processes inside the mechanism as follows:

3.1 Initially, the fee will be totally transferred to the Farebox revenue. Then operation & maintenance cost (OMC) will be immediately paid to the concessionaire. The amount of the OMC payment is determined by the number specified in the concession contract, called "OMC Threshold". The threshold may be specified in term of usage volume, which can be converted to cash amount. For example, OMC Threshold of 100,000 users means the fee collected from the first 100,000 users will be totally given to private concessionaire as OMC payment. The threshold must be agreed by both the public authority and the private concessionaire, and must be specified in the contract. The point here is that the OMC payment is fixed. If the concessionaire could improve operational efficiency, it takes all the gain from improvement.

3.2 The revenue after OMC cost will be divided into two streams: for public authority and concessionaire. The sharing ratio between the two parties must be also agreed and specified in the concession contract. For example, a sharing ratio of 30:70 (public: private) means 30% of the revenue after

OMC payment is given to the public authority and the remaining 70% is given to the concessionaire.

Table 1 is an illustration of mechanism of the new revenue-sharing scheme. For illustration purposes, it is assumed that (1) the OMC Threshold is 100,000 users, (2) the sharing ratio is 50:50 (public: private) and (3) the usage fee is 20 baht per user.

Table 1: Illustration of mechanism for the new revenue-sharing scheme

Case	User Volume (person)	Farebox Account (Baht)	OMC Payment (Baht)	Public Authority (Baht)	Private Concessionaire (Baht)
1	50,000	1,000,000		0	1,000,000
2	100,000	2,000,000		0	2,000,000
3	150,000	3,000,000	20 x 100,000 = 2,000,000	500,000	2,500,000
4	200,000	4,000,000		1,000,000	3,000,000
5	300,000	6,000,000		2,000,000	4,000,000

In case No.1, where the number of users (50,000) is lower than the OMC Threshold (100,000), the revenue collected from the user (1,000,000) will be entirely given to the private concessionaire. In case No.3, where the number of users (150,000) exceeds OMC Threshold, the revenue given to the concessionaire is the OMC payment (2,000,000) plus 50% of the revenue after OMC payment (50% of 1,000,000 = 500,000). Therefore, the concessionaire will receive 2,500,000 baht in total, while the public authority has 500,000 baht. The payoff profile of private concessionaire is illustrated in Figure 2.

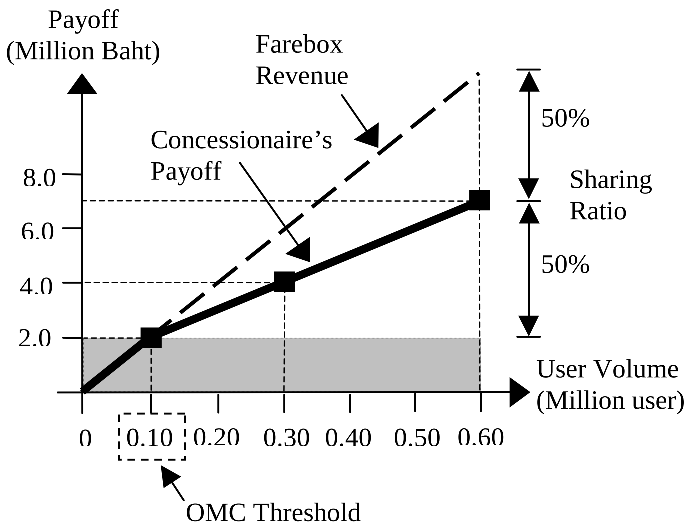

Figure 2: Payoff profile of concessionaire

Figure 3 illustrates four examples of payoff profile of the revenue-sharing scheme with different OMC Thresholds and Sharing Ratios. The profiles of Figure 3-A and B have an OMC Threshold of 0.10, while those of Figure 3-C and D are 0.30. On the other hand, profiles of Figure 3-A and C have a sharing ratio of <20:80> (public: private), while those of Figure 3-B and D are <80:20>.

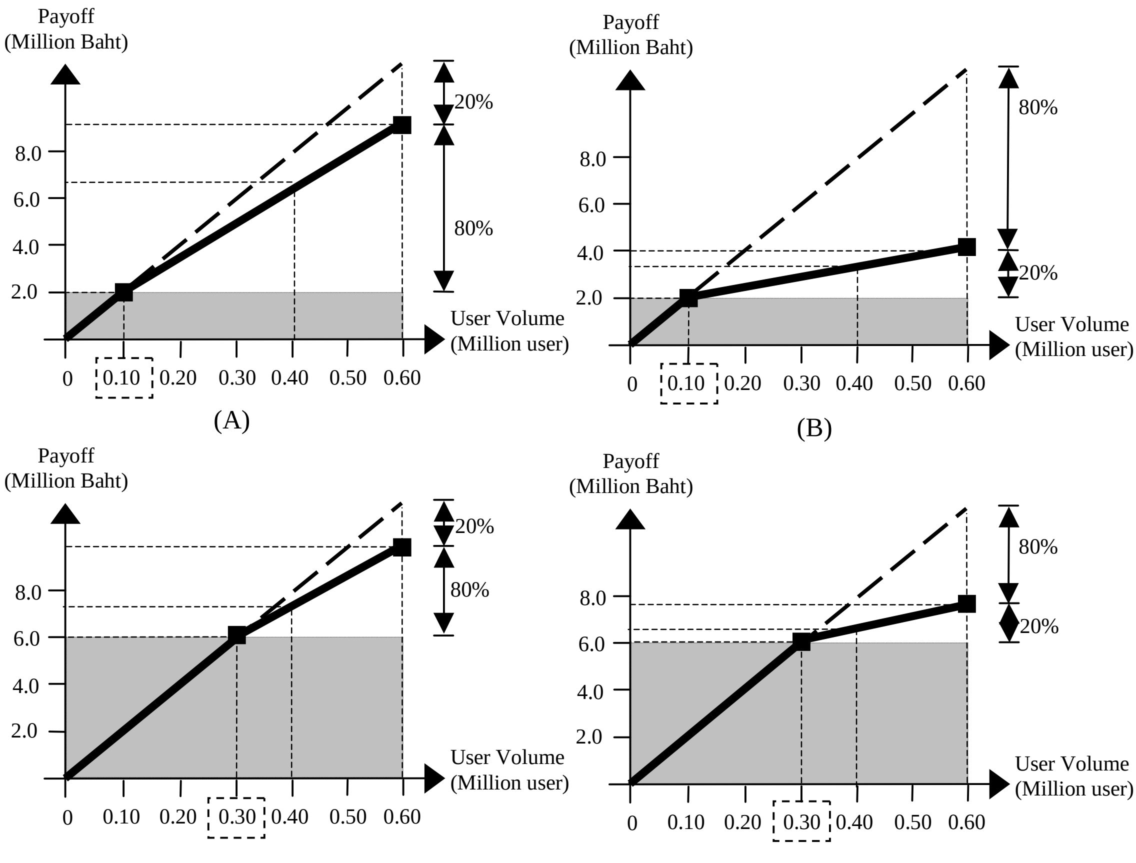

Figure 3: Comparison of concessionaire's payoff profile with different OMC Threshold and Sharing Ratio

It is obvious that the profiles with a higher OMC Threshold (Figure 3-C and D) give private concessionaires higher revenue than those with the lower threshold. For example, assuming the usage fee is 20 baht per user and the number of users is estimated at 0.4 million per day, the profile in Figure 3-D would give the concessionaire (0.3 x 20) + (0.1 x 20 x 20%) = 6.4 million baht, while that of Figure 3-B gives only (0.1 x 20) + (0.3 x 20 x 20%) = 3.2 million baht to the concessionaire. In Figure 3-B, revenue beyond 0.1 x 20 = 2 million baht must be shared with the government with the <20:80> ratio. In Figure 3-D, the concessionaire does not have to share any revenue with the public authority as long as the number of passengers does not reach the 0.3 million threshold.

Deciding a Sharing Ratio is also important. With a high ratio, the bigger portion of revenue from users beyond OMC Threshold must be given to public authority. For example, Figures 3-A and B have different Sharing Ratios with the same OMC Threshold. At 0.4 million users per day, the concessionaire profiled in Figure 3-A receives (0.1 x 20) + (0.3 x 20 x 80%) = 6.8 million baht. On the other hand, if the profile in Figure 3-B is used, the concessionaire receives only (0.1 x 20) + (0.3 x 20 x 20%) = 3.2 million baht. It is obvious that the sharing ratio is very influential to profitability of the concessionaire.

Key parameters

There are two key parameters for the mechanism: "OMC Threshold" and "Sharing Ratio". Their definitions and implications are explained as follows:

1 *OMC Threshold* is the number of users in which the service fee collected from them will be entirely given to the private concessionaire. The fee collected from users beyond the threshold must be shared according to the sharing ratio. Therefore, the higher the level of the threshold, the lower the financial risk the concessionaire takes.

   Therefore, the OMC Threshold should be at the level just sufficient for operation and maintenance cost. This has two implications. It would keep the concessionaire working hard to improve operational efficiency, while the financial risk of covering operation and maintenance cost becomes small. The public authority can utilize the OMC Threshold as a tool for risk adjustment.

2 *Sharing Ratio* is the ratio that is used to split revenue after OMC payment into two streams for the public authority and private concessionaire. The ratio is determined by profitability of the project. If financial appraisal indicates high profitability, the more revenue should be given to public authority. In such case, the sharing ratio may become 60:40 or 70:30 (public: private). By this concept, the concessionaire's excessive profit would be eliminated. The implication here is that public authority can utilize the Sharing Ratio Threshold as a tool for addressing the excessive profit problem.

In practice, the public authority and private concessionaire would negotiate for these two parameters. The new revenue-sharing scheme is applicable to multiple-subsystem projects with multiple operators. The subsystem with a high operation and maintenance cost (such as underground mass transit) and low user demand may be suitable for the high OMC Threshold and low Sharing Ratio. The subsystem expected to have low operation and maintenance cost (such as elevated mass transit) with high user demand may be suitable for the low OMC Threshold and high Sharing Ratio.

The new revenue sharing scheme proposed here is very flexible for adjustment to match a project's risk and profitability. It eliminates the key disadvantages of those conventional schemes explained earlier. Furthermore, in multiple-subsystem projects with multiple operators, the public authority can set the user fee at the same level across subsystems and use the two key parameters to fine-tune all subsystems to the same profitability level.

IMPROVEMENTS AND ISSUES FOR CONSIDERATION

From the concept and examples explained above, some key improvement and issues for consideration are as follows:

Improvements

1 The new scheme addresses the issue of revenue risk sharing between the public authority and the private concessionaire. The concessionaire does not have to share revenue with the public authority as long as the revenue is lower than OMC Threshold, which is the number of users that can generate sufficient revenue to compensate for operation and maintenance costs. Therefore, the concessionaire has a reasonably low risk of covering operation and maintenance costs, especially when compared to the conventional Percentage-of-Revenue model.

2 The new scheme also addresses the issue of incentive. The concessionaire still has an incentive to improve operational efficiency to reduce operation and

maintenance costs, because gain from the cost reduction is given to the concessionaire, as the OMC Threshold is fixed. Compared to the Revenue-Cap model, the new scheme better maintains an incentive to improve operational efficiency.

3. The incentive to improve service quality is also preserved, because there is no ceiling of revenue. The additional revenue derived from higher user demand because of better quality is not limited, compared to the Rate-of-Return-Cap scheme.
4. The new scheme is flexible and can be used for the Multiple-Operator system where financial configurations are different among subsystems and usage fees are fixed to be equal across the system. The public authority can use the two key parameters to fine-tune all subsystem to the same profitability level.
5. This scheme provide concessionaire with the reasonable and fair revenue-sharing scheme between public authority and concessionaires as well as among operators in the multiple-operator case. This environment would build up confidence for private sectors to invest in infrastructure development, which is the ultimate goal of the Public-Private-Partnership model.

Issues for consideration

The key issue to be carefully considered is the management of the scheme. Transparent measurement of actual user demand is very important, because the key input that determines the revenue given to both parties is the number of users. If the measurement is not performed correctly, then dispute between parties may occur very easily. However, this issue may be solved by modern revenue collection and information technology that is reliable and transparent. In large-scale systems, an independent regulatory unit may be established to take care of this issue.

CONCLUSION

This paper discussed three conventional revenue-sharing schemes: Percentage-of-Revenue, Rate-of-Return-Cap and Revenue-Cap. This paper also pointed out disadvantages of those conventional schemes, regarding risk burden and incentive to improve efficiency and service quality of the private concessionaire. Subsequently, it proposed a new revenue-sharing scheme that addresses the disadvantages of those conventional schemes. The new scheme tries to maintain an incentive to improve operational efficiency and service quality without transferring too heavy a risk burden to the private concessionaire. The new scheme can be used to maintain fairness among operators in the multiple-subsystem project, where each subsystem has different financial configuration as well as expected return. Finally, practical issues related to management of the new scheme are discussed.

MISPERCEPTIONS ABOUT THE ROLE OF ARCHITECTURAL DESIGN AND RISKS IN A PPP PROJECT

Peter Raisbeck[1]

Architecture, Melbourne University, Melbourne, Victoria 3101, Australia

Southern Cross station is to date one of the largest PPP projects undertaken in Australia. This paper describes a survey of 12 executives working in the various organizations associated with the PPP consortium responsible for delivering the project. The aim was to better understand perceptions and misperceptions of the architect's role in relation to the management of project risks arising out of their initial design. The overarching framework used to govern the survey was the PPP lifecycle alongside the idea that architectural design can be viewed as a research and development activity rather than simply as a problem solving activity. In the media, the architect's design was perceived as having impacted on capital or recurrent costs when in fact it mitigated technical and operating risks and had little bearing on the projects substantial write-downs. This counters the perception that the activities of architects and their designs create more risks than they mitigate.

Keywords: architecture, risk management, design, public-private partnerships.

INTRODUCTION

As Public-Private Partnership markets have grown globally, there has been a corresponding rise in research focused on PPPs. This research is broad and ranges across a number of fields including construction management and economics, innovation theory and project management (Zhang 2005; Leiringer 2006). Much of this attention has focused on the experiences in the well-developed UK Private Finance Initiative (Dixon *et al.* 2005; Demirag *et al*. 2004). In contrast, other studies have focused on the role of PPPs in both developed and developing countries (Satyanarayna 2003; PWC 2005). Evident in this body of research is the idea that risk sharing and allocation is 'one of the most important factors for successful PPP/PFI outcomes'. As is often reiterated, 'this means allocating each risk to the party best able to manage it'. In theory, this approach 'reduces individual risk premiums and the overall cost of the project, because the party in the best position to manage a particular risk should be able to do so at the lowest price' (Akintoye *et al*. 2005: 463).

The focus on risk has led PPP research to take two main paths of further research. Evident in these trajectories is a top down approach to PPP research. One trajectory is financial in nature and examines how financial benchmarks are used to manage project risk in the PPP model; in these studies, risk premiums and the concept of value for money are seen as fundamental indicators in PPP projects (Dixon *et al*. 2005; Fitzgerald 2004). The second trajectory is concerned with the governance and management of PPPs (Koch and Buser 2006). These governance studies examine from above how to govern

---

[1] raisbeck@unimelb.edu.au

PPPs at different scales. These scales include the national policies and regulations, project networks, knowledge management and less often the supply chain frameworks that appear to govern PPPs (Akintoye 2003; Corry 2004; Duffield 2001; Grimsey 2002). Nonetheless, in a few studies an overarching and aerial view of PPPs is eschewed in favour of an approach that privileges the user or the “4th P” (Majaama 2005).

PPPs and architecture

In contrast to these predominant trajectories, the aim of this study was to pursue a different, in a sense bottom up, trajectory arising out of the PPP risk allocation concept. This trajectory of research involves examining the extent to which risks in the PPP model are managed from the bottom up via architectural design processes. This is important if PPPs are to successfully deliver local community infrastructure rather than economic infrastructure or infrastructure associated with large bureaucracies such as in the health sector.

The importance of architectural design as an integrative process in PPP projects is underscored by the history of PPP projects. As David Gann, argues “the solutions concept” emerged in the infrastructure projects in the 1980s. These “build-operate-transfer (BOT)” projects can now be seen as the precursors of today’s current crop of PPP projects (2005: 572). In this context, the importance of the architect’s role is also reinforced by Gann who argues that at the design stage the architect is the prime “systems integrator” in building projects (2005: 573). By virtue of their primary and traditional role as the designers of buildings architects are key to conceiving, devising and integrating together various processes of construction innovation (Burry 2003). However, more often than not architects are generally associated with the iconic design of a building: usually, its image and aesthetic. This is despite the fact that the architectural design of a particular a particular PPP (or indeed PFI) project over the longer term has an impact on how that project is perceived and branded. A project’s iconic image, the way in which it enables the branding of a particular place, can obviously affect its overall success in commercial terms (Anholt 2005; Sklair 2005).

Project history and context

This paper extends our research into Southern Cross Station, a hybrid social and economic infrastructure project in Melbourne Australia. The station is, to date, one of the largest PPP projects undertaken in Australia (Raisbeck 2006). In July 2002, the Civic Nexus consortium was awarded the contract for the station. In this deal, Civic Nexus will operate the station for 30 years, after which time the station will revert back to public ownership. The consortium, owned by ABN AMRO Australia, included Leighton Contractors, Daryl Jackson architects in association with the London-based Grimshaw architects Honeywell and Delaware North Australia, a retail and hospitality group. This paper summarizes our survey of 12 executives working in the various organizations associated with the PPP consortium responsible for delivering the project. These stakeholders included senior executive project managers, consulting engineers, financiers and contractors who worked on the project. In addition, pilot surveys alongside benchmark surveys were conducted with the project architects. All the interviews and the identities of the respondents were confidential.

In August 2002, the Victorian state government finalized its agreement with Civic Nexus at which point the station was valued at $350 million dollars and it was agreed that Civic Nexus would also build $350 million worth of adjoining developments. In return, the State government will pay Civic Nexus an annual fee of $AUD 34M. It was calculated that this fee would amount to the government paying $AUD 1762M, including inflation to the Civic Nexus over the 30-year concession period. During this time, Civic Nexus was to be responsible for maintaining the facility.

The initial strategy for the architectural concept for the station was deceptively simple. The geometry of the station's 'wave-like' roof was designed to capture and extract the diesel fumes expelled from the diesel trains using the station without recourse to mechanical ventilation. The primary issues that impacted on the construction of this design was the fact that the station had to operate as the roof was being constructed above it. This limited the construction methods available and, consequently, the roof structure had to be designed as a prefabricated entity with structurally stable components during its erection. Thus, as it was being constructed, the station's roof needed to be clear of the tracks and associated infrastructure including any overhead electrified wires. Despite these issues being anticipated in the Station's EOI documents, constructing the station was problematic and, by May 2004, Leighton indicated that the project would seriously impact on company profits. At this point in time, Leighton cited the confined working environment, site access issues, the 'demands of the franchisee train operators' and 'complex design variations' as the causes of their problems. On 6 May 2002, Leightons issued a statement to the Australian Stock Exchange indicating that these issues were resulting in time delays on the project and consequently Leighton downgraded its profit forecasts and eventually wrote down $AUD 150M on the project.

RESEARCH METHODOLGY AND SURVEY DESIGN

In the media, the Station's unique wave-like roof design – the element that constituted the project's design signature more than anything else – was often perceived to be linked to the contractors' write downs on the project. Indeed, one respondent in our survey exclaimed: "Architects! What would they know about managing risks? " In response, the aim of this research was to understand and corroborate the activities of the architects in relation to the management of project risks arising out of their initial conceptual design. For some contractors and consultants, architects and their designs are often perceived as being the source of risk rather than being seen as risk managers. This points to the disciplinary schism that often exists in the Australian building and property industry. Indeed, much Australian construction management research is framed in terms of a contracting perspective rather than from the perspective of design innovation. Consequently, in Australia, the role of architectural design and its relationship to different procurement models and risk management tends to be downplayed (Manley and Blayse 2004).

Project phases

To begin to understand how design is linked to risk in this context, the overarching framework used to govern the research design of the survey was the PPP lifecycle. This concept enabled us to ascertain what activities the architects undertook during each phase of this lifecycle. This helped us to structure the survey in order to identify what risks the architects were managing in each of these phases and how their management of risk was perceived by other stakeholders. The phases in the survey were defined in the following terms:

Phase 1: project development (including EOI, tendering/bidding)
This stage included up to the end of bidding: initial briefing and project analysis; conceptual design of project; formation of the project team; and design of the project's financial structure.

Phase 2: design development and documentation process
This stage included: the development of the conceptual design with users and consultants; integration of logistical needs with the design; and further integration of the project's construction costs.

Phase 3: construction
This stage included: the construction of the project; the resolution of further design issues as they arose; the ongoing negotiation of logistical issues with user groups; and the management of budget with construction costs of as they arise.

Phase 4: conclusion and operation forecast
This included open questions regarding the overall impact of the architect's involvement with the project. It also addressed issues regarding the likelihood of any future building maintenance and design works.

Using the above organizing framework, the survey instrument was developed as a matrix to understand how the activities of the architects were perceived. As described below, these activities were defined and the survey respondents were then asked how these activities either contributed to or mitigated various risks in the PPP lifecycle.

Defining architectural activities in the survey
In the survey, architectural design was defined as a research and development activity rather than as a problem solving activity. Hence, it is viewed here as a process of research in order to develop new forms and ideas about buildings. This approach conforms to recent studies in architectural theory which argue that design, especially architectural design, is a research activity in its own right. In this view, architectural design is seen as a process whose task is not to simply optimize buildings in either functional, spatial, material economic or terms. Instead, it is viewed as a means to research, explore and experiment with new forms and ideas about buildings. In other words, it is as an activity of research in its own right, which results in innovative solutions and customized products that respond to complex situations. Southern Cross Station can thus be regarded as a complex product in which the architects of the station used the project as an opportunity to research and develop new innovations in regards to environmental performance.

These ideas prompted us to look to studies of R&D teams in order to define the activities of the architects. The definitions of these activities were based on a previous study into teams in the biomedical area (Mann *et al*. 2005). Based on this work, we define architects as the "information brokers" who assist in "orchestrating cooperation and knowledge growth to achieve innovation outcomes" (Mann *et al*. 2005). This helped to clarify what it was the architects did in each phase of the project. In line with this in the survey instrument, we defined the activities of the architects in the following ways:

- Creating design knowledge: researching design ideas, initiating new design approaches and solving problems through design.
- Design monitoring: providing advice on design issues, ensuring the design meets aesthetic, architectural and spatial requirements, and ensuring the design meets established cost and planning levels.
- Design liaising and management: communicating and negotiating design ideas to the client group, communicating to project team, planning and coordinating with the project team, and engaging in activities to build relationships within the team.

A scale of zero to five was used to gauge these responses: zero indicating that the architects did not undertake the activity and five indicating that the respondent perceived that the architect undertook the activity a great deal.

The intent of the above definitions was to actively counter the perception that architectural design is an ephemeral and entirely subjective or aesthetic activity. In contrast, it is conceived as a unique and often one-off activity. An activity that, in this instance, created new knowledge that encompassed both exploitative and exploratory notions of innovation (Benner and Tushman 2003). From this perspective, the architect's initial design produced prior to the bidding decision can be seen as the result of exploratory innovation that they then refined after they won the bid using exploitative modes of innovation.

Defining risks in the survey

Defining risks in the survey was more straightforward than defining the activities of the architects. Definitions of risk are more readily understood and these were adapted from work in the area of project and risk management (Jaafari, 2001) and related to a number of project specific risks including financing (including cost estimate risks), technical, integration, and environmental and operating risks. These were described to the survey respondents in the following ways:

- *Technical and operating risks:* probability that the project will not perform to required technical standards or to its required functionality.
- *Environmental and energy risks:* probability that the project will have adverse environmental impacts beyond permitted limits or have excessive operating energy consumption.
- *Capital costs risk:* probability that funds allocated to the project will be insufficient or that project will run over allocated time and consequently incur further costs.
- *Recurrent costs risk:* probability that the forecast income from the project will be below expectations or that the facilities brand image is diminished.

Again, as with the activities of the architects, a scale was used to assist in quantifying responses. The survey instrument employed a scale ranging from negative five (greatly mitigated) through to zero (no effect) through to five (greatly added to). In the tables presented here, this has been converted to a scale that ranges from zero to eleven.

The pilot survey

The survey was piloted with a small number of respondents prior to the full survey of 14 respondents. The respondents to the pilot surveys were familiar with both the project and the PPP model itself. The pilot surveys assisted in ascertaining the length of the survey in time (most respondents were interviewed between 30 and 55 minutes). More importantly, the pilot surveys helped to confirm and modify the relevance of the above defining terms including the PPP project phases, architectural activities, risk categories as well as the wording of the open ended questions and the usefulness of the scales.

DISCUSSION OF RESEARCH RESULTS

Perceptions of risk and the architect's role

In order to examine perceptions about the architect's activities and their initial concept, a matrix based on the survey data was designed to analyse how well they mitigated risks.

This was designed to identify any significant correlations between the creation of design knowledge in Phase 1 and perceptions of risks or financial losses related to either capital costs or future operating costs. This analysis was important because when first announced the redevelopment of Southern Cross was broadly promoted, and indeed branded, as a place which would be ‘a state-of-the-art’ design (Das and Costa 2000) Consequently, during the course of its construction the project had received a great deal of media attention. Indeed, the station’s iconic roof design was often cited in the media as a primary cause of the difficulties encountered during construction.

The survey responses appeared to confirm the way we had defined the activities of the architects and the role which the architects undertook (Table 1). From the open interviews, the ongoing activities of the architects and their ability to manage risks throughout all phases of the project were also reinforced. This result counters the perception that the architects were only interested in creating a conceptual or strategic design and that the architects did little to manage this design after Phase 1. Such a perception appears based on the premise that that once an architect creates a design, they then have little involvement with a project's construction management. This creates the more alarming impression that architects create risk in their designs that contractors then manage and “mop up.” However, as discussed below, all the respondents in our survey appeared to agree that throughout the projects phases, the architects were actively involved in creating design knowledge, design monitoring and design liaison and management.

Architect’s role and recurrent and capital costs

The executives in our survey perceived the architect’s initial design as mitigating operating and technical risk more so than either mitigating or exacerbating risks related to cost. This is borne out in the correlation analysis. Creating design knowledge in Phase 1 was negatively correlated with creating technical and operating risks (Pearson Correlation $r = -0.691$). In the media, one widespread perception was the concern that the station’s roof would not act to remove exhaust fumes as it was intended. However, our analysis suggests the opposite perception might be a factor. In other words, by creating unique design knowledge, by addressing issues of environmental performance in the Station’s roof design, technical and operating risks in the longer term are decreased. Surprisingly, creating design knowledge in Phase 1 was not associated with increased capital and recurrent cost and these appear appeared to be less significant (Pearson Correlation $r = -0.564$ and $r = -0.633$ respectively).

In Phase 2, the architects felt that they were still creating design knowledge whilst the other respondents saw this as having been primarily created in Phase 1. During this phase, the survey respondents felt that the architects were not creating as much design knowledge as they had in the second phase of the project. In contrast, the architects themselves felt that they were creating more design knowledge in this phase than in Phase 1. This is perhaps because during Phase 2 the architects were actively working with both the structural engineer and the steel fabricators to realize the initial conceptual design. Nonetheless, the survey respondents tended to agree that design monitoring, liaison and management increased in Phase 2 and then decreased slightly in Phase 3 the documentation period. This would suggest that the executive stakeholders tended to see the architect’s role as one that is primarily concerned with creating the initial conceptual design.

Table 1: Executive stakeholder perceptions of architectural design activities (means reported; 5 max)

	Architects	Others
Phase 1 Activities		
Creating Design Knowledge	4.50	4.00
Design Monitoring	3.25	3.67
Design Liaison and Management	3.00	3.44
Phase 2 Activities		
Creating Design Knowledge	4.75	3.38
Design Monitoring	4.75	3.79
Design Liaison and Management	4.25	3.83
Phase 3 Activities		
Creating Design Knowledge	3.50	2.68
Design Monitoring	4.50	2.95
Design Liaison and Management	4.00	3.09

In Phase 2, it could be argued that the architects perceived that they had actively been engaged in what might be called systems integration by undertaking design liaison and management. This is because in Phase 2 the most significant correlations were between the activity of design monitoring and technical and operating risks (Pearson Correlation r = - 0.606) and integration risk (Pearson Correlation r = -0.686). This suggests that the more the architects actively monitored and co-ordinated the more technical, operating and integration risks were minimized. This is also reinforced in Phase 3 in which design liaison and management appeared to have some correlation with decreasing integration risks (Pearson Correlation r = - 0.617) and more significantly decreasing capital cost risks (Pearson Correlation r = -0. 788). This correlation indicates clearly, despite the small sample size of this survey, that the activities of the architects may have lessened capital cost risk rather than increased them on the project. This is underscored by the fact that a number of the survey respondents recognized that the architects had worked to protect the commercial viability of the project in functional terms.

Not surprisingly, the architects themselves felt that they foresaw a number of risks early in Phase 1 of the project including risk concerning the projects, constructability. Moreover, the architects were extremely concerned that the contractors had not employed a time programmer and they were not party to cost planning decisions at an early stage of the process. Perhaps this is why across all the project phases there appeared to be some correlation with the lessening of integration risks with an increase in design monitoring activities (Pearson Correlation r = -0 .694).

Table 2: Executive stakeholder perception of risk created or mitigated by architects (means reported: 1 greatly mitigated; 6 no effect; 11 greatly added to)

	Architects	Others
Phase 1 Risks		
Technical and Operating	3.25	5.70
Environmental and Energy	3.50	5.10
Integration Risks	4.00	5.78
Capital Costs	5.50	5.85
Recurrent Costs	4.25	5.15
Phase 2 Risks		
Technical and Operating	1.25	5.00

Environmental and Energy	2.25	4.63
Integration Risks	2.25	5.00
Capital Cost Risks	2.75	6.13
Recurrent Cost Risks	5.25	5.42
Phase 3 Risks		
Technical and Operating	1.00	4.91
Environmental and Energy	2.50	5.18
Integration	4.25	5.14
Capital costs	3.50	5.64
Recurrent Costs	5.00	5.05
Overall Risks		
Technical and Operating	2.25	4.17
Environmental and Energy	1.75	4.58
Capital costs	4.00	6.71
Recurrent Costs	4.00	5.13

Overall, survey respondents more directly concerned with project delivery were obviously satisfied with the way in which the architects had managed risks. Table 2 indicates that the activities of the architects only managed to reduce or mitigate risks on the project to slight degree (range: 4.17 to 6.71). These results were confirmed in our interviews in which many of the survey respondents indicated that many of the risks, and financial losses, accounted on the project arose due to having to construct the station's roof whilst it was still operating. This was compounded by poor cost planning and programming alongside the unforeseen complexities of negotiating with a number of stakeholders who had jurisdiction over the station such as bus and rail operators. Consistent with the data gathered in relation to the architect's activities, the perceptions of how the architects managed risks seem to be more favourable than less favourable.

Table 3: Executive stakeholder perception of overall risks created or mitigated by the architects in Phase 2 (means: 1, greatly mitigated; 6 no effect; 11 greatly added to. Architects: Respondents A and B)

Risk category	**Project Executives**													
	A	**B**	**C**	**D**	**E**	**F**	**G**	**H**	**I**	**J**	**K**	**L**	**M**	**N**
Technical and Operating	1.5	1	3.5	3	2.5	2	7	3	8	5	4	8.5	10.5	3
Environmental and Energy	2.5	2	2.5	3	2.5	6	6	2	3.5	6	1	8.5	10.5	4
Integration	1.5	3	2.5	6	6	2	4	2.5	6	5	2	8.5	10.5	5
Capital costs	1	4.5	3	5	3.5	3	6	5	5	8	6	11	11	7
Recurrent Costs	4.5	6	4.5	3	4.5	3	2.5	5	6	5	6	10.5	11	4

Naturally, the architects themselves felt that their activities had significantly reduced project risks as had, most of the other key decision makers on the project. A small number of respondents felt that the architects had significantly added to the project risks (respondents I, L and M). This appeared to be the case with those project executives responsible for the Facilities Management and ongoing operations of the project after delivery. These respondents did not work with the architects during the design and design development stages of the building. Moreover, at the time of the survey, some parts of the building were still being commissioned and this may have influenced their criticism of the architects.

Taken together, both the descriptive statistics and the correlations indicate that the architects were able to develop an innovative conceptual design and then manage the risks associated with this design throughout the procurement process. In this project it was the capabilities of the architects to monitor this design and to communicate, plan, and negotiate various aspects of this design with other team members that was most important. This seems to be in accord with Gann's concept that architects are systems are "systems integrators" with a significant role in leading processes of design and construction innovation construction (2005). Such a view is at odds with other AEC professions and disciplines and this may be because perceptions of innovation is different for architects than contractors. Ankrah and Langford argue that the organizational culture of architects is quite different to that of contractors (2005). For example, they argue that architects have a greater tolerance of ambiguity than contractors do, and that for architects power is to be found in skills and expertise. For contractors it is to be found in the fostering and development of relationships. From this perspective, this research indicates that it is important to focus on the ways in which architects use their skills and expertise in relation to both create innovative conceptual designs and then to manage risks in the building procurement process.

FURTHER QUESTIONS

What the above results suggest is that the initial conceptual design despite its innovative features had very little bearing on project risks across the project. Whilst it was perceived by some, particularly in the media, that this initial design may have impacted on various risks this survey of project executives indicates that it in fact mitigated technical and operating risks an had little effect on capital or recurrent costs. Perhaps this was because they recognized that the architects had little direct control over cost planning. This is surprising given the fact that the contractor wrote down $150 million dollars on the project and promoted the idea to the media that design variations was one of the reasons for this loss. However the analysis of this project points to a range of issues that led to these write-downs, not the least being the mispricing of risk in the project at an early stage of the project. Whilst these general conclusions might appear to be favourably biased towards the architects but the general consistency of the responses of our survey's respondents points to the effectiveness of their activities.

This study, limited as it is, establishes that the activities of the architect were critical in managing the risks that arose out of the initial design. It points to the idea that architectural design is an activity that is often called upon to mediate between issues of overarching urban governance and fundamentals of financial risk. How do we manage the risks created by innovative designs? In the PPP model, where should the initial design and the further elaboration and creation of design knowledge take place? Should this be before or after the bidding process? When a company or organization chooses a particular procurement model, how should the role of the architects be considered? For example, would the contractors have written down so much on the project if the architects had more input into time and cost planning decisions? Whilst these questions may appear unnecessarily rhetorical, they point forward to considering further the role of architects in the procurement process. How should the role of the architect be accounted for in studies and theories of procurement?

CONCLUSIONS

In this project, the architects created a design that required a number of significant construction innovations. If we are to regard architects in having a role that creates new knowledge through an exploratory process of design, how is this to be factored into production theories of construction? Moreover, it is clear from this study that further research could be conducted that examines how the architects, contractors and facility mangers manage design and innovation in complex projects; in other words, how do they integrate various systems and sub-systems each project? It is important to answer this type of question because contractors are called upon more and more to deliver both the services and some of the solutions for a particular facility during the concession period. Overall, these ideas are useful because they point to the importance of theorizing the building procurement or production process as one that should take into account the role of architectural design. But more importantly this points to the need to understand the procurement process in greater detail from the bottom up rather than the top down in order for the PPP model to be itself better designed in the future.

ARE PUBLIC–PRIVATE PARTNERSHIPS EFFECTIVE INFRASTRUCTURE DEVELOPMENT STRATEGIES?

Michael J. Garvin[1]

Myers-Lawson School of Construction, Virginia Tech, 200 Patton Hall, Blacksburg, VA 24061, USA

Public-Private Partnerships (P3) have emerged over roughly the last two decades as a popular strategy for infrastructure development worldwide. Initiatives within the United Kingdom, Australia and Canada are well known while the use of private capital for infrastructure projects within emerging economies has become a global trend. Within the US, P3 arrangements have been used somewhat selectively thus far, but their momentum is building as states put enabling legislation in place to permit public-private initiatives and as "successes" such as the recent leases of the Chicago Skyway and the Indiana Toll Road are reported. Proponents of P3's tout numerous advantages while detractors often claim that the marginal benefits rarely materialize or that they are obtained at too great an expense. Thus, the question arises, are P3s effective as infrastructure development strategies? A research initiative is underway to answer this question in the context of the US. Thus far, the work has: (a) synthesized notable literature regarding P3s and infrastructure development, (b) developed a framework to measure the effectiveness P3s at the programme and project level, and (c) begun a longitudinal case-based study of both P3 programmes and projects where the framework is applied. Preliminary results are presented and discussed. While the research has not progressed far enough to make categorical conclusions, the early findings suggest that P3 initiatives in the US have had limited effectiveness and that the future success of these endeavours may depend upon establishing national guidelines for their implementation and assessment.

Keywords: contracting, infrastructure development, procurement, programme/project delivery, public–private partnerships.

INTRODUCTION

The public-private partnership (PPP or P3) movement is arguably the most significant, worldwide trend in the public sector. The United Kingdom's *Private Finance Initiative*, which began in earnest in 1992, has facilitated the delivery of nearly 800 projects valued at over £54 billion ranging from car parks to schools to tolled highways to power plants (HM Treasury 2007). Similarly, Australia's *Partnerships Victoria* programme has contracted 16 projects representing roughly $4.5 billion in capital investment since 2000 (State Government of Victoria 2007). Outside the developed world, the use of private capital for infrastructure projects within emerging economies has become quite common where financially challenged public administrations look toward the private sector to develop basic infrastructure (Esty 2003). In fact, a survey of a dozen national governments across the globe in the late 1990s indicated that a significant majority of the respondents expected "that the most successful government structure in 2010 will be one in which government focuses on policy and project/supplier management, allowing the private sector to deliver most

[1] garvin@vt.edu

traditional public services." (Economist Intelligence Unit 1999). Indeed, the prediction made by the survey's respondents seems on its way towards realization.

Within North America, Canada has seen its fair share of P3 activity within its provinces. A notable project is the Confederation Bridge, which was a design-build-finance-operate arrangement that established a fixed link between the mainland and Prince Edward Island. Another is the lease of the 407 Express Toll Route (ETR), where in exchange for nearly Cdn$3 billion a private sponsor leased this facility from the government for 99-years. Within the United States, activity in this market has started to pick up. Currently, over 20 states have enabling legislation in place that permits some form of public-private initiatives on state transportation projects (FHWA 2007). In addition, the recent leases of the Chicago Skyway and the Indiana Toll Road have attracted the attention of governments to investors (Gribbin 2006; Florian 2007). Still, only a few states – Indiana, South Carolina, Texas and Virginia – are truly active on this front.

Clearly, the interplay between (a) the general reluctance of public agencies and governments to raise taxes, (b) the emergence of private sector participants which are willing and most capable of handling the risks and delivering the services of infrastructure, and (c) the realization of pension fund and institutional investment managers of the attractiveness of privately financed infrastructure projects to the risk/return requirements of their clientele is driving the progress of this market. P3 activity or output, though, does not provide any indication of the effectiveness of such programmes or projects. Performance measurement theorists will certainly suggest that outcomes are far more important than output. Moreover, infrastructure is fundamentally a public good (infrastructure clearly is not a "free" good, as many consumers perceive since its costs are veiled by the variety of mechanisms used to fund its development and management). As such, the public has a right to expect that it provides a satisfactory level of service, has a reasonable price, and allots its benefits and costs equitably. This begs the question, are P3 outcomes better than or at least equal to more traditional infrastructure development and management strategies? Moreover, what is necessary for this market to develop and realize its potential? These questions motivate this research initiative, which is subsequently described and which benefits substantially from the groundbreaking work already done by various governments, agencies, professionals and researchers.

BACKGROUND

Characterization of P3

Any discussion regarding the P3 movement must start with an attempt to characterize and define this approach to project and/or service delivery. Unfortunately, a concise characterization is elusive. Kingsley and O'Neil (2004) presented a conceptual framework and model designed to assist with the development and measurement of P3 initiatives, but their model is founded upon the premise that P3 arrangements are truly "partnerships" where each partner has the perspective that their organizational identity and competitive advantage are enhanced through participation in the partnership. Examination of definitions offered by various parties such as the US National Council for Public-Private Partnerships, the Canadian Council for Public-Private Partnerships, and the National Government of the United Kingdom suggest that this is not the type of arrangement either sought or established in the infrastructure sector (Garvin and Chiara 2006). In truth, most P3 guidance documents emphasize the significance of clear and enforceable partnership “conditions”. In fact, one of the preconditions for success identified by the International Monetary Fund is whether the quality of services is “contractible”. Given these circumstances, this working definition is proposed for the infrastructure community: *A Public-Private-Partnership (P3) is a long-term contractual arrangement between the public and private sector where mutual benefits are sought and where the private sector provides operating services and/or puts private finance at risk.* Notably, this definition excludes the transfer or sale of infrastructure assets or services to the private sector. The transfer of an asset or service qualifies as “privatization”; this distinction is more than semantic. P3 arrangements are governed by contracts and the accompanying body of contract law. Privatizations are regulated enterprises where the governance and legal structures are quite different.

As Orr (2006) indicated, cash-strapped governments are quick to proclaim that private capital is a solution to infrastructure funding shortfalls and is an often used argument for P3 arrangements. This claim by governments is somewhat contentious. Since P3 projects typically require user fees, a government certainly has the capacity to use these fees as the principal security for the financial arrangement while also offering its general creditworthiness as secondary security. One would expect that the cost of capital for such an arrangement would be lower than the cost that a private sponsor could obtain, even if tax-exempt status is granted. Gribbin (2007), however, has argued that innovative private financing debt-equity structures can free these assets from the conservative bond investor clientele. Indeed, he may be correct. The holders of government bonds or even private tax-exempt bonds have relatively conservative appetites for risk, which introduces fairly conservative methods for assessing value. Alternatively, an entirely private debt-equity structure introduces investors with higher tolerances for risk, which will in turn tend to generate more liberal appraisals of asset value. While the cost of capital may indeed be higher, the perceived value of the asset under scrutiny is also likely higher. This notion was confirmed in an interview with an executive from the Fluor Corporation, who indicated that he would prefer to avoid tax-exempt status on privately financed projects because this typically introduces layers of financial conservatism that he viewed as unnecessary (personal communication, Herb Morgan, 26 April 2006).

Nonetheless, the state and society should demand more than an economic premium for granting the private sector the right to develop and/or operate facilities that are generally public goods. Indeed, the private players in this arena have the expertise, the agility, and the incentive to provide more – a higher quality of service, a reasonable price for the service, faster availability of the service, and net contributions to the environment. Otherwise, their expertise is wasted. Moreover, the risks of transferring these responsibilities to the private sector could be too great.

Relevant literature

State guidance documents

The United Kingdom has issued a variety of documents regarding P3. One of the most significant is the *Value for Money Assessment Guidance* document, which describes in great detail the procurement process for such projects. In Australia, the *Partnerships Victoria* document provides similar information. The central proposition of these guidelines is that P3 arrangements should always be considered for infrastructure development or service delivery, but they should only be pursued if they deliver **value for money**, which is loosely defined as the optimum combination of lifecycle costs and quality to meet user requirements. Each document attempts to clarify the process for conducting such assessments. Indeed, the manuscripts have a spirit about them, but they are very mechanical in nature. Similarly, Australia's *Contract Management Policy* document outlines the steps necessary to ensure proper allocation and management of the responsibilities and risks during a P3 concession. Likewise, Canada's *Public Sector Comparator* document is a self-help guide for government officials at all levels who may be considering P3 arrangements. As with the comparable UK and Australian documents, it aims to provide a tool for assessing the viability of a P3 project by comparing its benefits and costs with those of the project if it were delivered in a more traditional way. One interesting difference between the jurisdictions is the nature of governance. In the UK, for example, the national government has shaped the policy and fashioned the conditions that define the "partnerships" formed between the public and private sectors. Alternatively, in Canada, many public-private partnerships have been struck by provincial or local governments without a well-defined national policy or framework. The situation in the United States is identical to the one in Canada.

Other literature

The academy has produced numerous articles about P3. Many have addressed key, general components of P3 arrangements such as Chua *et al*. (1999). Zhang (2005) identified a variety of success factors and ranked them in order of importance through surveys of industry personnel and academics. Bing *et al*. (2005) grouped success factors into five categories: (a) effective procurement; (b) project implementability; (c) government guarantees; (d) favourable economic conditions; and (d) accessible financial markets. Other articles have looked more closely at specific P3 initiatives. Akintoye *et al*. (2003) used interviews to determine how best to achieve success in Private Finance Initiative (PFI) projects in the UK. They found that identifying and properly allocating risk, curtailing cost escalation, improving project completion times, introducing innovation, and reducing maintenance costs can help lead to successful projects. They also identified several challenges to achieving best value, such as the high cost of management, lengthy negotiations, and complex contractual relationships. Russell and Nelms (2006) discussed the implementation of Canada's *Public Sector Comparator* guide; their conclusion was that in practice a lack of clarity in the tool opens it up to a number of unintended uses as well as a variety of abuses that result from agenda-driven applications. Additional work has focused substantially on the risks of P3 projects. Froud (2003) discussed the risks of PFI projects and how the private sector must genuinely assume the risks given to it. He argued that value for money could only be achieved if private sector expertise, innovation, competitive efficiency, and risk transfer can overcome the increased transaction, contracting, and negotiation costs – not to mention the additional need for economic profit. Quiggin (2005) detailed aspects of risks in P3 arrangements, including the notion that partnering creates new risks. Finally, Loosemore and Ng (2007) identified the public and private risks in P3 arrangements and suggested how to best allocate them.

RESEARCH DESIGN

Fundamental propositions of the work

This endeavour takes a very particular view of the P3 movement, which is based upon past and current research by others *and* the writer's involvement in case-based research of large-scale infrastructure projects over the last decade. Many of these cases are reported in Miller (2000) and Miller (2002) (a number of cases have also been converted into educational case studies, which are available from the writer's website). These influences have produced two fundamental propositions that constitute the basis of the current work.

- **Proposition I –** the basic objective of a *P3 Programme* is to nurture the development of this market and to sustain its existence. To do so, a P3 Programme must establish equilibrium among four environments: (1) the state, (2) society, (3) industry, and (4) the market. Figure 1 depicts this notion conceptually.
- **Proposition II –** *projects* are the operational expressions of any P3 Programme. As such, any particular project can either maintain the equilibrium of the overall programme or distort it. Further, the collective performance of all projects will determine whether the P3 Programme is effective as a strategy or policy for infrastructure development & management. Each P3 Project should seek to provide a marginal improvement in one or more of the following areas: (a) quality of service; (b) price/cost of service; (c) time of service availability; (d) level of environmental impacts; and (e) equitable distribution of social benefits.

Certainly, neither proposition is entirely original or groundbreaking. Indeed, the equilibrium framework illustrated in Figure 1 incorporates concepts presented by Lessard and Miller (2000) regarding the risks of large engineering projects and by Linder and Vaillancourt Rosenau (2000) about the terrain of P3 arrangements, as well as other fairly familiar socioeconomic notions. Still, these propositions represent an important synthesis of ideas derived through grounded research, from relevant literature, and from common thought. Moreover, they provide the reader with a clear perspective of the underpinnings of the research, which found the entire programme.

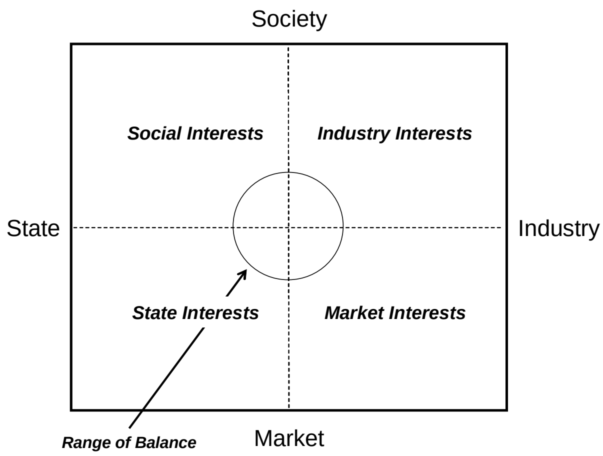

Figure 1: P3 equilibrium framework

Figure 1 shows four continuums (state, society, industry and market), four quadrants (social interests, industry interests, market interests and state interests) and a central space dubbed the "range of balance". The "state" is the elected or allotted body governing a jurisdiction. "Society" is the citizens living and working within a jurisdiction. "Industry" is the enterprises engaged in providing services & goods to the state and society within the jurisdiction. Finally, "the market" is the financial system that allows investors to exchange wealth and risk through time.

This framework is relatively flexible; in fact, a more general illustration of the relationships between the continuums and the quadrants may help to explain its relationship to P3 programmes. The extreme positions are found at the corners of the framework. For instance, when activities of the state and society are heavily, or even absolutely, aligned "pure socialism" exists. Similarly, absolute state and market alignment produces "big government", absolute market and industry alignment results in "unbridled capitalism", and absolute social and industry alignment relies on "pure philanthropy". The point of this description is not to comment upon the costs/benefits associated with these extremities, but rather to "calibrate" the reader's perspective.

The depiction in Figure 1, however, does take a particular stance; it advocates that the long-term success of a P3 programme depends heavily upon establishing a balance between the interests of the state, society, industry and the market. More than likely, creating a discrete "point" is not feasible, particularly since P3 projects are likely to scatter themselves into the various quadrants since each project's conditions will vary. *However, the central hypothesis of this work is that the scatter of a programme's projects must cluster within the 'range of balance'*. Otherwise, the programme will ultimately suffer from **bias** toward a particular quadrant (such as a clustering in the social interests region) or from **instability** if no clustering is observed at all. Thus, the equilibrium framework helps to establish the boundaries for the overall programme, and it provides a platform for plotting the general location of each project and evaluating a programme's evolution.

Research methodology

The research is continuing the longitudinal, case-based approach to study the effectiveness of P3 Programmes & Projects, and the framework just discussed provides the "basis" for the evaluation of effectiveness. As with all grounded or case-based research, the importance of construct validity (establishing correct operational measures for the concept under study) and reliability (demonstrating that the operations of a study are repeatable) are paramount to this endeavour (Yin 1994). Construct validity will be maintained by using multiple sources of evidence: (a) source documents such as enabling legislation, programme guidelines, RFP's and concession agreements; (b) third-party documents such as periodical articles, archival literature or position studies or papers; and (c) structured interviews with the principal parties involved. These various sources of information should "triangulate" to produce a credible chain of evidence. Reliability is achieved by applying a consistent study protocol throughout.

This approach, however, is not without its limitations. Foremost, the number of contemporary P3 initiatives in the US is limited, and while sampling would certainly help to solidify the findings of the research, to do so, would require expanding the scope of the study beyond the US. While this is clearly possible since the worldwide use of P3 is substantial, it is not necessarily feasible in the short-term, if the thoroughness of the methodology is to be maintained. In addition, experience to date suggests that obtaining the cooperation of principal stakeholders for structured interviews can be difficult since often these arrangements are politically 'charged'. This condition hinders, but does not prevent, establishing a credible chain of evidence.

Analytical techniques

The P3 Equilibrium Framework provides the perspective for the research, but it does not provide the tools necessary for *measurement*. At the programme-level, the analysis measures the *institutional environment* in two areas: (a) the soundness of the enabling legislation that typically initiates any P3 Programme and (b) the viability of the executive guidelines established as a result of the legislation. Table 1 depicts a variety of elements and issues for consideration as well as the impact of each when evaluating a programme's enabling legislation.

Table 1: Enabling legislation template

Element	Issue		Impact	Element	Issue		Impact
	Source of definition	Solicited Only	–		Comparative analysis	Not addressed	→

Legend: – No movement from origin; → Toward industry/market interests; ← Toward social/state interests; ↙ Toward state interests; ↖ Toward social interests; ↗ Toward industry interests; ↘ Toward market interests; ✓ Positive impact on P3; X Negative impact on P3

The ‘impact’ column illustrates the general direction of movement away from the equilibrium framework’s origin for a given condition; this is a ‘likely’ impact, so judgment is necessary to determine if the likely ‘vector’ is indeed correct for the case at hand. To illustrate, consider the element *scope of work or service*, which has several issues identified. For the issue “Source of Definition/Unsolicited Allowed”, an impact vector points to the right and down. This suggests that if the enabling legislation permits the state to receive unsolicited proposals for P3 arrangements where the scope of work or service has been defined by the private sector, then the locus of the P3 Programme would move right and down from the overall framework’s origin. The skew is down since an unsolicited project will require a reliable revenue source to generate the required ROI; therefore, this condition would push the programme toward *market interests*. A similar template exists for evaluating executive guidelines. In many ways, the executive template determines whether “holes” in the enabling legislation are filled or not by the agency responsible for the conduct of the programme. Ultimately, the programme-level assessment gauges whether a P3 Programme “gets off on the right foot” or not by identifying the general location of the origin.

At the project-level, the more general aspects of the programme become operational and therefore are more detailed. Thus, this stage of the analysis considers the project details of five major categories: (a) market conditions, (b) socio-environmental conditions, (c) acquisition & procurement process, (d) concession management, and (e) project performance, as illustrated in Table 2. Each category has a particular focus, and its criteria are similar to those used to evaluate a programme. For instance, evaluation of the *acquisition & procurement process* focuses upon determining whether or not this process preserves the state/society’s interests while also attracting private industry and introducing market forces. Several basic principles are fundamental to this balance such as scope definition, transparency, and competition. Garvin (2003) discusses these principles further.

The *project performance* category, however, is unique among all of the categories. This category does not ‘move’ the location of a project within the quadrant space. Instead, it either **reinforces** or **weakens** the P3 strategy for infrastructure development. If a P3 Programme’s projects do not produce tangible improvements in service quality/innovation, competitive or equitable prices for such service, and reasonable progress in service availability, then the viability of the approach itself is questionable, regardless of whether the proper balance has been struck.

Similar to the programme-level templates, this analytical tool supports locating a project within the equilibrium framework’s quadrants. For instance, consider “Acquisition & Procurement/Selection criteria & process/Transparent". This aspect of the template measures the selection process’ transparency – the notion that all stakeholders in the acquisition system, particularly the private respondents, can see and understand the acquisition/procurement process prior to its execution or prior to making a commitment to participate. A transparent system maintains the current equilibrium, while a less than transparent one will move the equilibrium toward state interests since this is likely to provide the state tremendous discretion in its selection of a vendor. Once all of the elements are assessed, a project can be located within the quadrants. As subsequent projects are evaluated, a cluster should develop.

Some might demand more “precise” measurements. This is not necessary, nor likely. First, the framework is intended to serve as a guide to channel the assessment effort not as an instrument to pinpoint an exact location. Second, quantifying all of the factors involved and establishing correlations between them would be a monumental, if not impossible, task. Moreover, its complexity could easily diminish its credibility since such an effort would undoubtedly create a "black-box". The techniques employed must be accessible to all of the stakeholders involved. Otherwise, the results of the research will not transfer as widely and as deeply as desired.

Case studies
Some of the cases being used in this research are shown in Table 3; they are categorized as either first or second-generation programmes or projects. This separation allows an interesting by-product, the appraisal of learning over time.

Table 3: Selected case study programmes & projects

EXAMPLE P3 PROGRAMME & PROJECT ANALYSIS

California's AB 680 Programme & Projects

In 1989, California launched one of the United States' first P3 initiatives since World War II to confront transportation funding shortfalls. Bob Poole of the Reason Foundation, among others, suggested that California might consider having the private sector propose and finance transportation projects (Poole 1988). Soon after, Assembly Bill 680 (AB 680) was enacted; in sum, the bill gave the California Department of Transportation (CalTrans) the authority to award up to four demonstration franchises to private firms. At least one project each had to be located in Northern and Southern California. The franchises would grant exclusive rights to finance, design, construct and operate toll transportation facilities. A proposed project could not utilize any state or federal government funds in the financial package. Finally, franchise holders would be allowed to receive a 'reasonable' rate of return, although a definition of 'reasonable' was not given by the legislation. Any monies beyond this would be required to be applied toward debt principle balances or paid into a State Highway Account.

Subsequently, CalTrans developed a procurement process to solicit interest, qualifications, and conceptual proposals from respondents. In 1990, CalTrans received eight conceptual proposals and selected four projects: (a) the SR 91 Express Lanes, (b) the Santa Ana Viaduct Express (SAVE), (c) SR 125, and (d) the Mid-State Tollway. The SR 91 Express Lanes was the only project to proceed quickly. By 1995, the project had installed four lanes within the median strip of 10 miles of SR 91, an existing eight-lane state route, at a cost of $126 million; the base rate of return expected by the project's developers was 17%. These lanes functioned as High Occupancy Toll (HOT) lanes, where passenger cars with a single driver can pay to utilize the express lanes while high occupancy vehicles can use the lanes free of charge. Interestingly, the project's developers obtained a very favourable "no-compete" provision in the concession agreement, which prevented the Orange County Transportation Authority (OCTA) or CalTrans from making any transportation improvements within a specified region. By 2001, OCTA began to view this no-compete provision as a tremendous constraint to transportation service in the region. Instead of legally challenging this provision, OCTA purchased the Express Lanes back from the developer in 2002 at a price of $207.5 million.

Of the remaining three projects, only SR 125 survives. It is a $411 million project to construct a 4-lane toll road in the San Diego metropolitan area, with an anticipated return on investment of 18.5%. After a lengthy process to obtain environmental permits and political consensus, construction began in May 2003 with an expected completion date of June 2006. Construction delays have pushed the anticipated opening date to June 2007, and the developer has requested that CalTrans extend its concession period from 35 to 45 years to facilitate obtaining "a reasonable return on its investment". CalTrans has yet to officially grant this request.

Programme & project analysis

The AB 680 Programme was a first generation effort to introduce substantial private involvement in infrastructure development and finance. Notwithstanding its good intentions, it stands as a relatively meagre P3 example, as the subsequent analysis will demonstrate.

Programme evaluation

The programme's structure and boundaries were established by the AB 680 legislation and CalTrans' subsequent execution plan. The assessment of the programme follows:

- Scope of Work or Service: very limited address – the projects had to provide transportation service, and would be unsolicited proposals. Loose geographic restrictions were created. Overall, these conditions forced the private sector to search for opportunities that would generate revenues in excess of their capital and opportunity costs. This situation pushes the locus right and down.
- Financing: specifically addressed in the legislation – no state or federal funds allowed; this also required potential respondents to find revenue generating possibilities that would produce an adequate return. These conditions push the locus right and down.
- User Fees: explicit discussion of user fees was not included; however, the disclosure of the private developer's desired rate of return and the requirement that receipts collected in excess of this would contribute to the debt principle balance or a state highway fund suggests an implicit plan to manage these fees. However, the state did not define what it considered a reasonable rate of return; thus, private developers were given the burden of proof that the rate they desired was appropriate. These conditions push the locus right slightly.
- Acquisition & Procurement: This process was not discussed in the legislation, but CalTrans did issue very general guidelines as well as very generic criteria for evaluation. In defence of CalTrans, they were handed a very difficult task – to evaluate and select unique proposals. Comparative analyses between proposals were not feasible, and the source selection method & criteria,

although published, were so general that the selection team would have the ability to argue in favour of any of the proposals received. The necessary approvals for the projects were not in place, nor could they be, given the structure of the process. Overall, these conditions move the locus right.

- Concession Management: the legislation was silent on this subject, and CalTrans guidelines were vague in this regard. The issues were addressed subsequent to award, so the terms were negotiated as part of the concession agreement. This situation generally favours the developer since once selected they possess the negotiating leverage. These circumstances push the locus right and slightly up.

Project analysis
This section will focus almost exclusively upon the SR 91 Express Lanes project since it is the only one operational. The appraisal of each of the project categories follows:

- Market Conditions: the traffic demand along SR 91 was well-established; the only unknown was how many travellers would opt to use the HOT lanes over the existing free lanes. This segment of the highway runs through a valley, so SR 91 was currently the most efficient means for getting north or south. Thus, the topography of the region itself supports a lack of competition. These conditions push the locus of the project slightly right.

- Socio-Environmental Conditions: technically, this was a greenfield project, although it utilized space in an already developed area. The scale of the project was moderate while the demographic impact was diverse. Moreover, the availability of a free alternative lessens, if not eliminates, any social inequity arguments. The user fees established would clearly reflect the ‘cost of service’ since the developer would set them at a minimally acceptable rate. Moreover, HOT lanes provide a market for users to determine how valuable their time is. These conditions do not push the locus one way or another.

- Acquisition & Procurement: the competition held amongst all of the projects was really over the expected transportation service that would result. The state had no idea of the “value” it was receiving since comparable proposals or a state-generated benchmark were not part of the process. CalTrans did publish its evaluation criteria, but as mentioned previously these criteria had to be quite general and subjective since CalTrans had little idea about what types of projects it ultimately consider. These circumstances move the locus right and up.

- Concession Management: generally, the issues or conditions related to renegotiation, termination, and facility return were not addressed by CalTrans. These conditions work in favour of the private developer since they are left for interpretation and negotiation. Risks were borne entirely by the developer, and through some rather deft design and planning, the developer eliminated or mitigated some of the most pronounced risks – right-of-way acquisition, environmental permitting, etc. The strict no-compete provision that the developer negotiated worked substantially to its advantage; so much so, that OCTA eventually had to buy-out the developer rather than challenge this condition. These circumstances move the locus right and up.

- Project Performance: in many respects, the SR 91 Express Lanes project was a success. It improved the quality of service, introduced a time/cost choice to the

> traveller, and delivered this service in a timely manner. A major issue, though, is whether the price was right. This concern was mitigated somewhat by the market forces that would drive tolls charged and the cap on the rate of return instituted by the state. Still, competing proposals over this scope of work could have assured the state and its citizens that it was receiving the best value that industry and the market could provide. Moreover, Lessard and Miller (2000) and Guash (2004) have demonstrated that the market or revenue risk is most pronounced in the early stages of these sorts of infrastructure projects. Thus, a more amenable strategy for the no-compete provision might have been adopted. Perhaps, a short-term (5–10 years) provision would have been sufficient to mitigate the revenue risk for the private sponsor, which might have kept a significant constraint from developing for OCTA.

The performance of the other three projects weakens this P3 Programme and lessens the credibility of this particular strategy. SAVE never proceeded beyond the conceptual design stage; its franchise was terminated in 2001. The Mid-State Tollway encountered substantial political opposition once design development and right-of-way acquisition began; its franchise was also terminated in 2001. SR 125 is under construction, but it is over budget and behind schedule. Thus, 16 years after award of the franchise, this project's service is still not available.

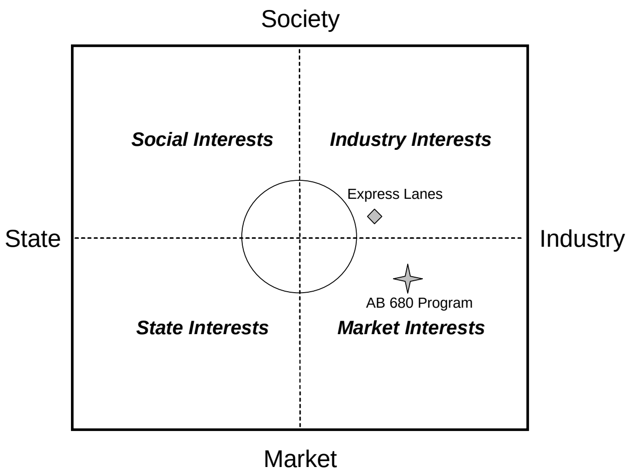

Figure 2: AB680 programme & express lanes project

Summary

The AB 680 Programme and its projects were well intentioned; however, this analysis suggests that a predominant bias toward market interests and a secondary bias toward industry interests at the programme level and vice versa at the project level caused its failure. Clearly, this is a hindsight analysis, but if the framework and templates proposed had been available, then perhaps they may have steered the initiative in a different direction, one that may have had a greater chance of success. Figure 2 illustrates the locus of the overall programme and the location of the SR 91 project.

CONCLUSION

The transition to a world where the propensity of infrastructure services is provided by the private sector appears to be underway. Essentially, governments will become the overseers of service rather than the service providers. Will this transition be beneficial? This endeavour seeks to answer this question by evaluating the effectiveness of P3 programmes and projects in the United States. An equilibrium framework and accompanying analytical templates will be applied to a longitudinal set of case studies. As the research progresses, an answer to the effectiveness question shall emerge, but perhaps more importantly, so shall lessons regarding the keys to P3 success for all the stakeholders involved and impacted by these initiatives. Early results of the research indicate that the contemporary P3 movement in US still has a lot to learn regarding these arrangements. A sub-optimal outcome, however, is not fixed; moreover, the P3 framework, in theory, can encourage both sectors to play to their strengths, the public as policymaker and standard-bearer and the private as innovator and efficiency-expert. The means to this end depends upon balancing the interests of the state, society, industry and the market.

ACKNOWLEDGEMENTS

The insights and feedback provided by Dr Michael C. Vorster of Virginia Tech regarding the P3 Equilibrium Framework are gratefully acknowledged. In addition, this work is funded by grant CMMI-0629260 from the National Science Foundation, whose support is gratefully acknowledged. TOWARD A CLIENT-DRIVEN REQUIREMENT MANAGEMENT FRAMEWORK FOR ACHIEVING BEST VALUE FOR MONEY

Daniel Forgues,[1] Lauri Koskela[2] and Albert Lejeune[3]

Studies have demonstrated the relationship between project failure and poor requirement management. However, there is almost no research in the construction industry about developing clients' capabilities to manage their requirements. The research objective is to propose a systematic planning, management and tracking of client requirements to improve the efficiency of the project team and construction suppliers' ability to generate best value for money. A constructive approach based on three case studies is used to develop and test a client-driven integrated requirement management framework. Such a framework could drastically leverage project contributions to business strategy using far fewer resources, while reducing cost and schedule.

Keywords: client, design management, green buildings, information management, project management.

INTRODUCTION

In the much-heralded Latham Report (1994), value for money (VfM) was placed first in a list of eight client wishes: many clients remain dissatisfied with the VfM they receive from the construction industry. However, as Green (1996) noticed, the industry did not capture the essence of VfM; it only retained the cost reduction aspect of it, leaving aside the much more important aspect of client/users satisfaction. The British government has nonetheless adopted VfM as its policy, and has supported numerous initiatives that strive to change its procurement and project management practices. Key to these efforts is a change of focus in the definition of project and programme requirements from capital costs to fit for purpose and whole life cycle costs.

The most successful of these initiatives are built around Sir Egan's (1998) five key targets: committed leadership, customer focus, integrated teams, quality driven agenda, and commitment to people. They draw from the automotive industry and project management best practices to change the construction paradigm by encouraging process integration and measure of performance, thus promoting continuous improvement in delivering value. However, the processes adopted for paradigm change proved to be expensive and not as successful as expected. It is argued here that these initiatives failed to address management and cognitive issues. The management issue is about building purpose: a building is more than an end product; it is a means to achieve a business objective. VfM, from this perspective, is

[1] daniel.forgues@etsmtl.ca

therefore not only about getting the best value from the project delivery process; it is also about maximizing the project outcomes for better services or business performance. The cognitive issue is about understanding the characteristics and purpose of the different activity systems in the process of defining and managing the expected project outcome with a minimum of waste.

This constructive research study aims to address the VfM management issue using a client-driven requirement management (RM) framework. It builds on the hypothesis that integration, alignment and balance of the management needs arising from the transformation, flow and value generation views for achieving VfM (Koskela 2000). The planning and design of a sustainable development demonstration project involving multiple stakeholders was used to experiment with a RM framework derived from system engineering and strategic management. The research preliminary findings are a first step to provide new empirical evidence on a unique case study where the building project purpose is the keystone of a business transformation programme.

MEASURING VALUE THOUGH REQUIREMENTS

The concept of VfM is explored using two perspectives: authors in Lean construction define value as the fulfilment of client requirements while minimizing the production of waste. Authors in IT and in project management associate Value with the ability to align projects and programmes with strategy (Henderson and Venkatraman 1999; Pmi 2003).

Whereas there is a consensus on the importance of capturing and managing client requirements, not much research has been done to explore how to define and manage clients' requirements within complex projects or programmes. An emerging view is that a programme is a set of projects and actions purposefully grouped to complete a transformation process, and, thereby, realize strategic benefits. Only fairly recently have programmes, such as OGC's (1999) "Achieving Excellence", conveyed the view that construction projects' outcomes could be one of the means of realizing strategic benefits. However, there are two key issues with today's industry practices in handling requirements that have to be resolved. One is the supplier's (professionals and contractors) understanding of the nature of the client (Bertelsen and Emmitt 2005); the second is about defining and delivering the best solution with a minimum of waste (Koskela 2000).

Defining client requirements demands a good understanding of what the client wants and why he wants it. It is common practice that the design team is responsible for establishing client and technical requirements. The issue in complex projects or programmes is that the "client" is a coalition of various stakeholders grouped together to achieve a specific business purpose. One of the key obstacles to the achievement of VfM is the need to cater for this range of stakeholders, each of whom may well have a different interpretation of what constitutes "good value" (Treasury 1994). Moreover, research demonstrates that there is no recognized process on how client requirements should be formalized within the brief: they are often established without the participation of key stakeholders, or lost or misinterpreted. Green and Simister (1999) and Barret and Stanley (1999) point out that identification of the client's needs and business opportunities through the briefing depends less on the ability to conceive design solutions, but more on the capacity to understand the nature of the client and to help him make strategic decisions, especially in complex projects and programmes, when multiple stakeholders are involved. Projects have to satisfy the differing requirements of several parties; the process of achieving a consensus cannot be taken for granted. Requirements have not only to be managed within the coalition that constitutes the team of client representatives and suppliers who have the responsibility to deliver the building, but also within the client organization.

The second issue is about the construction production process. According to the TFV theory, the Transformation (T) view is the one that prevails in construction and in project management: the process is concerned with breaking down the proposed solution into a hierarchy of work elements that are organized in time. However, two more views have to be managed concurrently in order to achieve VfM: the Flow (F) view, which looks at how material and information is efficiently managed through time and space: it is concerned with eliminating waste and reducing the time waiting of information, and; the Value (V) view which is concerned with the fit between client, design requirement and the end product.

The problem managing the F and V views is two-fold: the traditional sequential design process, in which the focus on functional and technical requirements tends to overshadow client requirements, (Kamara *et al*. (2002); and the adversarial business context created by traditional contracting methods, which discourage collaboration between contract parties to define the solution that will best fit the business purpose (Koskela *et al*. 2006). Consequently, the building sector suffers from poor or incomplete scope definition, and frequently experiences considerable changes that result in significant cost and schedule overruns (Hamilton *et al*. 1996). Transactional contracting implies that the contractor's responsibility is limited to achieving the deliverable: at the given date; according to the solution prescribed by the bidding documents; and without interference from the owner during the process. This means great contractor independence, and thus aversion to collaboration. It also means that requirements are presented in a prescriptive way, eliminating opportunities for proposing creative solutions to problems.

Reports and studies suggest that the use of Integrated Teams and relational forms of contracting should overcome these issues, and improve value generation through a collaborative, multidisciplinary approach to managing requirements. The success of initiatives such as the UK Department of Health Procure-21 seems to confirm this assertion. Integrated teams, nonetheless, face new challenges in managing the complexity of handling the multiple layers of client and technical requirements concurrently. Methods and tools have been developed in other disciplines or industries to handle complex, evolving requirements effectively. The research aims at testing a client-driven RM preliminary construct developed in previous research.

A CONSTRUCTIVE RESEARCH APPROACH TO VFM

Constructive research treats practice as a fundamental category for making constructs as well as in ensuing theorizing (Lukka 2000). Researchers adopt two roles in the constructive research process: an inquiry role, in which the researcher should be able to view the activity systems from a systemic perspective, and create models or constructs about the activity systems as if they were looking at them from above; in the intensive stage of the study, the researcher's attention switches to the change process and, there, primarily to the individuals' and the organization's problem and solution processes.

The process of constructive research is complex and non-linear. It requires understanding and interpreting the real world; it also necessitates creating and experimenting with models of a new reality. The idea of a client-driven RM approach as a means of aligning project results with strategy emerged from prior research on enhancing construction project delivery processes. Systematic RM is the process of capturing the documented statement of stakeholders' and users' wants and needs (quality), and ensuring that the solution efficiently meets these requirements (conformance). The systematic management of Requirement processes is identified as a project key success factor in system and software engineering literature.

The research was designed as a series of steps or iterations, moving from literature to interviews and case studies, in which models are used at each step as mediating artefacts when interpreting and acting on the real world (Figure 1). This paper presents part of the results of the third iteration.

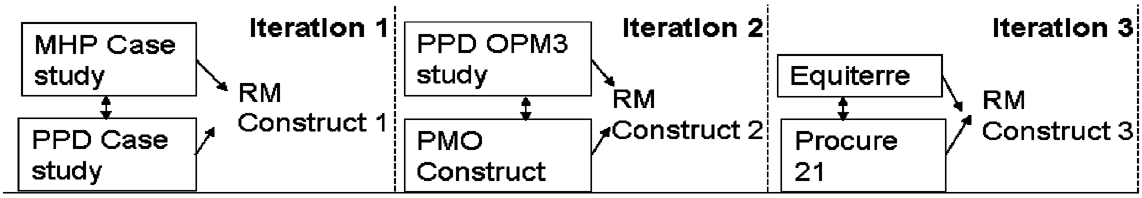

Figure 1: Constructive research iterations

The first iteration was conducted within the Canadian Services construction programme, which was experiencing serious problems dealing with complex evolving multiple client requirements. A weapon development programme using leading-edge RM processes was used as a case study to develop an RM concept of operations. The second iteration (Figure 1) explored the multiple levels of requirements of complex projects and programmes based on the Project Management Organizational Project Maturity Model (PMI 2004).

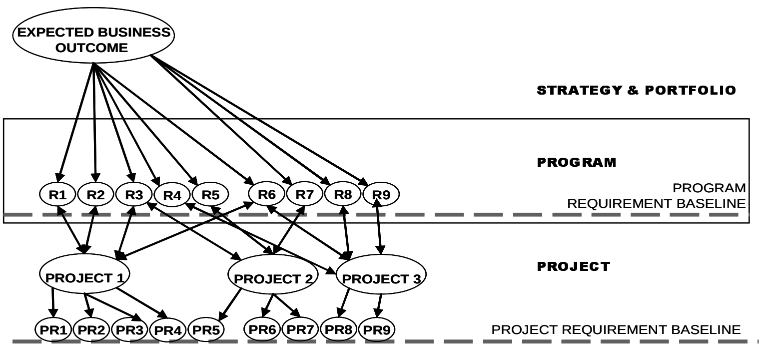

Figure 2: Programme requirement-based construct

This model contends that project outcomes should be aligned with strategy through portfolios, programmes and projects. Figure 2 proposes a systematic approach to provide this dynamic alignment from the strategy (providing the outcomes related to the business objectives) to operations (providing the building expected characteristics) through layers of requirements. Kauppinen (2005) identifies three levels of requirements: business requirements – high-level objectives of the organization or customer; user requirements – describe user goals or tasks that the users must be able to perform with the product; and technical requirements – more detailed descriptions of the user requirements, are defined from the point of view of the expert. Sommerville (2004) points out that some of the key problems in managing requirements result from a failure to make a clear separation between the different levels of requirements. Strategic alignment was identified as a possible answer to the issue of managing different layers of requirements in the organization, from the strategy (providing the outcomes related to the business objectives) to operations (providing the building expected characteristics).

The aim of the construct was to provide real-time dynamic alignment capability to manage a complex construction programme. In this model, the programme requirement baseline is the mediator between strategic and project requirements. Deviation from the baseline induces three possible courses of actions: at the project level, taking corrective actions; at a programme level, adjusting the programme strategy in delivering the expected benefits, or; at the business strategy and portfolio levels, adjusting the strategy according to emerging strategies from the program and the project context.

RESEARCH METHODS

Two other case studies – in which Integrated Design Process (a multidisciplinary approach to problem-solving having its roots in concurrent engineering, where it is combined with parallel task processing to reduce cost and delays in design and production while increasing the process quality. By encouraging collaboration, IDP addresses numerous problems associated with the management of Flow (F) and Value (V) in sequential design, such as briefing process disclosure and feedbacks (V) problems, or design process resolution of wicked (F) problems) or relational contracting were used to encourage collaboration – were identified to develop and test the construct: the first as a reciprocal case (Yin 2003), the second as an instrumental case study. The paper presents the preliminary results of the latter, an on-going green building demonstration project in Canada. The case study process was divided into two phases: The first phase – the Constructive Research inquiry stage – focused on the observation of the client and design team interactions; the second phase, on the construct experiment for the management of requirements regarding sustainability.

The inquiry stage aimed at understanding the management and cognitive issues related to integrated design and defining the best strategy to test the RM construct. A total of five brainstorming and four design workshops were observed in École de Technologie Supérieure e-collaborative design tools laboratory. The workshops were filmed, and all electronic documents and drawings recorded. A qualitative, grounded research interview-based case study was carried out to identify the client stakeholders' wants and expectations. Nine interviews were conducted, five with the shareholders and four with the stakeholders, to establish the shareholders' business objectives and the stakeholders' needs, expectations and. requirements regarding sustainability. The resulting data were analysed using Nvivo7 software, and prioritized in Doors client requirement module of the Doors data model (Figure 3).

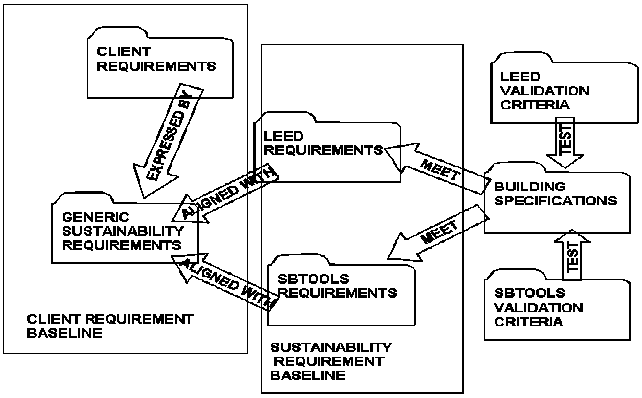

Figure 3: Doors data model

The model is the instantiation of the RM construct (Figure 1). The client requirement module (strategy) contains the sustainability business requirements, which are detailed in the generic sustainable requirement module. Generic requirements cover the programme's social, economic and environmental perspectives. They constitute the client's programme requirement baseline. The building requirements (LEED and SBTools) are the project sustainability technical baseline.

The intensive stage of the study aims at testing the use of systematic RM to manage the client's strategic and operational requirements. A preliminary RM modelling was realized to map the tracking process of the sustainability requirements. Two environmental benchmarking tools were selected to demonstrate the project's sustainable value: The Leadership in Energy and Environmental Design (LEED) Green Building Rating System™, the most popular rating system for the design, construction, and operation of high performance green buildings in North America, and SBTool 07, benchmarking software developed as part of the Green Building Challenge process, an international effort to establish a common language for describing "green buildings". Finally, a LEED/SBTool baseline was created to verify proposed design solutions against LEED/SBTool sustainability requirements, and to validate these solutions against client sustainability requirements.

CASE STUDY DESCRIPTION

Maison du développement durable

The Maison du développement durable project aims at building a sustainable building demonstration project in downtown Montreal. The client, Equiterre, is a non-profit organization devoted to promoting social equity and a more sustainable world. Equiterre has built its reputation on programmes that are now a few years old. Its board felt that Equiterre had to redefine itself to deliver a more powerful message. Equiterre's strategic objectives are to leverage the organization influence in sustainable development by creating a pole of attraction, a model of what sustainable development should be; and to consolidate the organization and its partners. To do so, Equiterre has created a coalition with eight other non-profit organization sharing similar values; these will be the partners and the tenants of the project. It has also devised a new sustainability programme, of which the demonstration project is the keystone.

Competition for public and private funding is fierce. The project aims to be a strong public statement and a platform to launch new programmes. It will also help to recruit public and private partners. As a demonstration project, it will attract visitors (and future members). It is totally funded through grants.

Equiterre has no experience in construction projects. However, it has formed a steering committee represented by executives and experts from large real estate organizations. The design team was selected through a multiple stage process based on the following criteria: working chemistry among the team and with Equiterre's project team; quality of their projects, experience in sustainable construction; and shared values with Equiterre. The team has realized the first certified LEED Gold project in the Quebec province, and has won numerous prizes. According to the contractual arrangements, the team had to use an integrated design process to achieve LEED/SBTool sustainability requirements. The aim is to receive international recognition by exceeding the most stringent certification requirements. The team also has to conduct workshops in Ecole de technologie superieure laboratory as part of the research programme.

The integrated design management process

IDP is an iterative approach originating from product and software development, designed to aggressively reduce uncertainties, in favour of earlier and better decision-making. It was successfully used in system engineering to drastically shorten the development time of software intensive advanced weapon systems, such as spy planes (U2 and SR71A) or satellites. Various formal or agile integrated design frameworks are now used in these industries.

RM plays a central role in these fields. Problems in handling requirements account for close to 60% of project failures (Standish Group 1994). Stage-gating, configuration management and requirement engineering methods and tools are considered as essential for developing the necessary capabilities for achieving required project performance. They are core requirements in achieving higher maturity levels in the Software Capability Maturity Model. It has proved in software development to drastically reduce waste, while providing a much better fit for purpose.

Integrated design is just emerging in construction, and there is no clear definition or framework for applying it. It has been identified as the best approach for delivering VfM, and it is also acknowledged as the best approach for delivering sustainable buildings. These two main strands – one driven by the Rethinking Construction movement, the other by the sustainability movement – are both aimed at increasing the industry's capability to deliver a better product with a minimum of waste. The first movement is client-driven; the second is supplier-driven. The Equiterre project is in the second category.

Testing the RM framework

The construction industry's aversion to innovation is well known. Testing an RM framework in an integrated design context is far-removed from traditional practice both on the client and supplier's sides. Alignment is not a concept commonly used in organizations that regard the management of real estate project portfolios. Alignment models are scarce, and belong to other disciplines. Moreover, critics of strategic planning and alignment maintain that the implicit dominance of a structured strategy process is questionable in an era when uncertainty and flexibility predominate. Ciborra (1997) argues that management, through knowledge and understanding of alignment, can classify their strategy in terms of boxes and linear relationships, but back in the real world, they have difficulty measuring those relationships or formulating processes to apply the alignment maps in practice. In other words, conventional theory on alignment does not address cognitive issues. The testing plan was built around "soft" approaches to IT system implementation to mitigate these issues (Table 1).

Table 1: Key ingredients in the testing learning cycle (Walton 1989; Ciborra 1997)

Walton	Ciborra
Alignment: • Vision aligned with business, organization, and technology strategies • System design and operational use aligned with vision	Alignment: • Grounded approach to alignment: understanding the business phenomena to enrich the geometric notion of alignment
Ownership: • Organizational commitment (sponsorship); stakeholder support for IT • System designed to tap and promote user ownership • Users feel strong ownership of the system	Care: • Familiarity, intimacy and continuous commitment by the various actors involved in the design, implementation and use of the system Hospitality: • New technology is highly ambiguous. Acceptance has to face ambiguity: coping becomes hospitality
Competence/Mastery: • Competence and IT literacy • System designed to use and promote mastery • Users mastering the system	Cultivation: • Is based on frequent misalignment and misfit: the technology being accumulated is greater or different in its potential, than current internal or external needs

Equiterre has set a steering committee at the programme level and a technical advisory committee at the project level. The inquiry stage was divided into two: observation of the supplier-driven process and observation of the steering committee handling of the programme. The supplier design process was staged in a series of one day and half a day Workshops, held from August 2006 to February 2007. The intensive stage of experiment was started in parallel with the inquiry stage. A qualitative grounded research technique was used for Requirements elicitation and analysis at the programme level. A Programme Charter, which outlined the programme strategy objectives, was derived from this analysis. The sustainability related objectives were broken down into characteristics. Both Charter and characteristics were mapped into Doors using the traceability links and then frozen into the client requirements configuration baseline. The LEED and SBTools benchmarks were then mapped and each criterion linked to a client configuration item. They constitute the project technical baseline. The proposed concept is now being assessed against these two baselines.

DISCUSSION

The case study had a unique feature that enabled the parallel inquiry and intensive stages. Two sustainability benchmarks were identified to obtain international recognition. However, neither the client nor the design team realized that the benchmarks were built around opposite design strategies. In contrast to SBTools, LEED does not demand any change in the traditional Sequential Design process (T view). It is essentially a checklist. The objective is to gather as many sustainability points as possible. The trend in the industry is to develop the design, conduct the energy simulation, and add technology to increase energy efficiency up to the desired score. There is no specification about if integrated design should be used, and how it should be managed. The design team was familiar with LEED and devised a series of workshops to meet the client's requirement for an integrated approach.

The brief prepared by the architect captured the space requirements, but not the business strategy and objectives, nor the constraints imposed by the project financing scheme. After one year of work, the concept was assessed against the programme expected characteristics and the project technical baseline. Whilst achieving most of the LEED sustainability criteria, the scheme did not achieve some core business objectives, and exceeded the cost targets. Management and cognitive issues were observed during the inquiry stage, with the conducting of workshops, which were also perceived by the client as quite ineffective and time consuming.

One management issue is the complexity of handling multiple levels of requirements. Because there was no organized process for managing the hierarchy of requirements, discussions moved from technical to business requirements and vice-versa: time was wasted in useless iterations between these two levels. A cognitive issue was the experts' difficulty in understanding what kind of information the client needed for decision-making. The experts pushed the client to make decisions to develop the design options, while the client was asking cost information to asses their business value. This is qualified as cognitive inertia and compartmentalization. One of the mechanisms behind such inertia is "groupthink", a mode of thinking that people engage in "when they are deeply involved in a cohesive in-group." "Groupthink" typically leads to an overestimation of the in-group, closed-mindedness and stereotypes of out-groups. Another possible mechanism is, paradoxically, almost the opposite of "groupthink", namely, fragmentation of viewpoints and lack of "shared mental models." Such fragmentation may make it impossible for experts from different contexts to "speak the same language" and exchange ideas about a problem.

The advantage to conducting the inquiry and intensive stage as two parallel processes was to make the client realize the value of a client-driven RM approach. SBTools shares System Engineering RM Vee model core principles of decomposition and abstraction: it was used as the sustainability technical requirement framework and integrated in Doors programme-based construct. The system is partitioned into finer and finer elements, while the requirements start at a highly abstract level to become more specific for the lower-level elements. SBTools first requires that sustainability targets be identified by the client at the beginning of projects (V). A reference model is developed by a third party to define the local benchmarks regarding common, good and best practices. A concept is generated through workshops and tested against the reference model. The client, after reviewing the score of the concept against the reference model, can then adjust his target. Then a series of steps are defined to refine the design for each component through design workshops. The result from iteration is adjusted against its related benchmark (T & V).

CONCLUSIONS

It is reported in this paper that preliminary research results from an instrumental case study aimed at providing a proof of concept for the programme-based RM alignment construct. They demonstrated the value of using client-driven RM to achieve VfM. The client was capable of comparing the proposed concept with his requirement baseline, and of identifying flaws in the design. They also highlighted the issues related to changing the industry's practices. Researchers have advocated that VfM is best achieved through integrated approaches and relational contracting, but did not address the management and cognitive issues related to these approaches.

This research is exploratory and still ongoing. The exploratory systematic RM construct will have to be experimented on in the second phase of the project. A reciprocal case study has been conducted in parallel, and a conceptual framework was developed to explore the socio-technical aspects of VfM. The intensive stage will be used to validate, better understand and extend this framework. Questions about the cognitive issues and their articulation against TFV theory will be further investigated.

RISK, VALUE, UNCERTAINTY AND REQUIREMENTS MANAGEMENT IN PROJECTS

Nigel Smith[1] and Steven Male

School of Civil Engineering, University of Leeds, Woodhouse Lane, Leeds, WF2 6SQ

Although much discussed and researched over the years, the difficulty of making effective decisions early in the project appraisal stage remains an issue. Preference and practice still play almost as important a part as data capture and methodology. Business and project process improvements in the industry are addressed, placing the client and the development of project strategy and its subsequent implementation at the forefront of those improvements. A framework to facilitate understanding management of the early stages of a project is proposed based upon the four major themes of the title: risk, value, uncertainty and requirements management. The paper draws on previous studies conducted by the authors and others into the significance of the early stages of a project. The arguments set out seek to demonstrate the feasibility of integrating those themes in the appraisal stage of projects, and potentially for later stages in the project life cycle, with a view to determining the best practice framework and methodology for undertaking this.

Keywords: appraisal stage of projects, requirements management, risk management, uncertainty management, value management.

INTRODUCTION AND RESEARCH METHOD

In the early stages of projects at a detailed process level extensive empirical studies linked to theoretical work concerning the relationship between the four major themes identified in this paper as a comprehensive package are missing from the research literature. More importantly, there is a dearth of systematic research at the formative stages of projects where early project decisions are made by clients, consultants, bankers and lawyers and, increasingly, by contractors under the newer forms of collaborative procurement (Graham 2001). The paper uses the term ‘strategic project management’ (Grundy and Brown 2002) to describe the overarching activity of setting up the early stages of a project and draws on work dealing with the strategic phase of projects and the project value chain (Bell 1994; Graham 2001; Male and Kelly 1992; Moussa 1999; Gorog and Smith 1999; Latham 1994; Standing 2000; Woodhead 1999).

The impetus for this paper also comes from the authors’ continued work in value and risk management for over nearly two decades. Smith has published widely on risk management (Smith 2002, 2003, 2006), on the integration of risk and value management (Smith and Afila 2007) and in the area of PPP/PFI (Smith and Merna 1996, Smith and Mackie 2005). Since the mid-1980s Male and Kelly have conducted a number of strategic studies in the value management (VM) area, notably for the

[1] n.j.smith@leeds.ac.uk

Royal Institution of Chartered Surveyors and consolidated in Kelly and Male (1993), and work funded by the UK's Engineering and Physical Sciences Research Council where the outcome was an internationally benchmarked best practice methodology for VM (Male *et al*. 1998a, 1998b). From 1998 onwards Male and Kelly, using a combined approach of action research (Bryman 1989; Robson 2002), grounded theory (Glaser and Strauss 1967, Goulding 2002) and reflective practitioner in-action approach (Schon 1991, 1999), subsequently tested for robustness and enhanced further that methodology through conducting in excess of 100 action-research focused industrial studies and systematically analysing the outcomes. That work has been consolidated in Kelly *et al.* (2004) and Male *et al.* (2007) within a historical, current and international analysis of VM and its potential future direction. In sum, the process has involved the interactive effects of research-driven practice and practice-driven research.

THE FORMATIVE STAGES OF PROJECTS

Many clients experience difficulties at the very earliest stages of the construction project life cycle in producing a robust project strategy, not least a 'brief' (Latham 2004). This early stage, defined as the 'appraisal stage', extends from 'inception' to 'sanction' (Simon *et al.* 1997); it can also be extended earlier to include a pre-brief or pre-concept/inception stage with clear relationships to business strategy and investment decisions (Kelly and Male 1993). Consequently, the appraisal stage contains two types of decision making under conditions of uncertainty, namely the viability decision (related to the investment decision as a business project and its correct definition) and the decision on the preferred and most feasible technical option (the appropriate technical project). Both processes require 'strategic fit' and may be completed before the contract and procurement strategy is determined, the project is sanctioned and often before the number of major organizations to be involved has been agreed. The appraisal stage is also where requirements need to be carefully thought through and made explicit, where strategic procurement issues need to be considered and also the organization's approach to managing uncertainty becomes important because it is at its highest. It is also the gestation period for value and risk parameters to be established.

Moussa (1999) split the overall project process into two major phases, project definition, covering the appraisal stage discussed here, and project delivery. In the case of the former, Woodhead (1999) undertook an in-depth analysis of the decision to construct process – one located within the appraisal stage – through the study of a range of different types of projects and their formative stages. He uncovered a collection of influences impacting on project definition and designated these influences paradigms and perspectives. The former comprise the rules, expectations, values and codes of practice that are explicitly or implicitly part of professional and other stakeholder groupings playing a part within the decision to construct process. Perspectives are those views existing within any given paradigm. Paradigms and perspectives shape and structure the process of the decision to construct. They also dictate its content. Woodhead also concluded that as the decision to construct progresses through a series of stages, each is impacted on by different decision roles, namely, the formal decision functions of decision approving, taking and shaping, and finally, that of decision influencing.

Although the appraisal stage also encompasses the formal establishing of a project, Graham (2001) indicated clearly the difference between the start of the strategic phase of a project and the start of the project itself. Projects go through a variety of changes within the client organization before they emerged as projects with a clear momentum ready for the construction industry to commence its work (Kelly *et al.* 2004; Woodhead 1999). The strategic phase of the project development process is therefore often 'messy', 'fuzzy' or 'ill-defined' and can be difficult to pin down in terms of a clear start date for a particular project. This adds to uncertainty and risks and also necessitates the management of different and potentially conflicting value systems. This is explored further in the next section.

UNCERTAINTY, VALUE, RISK AND REQUIREMENTS MANAGEMENT IN PROJECTS

Bell (1994), defining value as the intrinsic property to satisfy, notes it has an economic perspective in terms of the ratio of costs to benefits and where the primary mechanism for communication of value decisions is in monetary terms. She added that other authors have presented value in terms of characteristics, namely, use qualities, esteem features linked to ownership; market exchange properties; and cost characteristics. There are perceptual and utility dimensions to it. Bell (1994) also notes that the number of interfaces that exist between individuals, groups of individuals, or organizational units deciding on value also come into play.

Recent research by Smith and An (2006) demonstrates that new perspectives are emerging that are influencing the way risk assessment is viewed, particularly in terms of uncertainty, complexity and opportunity. Risk and uncertainty are key features of the appraisal stage, with risk management no longer concerned only with detrimental factors but with the inclusion of the concept of opportunity means that there is also the possibility of emerging factors that can have a positive impact on the project. Risk management, while not predicting the future, nevertheless provides a better approach in making key decisions (Chapman 1998; HSE 2003). However, in respect of the terminology and semantics of risk management the same terms are used by different industrial sectors in different ways to describe discrete activities that not only occur at different points on the project life cycle but are cyclic or repetitive processes involving different levels of certitude, and possibly different methodologies. There is no surprise that a degree of confusion exists. Nonetheless, risk management is usually defined with key phrases including coordination of activities or application of management policies, procedures, methods and practices to identify, analyse, evaluate, treat, control and monitor risk to minimize adverse effects (IRM 2002; AS/NZ 2004).

There also appear to be very close linkages between conceptual approaches to value and risk management and the ideas and concepts from within the emerging research field of uncertainty management (UM), and, also requirements management (ReqmtM) (Standing 2005). The focus of UM is on making decisions and managing in the face of significant uncertainty (Cooper and Chapman 1987; Chapman 1997; Chapman and Ward 2002; Hetland 2003), defined as a lack of certainty derived from high levels of variability and ambiguity (Chapman and Ward 2002). Chapman and Ward include risk within the definition of UM, as does Hetland (2003); they view it as incorporating upside risk (opportunity) and downside risk (threat). Male and Mitrovic (2005) have recently linked project uncertainty, risk, value and supply chain strategies together with a client typology using Hetland's thinking. Equally, Smith and Afila (2007) have investigated the links between value and risk management; the OGC (2007a) has produced a guide which explores their integration within the Gateway process; while CIRIA (2005), Dallas (2006) and Walker and Greenwood (2002) have explored the linkages between managing risk and value through the use of concepts, ideas, methods and toolboxes of techniques in a similar manner to Male *et al.* (1998a, 1998b).

Finally, requirements management, with its origins and methodologies in information technology, focuses on eliciting, documenting, organizing and tracking requirements, a ‘capability’ that is needed by a user to solve a problem or objective (OGC 2007b). Nomenclature in the requirements management area includes stakeholders and project teams, the ‘voice of the customer’, goals, functions and constraints to product and service specifications, including related systems behaviour. These terms also appear in the VM paradigm. The value and traditional risk paradigms also address the management of complexity, uncertainty and ambiguity through their respective methodologies, and implicitly also opportunity. Figure 1 brings together the key concepts discussed above.

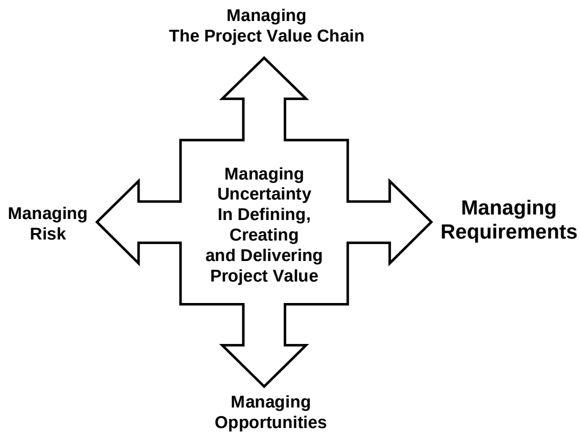

Figure 1: Managing uncertainty in project value (Male and Smith 2007)

The next section explores the above through the presentation of two case studies.

CASE STUDY: A LIBRARY PROJECT

A case study is presented drawing together different insights into the use of value and risk management, reductions to uncertainty, and also requirements management. The study is of a library project where value management/value engineering had been used in a reactive as well as proactive manner at different stages of that project.

The traditional VM paradigm has function analysis at its core (Kelly *et al*. 2004); variations on this technique have also emerged, including the function breakdown structure and objectives hierarchies (Male *et al*. 2007). They have differences in their application; some are more suited to existing products and others to problem definition and new product development. As part of the development process in function diagramming, Kelly *et al*. (2004) describe three function techniques linked to requirements capture. The techniques are the function priority matrix, developed due to a frustration of using FAST diagramming with large teams under collaborative procurement structures; the strategic FAST diagram, which is very useful for diagrammatically representing purpose related to function and the value engineering (VE) functional cluster diagram, relating major elements within buildings to the Royal Institution of Chartered Surveyors BCIS elemental analysis, functions and subsequently cost. In terms of interlinking, the function priority matrix is normally constructed first, then the strategic FAST diagram from constituents of the priority matrix and finally, if a value engineering constituent is required, the VE clustering diagram. Kelly *et al*. (2004) make the point that they are a series of linked function techniques that help structure information and requirements in a logical way within often competing value systems.

The study was conducted at the concept briefing stage, with each of the above techniques used to brief the project. As part of the study and prior to a VM workshop, the study leader and a 'briefing architect' interviewed key personnel in the university to establish their perceptions of the reason for the project, its key use requirements and major functional space requirements. Important constraints were also identified. During successive workshop activity, a series of function analysis techniques were used. The three primary techniques are brought together in Figure 2, together with an example of risk brainstorming using the functional cluster diagram approach where this technique was extended further at a similar stage in an MoD prime contract.

Typically a team will be taken through a structured workshop process, where initially an issues analysis is conducted (Kelly *et al*. 2004) to address uncertainty, risk and value through a joint exploration of information. Purpose analysis, objectives hierarchies and functioning diagramming are then used to take a team back to the basics of why a project exists, and what functions are necessary for the end product as a physical asset to be briefed, constructed and operated. Subsequently through a process of ideas generation and option development options are worked up, value added and risks mitigated; quantitative risk management would take place outside the workshop process. Action planning puts those options into implementation. Depending on the type of study, at this stage options may well fall into: strategic improvements to be addressed by the client; technical design and or construction-related options; project management and project process options and risk mitigation options.

In the case of the library project, the team were taken through the issues analysis and then subsequently into function analysis. First, the function matrix was developed, sorted and prioritized. Second, having established the strategic purpose of the project, spatial adjacency matrices and flow diagrams were used to prioritize space and identify any important spatial function requirements. Third, the VE cluster diagram was used to establish the functional requirements of the end product – the physical asset. Links between each major functional cluster and the BCIS functionally based elemental structure permit alternative technical options to be tied to function and subsequently cost parameters. The value management team appointed independently by the university and comprising client representatives, end users and technically based consultants, including a contractor, established the competing technical alternatives to meet the function while taking account of buildability, life cycle and onsite programme and logistics issues. The final output-based specification was agreed for each major function cluster with clear linkages established to each of the BCIS elemental breakdown structure as the normal cost-planning technique for cost consultants.

The VM team also took a holistic approach to the whole VE cluster diagram to ensure the technical integrity of the outline output specification; the cluster diagram also permits risk brainstorming against each of the elemental groupings. Finally, a cost consultant within the VM team established the appropriate cost/square metre rate for each of the BCIS elements using ideas on the most likely technical alternatives to drive this. This established the budget for the building and element-by-element cost ranges linked to functional requirements, leaving any subsequent designer freedom to choose appropriate technical solutions within specified cost limits. The final stage of the VM workshop process was to determine the appropriate procurement route through options generation. In summary the combined use of the techniques captured the requirements very quickly in the early stages of the project and, as a direct consequence, uncertainty and risk were progressively addressed through the workshop process with the elicitation and capture of requirements. Subsequently, this cascaded into the appropriate choice of procurement route.

CONCLUSIONS

The core of value management as a structured process is to ensure that an investment strategy achieves the desired impact and benefits for an organization. Dallas (2006) notes that a successful project of any type requires that the outcome is clearly defined (requirements) and communicated to those delivering the project (the team). He notes VM addresses this element. Equally, he argues that successful project delivery requires an effective delivery process where the impacts of the ‘unexpected and uncertainties’ are minimized. He contends that this is the role of RM.

This paper has argued that the coming together of RM and VM in theory and in the practice setting, normally around workshop processes, is not without its difficulties but is solvable; they however originate from different theoretical paradigms and have differing underlying philosophies and methodologies. Equally, additional work conducted by Male, Smith and Gronqvist with a large engineering contractor indicates clearly that value creation should be addressed first, by addressing opportunity-based options; second, by investigating the risks associated with those options; and third, by relating those risks additionally to a more general analysis of project risks. The clear implication is that the mental mindsets associated with generating and investigating opportunity-based options is positive, subsequently the workshop process should address the more negative aspects associated with risk analysis and mitigation. It is not uncommon for value management teams to be split into working groups, some focusing on value opportunities and the associated risks; subsequently, other working groups may investigate risks and mitigation measures. Consequently, this approach can move to more quantitative assessments associated with risk management.

The approaches identified in the paper have stemmed from a prolonged period of involvement and observation from action research studies, the purpose of which has been to intervene in organizational processes using research frameworks as well as generate further insights for subsequent research projects. A series of techniques have been presented that address the simultaneous management of uncertainty, value, risk, opportunity and requirements management. Figure 2 comes from within a value and risk framework and focuses on value by addressing opportunities (explicitly), uncertainty (implicitly) and risk (explicitly); neither study used computer software to capture requirements for subsequent management throughout the project life cycle. Software is now generally available, with origins however within the information technology domain, to also elicit and capture requirements, subsequently using that software to track these through different stages of the project.

At the post-project evaluation stage these computer-based software approaches for generating and tracking requirements can be used to audit information and determine if those requirements and subsequent benefits have been delivered. The paper has argued that there is no comprehensive framework that brings together the concepts, methodologies, tools and techniques that exist within the different and potentially complementary themes discussed here. This paper further proposes that a coming together and resolution of these apparently overlapping areas theoretically and empirically can only but strengthen the appraisal stage of projects, arguably the most important domain for impacting subsequently on the rest of the project life cycle.

COMPREHENSIVE PERFORMANCE EVALUATION FACTORS FOR PUBLIC CONSTRUCTION PROJECTS

Shih-Tong Lu,[1] Chun-Nen Huang[2] and Yao-Chen Kuo[3]

[1] *Department of Risk Management, Kainan University, No.1, Kainan Road, Luzhu, Taoyuan County, 33857 Taiwan*
[2] *Department of Security Management, Kainan University, No.1, Kainan Road, Luzhu, Taoyuan County, 33857 Taiwan*
[3] *Department of Property Management, Kainan University, No.1, Kainan Road, Luzhu, Taoyuan County, 33857 Taiwan*

Large-scale public construction projects take the majority of the government budget. Currently, the performance evaluation systems of government entities focus more on budget performing ratios or financial achievements. The life cycle of a large-scale public construction project includes budget allocation, planning and design, tendering, construction, inspection and acceptance and maintenance. All of these belong to an interrelated and integrated process, but they do not establish an effective overall evaluation model in government sectors. Although there are a few studies that propose evaluation indices or models for reference, these are mostly based on construction stages as weight datum. Therefore, this study adopts economy, efficiency and effectiveness (3E), proposed by Budaus and Buchholtz (1996), to construct a structure of the execution performance evaluation criteria, covering every stage of the life cycle of public construction project. This study applies the factor analysis and fuzzy analytic hierarchy process (FAHP) to find the important evaluation factors and their relative weight. It is expected to provide a reference for the relevant supervising sectors or audit offices of the government to evaluate and inspect the public construction projects.

Keywords: performance evaluation, public construction projects, 3E evaluation model, fuzzy analytic hierarchy process.

INTRODUCTION

The quality of public infrastructure is one of the most important elements affecting the economic development of a country. One of the world's renowned rating institutes of the competitiveness of different countries, the Institute for Management Development (IMD), sets the level of the development on public infrastructure as a critical index when evaluating the competitiveness of countries. Within the past few years, Taiwan's government has invested much effort to become more energetic, effective and efficient, and questions have been raised about whether government sectors are being overlapped and overstaffed, whether more financial funding is required for improvement, whether the government officers are well educated for updated rules and regulations, and whether project performance is well evaluated etc. All of these questions are important issues on the efficiency of the administrative of a government.

Recently, the performance evaluations of Taiwan's government sectors have mainly been restricted to the evaluation of their budget implementation rate. In other words,

[1] stonelu@mail.knu.edu.tw

the financial performance is the core part of the traditional performance system applied on different government sectors in Taiwan. However, in the large-scale public construction projects that take the majority of the government budget, the processes from budget allocation, planning and design, tendering, construction, completion and effectiveness after construction, the procurement of a construction belongs to an overall construction project. However, the government lacks a state-of-art model implemented for the evaluation of the overall construction process. Although Ho (1995), Chiang (1997) and Hsu (2004) conducted some studies for this issue, and suggested some indices and models associated with the addressed evaluations for references, most of them are established on the basis of assigning criteria to construction stages. In addition, Budaus and Buchholtz (1996) used a multi-dimension, economy, efficiency and effectiveness (3E) evaluation mode to construct a set of matrixes for the comprehensive performance evaluation of the government. The proposed model is also used to monitor the effectiveness of the administrative affairs in government sectors, and furthermore improve their financial balances. With regard to the construction and maintenance projects, the National Audit Office of ROC (1988) proposes many performance auditing methods and techniques, and also recommends the exploration of an evaluation model based on the performance perspective of 3E. However, those studies were only limited to the development of concept. There is no concrete indication as to which methods to adopt for a fair, objective and professional qualitative and quantitative performance measuring index in order to evaluate the public construction project to correspond to each construction stage, including budget allocation, planning and design, tendering, construction, inspection and acceptance and maintenance, in the life cycle of a construction project. Therefore, building a set of project performance evaluation models covering all stages of the life cycle of a public construction project to meet required qualities, times and costs is essential for the government. This is a very important objective when considering the sustainable development of a country. This study was conducted by considering three dimensions of economy, efficiency and effectiveness (3E) to construct the framework of the execution performance evaluation criteria, covering all stages of the life cycle of a public construction project. The factor analysis and fuzzy analytic hierarchy process (FAHP) were applied to investigating the critical evaluation factors and their related weight in this study. The results will be a set of important references for government sectors to evaluate the performance of the procurement and execution abilities of the construction projects in order to be successful in project control of construction projects.

LITERATURE REVIEW

In the past, only a few studies were conducted to investigate the project performance in public infrastructure construction projects. Based on the characteristics of public projects and the needs discovered during the construction stages of some infrastructure projects, Ho (1996) built a performance evaluation system that includes the functions of progress management, budget execution, quality management, administrative operation, environment management and so on, and established an integrated model to evaluate the performance of allocating and utilizing budget for project progressing. Compared to the past studies associated with project performance indices, Ho’s research revealed more related information in the management issue. Chiang (1997) constructed a model that measures the performance for the processes of closing project, controlling progress, managing cost, managing quality, controlling safety, managing hygiene and environment, administrating, and so on. Twenty critical indices were explored from conducting a questionnaire survey to twelve major infrastructure projects. Furthermore, the analytic hierarchy process (AHP) was utilized to determine the weight of each explored index, and finally the model including a set of the index used to evaluate the performance of a public construction project was proposed. The Construction Industry Institute (CII) developed a performance evaluation system, named as Quality Performance Measurement Structure (Steven et al. 1994) to measure the performance of the quality management in a construction project. They explored the significant performance indicators for the four major targeted fields and for each stage of the life cycle of a construction project, and furthermore determined the guideline of performance measurement for each explored indicator. Russell et al. (1996) established the Continuous Assessment of Project Performance (CAPP) for owner, engineer, and construction contractor organizations can use continuous or time-dependent variables, such as owner expenditures, construction effort hours expended etc., to predict project outcomes from start of detailed design through construction completion. Statistical analysis was performed to identify the significant indicators showing a statistically significant difference between the successful and less-than-successful project outcome. Results show that different indicators were predictors of success at different stage of the project life cycle. In addition, the research report conducted by the National Audit Office (1998) identified that there were many existed auditing methods and technical research directions that were found to be powerful to enhance project performance. The report adopts the 3E performance perspectives which were proposed by Budaus and Buchholtz (1996), and suggests multiple auditing concerns, as well as different evaluation models available for project development and performance measurement, such as ratio analysis, multiple-goal social science integrative evaluation approach and so on.

Although the reviewed studies have provided some indices and models for the performance evaluation of public construction projects, most of them were developed only for the construction stage, and for single dimension of 3E. They are not pursuable to be used for the performance evaluation for a overall public construction project since they were developed without the input of the information at all stages of the life cycle of a public construction project. Therefore, it is urgent to develop an evaluation method that includes the information at all stages of the life cycle of a public construction project, in order to practically measure the overall performance of a public construction project.

FUZZY HIERARCHICAL ANALYSIS FOR PROJECT PERFORMANCE FACTORS

Establishment of the hierarchal structure of evaluating project performance

At the beginning of this study, based on the interviews with experts and scholars associated with construction management, a hierarchical system of evaluating project performance, shown on Figure 1, was established in three dimensions of economy, efficiency and effectiveness (3E). Sixty-five indicators were identified as critical factors affecting project success of a construction project. Among the 65 indicators, 25 indicators are related to economy performance; 26 and 14 indicators are respectively related to efficiency performance and effectiveness performance.

Figure 1: Hierarchy of evaluating project performance

Determining the evaluation factor weights

In general, the factors used to evaluate the performance of a construction project are different on the levels of significance to influence project success. Many methods were employed to determine the level of significance of the effects on the project performance, such as the eigenvector method, weighted least square method, entropy method etc. (Hwang and Yoon 1981). The AHP developed by Saaty (1980) is a very powerful tool to assist users to carry decision making with multiple criteria, and has successfully been applied to many related cases in the construction industry (Mahdi *et* *al*. 2002; Al Khalil 2002; Cheung *et al*. 2002). However, during the operation of AHP implementation, it is easier and more humanistic for evaluators to choose "criterion A is much more important than criterion B," than "the importance of principle A and principle B is seven to one". Hence, Buckley (1985) updated Saaty's AHP to the case where the evaluators are allowed to employ fuzzy ratios in place of exact ratios to handle the difficulty in assigning exact ratios when comparing two criteria, and derive the fuzzy weights of criteria from geometric mean method. Therefore, in this study, we employ Buckley's method, Fuzzy Analytic Hierarchy Process (FAHP), to fuzzify hierarchical analysis by allowing fuzzy numbers for the pair-wise comparisons, and find the fuzzy weights as the level of significance of the effects of factors on project performance.

Fuzzy Analytic Hierarchy Process (FAHP)

The procedure for determining the performance factors weights by FAHP can be summarized as follows:

Step 1: define a linguistic variable

A linguistic variable is a variable whose values are words or sentences in a natural or artificial language. Five basic linguistic terms – "absolutely important," "very strongly important," "essentially important," "weakly important," and "equally important" with respect to a fuzzy five level scale (Figure 2) – were utilized to compare two project execution performance. (Chiou and Tzeng 2001) The scale of fuzzy number on the five basic linguistic terms had been defined by Mon *et al*. (1994), see Table 1, and was applied in this study to determine the weights of evaluation criteria. Each membership function, by means of scale of fuzzy number, is defined by three parameters of the symmetric triangular fuzzy number (TFN), the left point, middle point and right point of the range over which the function is defined.

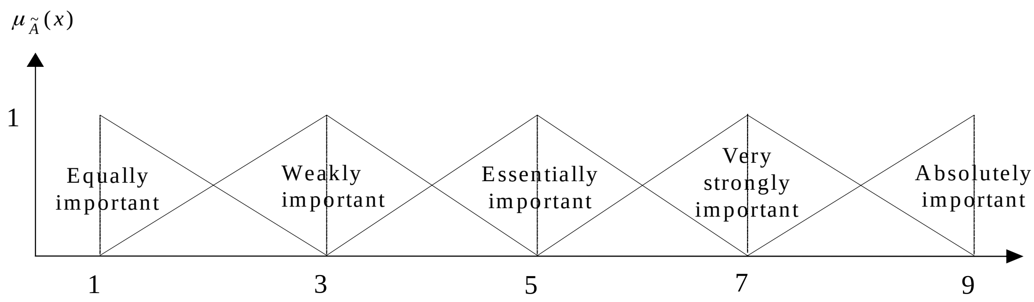

Figure 2: Membership function of linguistics variables for comparing two factors

Table 1: Membership function of linguistic scale

Fuzzy number	Linguistic scales	Scale of fuzzy number
$\tilde{1}$	Equally important (Eq)	(1,1,3)
$\tilde{3}$	Weakly important (Wk)	(1,3,5)
$\tilde{5}$	Essentially important (Es)	(3,5,7)
$\tilde{7}$	Very strongly important (Vs)	(5,7,9)
$\tilde{9}$	Absolutely important (Ab)	(7,9,9)

Note: this is synthesized from the linguistic scales defined by Chiou and Tzeng (2001) and the fuzzy number scale used in Mon *et al*. (1994).

Step 2: construct pair-wise comparison matrices among all the factors in the dimensions of the hierarchy system
Assign linguistic terms to the pair-wise comparisons by asking which is the more important between any two factors, such as

$$\tilde{A} = \begin{bmatrix} 1 & \tilde{a}_{12} & \cdots & \tilde{a}_{1n} \\ \tilde{a}_{21} & 1 & \cdots & \tilde{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{a}_{n1} & \tilde{a}_{n2} & \cdots & 1 \end{bmatrix} = \begin{bmatrix} 1 & \tilde{a}_{12} & \cdots & \tilde{a}_{1n} \\ 1/\tilde{a}_{12} & 1 & \cdots & \tilde{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 1/\tilde{a}_{1n} & 1/\tilde{a}_{2n} & \cdots & 1 \end{bmatrix} \tag{1}$$

where

$$\tilde{a}_{ij} = \begin{cases} \tilde{1},\tilde{3},\tilde{5},\tilde{7},\tilde{9}, & \text{factor } i \text{ is relative importance to factor } j \\ 1, & i = j \\ \tilde{1}^{-1},\tilde{3}^{-1},\tilde{5}^{-1},\tilde{7}^{-1},\tilde{9}^{-1}, & \text{factor } i \text{ is relative less importance to factor } j \end{cases}$$

Step 3: Use geometric mean technique to define fuzzy geometric mean and fuzzy weights of each criterion
Use the geometric mean technique proposed by Buckley (1985) to define the fuzzy geometric mean and fuzzy weights of each criterion as follows:

$$\tilde{r}_i = (\tilde{a}_{i1} \otimes \cdots \otimes \tilde{a}_{in})^{1/n}, \quad \tilde{w}_i = \tilde{r}_i \otimes (\tilde{r}_1 \oplus \cdots \oplus \tilde{r}_n)^{-1} \tag{2}$$

where $\tilde{a}_{in}$ is the fuzzy comparison value of performance factor *i* to performance evaluation *n*, thus, $\tilde{r}_i$ is geometric mean of fuzzy comparison value of performance factor *i* to each performance factor , $\tilde{w}_i$ is the fuzzy level of significance of the i^{th} performance factor, which can be formulated using a TFN, $\tilde{w}_i = (Lw_i, Mw_i, Uw_i)$. Here Lw_i, Mw_i and Uw_i are respectively for the low, medium and high values of the fuzzy level of significance of the i^{th} performance factor.

Step 4: defuzzify the fuzzy numbers
The fuzzy weights reached by pairwise comparison of each factor are a fuzzy number. Therefore, it is necessary that a non-fuzzy method for fuzzy numbers be employed for comparison of each factor. In other words, the step of defuzzifying the fuzzy numbers is to locate the Best Non-fuzzy Performance value (BNP). Methods applied to such step include mean of maximal (MOM), centre of area (COA), and α-cut (Teng and Tzeng 1996). Because it is not required to bring in the preferences of any assessor, and it is simple and practical for the COA method to figure out the BNP, COA method was used to defuzzify the fuzzy numbers in this study. The *BNP* value of the fuzzy number $\tilde{R}_i$ can be obtained with the following equation:

$$BNP_i = [(UR_i - LR_i) + (MR_i - LR_i)]/3 + LR_i, \quad \forall\, i \tag{3}$$

RESEARCH RESULTS

In this study, factor analysis was first implemented to explore the factors with significant impacts on the performance of Economy, Efficiency and Effectiveness associated with overall project performance. The significant factors of each dimension are presented in Figure 3. For the dimension of Economy, 11 out of 25 factors were considered as the factors with significant impacts on the overall project performance. For the dimension of Efficiency, 11 out of 26 factors with significant impacts, and 9 out 24 for the dimension of Effectiveness. Secondly, FAHP was applied to determining the weights of the explored factors from factor analysis depending on their impacts on the overall project performance of a public construction project.

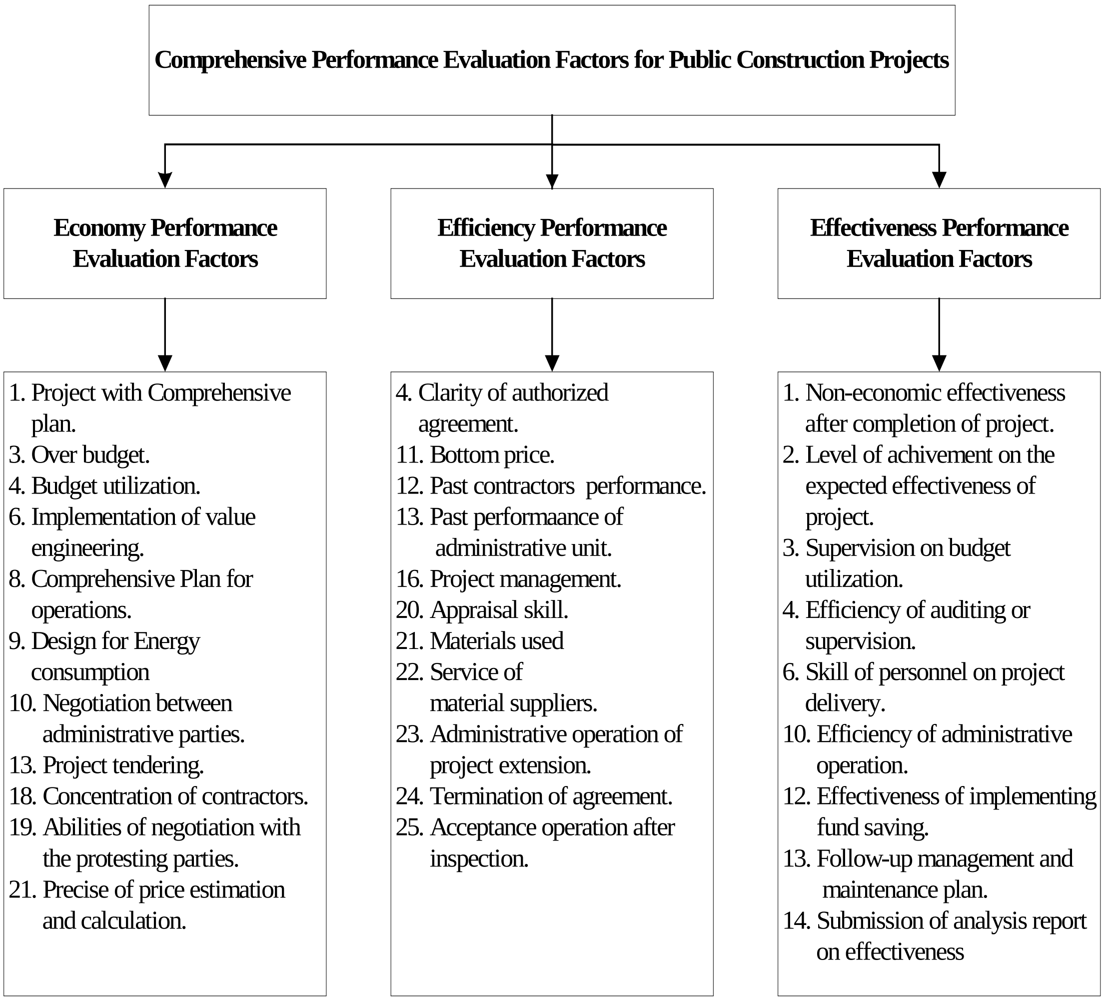

Figure 3: The major factors of each performance evaluation dimension

Based on the results of the FAHP analysis shown in Table 2, the order of level of significance for economy performance factors are: planned operation, comprehensively planned project, energy-saving situation, concentration of contractors, administrative negotiating abilities, negotiating abilities with the protesting public, situation of the use of valuable engineering, situation of price estimation and calculation, situation of budget digesting overbudgeting situation and situation of project tendering.

The order for efficiency performance factors are: materials of project, rear-service supply of materials, appraisal ability, allocation of bottom price, abilities of administrative unit, acceptance operation after inspection, project management, the clarity of authorized agreement, administrative operation of project extension, abilities of contractors and procedures for termination of agreement.

The order for effectiveness performance factors are: follow-up management and maintenance plan, effectiveness of auditing or supervision, namely the non-economic effectiveness after completion of project, efficiency of administrative support, effectiveness of implementing fund saving, execution abilities of personnel, submission of effectiveness analysis report, accomplishment degree of expected effectiveness of project and supervision on budget execution.

Table 2: The weights of major factors of each performance evaluation dimension

Economy performance		**Efficiency performance**		**Effectiveness performance**	
Factors	**Weights**	**Factors**	**Weights**	**Factors**	**Weights**
Project with comprehensive plan	0.1033	Clarity of authorized agreement	0.0963	Non-economic effectiveness after completion of project	0.1185
Over budget	0.0701	Bottom price	0.1048	Level of achievement on the expected effectiveness of project	0.1042
Budget utilization	0.0830	Past contractors performance	0.0659	Supervision on budget utilization	0.0937
Implementation of value engineering	0.0925	Past performance of administrative unit	0.0989	Effectiveness of auditing or supervision	0.1191
Comprehensive plan for operations	0.1069	Project management	0.0982	Skill of personnel on project delivery	0.1088
Design for energy consumption	0.1033	Appraisal skill	0.1050	Efficiency of administrative operation	0.1149
Negotiation betweenadministrative parties	0.0967	Materials used	0.1129	Effectiveness of implementing fund saving	0.1093
Project tendering	0.0557	Service of material suppliers	0.1092	Follow-up management and maintenance plan	0.1235
Concentration of contractors	0.1032	Administrative operation of project extension	0.0683	Submission of analysis report on effectiveness	0.1080
Abilities of negotiation with the protesting parties	0.0939	Termination of agreement	0.0422		
Precise of price estimation and calculation	0.0914	Acceptance operation after inspection	0.0984		

CONCLUSION AND RECOMMENDATION

Conclusion

1. Through the interviews with government officials, it was found that government sectors did not have a reliable performance evaluation system available for project control and management of public construction projects. This purpose of this study is to employ Fuzzy Multiple Criteria Evaluation (which corresponds to the management behaviours of human beings and is now widely employed in many academic studies) to establish a nationwide performance evaluation system for the project delivery of public construction projects.

2. This study underwent qualitative and quantitative analyses on the selection and the weights determination of significant performance indicators across all stages of the life cycle of public construction projects. At first, a questionnaire survey was conducted and then factor analysis was performed to identify the indicators considered as significant factors affecting overall project performance by the experts and scholars in construction management field. Secondly, FAHP was applied to determining the weight of the explored factor, as the level of significance on the impacts on project performance. Through the two steps addressed above, a state-of-art performance evaluation model was built to be objective, reliable, practical and operational for government sectors to evaluate the overall performance of public construction projects.
3. Through this study, many criteria that significantly affect the project performance identified by the experts in construction management field are explored. After collating the opinions of experts, it was found that the impacts of economy, efficiency and effectiveness on the project delivery performance of public construction projects are 32.4%, 33.5% and 34.1% respectively. It is believed that theses three dimension have a similar size of effects on the project delivery performance of public construction projects. However, the dimension of effectiveness performance has the highest concerns, and the dimension of economy performance has the least.

Recommendations

1. This study established the evaluation model mainly based on the financial performance, and yet has not completely included the realm of financial performance. Although the factor analysis and FAHP were used to develop the performance evaluation model in this study, it is suggested that other analytic double-check procedures could be studied and developed in advance to compare the merits and demerits, as well as the applicability of implementing different approaches. In addition, the evaluation criteria can be transformed to the format of ratio to reflect the financial criteria, such as the different financial ratios, operation ratio, proficiency ratio, growth ratio, and so on. With the input of more information, a new complete performance evaluation model related to the proficiency of business operation can be successfully developed.
2. This study divided different evaluation criteria into three groups: economy, efficiency and effectiveness (3E). However, some of the criteria – such as whether the plan and design are well performed, whether new construction methods and new regulations (e.g. slope development and vibration resistance standards, etc.) are well identified and considered as alternatives in the plan and design stages, whether there is any required change due to improper design during construction period, or any increase on the public expenses, and difficulties of maintenance in the later days, or reduction in valid life and increase in needs of additional maintenance and remodel – are related to both dimensions of the efficiency and the economy. It is difficult to put a criterion addressed above to any to the 3E dimensions. Therefore, it is suggested that the evaluation criteria can be grouped according to the following categories: planning, design, public bidding, tendering, construction, acceptance after inspection, and proficiency after completion of construction. It is believed that it is easier to classify the criteria into several groups before any analysis is performed.

A REAL OPTIONS APPROACH TO MEASURE THE TOTAL VALUE OF A PPP PROJECT

Michaela M. Schaffhauser-Linzatti[1] and Bettina Schauer[2]

Public–private partnership (PPP) has gained recognition in financing and managing ventures of public interest by involving private investors. Among others, the public party has to decide which partners to choose; the private party is at first concerned whether to participate anyway. We apply a real options approach to solve both questions. Adapting the underlying model to the specific PPP design, a call value is attached to each possible partnership. To do so, the model is flexible enough to be adapted to any specific PPP construction. As main parameters we introduce a statistical estimate of the underlying service's use as well as fixed and variable fees offered by the potential private partners. The results offer a comprehensive decision basis for all parties concerned.

Keywords: decision support, investment, models, public–private partnership, real options.

INTRODUCTION

Financial restraints of public budgets enforce the inclusion of private initiatives to support public ventures like building, renewing or operating infrastructure of public interest. Numerous concepts operating under the term public–private partnership (PPP) combine the multiple interests of public as well as private partners (Montanheiro 2002). In general, each of the partners participates in a joint project like motorway construction or railway operation and supports it with their individual strengths. Among other things, public institutions may provide a better credit risk and special rights, private organizations know-how and financing. The particular role of each partner is subject to a comprehensive, project-specific contract. The application of PPP projects has been introduced by politicians and practitioners and is now common use internationally.

Academic employment on PPP, however, did not gain recognition until the first empirical projects were finished. Most of the published work is descriptive; theoretical aspects are still underrepresented (Knudsen *et al.* 2001). They mainly concentrate on the interplay between the partners by applying game theory and principle–agent theory (see 'Theoretical framework' below), but do not pay adequate attention to model-based evaluation approaches. So far, well-known instruments developed for other evaluation problems have not been employed to PPP project calculations in spite of their appropriateness. Among these approaches, real option pricing seems to be

[1] michaela.linzatti@univie.ac.at

promising, mainly because it allows for simultaneously regarding the different perspectives of the divergent stakeholders and for incorporating uncertainty. This uncertainty relates to the expected future benefits resulting from the joint project, e.g. to what extent the services being offered are accepted, and consequently to the returns of these services.

This paper focuses on the question how to evaluate a PPP project by means of a real options model. Real options theory applies classic option pricing to real investments; the term ‘real option’ is used to distinguish options arising in contexts other than purely financial ones, e.g. in the pharmaceutical, biotech, petroleum and energy industries (see Boer 2002). In general, an option provides the right to buy or sell an asset, originally a stock, for a predetermined price at some point in time in the future. The holder of the option is not forced to exercise this right, and will only do so if it seems to be opportunistic. PPPs are real projects per definition; hence, real options theory is a promising approach as the decision to exercise an option is very similar to decisions taken in PPP projects, e.g. when deciding whether to participate and thus invest in a partnership.

Regarding a PPP project as an option offers the flexibility to model the enhancement, delay or termination of the partnership depending on whether conditions turn out favourably, which can be modelled by using the option to expand, to defer or to abandon (see Trigeorgis 1996). Thus, real options evaluation incorporates comprehensive and dynamic aspects in contrast to the more or less static treatment of costs and revenues applied so far. We show that our real options model offers an adequate theoretical approach for PPPs with a straightforward implementation.

The paper is structured as follows. The next section describes the theoretical framework of real options models, concentrating on their structures and fields of application. The third section derives our real options model adapted for PPP evaluation; the fourth section discusses its practical use and limitations; finally the concluding section summarizes the results.

THEORETICAL FRAMEWORK

Among the theoretical approaches to decide on PPP problems, game theory and net present value based models have been mostly applied so far. Game theory models strategies of decision makers as well as information available concerning the status of competitors (von Neumann and Morgenstern 1944), while using decision theory the agents play against nature (Arrow 1957; Raiffa 1997). Hereby, the popular decision tree analysis demands the complex and time-consuming assignment of probabilities to uncertain variables and preferences to uncertain outcomes (Poh *et al.* 2001). Principal–agent models (Ross 1973) have been recently applied for PPP (Pongrisi 2004); however, they concentrate on the exploitation of information asymmetry to maximize revenues and not on valuation (Renzetti and Dupont 2003; Trebilcock and Iacobucci 2003). Finally, the traditional economic models based on cash flows require satisfyingly fixed conditions and constant discount rates and hence undervalue high risks in long-term projects (Amran and Kulatilaka 1999; Graves and Ringuest 2003).

Real options analysis does not face these – partially prohibitive – drawbacks. It is well suited for projects with a high level of exogenous and partly endogenous uncertainties (Neely 1998) like the market pay-off, budget, performance, market requirements and schedule uncertainty (Huchzermeier and Loch 2001) as it retraces the projects’ continually changing processes, rewards risk taking, and is able to evaluate project options on the price path of traded assets in the sense of financial investment opportunities (Myers 1977). To do so, the binominal model and the Black–Scholes formula can be applied.

The multiplicative binomial option pricing model by Cox and Rubinstein (1979) is based on constructing a replicating portfolio and determining its costs in order to determine the value of the option equivalent. Its iterative process divides the time of expiration into discrete steps similar to the decision tree analysis. However, Trigeorgis (1996) points out the disadvantages for evaluation of long-term projects. First, the underlying decision trees quickly become unmanageable as they grow exponentially with the numbers of decisions. Second, appropriate, and most probably changing discount rates over the whole period have to be found. Finally, the call value in the binomial model converges to the results of the Black–Scholes formula in case of $t \rightarrow \infty$.

If long-term statistical records are available to measure the risk of an underlying asset by determining the volatility of the price movements and thus the volatility of the rate of return such as for financial assets, the Black–Scholes formula for option pricing (Black and Scholes 1973) can be applied for real projects. However, there is usually no volatility observable for real projects. Thus, historical data from similar projects can be used as an approximation, or the volatility is derived through estimations of the value of future cash flows and the consequent deviation (Perlitz *et al.* 1999). The Black–Scholes formula uses the input parameters S = current value of the underlying asset, K = strike price of the option, t = life of option expiration, r = riskless interest rate corresponding to the life of the option, σ^2 = variance of the underlying asset, and $\Phi(.)$ = the cumulative normal density function:

$$v = S\Phi(d_1) - Ke^{-rt}\Phi(d_2)$$

$$\text{where } d_1 = \frac{\left(ln\left(\frac{S}{K}\right) + \left(r + \frac{\sigma^2}{2}\right) t \right)}{\sigma\sqrt{t}},\ d_2 = d_1 - \sigma\sqrt{t}$$

By analogy to the financial options evaluation with Black–Scholes, the expected benefits of a PPP project correspond to the stock price, the project costs to the strike price, the date on which the implementation of the project is decided on to the exercise date, and the variance of the expected benefits to the volatility. The long-time maturity enforces an adaptation of some input parameters like the risk-free interest rate. As the project is not traded such as financial options, Perlitz *et al.* (1999) suggest deriving the underlying asset by spanning, i.e. creating a twin security by duplicating cash flows of the non-traded asset to a traded portfolio, by hotelling, i.e. estimating the market potential of the future products of the projects, or by future cash flows.

MODEL

In its basic outline, the real options model is based on a BOT (build–operate–transfer) structure of a PPP project (Akintoye *et al.* 2003). In such a structure, the private partner builds and operates the project which is transferred to the public partner at a known time. Until then, the public partner supports the project, among other things, by granting special rights or by taking credit risks, and is rewarded by fees. Hence, a real options model has to comprise computational decision bases for both partners.

Underlying assumptions

We suppose one public and a number of potential private partners i, with n being the total number of potential private partners i. The public partner is in search of the best private partner in order to share risk, know-how and investment. Each private partner must decide whether to make an offer, and, in the event of participation, decide on an offer of the fee payments. Note: To simplify the BOT-model without reducing its explanatory power, we incorporate the transfer step as follows. After finalization of the project in period T, the public partner pays a redemption rate R which is fixed at the beginning of the partnership to the private partner. To integrate R into the model without further calculation in T, R is discounted by a constant interest rate r_c which is also fixed in advance, increases the investment of the public partner and reduces the initial costs of private partner in t = 0, respectively. Hence, I and C_0 in the model (see Equations 6 and 12 below) are already adjusted by the discounted R.

As an example, the model is embedded into the realistic and frequently used application of PPP motorway building and operating. The public partner plans to enlarge the motorway network by a specific route and chooses to take in a private partner.

Each possible private partner offers to pay the public partner an annual total fee (TF) which consists of a fixed and a variable part, F_f = fixed fee and F_v = variable fee.

$$TF = F_f + F_v*q \qquad (1)$$

where the uncertain variable q equals the total number of driven kilometres (or quantity consumed) by the customers. q is estimated by the public as well as by each private partner independently and is supposed to follow a normal distribution with mean $\mu = \mu(p)$ and standard deviation $\sigma = \sigma(p)$. q is correlated to the road charge p (or any fee) the customers have to pay. p is determined by each private partner:

$$q = q(p) \qquad (2)$$

In this price–demand function q is assumed to be a monotonically decreasing function of p; a quantity q_0 might be assumed not to be exceeded even if the service is offered for free.

Hence, the total earnings (TE) of the private partner are:

$$TE = p*q. \qquad (3)$$

Beside the TF pay-offs to the public partner, each private partner faces additional total costs (TC) to third parties, C_f = fixed costs and C_v = variable costs per kilometre:

$$TC = Cf + Cv*q \qquad (4)$$

Thus, the total pay-off (TP) of a private partner consists of TF and TC:

$$TP = TF + TC \qquad (5)$$

As easily can be shown, TP converges asymptotically towards $C_f + F_f$.

Public partner

The decision of the public partner is to find the optimal private partner i, which is the partner yielding the highest call value V_i. To make a profit, V_i must not be negative for the public partner in any case (for introducing welfare, see Discussion, below). Note: The project requires another investment cost I which might occur, e.g. because of legal requirements or acquisition of realty. I is assumed to be independent of the private partner and has to be paid by the public partner.

Hence, the optimization criterion is to maximize the call value V_i of the public partner's decision:

$$Vi = TF\Phi(d1) - I * e{-}rt\Phi(d2) \tag{6}$$

$$\text{where } d_1 = \frac{\left(ln\left(\frac{TF_i}{I}\right) + \left(r + \frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}},\ d_2 = d_1 - \sigma\sqrt{t}$$

Consequently it follows:

Do not invest, if $\max_{i=1}^{n}(V_i) < 0$ (7a)

Choose the private partner *i* yielding $\max_{i=1}^{n}(V_i)$ (7b)

Private partner

The decision of each private partner is to make an offer for TF, consisting of F_v and F_f, depending on each private partner's choice for p and according expectation for q. Hence, the optimization criteria are first to find the equilibrium (Equation 10) of marginal revenues (MR) (Equation 8) and marginal costs (MC) (Equation 9), and second to determine the decision's call value V (Equation 11). Note: The private partner has to invest another C_0 which refers to the initial investment for offering the service (e.g. building the motorway).

Assuming that the private partner defines the price p per kilometre and the kilometres driven q are a function of the price *q = q(p)* the marginal revenue corresponds to:

$$MR = \frac{dTE}{dq} = \frac{d(p * q)}{dq} = p \tag{8}$$

$$MC = \frac{d(TC + TF)}{dq} = \frac{d(C_f + C_V * q(p) + F_f + F_V * q(p))}{dq} =$$

$$\frac{d((C_V + F_V) * q(p))}{dq} = C_V + F_V \tag{9}$$

$$p_{\lim} = C_V + F_V \tag{10}$$

The call value of a private partner's investment decision is given by

$$V = TE\Phi(d1) - (TP) * e{-}rt\Phi(d2)$$

$$\text{where } d_1 = \frac{\left(ln\left(\frac{TE}{TP}\right) + \left(r + \frac{\sigma^2}{2}\right)t \right)}{\sigma\sqrt{t}},\ d_2 = d_1 - \sigma\sqrt{t} \tag{11}$$

Consequently it follows:

$$\text{Invest, if } V > C0 \tag{12}$$

DISCUSSION

The real options model presents an evaluation approach for a PPP motorway project with a BOT structure, in which one public partner chooses among a number of private partners to cooperate with. Of course, multiple enlargements of the model are possible.

The model can be applied to all construction and building projects as well as to services for which PPP is generally applicable.

It can also be easily extended to partnering structures other than BOT. In such cases, additional variables like different quantity measures or fixed investments might possibly be introduced. Note that according to the application, F_{fi} could also vary per time period yielding F_{fij} with j being the index of the period.

Some PPPs include contractually guaranteed minimum sales, i.e. the private partner ensures a minimum q_i and consequently a minimum total F_{vi}. This case can be easily implemented into the model by including the minimum $F_{vi} * q_i$ into F_{fi}.

In this model, p is assumed to be determined by each private partner independently. However, lower and/or upper price limits might be introduced by the government.

Interrelations among the public and private partners can be included into the model by combining the real options model with game theoretic aspects. The combination of real options and game theory has already been applied to model the interrelations between partners and competitors within the scope of R&D projects (Grenadier 2000a, b; Weeds 2002; Lambrecht and Perraudin 2003).

It is easy to modify the model, when public and private partners agree on constant percentages among fixed and variable fees, lower and upper boundaries of such percentages, or a split of the realized revenues, fixed or variable costs.

Public projects should not be carried out only for financial gain, but mainly to increase public welfare. Direct financial reliefs for customers such as price reductions or remissions are easy to include in the model. Non-monetary, indirect or long-term reliefs such as environmental pollution or safety aspects force the introduction of welfare parameters well known in economics (Varian 1999). Such social cost–benefit calculations are best introduced into the model by either increasing the annual F_f or by including a welfare ratio into F_v. In such cases, Equation 7a has to be modified accordingly.

CONCLUSIONS

This paper develops a real options model for evaluating PPP projects. By adapting the Black–Scholes formula for financial options, we show that this approach is suitable as a decision basis for all participating parties (a) whether to take part in such a joint project; and (b) which partner to choose. Hereby, the public partner invites private partners to build and operate a project of public interest and transfer it back after a previously defined time. The public partner makes the initial investments and in turn receives fixed and variable fees from the private partner. Each party is willing to join the project if the value of their call option exceeds their initial investment for acquiring the option. The public partner enters into partnership with the partner offering the highest return. Our model covers uncertainty and is flexible enough to integrate possible further enlargements. It reflects realistic conditions and can easily be implemented.

THE HIERARCHY AND RELATIONSHIP OF PROJECT PERFORMANCE CRITERIA IN INDIAN CONSTRUCTION PROJECTS

K.N. Jha[1] and M.N. Devaya[2]

Department of Civil Engineering, Indian Institute of Technology Delhi, Hauz Khas, New Delhi-110016, India

The assessment of the success of a project has always been a subject of debate because of the large number of criteria by which the various participants of a project would like to assess the project. The aim of this study is to identify the important success criteria, arrange them in a hierarchy, and analyse the relationships among them in order to present to a project manager a 'bird's eye view' of the criteria that need to be concentrated upon depending upon the role of each criterion in terms of its ability to influence other criteria. Twenty-two criteria were identified from published literature and the most important 14 were selected based on a questionnaire survey, where the respondents were asked to rank each of the criteria in terms of its importance. These 14 criteria were then analysed using ISM and Micmac analysis. The results show that efficiency of project execution is the most influential criterion. The methodology presented in the study could be useful in several areas of construction management.

Keywords: India, project management, project performance.

INTRODUCTION

Defining the success of a project has always been full of ambiguity and there is no universal definition of success. McCoy (1986) observes that a standardized definition of project success does not exist nor is there an accepted methodology to measure it. The problem in the case of a construction project is compounded by the presence of different players (client, consultant(s), contractors), which have differing and at times conflicting objectives.

Success is viewed from different perspectives of individuals and the goals are related to a variety of elements including technical, financial, education, social and professional issues (Parfitt and Sanvido 1993; Lim and Mohamed 1999). Each industry, project team or individual has a definition of success. Failures and successes are relative terms and they are highly subjective (Parfitt and Sanvido 1993). Definition of success or failure can even change from project to project. Success for one participant may be a failure for another (Jha and Iyer 2004; de Wit 1988).

The perception of success or failure is also time dependent. The Denver airport project in the USA reveals that what was viewed as a failure during the construction phase is now treated as a success owing to high inflow of revenue and improved life style of local inhabitants (Griffith *et al.* 1999).

[1] knjha@civil.iitd.ac.in

Traditionally, project success is defined as the degree to which project goals and expectations are met and the project requirements are fulfilled and the project performance is evaluated using schedule, cost and quality performances, also known as the ‘iron triangle’ (Atkinson 1999).

Subsequently researchers have proposed different objective and subjective sets of project performance criteria in addition to the iron triangle. Some of the criteria used for evaluating the project performance are: perceived performance; client satisfaction; contractor satisfaction; project management team satisfaction; technical performance; technical innovativeness; efficiency of project execution; managerial and organizational expectations; personal growth; project termination; functionality; and manufacturability and business performance (Baker *et al.* 1983; Ashley *et al.* 1987; Freeman and Beale 1992). Further, a number of other studies have been conducted by different researchers who try to develop different frameworks for defining project performance parameters (Baccarini 1999; Songer and Molenaar 1997; and Chan *et al.* 2002). Some attempt has also been made to find the relative weight of the performance criteria. The studies, so far, have however neither tried to understand the inherent interrelationship(s) among the different performance criteria, nor tried to prioritize them scientifically.

OBJECTIVES

Based on the brief discussion above of the need to better understand the criteria affecting project success, the present study was carried out with a view to:

1. identify and rank the success criteria or parameters in a construction project;
2. better understand the role of individual criteria, and the interaction among them.

It is hoped that the results will throw new light on the prioritizing of activities of a project manager.

RESEARCH METHODODLOGY

As discussed earlier, several researchers have presented alternative criteria for evaluation of success of a construction project. From the different criteria already identified in published literature, a list of 22 criteria was drawn up on the basis a general agreement among professionals. This list was used to prepare a questionnaire to enable ranking of individual criteria. Responses to this questionnaire were obtained from 33 professionals in the Indian construction industry. The top 14 criteria were chosen for further analysis using interpretive structural modelling (ISM) and Micmac analysis. It may be noted that though these systems analysis tools have been relatively extensively used to analyse interrelationships among different variables in areas such as material management (Mandal and Deshmukh 1994) and supply chain management (Faisal *et al*. 2006), their use in the construction sector is not common. The ISM methodology (Sage 1977) uses the opinion of a group of experts to analyse the relationship between each pair of criteria and develop a model which shows the criteria arranged in a hierarchy showing their interrelationships. This enables practitioners to focus on key criteria. The Micmac analysis uses the same input as the ISM and classifies the criteria into groups depending on the driving power and dependence of each criterion. This classification could be very helpful to a project manager to understand the role of each criterion in terms of the overall success of the project.

RANKING THE PROJECT SUCCESS CRITERIA

Twenty-two project success criteria identified from a literature survey were used to develop a questionnaire. The respondents were asked to award a score to each of the criteria on a Likert scale of 1 to 5 corresponding to ‘Not at all important’, ‘Slightly important’, ‘Moderately important’, ‘Highly important’ and ‘Extremely important’, respectively. Questionnaires were administered personally to executives of construction firms and the responses were filled in the presence of the authors. A total of 33 responses were obtained in which 10% of the responses were from executives in the top management, 36% from middle management and 54 % from lower management. Out of the total respondents, 48.5% of the respondents had 11–20 years of experience and 15 % had more than 20 years. Further, 54% of the responses were from people working in the private sector, and the rest from government-controlled companies. Companies with more than 500 employees contributed 88% of the responses and 43% of the responses were from companies having more than US$200 million in annual sales.

The responses were analysed using SPSS, and the individual score for any criterion was determined as the average of all the 33 responses. The resulting scores for each of the 22 criteria are listed in Table 1. It may be noted that the maximum score for a criterion is 5.

Table 1: Ranking of project success criteria

Rank	Project success criteria	Code for reference	Mean score (scale of 1–5)	Remarks
1	Quality compliance	C_1	4.76	Considered ‘extremely’ important
2	Safety and health compliance	C_2	4.73	
3	Cost compliance	C_3	4.64	
4	Client satisfaction	C_7	4.61	
5	Profitability	C_5	4.42	Considered ‘highly’ important
6	User satisfaction	C_6	4.21	
7	Personal growth	C_9	4.15	
8	Efficiency of project execution	C_8	4.06	
9	Schedule compliance	C_4	4.03	
10	Organizational and managerial expectations	C_{10}	4.00	
11	Perceived performance and functionality	C_{11}	3.97	Considered important
12	Meeting technical performance and functionality specifications	C_{12}	3.91	
13	Reduction of disputes	C_{13}	3.67	
14	Contractor satisfaction	C_{14}	3.67	
15	Project management team satisfaction	C_{15}	3.48	Not considered for further analysis
16	Technical innovation	C_{16}	3.45	
17	Environmental sustainability	C_{17}	3.42	
18	Technical performance	C_{18}	3.42	
19	Functionality	C_{19}	3.33	
20	Preparing for the future	C_{20}	3.27	
21	Meeting design, functional, technical, managerial and organizational goals	C_{21}	3.12	
22	Project termination	C_{22}	2.48	

From Table 1 it can be seen that quality compliance, safety and health compliance, cost compliance and client satisfaction, having mean scores of 4.76, 4.73, 4.64 and 4.61, respectively, were identified as the most important factors defining success of a construction project. Given that these were the only factors scoring more than 4.5, they could be identified as ‘extremely important’. The appearance of criteria related to quality and safety with such high values is indicative of the changes in the priorities in the Indian construction scenario, which has been traditionally regarded as slack in terms of the importance accorded to these issues. Profitability, user satisfaction, personal growth, efficiency of project execution, schedule compliance and meeting organizational and managerial expectations are the criteria with mean scores between 4 and 4.5 and can be considered as the 'highly important' criteria. The criteria with mean scores between 3.5 to 4 are: perceived performance and functionality, meeting technical and functional specifications, reduction of disputes and contractor satisfaction. The remaining criteria (C_{15} to C_{22}) had mean scores ranging from 2.48 to 3.48 and were considered less important for further analysis and were dropped from the subsequent analysis. Hence, only the 14 criteria (C_1 to C_{14}) discussed above have been selected for further analysis since these are the most important criteria. A project's success or otherwise could be determined to a large extent by its performance in these 14 criteria and to a lesser extent in the remaining eight criteria. Further, keeping these eight criteria in the model development would have resulted in a large number of links and cross-links making it difficult to interpret.

INTERPRETIVE STRUCTURAL MODEL

Development of the model

ISM is a systems analysis tool used for identifying and summarizing relationships among specific variables that define a problem or issue or system (Sage 1977). It provides a means by which order can be imposed on a system. Therefore the 14 project success criteria are considered as the variables or components of a system whose output is a successful project. The technique is based on an analysis of interaction between variables in terms of a 'cause–effect' format, as identified by a panel of experts. In this case, a panel of three experts (different from the 33 respondents who scored the 22 criteria) were asked to opine on which of the following statements, referred to as V, A, X and O in further analysis, best define the relationship between any two criteria '*i*' and '*j*':

- criterion *i* helps meet criteria *j* (V);
- criterion *i* is helped by criteria *j* (A);
- criteria *i* and *j* help each other (X); and
- criteria *i* and *j* are unrelated (O).

For example the relationship between C_1 and C_{13} is defined as V which means that making efforts to meet project success criterion C_{13} helps meet project success criterion C_1 (see Figure 1). The relationship between C_1 and C_8 is defined as A which indicates that making efforts to meet project success criterion C_8 helps meet project success criterion C_1. It can be seen that the relationship between C_1 (quality compliance) and C_{14} (contractor satisfaction) is defined as X, which means that the relationship is both ways, that is making efforts to meet either of these criteria helps meet the other criterion. The relationship between C_9 (personal growth) and C_{14} (contractor satisfaction) is defined as O, which means that criteria C_9 and C_{14} are not related.

ISM methodology recommends the use of expert opinion to identify the relationship between the variables. This input of the experts has been summarized to form the that experts could obviously differ on their perception on the relationship between two criteria, and Figure 1 was drawn up on the basis of a majority opinion among the experts.

Code (*i*)	Performance criteria (*j*)												
	C_{14}	C_{13}	C_{12}	C_{11}	C_{10}	C_9	C_8	C_7	C_6	C_5	C_4	C_3	C_2
C_1	X	V	X	X	X	O	A	V	X	O	O	V	O
C_2	V	V	O	O	V	O	A	V	O	V	O	V	
C_3	O	X	O	A	O	O	O	V	V	V	A		
C_4	V	X	O	O	V	O	X	V	O	V			
C_5	X	A	O	O	V	O	A	A	O				
C_6	O	O	A	X	V	O	O	X					
C_7	O	X	A	X	X	O	A						
C_8	V	X	X	O	V	V							
C_9	O	O	O	A	X								
C_{10}	X	X	A	A									
C_{11}	O	V	A										
C_{12}	X	V											
C_{13}	X												
C_{14}													

Legend:
V = criterion ‘i’ helps meet criterion ‘j’
A = criterion ‘i’ is helped by criterion ‘j’
X = criterion ‘i’ and ‘j’ help each other
O =criterion ‘i’ and ‘j’ are unrelated

Figure 1: Structural self-interaction matrix (SSIM)

The ISM software called ‘Concept Star’ from Sorach International has been used to analyse the SSIM data. Though the details have been omitted in this paper, it has been established that the model generated could have inconsistencies on account of transitive links (if A is related to B (A _ B) and B _ C, then A has to be related to C; or if A_ B and B is not related to C, then A cannot be related to C) (Sage 1977 and Sorach 1999). In this case also, the model generated was examined for inconsistencies by the authors using their experience, and ironed out using the ‘secondary links’ feature of the software. For example, the three experts have given a ‘V’ to the relationship between schedule compliance (C_4) and contractor satisfaction (C_{14}), as shown in Figure 1. ‘V’ means that meeting the schedule compliance criterion will help meet the contractor satisfaction criterion, but not vice versa. Hence the two are related. However owing to transitivity, the ISM software did not permit this relationship and this inconsistency was removed by introducing a link using the 'secondary links' feature of the software. The final model obtained is shown in Figure 2.

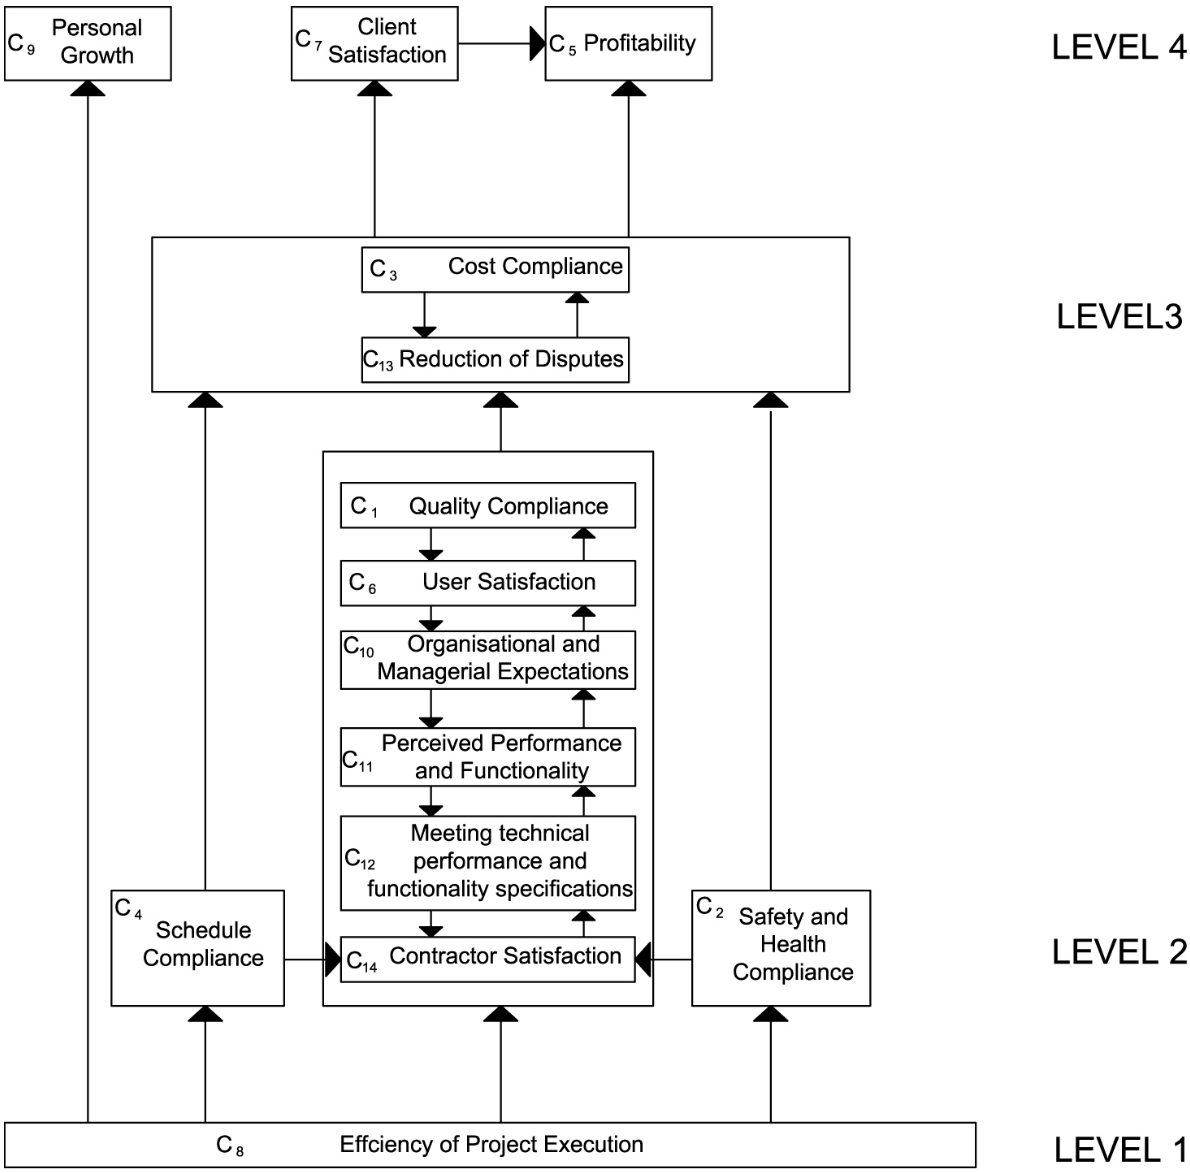

Figure 2: Interpretive structural model (ISM)

Analysis of the model

It can be seen from Figure 2 that the 14 criteria have been placed in a hierarchy, which places 'efficiency of project execution' at the first level, shown at the bottom of the figure, and also that this criterion is linked to all the other criteria. This finding can be taken to mean that focusing on this criterion helps meet all the other (success) criteria. Conversely, if the project execution is not managed efficiently, all other criteria are likely to suffer. In other words, a project management team efficiently executing the project gives maximum payoffs in terms of project success.

Eight of the 14 criteria (56%), fall in the second level, and if we include the first level criteria, and exclude personal growth (for reasons discussed later) then a substantial 69% of the criteria fall in the lower half of the model. This uneven distribution means that there are a larger number of success criteria that have to be addressed for the project to be considered a success. Six of the eight criteria in the second level are interrelated and hence the payoffs from taking measures to meet these criteria are likely to be more as compared to actions taken on schedule compliance and safety and health compliance. This does not however detract from the importance of these two criteria, it is just a question of relative gains.

Cost compliance and reduction of disputes are at the third level and they are affected by all the criteria discussed until now. Hence cost compliance and reduction of disputes will be achieved if attention is paid to the factors in the first two levels. These two criteria directly affect profitability and client satisfaction.

The criteria at the end of the hierarchy shown at the top of Figure 2 are profitability and client satisfaction, which can be taken to mean that these are most influenced by the other criteria and do not themselves influence any of the other criteria. In other words, so long as other criteria are appropriately addressed, profitability and client satisfaction are automatically taken care of. This can also be interpreted to mean that even by concentrating on other success criteria, a project management team can show results in terms of profitability and client satisfaction.

Figure 2 shows that there are three paths between efficient project execution and profitability/client satisfaction. The paths through schedule compliance and safety and health compliance are direct and hence more autonomous than the third path, since these two criteria do not interact with other criteria at the same level and they directly influence cost compliance and reduction of disputes. Hence, schedule compliance and safety and health compliance have less influence than the other six criteria in the second level. These six criteria that can be considered to be relatively more important are: quality compliance, user satisfaction, organizational and managerial expectations, perceived performance and functionality, meeting technical performance and functionality specifications and contractor satisfaction. Thus management will derive greater payoffs by focusing on these six criteria; however, it must be kept in mind that schedule compliance and safety and health compliance are important criteria, hence their presence in the second level.

Figure 2 also shows an interesting relationship between personal growth and the other criteria. This criterion is not linked to the system except for a dependence on efficiency of project execution. To that extent it can be identified as an autonomous criterion, which does not form a strong part of the system and does not directly affect any of the other project success criteria. Given the relatively high position of personal growth in Table 1 (score of 4.1), it can be stated that its importance lies as a motivational factor for the members to continue to strive for the success of a project.

MICMAC ANALYSIS

Micmac analysis (impact matrix cross-reference multiplication applied to a classification) (Arcade 2003) has been used to analyse and better understand the role of different components of a system. The Micmac analysis is an extension of the ISM in that it gives a numerical value to the strength of relationship between two variables or criteria. The criteria are analysed on two aspects. First, the number of criteria that the criterion under consideration affects; this gives its driving power or ‘influence’, i.e. its capability to influence other criteria. Secondly, the number of criteria that influence the criterion under consideration; this gives its ‘dependence’. The positions of the criteria are plotted on the influence–dependence map from which useful inferences can be drawn.

In the present study, the method was used to analyse the 14 criteria listed in Figure 1, and understand each of them in terms of their ability to influence others, be influenced by others, and so on. The analysis was carried out using the special Micmac software developed by ‘3IE’ (Institut d’Innovation Informatique pour l’Entreprise). The SSIM developed for the ISM analysis was used as the input data for the Micmac software.

Influence–dependence map

The results from the Micmac analysis are often presented in the form of an influence–dependence (I-D) map, and the individual points are plotted using the conventional x–y coordinate system. It may also be mentioned that conventionally, the map is divided into four quadrants, and the role of a particular criterion (or parameter) understood in terms of the position. This map obtained for the 14 criteria used in this study is shown in Figure 3. Now, given that the ‘dependence’ increases from left to right, and the influence increases from bottom to top, the area near the origin (the south-west quadrant) consists of points low on both scales and therefore those which can be considered as independent (or autonomous). Similarly, areas defined by the north-west and south-east quadrants are characterized by points with high influence with a low dependence and vice versa. These are sometimes also referred to as the influent and the dependent areas respectively. The north-east quadrant, comprising factors high on both dependence and influence, defines the so-called relay factors.

In the present study, based on the total score of each of the 14 criteria, the I-D coordinates were calculated and the criteria were plotted on the I-D map, as shown in Figure 3. This representation is discussed in greater detail below:

Influent factors

As mentioned above, these criteria in the north-west quadrant represent the subset that influences other criteria strongly, and depends little on them. ‘Efficiency of project execution’ occupies the position of highest influence and hence can be considered as the most important criterion. The other important factors since they are highly influent are: meeting technical performance and functionality specifications; quality compliance; schedule compliance; safety and health compliance and user satisfaction.

Relay factors

These factors, located in the north-east quadrant, have high influence and dependence, and need to occupy a high place in the decision-making process. Interestingly, the only criterion in this category in the present study is reduction of disputes. It can be well appreciated that reducing the disputes in a construction project will have far-reaching implications on the success of the project and hence the importance of this criterion. Indeed, the attention given by a construction company to reduction of disputes pays high dividends since it is both highly influential and is dependent upon other criteria.

Depending factors

Lying in the south-east quadrant of the I-D map these factors are more dependent and less influent. It may be noted that these factors could be called less critical from the point of view of decision making as they could be ‘taken care of’ if the factors that influence these are appropriately addressed. In the present study, as illustrated in

Figure 2, the criteria in this category are: contractor satisfaction; organizational and managerial expectations; client satisfaction and profitability.

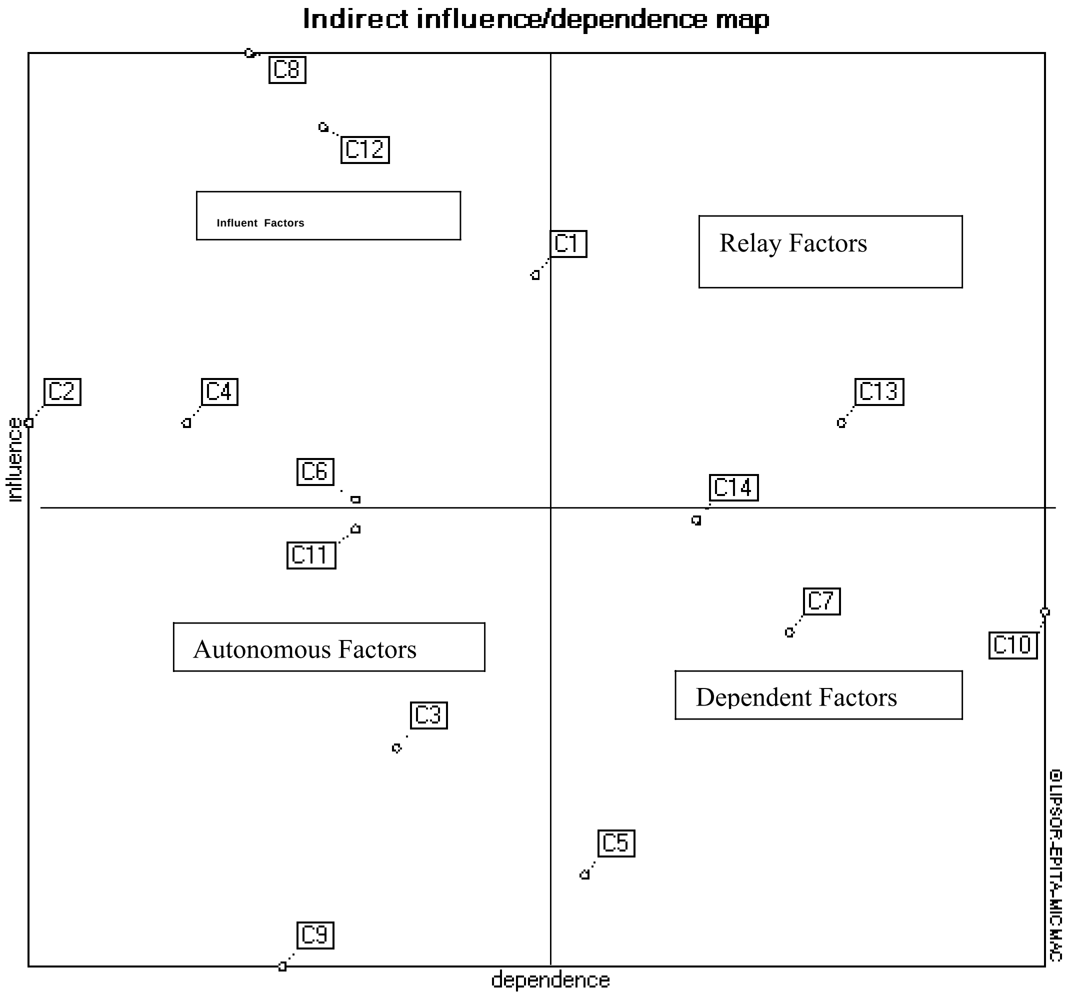

Figure 3: Indirect influence–dependence map

Autonomous factors

Factors located in the south-west quadrant are low on dependence and also influence – and could be looked upon as 'autonomous' or 'independent' in nature, and appear out of line with the system. Among the criteria in this part, a distinction is made between 'disconnected factors' and 'secondary levers', as discussed below.

Disconnected factors

These are situated near the origin and their evolution therefore appears to be excluded from the systems' global dynamics. Personal growth falls into this category, which is also brought from the ISM analysis mentioned above. In other words, it may be concluded that personal growth may not be specific to this system, i.e. project success, but is possibly a common requirement for all enterprises.

Secondary levers

These criteria are located above the diagonal and are more influent than dependent. These are, thus, not disconnected from the system and have some (albeit a low level of) influence on the other criteria. In the present study, perceived performance and functionality and cost compliance fall in this category.

It is clear from the methodology followed here, and that used in the Micmac analysis in general, that some issues could lie close to the borderlines of the quadrants, and thus such criteria need to be interpreted in a manner that they lie in a grey zone. For example in the present idea, C_1 lies on the border of the relay factors and influent factors and could therefore be a relay factor or an influent factor.

CONCLUSIONS

Twenty-two construction project success criteria were identified from published literature and later used in a questionnaire survey to determine their relative ranks. From this list, the top 14 criteria were identified and more rigorously analysed using interpretive structural modelling and Micmac analysis, which have been routinely used in the areas of material management and supply chain management though their application in the area of construction management is rare. Within the constraints of the questionnaire used and the analysis carried out in this study, the following conclusions can be drawn:

1. Efficiency of project execution emerges as a key success criterion having an influence on all the other success criteria under consideration.
2. Profitability and client satisfaction can be identified as criteria that are most influenced by others, and they themselves do not have an influence on the other success criteria.
3. Nine of the success criteria, that is 69%, are located in the first and second level of the model and six of them are interrelated. Hence construction project success requires attention to a large number of criteria, but the fact that six of them are interrelated spreads the effect of the efforts.
4. Personal growth is an autonomous factor that is not an intimate part of the system.

The findings of the paper can be useful to a project management team in focusing their attention on certain criteria with the tacit knowledge that some of the other criteria would then automatically be taken care of. In other words, the project manager can logically prioritize the criteria requiring attention.

EXPLORING KEY ATTRIBUTES INFLUENCING CONSTRUCTION CLIENT SATISFACTION: A QUESTIONNAIRE SURVEY

Jianxi Cheng,[1] David Proverbs and Chike F Oduoza

School of Engineering and the Built Environment, University of Wolverhampton, Wulfruna Street, Wolverhampton, WV1 1SB, UK

Satisfying clients and creating a harmonized relationship amongst project participants can facilitate improved project performance and perceived success, and are thus critical for the existence and competitiveness of participants in the construction marketplace. However, client satisfaction as an important aspect of business remains an elusive issue to a majority of construction professionals. This research aims to explore key attributes influencing client satisfaction. The findings of a UK-wide questionnaire survey of public and private sector construction clients are reported. Descriptive data analysis is applied to investigate key aspects of client satisfaction. From the results, it is revealed that there exists a lack of clear understanding of the concept of client satisfaction. Clients' strategic decisions and their characteristics are found to have a crucial impact on their own satisfaction. The overall quality of services provided by service providers (consultants and contractors) plays a fundamental role influencing client satisfaction amongst other key attributes. Furthermore, the impact of strategic decisions on client satisfaction is shown to have strong links with different project stages. The results demonstrate that clients' optimum decisions and improved service quality from service providers can positively underpin project performance and lead to heightened client satisfaction and perceived project success. The findings will improve the understanding of the conception of client satisfaction and benefit both clients and their service providers.

Keywords: client satisfaction, performance, questionnaire survey, service providers, strategic decisions.

INTRODUCTION

In the construction domain, satisfying clients and creating a trustworthy and harmonized project relationship can facilitate improved project performance and perceived success and are thus critical for the existence and competitiveness of participants in the construction marketplace (Latham 1994; Egan 1998, 2002). Client satisfaction plays a fundamental role in determining the perceived success of a project and represents the bottom line of successful project implementation (Ashley *et al*. 1987; Bresnen and Haslam 1991; OGC 2002).

In the UK construction industry, however, client satisfaction has been a problematic issue for some considerable time (Banwell 1964; Latham 1994; Egan 1998; Egan 2002), and is an aspect of business that until now has been given little priority (Johnston 2004). Dissatisfaction is widely experienced by clients of the construction sector and may be caused by many aspects but is largely attributable to overrunning project costs, delayed completion, inferior quality and incompetent service providers

[1] j.cheng@wlv.ac.uk

including contractors and consultants (NAO 2000; HSE 2002; CJ 2004; WNSL 2006). Client strategic decisions also have a significant impact on their own satisfaction levels (Naoum and Mustapha 1995; Kumaraswamy and Dissanayaka 1998; Soetanto 2002; Cheng and Proverbs 2006). Decisions taken at earlier stages can significantly reduce costs and increase client satisfaction (Macmillan *et al*. 2001; Bartolo 2002). Poorly informed strategic decisions made by a client such as choosing a contractor without appropriate consultation or consideration could result in an under-performing project and ultimately cause client dissatisfaction.

However, the nature and significance of strategic decisions and their impact on client satisfaction has not been clearly identified and client satisfaction as an important aspect of business remains an elusive issue to a majority of construction professionals.

This research aims to explore key attributes influencing client satisfaction. The literature will be first reviewed and the client satisfaction phenomenon will be discussed. Descriptive data analysis is then applied on the results of a UK-wide questionnaire survey of construction clients so as to reveal the contributing key factors affecting levels of client satisfaction and seek improvement approaches.

CONCEPT OF CLIENT SATISFACTION

Satisfaction is difficult to define and there is little consensus towards its definition (Oliver 1981, 1997). The existing literature mainly focuses on the concept that the customer or client will make a comparison between the product or service and a certain standard (Smith 1969; Churchill and Serprenant 1982). If the outcome of a product or service meets or exceeds the customer’s expectation, satisfaction in general is achieved or exceeded (Locke 1970; Churchill and Serprenant 1982). The levels of satisfaction achieved or exceeded by the customer/client hence are dependent on the outcome of the comparison and the customer’s perceptive thinking. Hence, it is a highly subjective and complex matter that is challenging to measure reliably and objectively.

In the construction industry, there is a lack of clear understanding of the concept of client satisfaction (Cheng *et al*. 2006). The measurement of client satisfaction is often associated with performance and quality assessment in the context of products or services received by the client (Parasuraman *et al*. 1985, 1988; Soetanto and Proverbs 2004). Understanding of the clients and their business needs so as to help the industry to provide a better service to clients have always been the reason that the industry exists (Boyd and Chinyio 2006).

SATISFACTION ASSESSMENT

A number of models have been developed to facilitate the measurement of satisfaction such as SERVQUAL (Parasuraman *et al*. 1988; Siu *et al*. 2001), performance assessment (Soetanto and Proverbs 2004) and Business Excellence models (EFQM 2005; Cheng *et al*. 2005).

Several conceptual models have been developed based on the SERVQUAL principles to measure service quality and to reveal the interrelationship with client satisfaction in the construction industry (Hoxley 1998; Love *et al*. 2000; Siu *et al*. 2001). Client satisfaction is generally seen as the difference between perceived quality and actual quality performance and is related positively to service quality. However, the frame of reference or the standard of comparison used by clients to determine their satisfaction levels (Smith *et al*. 1969), have been somewhat ignored in these models and hence the applicability of these models to predict the levels of client satisfaction is limited.

Satisfaction measurement is regarded as an assessment of an internal frame of mind, tied to mental interpretations of performance levels. A client's internal frame of mind, mainly concerned with individual (i.e. the client) background, experience and perceptions, are likely to have an impact on the assessment of performance.

The EFQM (2005) Business Excellence model, which recognizes there are many approaches to achieving sustainable excellence in all aspects of performance, is a practical tool that can be used as a self-assessment tool or as a guide to identify areas for improvement.

Client satisfaction with the performance of their service providers including construction consultants (e.g. chartered surveyors, architects and engineers) and contractors on construction projects has been measured by assessing key performance indicators (KPI) in the UK construction industry (BSRIA 2003; RICS 2004; CE 2005).

The assessment of importance and performance of construction services issues were adopted by construction consultants to measure client satisfaction and address serious issues for their business excellence using client questionnaire survey approaches (Cheng *et al*. 2005). During which issues such as what levels of performance should consultants aim to achieve in order to satisfy their clients and what performance criteria should be prioritized so as to make most efficient use of resources and efforts in this regard can be addressed.

THE CLIENT SURVEY

In order to obtain reliable industry feedback in the context of investigating factors influencing client satisfaction, a UK-wide questionnaire survey of construction clients from both public and private sectors was conducted. A structured questionnaire was sent to each client.

Public sector clients, the largest client group in the UK construction industry, were chosen from the Municipal Year Book (MYB) (2006) which consists of all UK local councils and central government departments. Private sector clients were selected from the UK TOP 100 client list of the annual survey from the Building magazine (*Building* 2005), which represents a majority of the UK's private sector construction clients in terms of output.

The questionnaire was divided into three main sections, namely client characteristics, client strategic decisions at different stages and service quality of service providers, each of which containing a series of interrelated questions.

Each question required the respondents to provide a score against each of the two categories, the importance of the issue to the client and the performance (in the case of perception on services provided by service providers) or effectiveness (in the case of strategic decisions made by the client).

A five-point Likert scale from one (indicating the least effective/worst performance or least important) to five (indicating the most effective/best performance or most important) was adopted to measure respondents' attitude to the questions. It was adopted because the five-point Likert scale is simple to construct, likely to produce a highly reliable scale and commonly employed in the research field (Dawis 1987; Bernard 2000).

The questionnaire was designed as a research instrument to examine the impact of strategic decisions on client satisfaction within which factors influencing satisfaction levels were investigated, as developed in earlier satisfaction assessment models (Parasuraman *et al*. 1985; Soetanto and Proverbs 2004; EFQM 2005; Cheng *et al*. 2006). The performance criteria of consultant and contractors are defined as those used to measure the overall performance of the services based on the views of clients. The criteria were developed on the basis of the EFQM (2005) Business Excellence model and the results of a pilot survey of clients, supported by a literature review in the domain of performance and client satisfaction measurement (Cheng *et al*. 2005; Cheng and Proverbs 2006).

RESULTS

A total 800 questionnaires were distributed to pre-selected clients as sourced from the MYB (2006) and the Building's (2005) Top 100 clients list. 66 valid responses were received, representing a response rate of 8.3%, indicating a relatively good feedback from clients given the sensitivity of the data subject involved in the research.

Client characteristics

Table 1 demonstrates the client characteristics from the respondents.

About 80% of client individuals have more than 20 years' experience in construction, 90% of them hold medium or senior positions in their organizations and about 80% are decision-takers or approvers, indicating a majority of clients are experienced construction professionals who understand their organizations' decision-making mechanism and process (i.e. 44% of clients have worked in their current organizations for more than 10 years).

Public sector clients represent 87% of the respondents including central government departments, local governments and other public sector clients e.g. universities with private sector clients represent the rest of the respondents.

Building project (67%) is the predominant project type clients mainly procure, followed by infrastructure project (10%). Half of clients' projects are procured via traditional route, followed by Design & Build route (34%). However, only 3% of clients procure their projects via PPP/PFI route, reflecting a lack of understanding of and clients' reluctance to partnering procurement.

Although 47% of clients reported overrun project costs and 60% experienced delayed completion, clients still scored a highly satisfactory 4 (out of 5) for the overall quality of their projects, indicating that there exists a lack of clear understanding of the satisfaction concept.

It is suggested factors influencing client satisfaction are not limited to overrun costs and delays and there seems to be somewhat inconsistency of clients' perception on the assessment.

Table 1: Client characteristics

Description of clients characteristics	Criteria of measurement	Rate of responses (%)
How many years have you been involved in construction?	< 5 years	0%
	5-10 years	0%
	11–20 years	20%
	>20 years	80%
How many years have you been working in this organization?	< 5 years	32%
	5-10 years	24%
	11–20 years	33%
	>20 years	11%
What is your vocational background?	Architect	27%
	Designer/Engineer	30%
	Quantity Surveyor	13%
	Project Manager	13%
	Others	17%
Your position in your organization?	Senior (Directors)	43%
	Medium (Managers)	47%
	Low (Engineers)	10%
Which managerial role do you play in the project decision-making process?	Decision-approvers (e.g. main board members)	27%
	Decision-takers (e.g. senior managers)	53%
	Decision-shapers (e.g. expert focus group)	10%
	Decision-influencers (e.g. internal/external people who influence)	10%
The client organization:		
What type of organization are you?	Private sector	13%
	Central government	3%
	Local government	57%
	Other public sector	27%
	Others	0%
How many employees does your organization have?	< 10	3%
	11–50	16%
	51–249	7%
	250–500	27%
	>500	47%
Which construction sector does your organization mainly procure in?	Building	67%
	Infrastructure	10%
	Energy	3%
	Utilities	10%
	Others	10%
How many projects similar to the Case project type have you completed during the last ten years?	0	0%
	1-2	14%
	3-5	23%
	>5	63%
About the case project:		
What type of project is it?	Building	80%
	Infrastructure	14%
	Energy	0%
	Utilities	3%
	Others	3%
What procurement route did you adopt for this project?	Traditional	50%
	Design & Build	34%
	PPP/PFI	3%
	Management Contract	3%
	Others	10%

What type of contract does the project use	JCT	57%
	ICE	10%
	GC works	3%
	NEC	17%
	Others	13%
What are the original contract value and the outturn value (e.g. £ millions)?	Original value < Outturn value	47%
	Original value = Outturn value	43%
	Original value > Outturn value	10%
What are the planned and the actual duration from inception to completion?	Original value < Outturn value	60%
	Original value = Outturn value	30%
	Original value > Outturn value	10%

The analyses of importance and performance/effectiveness adopted the commonly used performance-importance approach by using average satisfaction scores (Martilla and James 1977; Soetanto 2002; Cheng *et al*. 2006). Average satisfaction represents the discrepancy between perceived levels of performance (P) or Effectiveness (E) and importance (I), that is, the subtraction of I from P (P - I) or E (E-I). The value of average satisfaction may be positive (indicating high levels of satisfaction but possibly excessive effort), zero (indicating optimally satisfied) and negative (indicating dissatisfaction).

Client strategic decisions

Clients were asked to give scores on how important and effective their strategic decisions are to the project/business. The importance factor represents clients' expectations on a particular decision issue and the effectiveness factor reflects clients' perception on the real effect of a particular decision made. Table 2 shows Effective Mean and Importance Mean and Satisfaction Mean scores with standard deviations which demonstrate the range of variation.

Table 2: Client strategic decisions at different project stages

Client strategic decisions	**Importance Mean (I)**	**Effectiveness Mean (E)**	**Satisfaction Mean (E-I)**	**Standard Deviation (SD)**
Pre-design stage	4.10	3.84	-0.26	0.9012
Decision of "Build/No build" after the project appraisal	4.47	4.33	-0.13	0.6182
Probable procurement method after decision of "Build"	4.27	3.93	-0.33	0.8300
Organizational structure	3.50	3.33	-0.17	0.9339
Work procedures	3.87	3.83	-0.03	0.7520
Consultants to be engaged	4.37	4.17	-0.20	0.7916
Other service providers to be engaged	3.80	3.77	-0.03	0.7746
Outline of project	4.00	3.60	-0.40	1.0796
Estimated costs	4.47	3.87	-0.60	1.0520
Review of procurement route	3.77	3.73	-0.03	1.0796
Details of project	4.23	3.90	-0.33	0.9866
Full development control approval	4.20	3.80	-0.40	0.8000
Co-ordination of elements of the project	4.23	3.80	-0.43	1.1160
Design stage	4.13	3.83	-0.30	0.9528
Information sufficient to obtain tenders	4.43	4.10	-0.33	1.0435

Balance required under the building contract	3.83	3.57	-0.26	0.8622
Tender stage	4.09	3.99	-0.10	0.9637
Documentation required for tenders	4.53	4.03	-0.50	0.8466
Identification and evaluation of potential contractors	4.30	4.03	-0.27	1.1528
Appointing the contractor	4.17	4.17	0.00	1.0328
Arranging site handover to the contractor	3.38	3.73	0.35	0.8226
Construction stage	4.19	3.68	-0.51	1.0907
Cost management strategy	4.59	3.93	-0.66	1.0796
People strategy	3.69	3.52	-0.17	0.8975
Settling the final account	4.29	3.59	-0.70	1.2949
Occupancy & Maintenance stage	4.09	3.76	-0.33	1.0413
Life cycle costing	4.07	3.66	-0.41	1.0520
Maintenance strategy	4.11	3.86	-0.25	1.0306
Disposal stage	3.02	3.04	0.02	0.7968
Demolition of project	2.89	3.00	0.11	0.8307
Transfer of project	3.15	3.07	-0.08	0.7630

DISCUSSIONS

Previous research indicated that the impact of strategic decisions on client satisfaction depends as much on timing as on the subject of the decision (Cheng *et al*. 2005; Cheng and Proverbs 2006). Client satisfaction, as a directly immeasurable subject, in fact is measured through the assessment of the service providers' performance and service quality (Cheng and Proverbs 2006). There exists a conceptual structure that indicates the influence of strategic decisions on client satisfaction and the correlation between them.

From the results, it is shown that clients in general are not satisfied with their strategic decision-making across a majority of project stages (e.g. Satisfaction Mean from -0.51 at Construction stage to -0.10 at Tender stage). Disposal stage is the only stage in which clients perceive the effectiveness of strategic decisions as satisfactory and strategic decisions have a positive impact on client satisfaction (SM=0.2;SD=0.7968).

Clients consider Build/No-build (I= 4.47), Procurement (I= 4.27) and Estimated costs (I=4.47) are the most important strategic decisions made at Pre-design stage. The results are consistent with previous research findings (Macmillan *et al*. 2001; Bartolo 2002; Soetanto 2002). The Effectiveness Means of the decisions are all above 4 (out of 5), indicating they are very effective decisions made by clients. However, the effectiveness of the decisions are not as high as clients expected i.e. client expectations are not being met, leading to slightly negative client satisfaction (SM= -0.13, -0.33 and -0.60 respectively). Standard Deviations suggest that clients in general are satisfied with their decisions.

The results indicate that effectiveness of client strategic decisions are not meeting clients' expectations and hence there may exist certain issues which need to be addressed properly during the decision-making and implementation process in terms of their effectiveness.

Service quality

Service quality is usually seen as an antecedent and pre-requisite of client satisfaction. Performance factors were assessed through a range of quality criteria involving key aspects of the services provided by contractors/consultants to clients (Cheng *et al*, 2006). Table 3 demonstrates clients' perception of satisfaction on services quality.

Table 3: Client satisfaction on service quality

Quality criteria	Importance Mean (I)	Performance Mean (P)	Satisfaction Mean (P-I)
Service delivery	4.12	3.90	-0.23
People of service providers	4.03	3.91	-0.11
Communications with clients	3.10	2.96	-0.14
Overall	4.00	3.80	-0.20

The results show that clients are slightly dissatisfied with the services they received from the service providers (SM= -0.20). However, the overall performance mean score achieved 3.80 (out of 5), indicating clients perceive a good service quality has been provided by their service providers (contractors/consultants).

Nevertheless, the performance mean score (3.80) is slightly lower than the importance mean score (4.00), suggesting clients' quality expectations are not being met by the performance of service providers who should seek improvement approaches to better satisfy their clients. Understanding client business and satisfying their needs are the key issues for service providers to address so as to improve their service quality (Ashley *et al*. 1987; Cheng *et al*. 2006). Improved service quality from service providers will positively underpin project performance and lead to heightened client satisfaction and perceived project success, which will benefit both of clients and their service providers.

CONCLUSIONS

In the construction industry, client satisfaction plays a fundamental role in determining the perceived success of a project.

From the results of a UK-wide survey of construction clients of public and private sectors, it is revealed that there exists a lack of clear understanding of the concept of client satisfaction. Client strategic decisions and their characteristics are found to have a crucial impact on their own satisfaction.

The overall quality of services provided by service providers (consultants and contractors) plays a fundamental role influencing client satisfaction amongst other key attributes. Furthermore, the impact of strategic decisions on client satisfaction is shown to have strong links with different project stages.

Improved service quality from service providers will positively underpin project performance and lead to heightened client satisfaction and perceived project success, which will benefit both clients and their service providers.

THE INFLUENCE OF AN INFORMATION ENVIRONMENT ON CONTRACTORS' PERFORMANCE THROUGH IDIQ PROCUREMENT DELIVERY

Dean T. Kashiwagi[1]

Performance Based Studies Research Group, Arizona State University, PO Box 870204, Tempe, Arizona, USA

The motivation behind alternate delivery systems has been the poor performance of the traditional design-bid-build process. Construction professionals have identified public contract law and bureaucratic procurement/contract offices as one of the sources of problems in construction industry. The United States Army Medical Command (MEDCOM) (approximately $100M in construction renovation awards per year) attempted to overcome this obstacle through a partnership with the Performance Based Studies Research Group (PBSRG) at Arizona State University. The MEDCOM implemented the information environment portion of the Performance Information Procurement System (PIPS) into IDIQ contracts through the specifications. No procurement was conducted in the research and the concept has met with preliminary success, minimizing construction management issues by over 50%.

Keywords: best value procurement, construction performance, performance specification.

INTRODUCTION

The US Army Medical Command (MEDCOM) uses the Corps of Engineers (COE) contracting/procurement offices to deliver approximately $100M of construction per year (maintenance, repair, and modification). This is done through a delivery system called Indefinite Delivery, Indefinite Quantity (IDIQ). IDIQ is a system that pre-qualifies contractors before allowing them to compete for individual task orders. The advantage of the IDIQ delivery system is the time savings. Competing IDIQ contractors is far easier and involves a shorter time period than attempting to get a multitude of jobs through the traditional design-bid-build process (FAR 1997). The contractors can be selected by low price or the COE's best value process, which is heavily influenced by price. However, despite the flexibility the IDIQ system provided, the MEDCOM division was still unable to satisfy the programme demands.

The MEDCOM was introduced to the Performance Information Procurement System (PIPS) research, a best value approach to construction procurement, supported by the Performance Based Studies Research Group (PBSRG) at Arizona State University (ASU). The MEDCOM saw that the research provided results that supported the idea that theoretical concepts, processes, and structures based on leadership principles (accountability, alignment, performance measurement, and value-based), rather than management principles (control, direction, no performance measurements, and price-based), would optimize the delivery of construction (Kashiwagi *et al*. 2006) as well as

[1] dean.kashiwagi@asu.edu

the documented bureaucracy of the Corps of Engineers (COE) (Antonovich 1997; Putten 1999). The concepts included:

1. Minimization of data flow and necessary number of communications among participants.
2. Minimization of client documentation.
3. Outsourcing to the best value, considering cost and performance (past and present).
4. Utilization of a quality control (QC) plan as a selection criterion. The QC plan identifies the risk that the contractor does not control and defines how the contractor will attempt to minimize the risk.
5. By defining the risk that they do not control, the contractor has also defined what they do control (everything not listed as a risk that they do not control).
6. Also included in the selection criteria is a submittal of value added items identified by the contractor.
7. The contractor is able to use the QC plan and a risk management system to minimize change orders, quality issues and construction delays, due to risks that the contractor does not control.
8. Items or risks that the contractor controls are enforced by the design and specification.

This paper focuses on the implementation of best value concepts by the US Army Medical Command (MEDCOM), the results of the implementation, and potential of information environments in the delivery of construction and organizational efficiency. In the research, no procurement is performed, only the application of an information environment and the culture transformations that it requires.

BEST VALUE AT THE MEDCOM

MEDCOM noted the testing results of the Best Value/PIPS system over a 12-year period, and the validity they added to the research theory. Results included (www.pbsrg.com):

1. 440 tests on $480M of construction.
2. 98% performance (on time, on budget, meeting client's expectations).
3. Zero contractor generated cost change orders on 98% of the projects.
4. Construction management decline by as much as 80–90%.
5. Contractors profit increase from 5–20% and minimized fiscal risk on 100% of the projects

MEDCOM attempted to convince the COE to select IDIQ contractors and award task orders based on the following best value principles. Besides the theoretical best value concepts, the following was also requested:

1. Use past performance information without translation.
2. Use non-technical risk assessment/minimization and value added submittal.
3. Award a project based on price and performance. The performance should include the vendor's past performance; vendor's ability to identify, plan to

minimize, and prioritize project risks that they do not control; added value; and an interview. The proposed process to measure and compile the vendors' performance is illustrated in Figure 1. No qualifications should be considered.

4. Use a pre-award / quality control preplanning phase before the award.
5. Implement the quality control plan into the contract and force the contractor to self manage their project based on risk by using a weekly risk report that would only document cost, time and quality risks.
6. Use an information environment that minimizes the flow of information, moves the critical information to the right place in the shortest period of time, and forces the source of risk or non-performance to be accountable (Sullivan *et al*. 2006).

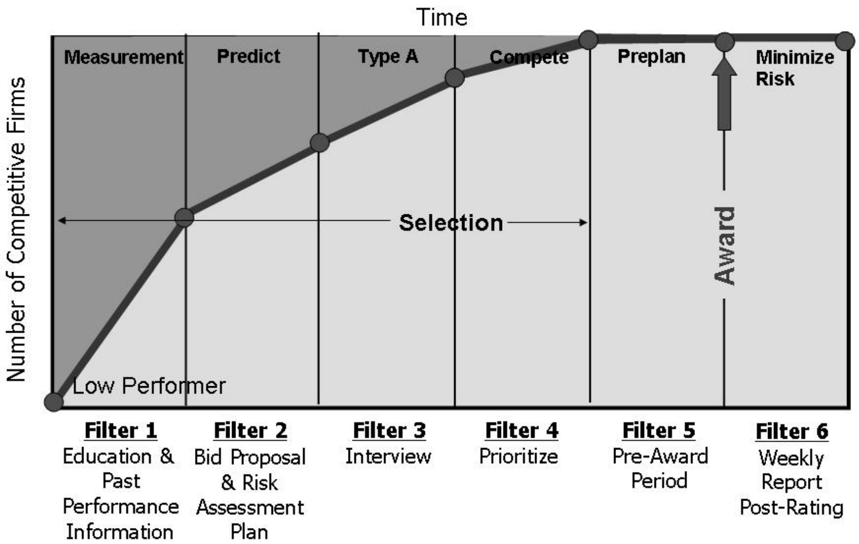

Figure 1: Performance information procurement system (pips) filters: a best value process for measuring vendor performance (Kashiwagi 2004)

The attempt was unsuccessful. The COE decided there were too many changes and believed that some of the changes were not legally allowed (this is a point of disagreement between several COE agencies). Some of the changes/ misunderstandings included:

1. The COE were under the misunderstanding that the process was proprietary and that Arizona State University (ASU) would be running their procurement. It is illegal for the COE to outsource its procurement (FAR 2002).
2. The COE felt that non-COE personnel could not be on the selection team.
3. The Army Federal Acquisition Regulation (AFAR) would not permit the use of weights and numbers in a best value selection (FAR 2002).
4. The pre-award phase – where the best value contractor creates their quality control (QC) plan, quality assurance (QA) checklist and schedule – was not allowed by the Federal Acquisition Regulation (FAR), due to the requirement to have discussions with all the offerors before the award of the contract (FAR 2002).

5. The existing COE quality assurance plan was verification of the technical requirements, while the QC plan for the Best Value/PIPS was to minimize risk that the contractor did not control.

The above points of resistance were either misunderstandings or items that could easily be adapted to ensure regulation compliance. However, current Director of the Facility Life Cycle Management Division at MEDCOM, realized that the cultural change required to implement Best Value/PIPS in the COE was too drastic, and he proposed to obtain higher performance results another way. With assistance from the Performance Based Studies Research Group, the Director of MEDCOM proposed to overcome the COE's resistance to change and policies by using the theoretical concepts of a best value environment as a component of the technical requirements/specifications of the IDIQ contract that the COE would award to the IDIQ contractor. The Director proposed that the best value environment and an information environment as presented by Kashiwagi (2004), were the same, and therefore was specifiable. In other words, the Director of MEDCOM proposed that instead of forcing the COE to change its Best Value procurement process to procure services from higher performing IDIQ contractors (by definition: efficient, experienced, capable of being on time, minimize risk and change orders, and meet the client's expectations), that the best value practices/information environment could be made a requirement in the specifications. This would force contractors who won the COE awards to comply with the best value practices of a high performing contractor. This hypothesis makes one of the following assumptions:

1. A lower performing contractor can become a high performer by using a best value/information structure.
2. A contractor who competes on a specification that requires them to report the delivering of construction through a best value/information environment structure will educate/train their personnel to act in a manner to deliver performing results.
3. An information environment forces accountability regardless of the selection process.

The Director of MEDCOM proposed that in order to test the hypothesis over three years, the following items would be measured:

1. The number of projects where the source of the problem was not immediately identifiable.
2. The number of projects where the source of the problem was the contractor.
3. The number of projects where (if the source of the problem was the contractor), the contractor would not immediately take action at their own expense to solve the problem.
4. The number of projects that were completed by the same contractors, before the integration of the best value environment, where problems could have been solved by the best value environment.
5. The interest of the contractors to learn the process, and implement training programmes in their companies.
6. The number of companies that would take the programme to other clients.

The current estimate of the number of projects with performance issues is 15 (out of 150) or 10%. Out of the projects with performance issues, only 5 (3.3% of total) are due to the contractor.

THEORETICAL FOUNDATION OF BEST VALUE/ PERFORMANCE INFORMATION PROCUREMENT SYSTEM (PIPS) PROCESS

The approach of the US Army Medical Command (MEDCOM) included an understanding that the Corps of Engineers (COE) used a price-based construction/services environment (Kaji 2006.) By comparing the price based and best value environments, the MEDCOM identified the following characteristics and assumptions of the price based environment (Kashiwagi 2004):

1. Construction services were considered a commodity.
2. The Client's design personnel could direct, manage, and inspect the commodity contractors to deliver an acceptable product using minimum standards, details and an overall design.
3. The best price was the lowest price (because the contractors were all the same).
4. The contractors were being asked to deliver a product based on the minimum requirements.
5. The client's representatives were the experts in terms of identifying "acceptable" quality.
6. The process does not give credit to the highly trained craftsperson, and may have a detrimental effect on the number of skilled craftspeople, the level of quality of those who remain in the industry, and the ability of the industry to quality control their own work.
7. The client's representative directs the contractor and their personnel.
8. The process requires more people than the best value sector where the best value contractor uses their most highly skilled craftspeople.
9. Because the design /specifications are shaped by technical specifications, the quality of work is the minimum and always has a downward movement.
10. The process requires more experts, more direction, more inspection, and more confusion on what is the best quality.
11. With one party doing the work, and one party controlling the work (through management, control, inspection and direction) the amount of communication/data flow is increased.

When compared to the best value environment, confusion in the price based environment is increased simply as a result of an increased number of individuals (managers, inspectors, experts, designers, clients). The confusion results in a need for more management/inspection to sort out the confusion. In the confusion, no one is accountable, forcing every participant to protect themselves before thinking in the best interest of the client or the organization that the individual is employed by. The authors propose this condition as the definition of a bureaucratic environment. It is easier to point fingers and require an individual to show that another entity did not follow rules than it is to identify the solution. The rules become the defence for the bureaucratic action. This causes a bureaucracy, where several organizations are involved, and in each organization, the individuals representing the organization are acting in their own best interest. This is the cycle of bureaucracy (Figure 2).

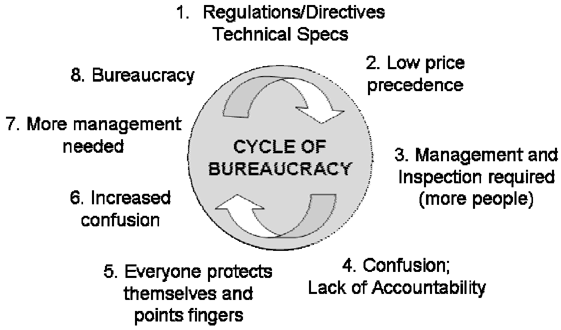

Figure 2: Cycle of bureaucracy

A contribution of the authors is the understanding that bureaucracy:

1. Happens in all organizations at various levels.
2. Happens between organizations.
3. Happens with every individual who works in a bureaucratic environment.
4. When the client forces the vendor to act defensively, the client and the vendor's personnel, and all other participants become bureaucratic.
5. Bureaucracy is created by a price based market structure, a lack of information and fear.

The authors hypothesized that an information environment specified in the specifications would mimic a best value environment without altering the procurement system. The authors further hypothesized that the contractors would understand that an information environment would maximize their efficiency and profit, and therefore be in their own best interests. This realization coupled with the information environment would increase the performance of the IDIQ contractors. The Director of MEDCOM requested that the Performance Based Studies Research Group at Arizona State University (ASU) set up an information environment in the IDIQ contract where performance metrics would be constantly measured. The goal was to create a best value information environment, embed within the technical specifications like a Trojan horse within the COE bureaucracy, and then to measure the results. Through measurement, accountability would be realized and the information environment would in essence encourage the contractors to improve and perform. The environment would make every participant accountable, as all would be measured (contractors, MEDCOM personnel, COE personnel, etc.). Performance-based specifications have been proposed before (FAR 1997); however, simultaneously using specifications with minimum standards, best value concepts, and an information environment, is a new contribution to the delivery of construction.

THE MEDCOM BEST VALUE/INFORMATION CONCEPTS/ENVIRONMENT AND TEST RESULTS

The MEDCOM decided to incorporate the following into their specifications:

1. Checklists that forced the use of preplanning and a quality control plan that minimized the risk that the contractor did not control. These checklists applied to both the design stage (work plan) and the construction stage.
2. The use of a quality control plan (focused on risk identification and minimization), a quality assurance checklist, a schedule and a weekly reporting system tracking the risk that the contractor did not control.

The MEDCOM then used the information system to compile multiple weekly risk reports and develop current performance barcodes or measurements for the entities involved. Performance measurements were computed for the contractors, as well as the COE project managers, the MEDCOM project integrators, and the procurement offices.

The key component of the best value environment uses the concept from the Information Measurement Theory (IMT) asserting that an individual who is experienced and understands the system can (Kashiwagi 2004):

1. Identify what they are responsible, and what others are responsible for.
2. Understand that the greatest risk comes from parties who they have no control over.
3. Understand that while an individual can only control themselves, they must understand the role of others in order to minimize risk through simple coordination/ communication.
4. Act as a team player and facilitates a “win-win” with those they work with.
5. Minimize risk that they do not control and no sharing of risk, just allocation.

There are four key components to the information system. First, the contractor is asked to separate the risks they control from those that they do not by identifying the latter. The contractor is then told that whatever is not on the QC plan (risks that they do not control), is risk that they do control (except for unforeseen risks). The contractor is then directed to identify how they will minimize the concerns or risks. The authors are making the assumption that it is much easier to have the contractor identify risks to the project that they do not control, than it is to identify all the risks that the contractor does control. It also transfers the risk to the contractor by having the contractor identify the risks. The authors are also assuming that a non-experienced contractor cannot as efficiently identify the risks that they are not responsible for. This is because (Figure 3):

1. Experienced contractors know the roles and impact of different participants.
2. Inexperienced contractors are reactive, and only know their risk in terms of what they are supposed to do.
3. Experienced contractors do not need to be managed and directed.

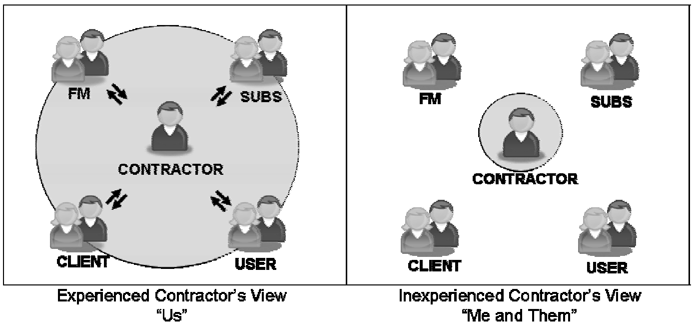

Figure 3: Experienced vs. non-experienced "sphere of perception"

The second key component is to make it a requirement that the vendor/contractor minimizes risk that they do not control. If they execute their risk minimization steps, and are not able to minimize the risk, the risk will be placed on the weekly report which identifies:

1. Why the contractor was not able to minimize the risk.
2. What or who is the source of the risk.
3. What needs to be done by the source of the risk to minimize the risk.
4. What the impact to the project will be in terms of time, cost, and expectation.

The third concept is that it is by contract, and in the best interest of the contractor, to report the risk on the weekly report (Figure 4.1–4.4). The QC plan, QA checklist and weekly report protect the contractor. All documents identify the risks that the contractor does not control and, by definition, protects the performing contractor. The weekly risk report is sent to the COE PM, but also is directly inserted into a system that compiles the information from all MEDCOM projects into a Director's Report that identifies:

1. The top ten projects that bring the greatest risk.
2. Relative performance numbers of the contractors and client representatives involved.
3. Identification of the relative performance of the contractors' critical personnel and subcontractors.
4. Performance of the client's organization in delivering construction services.

The fourth concept is that the contractor is rated on the finished project, and that rating becomes 50% of their future performance rating. All key individuals on the project and critical subcontractors also receive the same rating.

PRELIMINARY TEST RESULTS

The MEDCOM performance before the test was run included:

1. A problem a day floated up through the bureaucracy and was presented to the MEDCOM construction manager.
2. 50% of the projects are on time, and on budget.
3. Contractors on 80% of the projects do not preplan and minimize risk.
4. None of the contractors had a QC plan that protected themselves and the clients.

5. 25% of the projects are delayed and the reason is unclear.
6. None of the contractors had their own QC plan, QA checklists and weekly risk report.
7. No contractors came to the annual training at ASU seeking education.

The information environment was initially pilot tested on six projects (no procurement was performed, only application of the information environment) and within eight months it was expanded to encompass 87 projects. In the past year, it has been implemented on all projects with a budget value greater than $300,000 (USD), which, is at the time of publication, 189 projects with a construction value of over $289,000,000 (USD). In summary, the current estimate of the number of projects with performance issues is 15 (out of 189) or 8%. Out of the projects with performance issues, only five (2.6% of total) are due to the contractor. Other results include:

1. 99% of projects currently on budget (no contractor changes to budget).
2. Average contractor budget increase is .03%.
3. 95% of projects currently on time (no contractor changes to schedule).
4. 9.8 owner satisfaction on completed projects (1–10 scoring, 10 being the highest).

Figure 4 displays the results of the Information Environment. Figure 4.1 shows the overall output of the construction delivery. Figure 4.2 shows the overview of a project showing client and contractor generated risks. Figure 4.3 shows the top ten risk projects. Figure 4.4 shows the differential of the contractor performance. However, any entity's performance who is involved in the project can be compared (COE, PM, PI, etc.). Once the project is finished, the project is rated and modifies the new contractor performance line.

There has been a change in attitude of the contractors. In the first year when the contractors were exposed to the process, none of the contractors expressed an interest in an education of the process or running the process except through forced tests. The second year, four of the six contractors invested in further education of the process.

In the third year:

1. Three contractors invested heavily into education of their personnel.
2. All six contractors spent additional time with MEDCOM personnel learning about the system.
3. All six contractors are attending the annual education/training at Arizona State University at their own expense.
4. One of the contractors is bringing other clients to the training, encouraging them to use the Best Value approach.
5. All contractors are sending in the weekly reports that generated the performance/ risk information.

4.3 Risk ranking of projects

4.4 Comparing vendor performance

Figure 4.1–4.4: Results of an information environment

Other preliminary results include:

1. Projects *started* with the best value environments have had no outstanding issues where the contractor is at fault.
2. The information system has quickly identified that the biggest source of risk is the client and procurement/contracting offices.
3. There have been no disagreements or arguments over who is the source of risk that is identified by the process.
4. Contractors are slowly learning about minimizing risk that they do not control.
5. Meaningful quality control plans have been a challenge.
6. The contractors and users have had a difficult time understanding the connection and use of the QC plan, QA checklist and the weekly report.

CONCLUSION

The authors proposed that an information environment can be directed into the technical specifications without changing the procurement system and force best value practices. This hypothesis is dependent on the contractor using a QC plan that minimizes risk that they do not control. The use of the QC plan, QA checklist, weekly risk report and information environment director's report, all of which are documented by the contractors, has provided MEDCOM with an accurate performance history of construction projects on a weekly basis. Preliminary results indicate that the more efficient environment has maximized the profit of the contractors (Welker 2007). Most of the projects are still in the design phase, and construction results will be forthcoming.

IMPROVING SATISFACTION WITH CONSTRUCTION PROJECT OUTCOMES: THE ROLE OF CULTURE

Nii Amponsah Ankrah,[1] David Proverbs[1] and Debrah Yaw[2]

[1]*School of Engineering and the Built Environment, University of Wolverhampton, Wulfruna Street, Wolverhampton, WV1 1SB, UK*
[2] *School of Business and Management, Brunel University, Uxbridge, UK*

The quest to evolve an industry that performs well requires an evolution of the process of delivery. To this end, new approaches such as lean thinking and partnering have been introduced into construction. Underlying many of these new approaches is a need for fundamental changes in the culture within the construction project organization. Many have thus called for cultural change on construction projects. In order to establish which dimensions of culture need to be changed, and the direction of such change, this research was undertaken to look for empirical evidence that such changes will lead to performance improvement. The satisfaction of participants with project outcomes was measured as a proxy for performance. Data on cultural orientations and satisfaction levels was collected through a questionnaire survey of UK contractors. Although factor analysis revealed five principal dimensions of culture – workforce orientation, performance orientation, team orientation, client orientation and project orientation – only team orientation and workforce orientation were found to lead to improved satisfaction. It is recommended therefore that more effort and resources are devoted towards improvements in these regards.

Keywords: construction project organization, organizational culture, participant satisfaction, team orientation, workforce orientation.

INTRODUCTION

The extent to which a construction project is delivered to the satisfaction of stakeholders is contingent on a number of factors. One of these factors is the process employed in delivering the project. When the process goes wrong, built facilities may end up defective, over-budget, late, aesthetically, environmentally, and functionally inadequate, with huge operating costs, and participants in litigation, leading to stakeholder dissatisfaction. The quest for improvement thus requires an evolution of the process of delivery (Riley and Clare-Brown 2001). To achieve this evolution, various ideas such as lean thinking, partnering and supply chain management have been introduced into construction. Underlying many of these new approaches is the need for a fundamental change in the attitudes of participants, nature of relationships between project participants, and their approaches to work. Many have therefore called for a change in the culture of the industry (cf. Egan 1998), and this study was undertaken to empirically determine which dimensions of culture need to be changed, the direction of such change, and the consequences for performance and satisfaction of project participants.

WHAT IS CULTURE?

Culture has over 164 definitions (Allaire and Firsirotu 1984) reflecting very divergent views, and also reinforcing the view that the concept of culture exists in a constant state of change. The first use of the term in its true anthropological sense is attributed to Edward Tylor who defined culture as “that complex whole which includes knowledge, belief, art, morals, laws, custom, and any other capabilities and habits acquired by man as a member of society” (Rooke 2001). More detailed reviews of some of the various concepts of culture are presented in Keesing (1974), Smircich (1983), Allaire and Firsirotu (1984), and Ankrah and Proverbs (2004). Common themes running through many definitions are that culture is learned and shared, determined by contextual factors, with common underlying basic problems, and shapes attitudes, perceptions and behaviours (Ankrah and Proverbs 2004). From this, culture may been defined as that unique configuration of solutions – embodied in attitudes, behaviours and conditions – that a construction project organization and its members adopt in dealing with various organizational problems at the project level.

The culture of the construction project organization and project delivery

According to Newcombe (2003), the stakeholders within the construction project organization (CPO) interact with the project in two primary arenas; cultural and political, with the cultural arena represented by the ideology or shared values of the project participants. It is believed that the project-based arrangements that characterize the production of the built environment make the potential impact of culture even more pronounced than in other industries (Ofori 2000). The culture of the CPO is often associated with such attributes as fragmentation, antagonism, mistrust, poor communication, short-term mentality, blame culture, casual approaches to recruitment, machismo and sexism (Egan 1998; Dainty *et al.* 2002; Serpell and Rodriguez 2002). These attributes are in turn associated with project outcomes like litigation, poor health and safety performance, and inferior quality.

Whilst such associations are helpful to the extent that they focus attention on the failings of the industry, and point to aspects that need to be improved, they are sometimes arbitrary and often based on no more than anecdotal evidence, and as such do not provide a useful systematic basis for assessing the real impacts of culture. This suggests the need for systematic empirical research. Some researchers who have attempted to examine some of these associations include Fenn *et al.* (1997), Soetanto *et al.* (1999), Cooper (2000), Ngowi (2000), Thomas *et al.* (2002) and Phua and Rowlinson (2003). This research seeks to carry forward this research agenda but focusing on participant satisfaction.

Diagnosing culture

An assessment of culture requires the identification of aspects important to culture (Hofstede 2001). Such aspects are typically referred to as *dimensions* of culture. Various dimensions have been advanced for studying culture and many of these are catalogued in Ankrah *et al*. (2005). However, within the context of the construction project, it has been argued *ibid* that some of these dimensions are inappropriate. To identify which dimensions are most relevant within a construction project context, these dimensions need to be considered in the light of the unique problems of the construction industry. The problems of the construction industry are well documented, and nowhere better articulated than in the major construction industry reports that have been published since the Simon (1944) report. All these reports have examined the problems of the construction industry and have in the main recounted the same industry failures time and time again. In trying to identify relevant dimensions for this research based on the construction industry's problems, the landmark Egan (1998) report was consulted. The dimensions identified are outlined in Table 1.

In a report prepared by the CRISP Culture and People Task Group (CRISP 2002) on a research strategy for culture and people in construction, a number of dimensions were proposed by construction industry experts. A comparison of these dimensions and the dimensions shown in Table 1 clearly shows that the chosen dimensions are consistent with the aspects considered important in CRISP (2002). This provides validation for the dimensions shown in Table 1 and demonstrates that they are relevant within a CPO context.

Table 1: Dimensions associated with the Egan (1998) agenda for change

Industry problems	Related dimensions
Leadership	Leadership, Control, Professionalism, Participation (decision-making), Communication, Exercising authority
Client focus	Communication, Client education, Respect for client, Sensitivity to client/customer's needs, Monitoring client satisfaction
Team integration	Communication, finger-pointing, Participation, Collaborative working, Openness, Conflict, Subcontracting, Partnering
Delivering quality	Learning & innovation, Emphasis on quality, Performance measurement & continuous improvement, Driving the schedule, Doing it right
Commitment to people	Health & safety, Site tidiness, Respect & Support for workforce, Training, Retention, Commitment to people, Recognizing performance

PROJECT PERFORMANCE

Performance can be considered as an evaluation of how well individuals, groups of individuals or organizations have done in pursuit of specific objectives which generally revolve around satisfying key stakeholders (Mullins 2005). Measures of performance vary significantly, and in construction typically include construction cost, construction time, cost and time predictability, client satisfaction with product and service, defects, profitability, productivity and safety (DTI 2005). In this research, the satisfaction level of participants with project outcomes was used as a proxy of performance. Satisfaction is defined in Chan *et al.* (2002) as the level of 'happiness' of people affected by the project including key project participants. It is an attribute of success, which is both dependent on performance and personal standards or expectations (Liu and Walker 1998). Satisfaction, described *ibid* as an aptitude (an effect or emotion), is thus a subjective assessment of performance.

METHODOLOGY

A quantitative approach was adopted for this study involving a survey research design to obtain a numeric description of trends, attitudes, or opinions of CPOs (Babbie 1990). This kind of research enables researchers to establish "which variables are significant, and to what extent, in a scientific way" (Walker 1997). Data collection was by means of a questionnaire survey of contractors with the unit of analysis being the construction project. The questionnaire was therefore designed to elicit information about the construction project in respect of project characteristics, performance outcomes and cultural orientations. Table 2 shows a sample of the questionnaire items.

Table 2: Sample of questionnaire items

Variable	Measurement
Participant satisfaction	How satisfied was the client with service on Likert scale of 1–5 (very dissatisfied – very satisfied) How satisfied was your company with the level of profitability of this project on Likert scale of 1–5 (very dissatisfied – very satisfied)
Contact & communication with client (C1)	How important was it to the project organization to have lots of contact and communication with the client on Likert scale of 1–5 (no important – utmost importance) During this project there was very little contact or communication with the client on Likert scale of 1–5 (strongly disagree – strongly agree) The project arrangements were such that there was limited access to the client to discuss project-related issues on Likert scale of 1–5 (strongly disagree – strongly agree)

Analysis involved the use of principal component factor analysis to derive a parsimonious set of underlying dimensions that could then be correlated with performance, with multiple regression employed to derive a regression model showing the effects of the cultural dimensions on the performance outcomes. This approach has been utilized in research on culture like Hofstede's (2001) seminal work on culture.

The sampling frame used in the survey was drawn from a database of contractors listed in the UK Kompass (2006) register. Including the pilot survey, a total of 551 questionnaires were mailed out to participants for completion: 85 questionnaires were returned representing an overall response rate of 15.42%; 64 of these questionnaires were analysed in this report.

RESULTS AND DISCUSSION

The profile of projects captured in this survey is presented in Table 3. Most of the projects captured in this survey were private sector new work in the building category, specifically housing and commercial building projects. This outcome is not surprising for a nationwide survey of this nature considering the fact that, according to the DTI, the private sector accounts for some 67% of all construction output, new work accounts for about 53%, building projects make up about 77%, and housing currently constitutes about 40% of construction output in the UK (DTI 2005). Most of these projects were considered by respondents to be either moderately complex or simple.

Table 3: Characteristics of construction projects surveyed

Project type		Number of projects	Percentage of projects
Proj_type1	Public	24	43
	Private	32	57
Proj_type2	New work	34	61
	Refurbishment	16	28
	Redevelopment	5	9
	Demolition	1	2
Proj_type3	Civil Engineering	10	19
	Building	44	81
Proj_type4	Commercial	13	25
	Industrial	7	13
	Housing	13	25
	Infrastructure	6	11
	Leisure	3	6
	Education	3	6
	Mixed use	6	11
	Health	2	4

In terms of the locations of these projects, all the UK regions were well represented, and majority of these projects (41%) had been procured by traditional procurement arrangements. This finding is consistent with RICS (2006). Contract prices ranged from £15K to £18M with contract durations from three weeks to five years. This is a reflection of the range of projects undertaken in the construction industry, from simple jobbing projects to very complex mega projects. Median contract price and duration of the projects were between £0.86M and £2.00M and 9–12 months respectively, consistent with RICS (2006) and DTI (2005).

The main contractor was reported as the most influential project participant overall, and the performance ethos was found to be in the order: health and safety (H&S)–quality–cost–time with H&S as most important and time as least important objective.

It can be concluded from these results that generally, the sample is representative of construction projects in the UK.

The culture of CPOs

Respondents were asked to indicate the extent to which certain perceptions and attitudes, behaviours and conditions existed on the construction project. Orientations were assessed on a scale of 1 to 5, with 1 representing a low orientation and 5 representing a high orientation. Means and standard deviations for each dimension are summarized in Table 4. The lowest rated dimension was *blame culture* (T8), which was rated low. The fact that it was not rated very low implies that a certain level of finger-pointing does exist, meaning that there is some scope for improvement.

The orientations of CPOs on the dimensions of *control of workers' behaviour* (L3), *participation of all participants in planning & goal-setting* (L4), *keeping operatives informed* (L5), *identification with project* (T6), *innovation* (P1), *learning on project* (P2), *monitoring performance* (P3), *waste elimination* (P5), *driving down cost* (P7), *subcontracting* (W1) and *recognizing good performance* (W8) were all neutral. It would have been expected that with all the reports and research commissioned to address the poor performance of the construction industry (cf. Egan 1998), the orientation in respect of dimensions like *monitoring performance, waste elimination* and *driving down costs* would have been very high with CPOs conscientiously striving to achieve better performance. However, this is not the case, according to the data. The remaining dimensions were all rated high. Significantly, no dimension of culture scored very high.

These findings are particularly useful for those seeking change in the culture of the construction industry as it clearly identifies those areas where improvements are possible. Whether such improvements will improve performance requires further investigation.

Principal component factor analysis was applied to these 37 cultural variables not only to demonstrate convergent validity, but also to develop a parsimonious set of dimensions suitable for the subsequent analyses. It has been specified in Hair *et al.* (1998) that the preferable sample size for factor analysis is 100 or larger. However, it has also been argued in Field (2000) that under certain circumstances the sample size may not be critical. For instance, where all communalities are greater than 0.6, samples less than 100 may be perfectly adequate (*ibid*). Indeed, there is even evidence of published research where factor analysis has been performed on similar or much less data (cf. Kaming *et al*. 1997; Liu 1999; Leung *et al.* 2004). Therefore, whilst the potential biases associated with a small size as highlighted in Lingard and Rowlinson

(2006) are noted and whilst recognizing also that the debate on sample size is on-going (cf. Hair *et al.* 1998; Field 2000; Osborne and Costello 2004), factor analysis was considered suitable for the data reduction purposes.

To further test the suitability of the data for the factor analysis, two measures – the Kaiser-Meyer-Olkin measure of sampling adequacy (MSA) and the Bartlett test of sphericity – were obtained. These two tests provide the minimum standard that should be passed. The MSA obtained was 0.776, with .50 specified as a minimum (Hair *et al.* 1998). With the Bartlett test, a significant result was obtained ($p < 0.001$).

To achieve the most representative and parsimonious set of factors possible, a five-component solution was extracted based on the percentage of variance criterion (Hair *et al.* 1998), which specifies that for social science research selecting a solution that accounts for 60% of the total variance is satisfactory. In this research, this coincides with five components that account for 63.863% of the total variance. The varimax rotated components are shown in Table 4.

Table 4: Rotated component matrix showing descriptive statistics of dimensions of culture

			Std.	**Component**				
		Mean	**Dev.**	**1**	**2**	**3**	**4**	**5**
W4	Motivating workforce	3.51	.624	0.816				
T3	Emphasis on teamwork	3.58	.676	0.803				
T7	Free & open communication	3.77	.706	0.757				
W7	Site tidiness	3.86	.702	0.755	0.410			
W8	Recognizing good performance	3.31	.803	0.744				
L5	Keeping operatives informed	3.38	.692	0.733				
L4	Participation	3.19	.720	0.728				
L6	Communication	3.62	.722	0.715				
T4	Dealing with conflict by compromise	3.54	.670	0.695				
T1	Collaborative working	3.94	.615	0.685				
W5	Training	3.58	.834	0.677	0.534			
L2	Supportiveness & appreciation	3.68	.622	0.658				
W3	Respect for all workers	4.07	.678	0.653				
P9	Environmental friendliness	3.58	.698	0.627				
C2	Research into end-user needs	3.65	.851	0.618			0.424	
P2	Learning on project	3.39	.572	0.607	0.406			
L3	Control of workers' behaviour	3.48	.727	0.586				
W2	Showing concern for workers	4.22	.620	0.581	0.413			
C6	Respect for client	4.36	.661	0.528		0.422	0.458	
W6	Safeguarding health & safety	4.22	.677		0.773			
P4	Providing performance feedback	3.51	.638		0.651			
P6	On-time delivery	3.93	.565		0.611			
P8	Quality & getting it right first time	3.94	.604		0.535			
P3	Monitoring performance	3.46	.567		0.480			
T8	Blame culture	2.05	.720			-0.831		
L1	Access and approachability	4.34	.623			0.730		
T5	Information sharing	3.92	.636			0.581		
T2	Trust	3.64	.650			0.532		
P1	Innovation	2.88	.653	0.439		-0.465		
P7	Driving down cost	3.48	.587					
C3	Educating client	3.55	.774	0.410			0.749	
C4	Monitoring satisfaction	3.87	.707				0.683	
C5	Precedence of client's needs	3.78	.700			0.473	0.646	

C1	Contact & communication	4.16	.824				0.553	
T6	Identification with project	3.19	.604					0.716
W1	Subcontracting	3.40	1.068					-0.568
P5	Waste elimination	3.36	.635					0.506

Variables like motivating workforce (W4), emphasis on teamwork (T3), free & open communication (T7), site tidiness (W7), recognizing good performance (W8), keeping operatives informed (L5), participation (L4), and communication (L6) were loaded highly and positively on component one. This component was therefore labelled *workforce orientation*. The highly loaded variables on component two were safeguarding health & safety (W6), providing performance feedback (P4), on-time delivery (P6), and quality & getting it right first time (P8). All these dimensions relate to the delivery of projects to specified standards and was therefore labelled *performance orientation*. Component three had the variables blame culture (T8), access and approachability (L1), information sharing (T5), and trust (T2) highly loaded on it giving an indication of *team orientation*. The variables educating client (C3), monitoring client satisfaction (C4), precedence of client's needs (C5), and contact & communication with client (C1), all clearly making reference to relations with the client, were highly loaded on component four which was therefore labelled *client orientation*. Component five was significant loaded by the variables identification with project (T6), subcontracting (W1) and waste elimination (W5). This component was therefore labelled *project orientation*.

A comparison of these principal dimensions with other research on culture provides some evidence of the validity of these results. For instance people orientation, results orientation, team orientation and client orientation are all discussed in Liu (1999) and Zuo and Zillante (2006).

Participant satisfaction

In this research, participant satisfaction was assessed by aggregating the variables client satisfaction with *service*, *quality*, *cost* and *time*, management satisfaction with *harmony* and *profitability*, operative satisfaction with *site conditions & facilities* and *wages*, and number of *claims*. With the exception of claims, there was a positive association between all the other satisfaction variables indicating that they all vary together. There is support in the construction management literature for this finding, with Dozzi *et al.* (1996) for instance noting that if a project is profitable for the contractor, there is a greater chance of the client being satisfied. The negative association between claims and all the other variables also indicates that claims are inimical to satisfaction. Chronbach's alpha obtained for these nine variables was 0.768. It is not uncommon to find such a measure of participant satisfaction in the research literature (cf. Chan *et al.* 2002; Leung *et al.* 2004; Zuo and Zillante 2006).

A model of culture and participant satisfaction outcomes

The correlation matrix of participant satisfaction and the dimensions of culture (Table 5) shows that satisfaction of participants is significantly and positively associated with the workforce orientation ($r = .299$, $p = .024$) and the team orientation ($r = .351$, $p = .007$). This implies that as workforce and team orientations on a project improve, the satisfaction of project participants also grows. These same relationships were found in Zuo and Zillante (2006), which reported significant correlations between integration, cooperation and people orientation and project team satisfaction.

Table 5: Correlation matrix of cultural dimensions and participant satisfaction

		Workforce orientation	Performance orientation	Team orientation	Client orientation	Project orientation
Satisfaction of participants	Pearson Correlation	.299*	.174	.351**	.148	.073
	Sig. (2-tailed)	.024	.196	.007	.271	.592
	N	57	57	57	57	57

* Correlation is significant at the 0.05 level (2-tailed).
** Correlation is significant at the 0.01 level (2-tailed).

In order to assess the predictive ability (or magnitude of effect) of the individual variables, multiple regression was applied to the data (Field 2000). The two variables (team and workforce orientation) were included in the regression by forced entry. Results are presented in Table 6.

From Table 6, the final regression equation for participant satisfaction can be presented as:

PARTICIPANT SATISFACTION = -.012 + .240 (WORKFORCE ORIENTATION) + .359 (TEAM ORIENTATION)

Table 6: Regression analysis results for participant satisfaction

R	.423	Std. Error	.9227				
R^2	.179	Adjusted R^2	.149				
Durbin-Watson	1.828						
Analysis of variance	df	Sum of Squares	Mean Square	F	Sig.		
Regression	2	10.023	5.012	5.886	.005		
Residual	54	45.977	.851				
Total	56	56.000					
Variables in equation	B	Std. Error	Beta	t	Sig.	Tolerance	VIF
(Constant)	-.012	.123		-.097	.923		
Workforce orientation	.240	.125	.241	1.919	.060	.964	1.037
Team orientation	.359	.148	.305	2.429	.019	.964	1.037

Although the results of the t-test indicate that for prediction purposes, it is not worth having workforce orientation in the equation if team orientation is in it ($t = 1.919$, $p = .060$), the value of R^2 for the model (.179) indicates that the two variables account for approximately 18% of the variation in participant satisfaction. The analysis of variance (ANOVA) which tests whether or not the model is a useful predictor of participant satisfaction, gave a highly significant result ($F = 5.886$, $p = .005$), indicating that this model significantly improves the prediction of participant satisfaction. The VIF values (variance inflation factor) indicate that there is no multi-collinearity within the data (Field 2000). Analysis of the residuals and the Durbin-Watson value of 1.828 (Table 6) indicates that none of the assumptions of regression have been violated.

Discussion

The multiple regression confirms the positive associations between participant satisfaction and the workforce and team orientation that was found in the correlation matrix. This finding also reinforces previous research findings in this domain (cf. Zuo and Zillante 2006). As indicated previously, workforce orientation encompasses the amount of effort put into motivating the workforce, emphasis on teamwork, the extent of free and open communication on site, the emphasis on site tidiness, recognition of good performance, keeping operatives informed of project developments, the extent of participation in planning and decision-making by the workforce, communication between managers and operatives, and so on. These aspects have been linked to greater goal commitment, and as found in Leung *et al.* (2004), the greater the goal commitment, the greater the satisfaction of participants. The importance of workforce orientation is also corroborated by evidence in Liu (1999) and Zuo and Zillante (2006). Workforce orientation, generally speaking, is not an area for which the UK construction industry is renowned for exemplifying good practice (Fellows *et al.* 2002). As shown in Table 3, CPOs are generally moderate in orientation in respect of aspects like recognizing good performance, keeping operatives informed and participation in planning and decision-making, and just above moderate in respect of the other dimensions. Improvements in regard of these aspects are therefore called for.

Team orientation encompasses aspects like blame culture (or absence of it), the extent to which management is accessible and approachable, amount of information sharing, and the degree of trust. Because of the fragmented nature of construction, a high team orientation with better integration, cooperation and coordination of construction project teams is often a prerequisite for project success (Cicmil and Marshall 2005). It leads to greater levels of knowledge and cooperation, and as a result more specific goals are set, there is greater goal commitment, and participant satisfaction is improved (Leung *et al.* 2004). This is consistent with Baiden *et al*. (2006), which posit that team orientation promotes a working environment where information is freely exchanged between the different participants. Baiden *et al*. (2006) refer to the "integrated construction project team" in which integration is used to describe the introduction of working practices, methods and behaviours that create a culture of efficient and effective collaboration by individuals and organizations. Team orientation is generally high as can be seen from Table 3, with a low blame culture across the projects surveyed. But there is room for further improvement.

With the evidence presented so far, it appears reasonable to suggest that both workforce orientation and team orientation of construction project organizations can and must be improved, especially as it is universally recognized that these are traits necessary for employee satisfaction and organizational effectiveness (Belout 1998; Robbins 1998; Mullins 2005). Organizational (CPO) effectiveness will in turn translate into management and client satisfaction (Belout 1998).

A CALL FOR DEBATE & FURTHER RESEARCH

A number of questions remain unanswered that call for further debate and research. For instance, whilst it is very easy to recommend on the basis of the empirical evidence uncovered in this research that a lot more effort and resources need to be devoted to improving workforce orientation and particularly team orientation, this also seems to suggest that there is no need for CPOs to pay any further attention to other aspects like performance, client and project orientations because there is no evidence they have an impact. This defies common logic and warrants further examination. Moreover, there are several other measures of performance, some objective like cost, time, H&S and disputes, and others subjective like quality, learning and innovation. Some of these measures of performance may also be associated with the other dimensions of culture. However, this can only be established by further investigation and this could form the focus of subsequent research.

CONCLUSION

This research was undertaken to look for empirical evidence that changes in culture will lead to performance improvement. Here, the satisfaction of participants with project outcomes was measured as a proxy for performance. The results indicate that whilst there are five principal dimensions of culture – *workforce orientation*, *performance orientation*, *team orientation*, *client orientation* and *project orientation* – only team orientation and workforce orientation are directly associated with improved satisfaction. Therefore, it is recommended that CPOs devote more resources towards the improvement of team and workforce orientation for greater participant satisfaction. Although this paper has not explored how such improvements can be achieved, there are a number of texts such as Baiden *et al*. (2006) that are relevant and insightful in this regard and recommended for further reading.

USER ANALYSIS AND END-USER INVOLVEMENT

Ritsuko Ozaki[1] and Satoshi Yoshida[2]

The customer focus literature claims that end-user orientation can help firms boost their businesses, including the construction industry. However, satisfying customers is not easy, as customers are complex and have different requirements. This is particularly true in the building industry, which accommodates numerous different users. In this light, by using architectural concepts of ‘user composition’, ‘product functions’ and ‘product structure’, this paper presents a way of categorizing end-users to clarify their product function requirements. This categorization can facilitate a firm in developing a more focused product that meets the diverse requirements of its customers. The paper also discusses the ways end-customers can be involved in construction projects and design processes. Such involvement can give end-users a sense of ownership and thus make them satisfied customers.

Keywords: architecture, client, construction management, design and build.

INTRODUCTION

Why does the industry need to analyse and understand its users? In recent years, many researchers in marketing have stressed the importance of the need for satisfying users. They believe that high customer satisfaction leads to successful business. This is due to customer loyalty (i.e. their willingness to return to the same provider) and/or to the positive reputation gained by the firm through a satisfied clientele base (i.e. word-of-mouth referrals). For example, Japanese housebuilders generate extensive business from customer loyalty and word-of-mouth sales (Barlow and Ozaki 2005). In order to achieve high levels of customer satisfaction, it is crucial for any businesses to capture what users require and produce products that meet those requirements.

In this light, based on a literature review, this paper presents a conceptual discussion as to how users can be classified and analysed, and how their requirements can be incorporated into product development (i.e. building projects). This will be done through the use of architectural concepts, which demonstrate the importance of understanding complex customer specificities in the competitive marketplace.

This paper initially discusses the concepts of ‘co-production’ and ‘user innovation’, which emphasize the importance and significance of user involvement in product development. After reviewing this literature, the paper introduces the architectural concepts of ‘user composition’, ‘product function’ and ‘product structure’. These concepts are then used to describe the characteristics of design processes and the complexity of users. In turn, this helps us to categorize users and their required product function and facilitates a more focused product customization. Finally, the paper presents a case study of a construction project in which the ways of involving

[1] r.ozaki@imperial.ac.uk

end-users in the product development process are examined and lessons are drawn from it.

CO-PRODUCTION AND USER INNOVATION

There are difficulties in meeting user demands especially when there are so many users with diversified and sometimes conflicting requirements. Therefore, one important question in construction projects is how to reflect user requirements in the actual physical form of buildings. In order to produce a building on users' terms, the product must have a certain degree of flexibility to meet individual aptitudes and interests. For example, this can be achieved by increasing customer choices in design and increasing user involvement in the decision-making process. In the housebuilding business in Europe, customers' design participation has become widespread. As an instance, flexible plan forms (i.e. the possibility of changing the internal layout of developments after they have been built) in France and the communal covered open space in Denmark result from user design participation (Woolley 1994). Such participatory housing may look fairly conventional, but on closer inspection, one can see the influence of users in many different ways, such as internal layouts, as well as choices of house types available to users. These examples suggest that user participation can bring about innovation in house building. Innovative approaches such as this can lead to new and more user-friendly forms of housing design, reflecting users' interests and ideas (ibid.).

A company can offer each individual user the chance of contributing to product design by bringing the user into the product development process. This will be a method for the business to adapt to the requirements of the users and tailor the product specifically for them (McKenna 1991). The literature of 'user innovation' claims that users feel satisfied with innovative companies and innovative products and services which materialize their requirements and desires (Ellis and Curtis 1995). Moreover, an accurate understanding of user needs is identified as a key to success (Herstatt and von Hippel 1992). Feedback from them, as well as an accurate understanding of their contexts, is crucial to desired outcomes (Herstatt and von Hippel 1992; Leonard-Barton 1984).

Indeed, users' participation in design has become widespread. Some companies put emphasis on pro-active user relationships by anticipating what users like and learning from them in order to provide customer-focused products and services. In particular, when a product has many unspecified users with highly heterogeneous requirements, a product that reflects the average user requirements will leave many of the users dissatisfied. One way of responding to this problem is to enable users to modify products to create a better fit to their own requirements. This approach has become common in the development of software applications (Franke and von Hippel 2003; Lakhani and von Hippel 2003). Skilled users can create customized and superior versions by integrating their knowledge into product design (Leonard-Barton 1984; von Hippel 1988), and the experiences of those 'lead users' do present solutions to problems (Slaughter 1993). This leads to a high level of customer satisfaction. Lead users need the product and also the ability to make improvements on that particular product in order to use it. As lead users, they like working on the problem and improving the product and they enjoy the reputation gained from making high-quality contributions to its development (von Hippel 2005).

Similarly, the literature on ‘co-production’ emphasizes users’ active involvement in product development. Udwadia and Kumar (1991), for example, talk of ‘co-construction’ of new products, which takes into account user requirements through information technology. This process can include user experimentation and subsequent design modifications, and leads to a close collaborative relationship between producers and consumers/users, and subsequently a shared ownership of the final product. In such co-production, users can play an active role in the production of goods and services on their own terms (Ostrom 1996). Positive attitudes towards bringing users’ ideas into the product development process of design, delivery and after-care can change the whole situation. Innovative approaches such as this can lead to new and more user-friendly forms of products and services which reflect user requirements.

However, construction is different from software. End-users cannot modify the product on their own and create an improved or customized version like they might do with software. So, the question is: How can users’ heterogeneous needs and requirements be incorporated into product design? Architects and designers need to obtain feedback on in-use performance of the products. Thus, what they need is a voice from people who actually use the product, even though their experience and knowledge cannot be integrated in the same manner as computer software design. In this light, the following sections discuss ways of co-producing buildings.

USER ANALYSIS

There are certain features of the construction industry that potentially make it difficult to identify who their customers are. Unlike in some sectors where end-users are clearly ‘seen’ (e.g. banking) and therefore their requirements are easily taken into account, in the construction industry end-users tend not to be regarded as customers by firms who customarily are inclined to think only of their immediate clients. For example, in the social housing sector, the customers of a construction company are usually local authorities, and end-users who will actually live in the houses are often not taken into consideration in the product development process. Goldman et al. (1995) found that fewer than 10% of industrial and service firms consider the end-users to be their customers.

Nonetheless, the requirements of ‘ultimate customers’ cannot be neglected. Feedback and information from end-users must be incorporated into the product development and design process. Specific requirements of end-users have to be captured in order to achieve a maximum level of customer satisfaction, which ultimately will contribute to the success of the business. Therefore, we need to know who the end-users are, what their requirements are and how they can be involved in the product development and design process. To answer these, we use a few architectural concepts, such as ‘user composition’, ‘product function’ and ‘product structure’.

Characteristics of design process mechanism

In order to discuss how users can be involved in product development, and how their requirements can be incorporated into design, we will first show the mechanisms of the design process and its characteristics (Figure 1). The diagram below shows that the four phases in the architectural design process influence each other with feedback constantly being given. It is also clear that customers and their requirements form the basis of the design process.

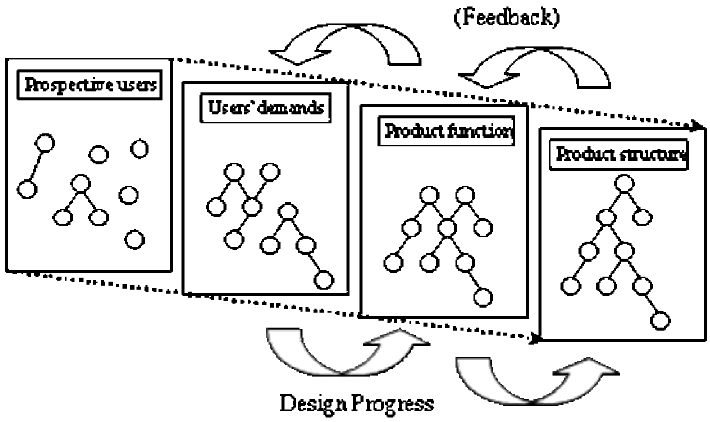

Figure 1: Four aspects of the design process

Prospective users
There are different types of prospective users for each product. The prospective users have different characteristics and may have structural relationships among themselves (user structure). For example, while some products are used only by individual customers, other products are meant for a large number of the general public.

User demands
The totality of user requirements is closely linked to user structure. It is quite straightforward to understand the requirements of single users, but it becomes complex when a product has many different users. The level of difficulty becomes greater particularly when the users of a product cannot be identified. User requirements can vary greatly but remain unidentified. Furthermore, the requirements of users can be things such as wishes, hopes and feelings, which cannot be clearly expressed and, therefore, sometimes come into conflict with each other.

Product function
A product is developed based on the composition of various product functions (Fujimoto 2002). It is therefore essential to make product functions right in order to make the product right. However, different users possibly require different functions from the same product. This heterogeneity nature of users and their requirements suggests the importance of understanding the relationship between user characteristics and product functions, which we will look at in the next section.

Product structure
The product structure is constructed based on product functions (Ulrich *et al*. 1995). At this stage, the developer or producer of a product could have strong input into the product design based on their experience and knowledge. This could result in an end product showing the design/architectural firm's usual design characteristics (Fujimoto *et al*. 2001), which may not necessary reflect users' ideas.

It is clear that we need a good understanding of users and their characteristics in order to produce a product whose functions meet their demands.

Classification of user composition
Product users differ in each industrial sector. For example, in the case of personal computers, the users are independent from each other, whereas public buildings are built for the use of a large number of the general public. These two cases have distinct types of user groups, whose requirements affect the process of product development.

Figure 2 shows a comparative analysis of user characteristics in a number of industrial sectors. Elements on the left column are products from different sectors, and the rows show functional characteristics and the number of potential users.

		Multiple functions			**Single function**		
		A large number of the general public	A large number of private groups	A single user	A large number of the general public	A large number of private groups	A single user
Single production	City Hall	Entrance hall, Conf. room, Track bay	Offices, Meeting room	Mayor's office	Lift, Restaurant,	Locker room, Store-room	-
	Residence	-	Living room	Children's room	-	Bath-room	(Kitchen)
Mass production	Private Car	-	-	Driver's seat	-	-	Rear seat
	PC	-	-	o	-	-	-
	Application software for PC	-	-	-	-	-	O
	Dining Table (restaurant)	-	-	-	o	o	O
	Office Desk	-	-	o	-	-	-

Figure 2: User composition

Every product has a specific composition of prospective users. Here, we identify three types of users: a single user, a number of private groups and a number of the general public. The difference between the three user types has significant impacts on product design.

For products with ‘single-user’ and ‘single-function’, such as software applications, the user requirements can be captured straightforwardly. Products of this type have a main function that characterizes them and so customers can select the function that best fits their needs.

In the case of products with ‘single-users’ but with ‘multiple-functions’, it is more complicated to adjust functions to user requirements. Mobile phones and personal computers are examples of this type. Every customer principally wants not only the main function, but also certain sub-functions to meet their individual requirements. Conflicts between requirements for sub-functions need to be resolved by prioritising sub-functions.

Products of ‘multiple-users’ and ‘single-function’ have two user types: a number of private groups (specific users) and the general public (unspecific users). The simplicity of the single function can be understood with the example of a bathroom: one takes a bath in the bathroom. The requirements of product functions are therefore straightforward, and this example suggests that engineers can focus on a single product function without any conflicts in relation to user requirements.

The most complicated type is ‘multiple-users’ and ‘multiple-functions’, such as the living room of a house, and the entrance hall and conference rooms of a city hall. The former concerns multiple users that are a private group of people (e.g. family), and the latter relates to multiple users of unspecific groups of people (e.g. the general public). In both cases, users often have specific requirements, and engineers and/or architects try to meet the users’ expectations with regard to the main functions and sub-functions of the product. This requires them to hold consultation sessions with their clients. While it is relatively easy to obtain opinions about the living room from all of the family members of a house, it is much harder to obtain all the differing opinions on the entrance hall of a city hall from its potential users. Clearly, the user structure (e.g. specific customers vs. a large number of the unspecific general public) has a significant effect on product functions, and consequently on product structure. Figure 3 shows the complexity of a product with “multiple-functions” and “multiple-users” of the “general public”, and the importance to obtain information in the development of products of this type.

User type	Single function	Multiple functions
single users	application software	cell phone, PC
a large number of a private group of people	private car	residence
a large number of the general public	tram	city hall

Figure 3: Key points of customer composition and product function

An analysis of users, based on the architectural concepts of user composition, can provide a ‘framework’ for a better understanding of the complex relationships between user characteristics, product functions and product structure, and consequently of user requirements. This user classification approach can be applied to a product with complex features, such as a public building, where users can be quite diverse within one product class. By categorizing multiple users according to their use of the building, their wide-range and distinct function requirements can also be categorized. In turn, this helps the producers and architects to work better on the design of each of the product functions. User composition can help firms to segment their customers, which facilitates a more user-oriented production.

INVOLVING USERS IN DESIGN PROCESS

So, how can users, especially end-users, be involved in the design process and express their opinions, and how do they take part in product development?

In recent years, the scale of building projects has increasingly become bigger. These projects have a greater impact on their social and natural environments and, therefore, leave many issues to be resolved (e.g. structure, material, cost, schedule, environmental factors such as wind, temperature and earthquakes, etc.), which small projects do not necessarily have to deal with (Yoshida and Yashiro 2004). Thus, large projects inevitably have more stakeholders. For example, a project to build a city hall has a number of stakeholders including the mayor of the city (i.e. client), architects, construction engineers and other engineers, researchers and citizens (i.e. end-users). Furthermore, such a large project is likely to have many users – both specific and unspecific – and therefore the number of functions required by different users and issues to be solved are significantly more than, and different from, those involved in a project building a residential house that is used only by its household members.

In a large building project, while construction engineers deal with issues and agendas that are physical, architects make sure that the design is made from not only the pure design perspective, but also from the historical, social and psychological viewpoints. This requires the architects to consult with people who are aware of the historical and psycho-social contexts. This is where end-users ‘can’ come into the picture. End-users’ opinions about the project can be collected and discussed in a number of forms. The bigger the project is, the more information is required. Typically in a large building project, formal interviews with representatives of the public and/or a questionnaire surveys involving the wider public are conducted. But consultation exercises can also be held. These have more elements of active user participation than mere interviews and questionnaire surveys. Such public consultations, i.e. meetings that involve both designers and users, include the ones with international environmentalist groups to discuss ecological matters.

There are a few stages in end-user involvement in the design process. We identify three levels: (1) input and feedback, (2) controlling and (3) accomplishment. ‘Input and feedback’ is the least pro-active form, in which end-users put forward their demands and see how their demands are treated. In ‘controlling’, end-users are involved in the actual design process and get to observe how the project is being conducted, but they are not involved in the technical aspects of it. Lastly, end-users get involved in all levels of activities (‘accomplishments’). In this case, they develop abilities to technically intervene in the project. In reality, the first two levels are more feasible and should be achieved in building projects, but end-users’ technical intervention can be difficult to achieve.

There is an advantage to such active end-user participation. Alexander (1964) points out that user participation makes a strong sense of solidarity among participants. Such solidarity helps them explicitly express their requirements, which otherwise may remain unsaid, and thus make them strongly motivated as participants. With the experience of participation in product development, the end-users’ sense of responsibility will be raised; and their newly acquired sense of responsibility concerns not only the project context itself, but also many other issues including the environment and culture.

Through looking at the ways in which users can be involved in (public) building projects, we identify four implications of end-user participation in general:

- The expansion of the boundary of the meaning of “customers”.
- Customers (end-users) taking part in many aspects of a project (design, product development).
- Customers developing their sense of ownership and responsibility through the experience of the participation.
- Participation helping the concepts (social meaning) of the product (e.g. a city hall foyer as ‘a place of comfort’ for the general public) to penetrate into society.

A case of a university building

However, current design practices have not fully embraced this concept of active end-user involvement. The following reported case shows which parts of end-user participation need improving.

In his report, Peterson (2003) gives an account on user perceptions of a new university building, which was a 25 million pound project with the total net (i.e. usable) space of 3,600m^2. He finds in his questionnaire survey and face-to-face interviews that there are criticisms of the open-plan workspace, cellular space and the reduction in storage and shelving space. In a university, there are different users: lecturers, researchers, administrators, students, anonymous visitors and many other support staff. Each of these stakeholders has different ways of using the building space and therefore different requirements. However, the different and diverse ways of use do not appear to be considered well. Peterson summarizes that, although staff approve of the new building project overall, the quality of the office space is perceived by the vast majority of staff to be inferior to the space they were occupying at the time his survey was conducted.

> "Not sure how all colleagues will get on working with each other. We have different ways of working and so this may cause friction" (administrative staff).
>
> "I worry all my stuff won't fit in new offices and I will need a big clear out" (academic staff).
>
> "I think the new building will look better from the outside and is good in terms of image but I have concerns about the lack of space and general working conditions. The work environment will be cramped for support staff and morale could drop. This could affect the standard of work" (administrative staff).
>
> "All the money seems to have been spent on the shop front with savings made on the poor quality office space" (administrative staff).
>
> "The new building may get us back into proximity with each other, at least for more of the time than we have at present, but I'm sure that we will find ways of restricting access to students who may wish to interact with us. The greater emphasis on research outputs will no doubt give staff the excuse not to come into the school" (academic staff). (Source: Peterson 2003: 36, 43, 45)

The design of the new building is in general unpopular and its users are dissatisfied. One of the reasons why so many staff complained about their office space is because the consultation was done only with the former Head of the school who acted as a representative for the whole institution. His vision was to increase communication and foster interactive culture, and the design of the building does reflect it; however, it fails to reflect the way that individual staff in the school work.

Communication seems to be encouraged and facilitated well by the new design, which embraces the interactive culture (e.g. the café forum area where there is a café and space for discussion). In press advertisements, the school says that it is a "truly friendly and helpful" place, a claim reflecting the vision of the school. The new building will bring about more contact between staff and students and will change the old culture:

> "We lost a lot of the out-of-class contact that we may have had with them (the students), and the College Senior Common Room has become the focal point for (students') coffee and lunch breaks…We make much of our so-called friendly atmosphere" (academic staff). (Source: Peterson 2003: 45)

Contrary to dissatisfaction with the physical design of the building, Peterson's respondents seem to approve of the image that the new building creates. His respondents – academic staff, administration staff and students – all agree that the new building is important to enhance the reputation of the school. They think that the new physical environment will change the image of the school and take it forward in a competitive global market:

> "The new building will have a symbolic impact, the investment suggests that the school is going places and has the full backing of the college. It will also help for PR and marketing purposes" (academic staff).
>
> "It will play a symbolic role in defining the new business school and … may signal a break away from the old business school culture" (student).
>
> "It will help the school present a more modern image and attract better calibre staff and students" (student). (Source: Peterson 2003: 38, 43)

Peterson (2003) also interviewed the Rector of the college and the financier of the new building project. In the interview, the Rector says that the new frontage and entrance are 'critically important' in providing the college overall with a modern and outward looking face. The funder also mentions the poor signage and physical presence of the college was a fundamental driving force in his desire to bequeath the money to fund the project. Peterson believes that the building project will become part of the corporate identity of the school and can potentially play an important role in the future success and growth of its brand.

This case illustrates the importance of recognising who the end-users are and of consulting them to understand the way in which they work and how they use their work space. The problem with this particular project was that only the Head of the school, who was also one of the end-users, was consulted by the designers. Although his view on increasing communication and interaction was reflected and shared among the staff and students, his perception of the way other staff worked and used the building and space was not representative of the majority. This suggests that representatives from each of the different stakeholders (e.g. lecturers, researchers, senior administrators, administrative staff and students) should have been invited to user consultations.

So, in light of our four implications of end-user participation (see above), the following lessons can be drawn from this case.

- The expansion of the meaning of customers: to identify end-users in each category of stakeholders is crucial.
- End-users taking part in various aspects of a project: various end-users need to be part of not only the image and vision of the school, but also the physical design, which should reflect the way they work.
- Users developing a sense of ownership and responsibility through participation: without being involved, end-users do not feel that they own the project or building and do not feel responsible for the project or the impact that the building creates.

- Participation helping to penetrate the social meaning of the product: the new culture, images and visions need to be fully shared among all the stakeholders during the consultation, rather than after the implementation.

CONCLUSION

As the concept of co-production suggests, users' active involvement in the product development process can lead to success in business. Users get the product made on their terms; and this gives them a sense of ownership and makes them feel satisfied. Satisfied customers are always good news for a firm. User analysis based on architectural concepts can help any firm to analyse their customers and their function requirements in order to meet user requirements and ultimately to make their projects and therefore their businesses more successful.

However, product users are complex. Firstly, the term encompasses many different types of customers, including end-users who actually use the product and are often overlooked in the product development and design processes. Secondly, there can be different kinds of end-users for one product and this implies they have different function requirements. However, in the light of the customer satisfaction, it is crucial for any firm to identify who the customers are, to analyse what they require and to reflect their requirements in the end product.

This paper has shown how user characteristics and their demands form the foundation of product design by using the architectural concepts. The paper has discussed approaches to involve users in the process of product development and implications of their participation. The case study of building a new university building has offered a number of lessons, which raises our awareness of the complexity of user composition, their requirements, and the way representative end-users can be involved in the design process. Nonetheless, despite the complexity and difficulty, design practitioners should maximize end-user involvement. This paper only offers the concept and does not involve any empirical studies. The next step therefore would be to look at a real building project and analyse the way end-users participate in the project and make recommendations to the actual practice.

An overview of a policy focused research study to improve property asset management across the UK civil government estate is presented. The study was commissioned by the UK's Office of Government Commerce (OGC). Property asset management involves the whole life management of property assets from 'cradle to grave' and is defined in the study as covering land and built assets, including buildings and civil infrastructure used by a central government organization, regardless of tenure. An interlocking research methodology was adopted for the study combining literature research, questionnaires, interviews and a policy workshop. The study was conducted to inform the development of the OGC's embedding programme for property asset management. The three principal research results are presented; a property asset management board to overcome fragmentation of the central civil government estate, a maturity matrix in property asset management and a route map to excellence.

Keywords: asset management, benchmarking, central government, government departments, property management.

INTRODUCTION

The paper presents the context and results of policy-oriented research conducted between December 2005 and May 2006 and commissioned by the UK's Office of Government Commerce (OGC), an independent office of Her Majesty's Treasury (HMT). The research (OGC University of Leeds 2006) investigated the improvement of property asset management (PAM) within the £220bn central civil government estate (CCGE). The report was launched at an OGC Conference in June 2006 by the Chief Secretary to the Treasury, the Right Honourable Stephen Timms MP, and following a period of consultation he launched subsequently the route map to excellence in November 2006 (OGC 2006).

The OGC study sits within broader international developments dealing with the management of physical assets at national, regional and local government levels. The Australian Federal and State governments have addressed this issue for a number of years (ANAO 1995; ANAO 1998; ANAO 2003; DPWS 2001; APCC 2001; Barrett 2003; NSWT 2004; DTF 2005). The Federal Government of the United States identified real estate and its management as a high risk Federal programme in January 2003 due to significant underinvestment (FRPC 2004). In that same year the General Accounting Office testified that Federal property is deteriorating seriously and that there is insufficient reliable data on which decision makers can base future investments in physical assets. In the UK local authorities have analysed and justified their

[1] stevenmale@stevebbcm.u-net.com

investment in physical assets for some time (Audit Commission 2000). The OGC has conducted previous research into workplace strategies within the CCGE (OGC University of Reading 2004). The research reported here also has a direct relationship with three parallel studies in the CCGE. The first is to determine the skills framework necessary for property asset management as part of the wider Professional Skills for Government initiative (OGC Howarth 2006). The second involved benchmarking and measuring property management in the CCGE (IPD 2005; OGC 2006) and the third, conducted by the UK National Audit Office (NAO 2006), investigated the better use of public sector assets.

The research study was also conducted against the background of the UK government's Efficiency Programme (Gershon 2004), the relocation of civil servants outside London and the South East (Lyons 2004a), the Comprehensive Spending Review 2007, and a fundamental review of government expenditure on and the better management of public sector assets (Lyons 2004b). The second Lyons' report had a direct consequence for the OGC study reported here, setting a series of targets to be achieved by 2010, including identifying potential savings in the order of £760m that could be made from within the management of the administrative central civil government estate (CCGE); that is, the estate used to support the managerial and administrative 'machinery' of government. This target set the initial reference point and strategic context for subsequent efficiency gains as part of the research.

STUDY SCOPE, DEFINITIONS AND METHOD

The study was commissioned to inform the development of OGC's embedding programme for property asset management within the CCGE. The study scope was to address:

- base-lining the current state of property asset management in central government as a datum against which the success of OGC's embedding programme can be assessed;
- developing a series of models or frameworks to promote property asset management excellence in the CCGE and also setting out a model of maturity for PAM against which central government departments and other central public sector organizations are able to judge their own status and progress towards excellence;
- clarifying the effectiveness of options for central interventions that could result in potential efficiency gains which would also guide the development of OGC's embedding programme.

The study defined property asset management (PAM) as a holistic approach for aligning service delivery requirements with the performance of property assets over time to meet business objectives and drivers for a central government organization. Property assets comprise land and built assets including buildings and civil infrastructure. PAM has a strategic component dealing with investment in property over the long term – three, five and up to 10 years and beyond; and an operational component covering the short to medium term – one to three years – within which budgetary allocations operate. The issues related to time dimensions will be addressed further in the discussion and conclusion section of the paper. The study differentiated between property assets that are *operational*, involving a close relationship between physical assets and frontline service delivery and *administrative* assets supporting the 'machinery' of government, comprising primarily commercial office accommodation and also the primary focus of the study.

Research methodology

From the outset the PAM study had a policy driven focus. A triangulated research methodology was adopted (Blackie 2000). Existing best practice was identified through literature research, supported by empirical fieldwork conducted previously for a significant government agency to develop a national asset management framework to manage the agency's £23bn asset base and £300–400m annual capital and operational expenditure programmes; this methodology influenced the method for the OGC study. The researchers also shared information with other ongoing OGC and NAO projects as noted above.

The literature review covered national and international Government sources noted earlier and also reports produced within the UK private sector (RICS 2002) and from professional institutes (IAM 2002; RICS 2005). An OGC questionnaire was piloted and distributed to the heads of estate of 86 government departments. Multiple follow-ups were instigated by OGC personnel; 49 questionnaires were returned, a response rate of 57%. Response rates of 20–30% can be anticipated using no follow-ups and 50–70% using multiple follow-up procedures; the response rate for this study can be considered good. Data were analysed both quantitatively with simple frequency distributions and qualitatively from comments made through the use of open-ended questions.

Interviews were held with 32 individuals across a range of government organizations, 30 with heads of estate (horizontal data collection) and two detailed interviews with more senior personnel within two major departments (vertical data collection). Interviews were conducted across different sizes of government departments, from those with responsibility for managing significant government property assets nationally and regionally to smaller departments occupying perhaps only three floors or less in a commercial office block. Additionally, detailed examples of estate management strategies were also provided by a number of central government departments and organizations. A 2.5-day policy workshop was conducted comprising the Leeds research team, OGC and invited delegates from government departments, executive agencies and non-departmental public bodies (NDPBs) (or arms-length bodies – ALBs – as they are sometimes termed).

Property assets and the public sector

Sir Michael Lyons (Lyons 2004b) noted that as at December 2003 the whole of the public sector owned assets worth around £658 billion; £220 billion or 33% is held by central government and ALBs. An important issue for the research was the definition of property assets within the UK central civil government estate. In August 2005 the Cabinet Office set out a classification of new and existing bodies falling within departments' remit to ensure appropriate structures and governance arrangements are in place (Cabinet Office 2005a).The remit of the study covered directorates within departments; departments running on agency lines; executive agencies; public–private partnerships; offices 'independent' of their parent departments (such as the Office of Government Commerce and the Office of the e-Envoy); executive non-departmental public bodies (NDPBs); government-owned companies; and contracted-out services.

As at March 2005 there were 910 public bodies sponsored by UK government departments (Cabinet Office 2005b) made up of 21 public corporations, the Bank of England, 26 NHS bodies and 861 NDPBs. The NDPB group comprises 211 executive NDPBs, 458 advisory NDPBs, 42 tribunal NDPBs and 151 independent monitoring boards, the arms-length bodies (ALBs) referred to earlier. The impact on the management of the CCGE is considerable; much of the asset base resides out of the immediate direct control of central departments, and is under the control of either executive agencies or other ALBs. As of the third quarter of 2005, there were 533 690 members of central civil service staff in post (ONS 2005), approximately three-quarters of these work in executive agencies (ALBs), and approximately 130 000 working directly within central government departments. Thus, a significant proportion of the associated space to accommodate civil servants also resides within these types of structures. The full impact of potential efficiency gains across the CCGE using a more integrated approach to property asset management has to be secured within a highly decentralized and fragmented government structure – an important challenge for the research study and addressed through research outcomes.

RESEARCH RESULTS – THREE PRIMARY RESEARCH OUTPUTS

The three primary research outputs, the property asset management board, a maturity matrix and route map to excellence are presented.

The property asset management board

The research team recommended the creation of a property asset management board (PAMB) as the primary vehicle to overcome fragmentation where departmental structures have decentralized arrangements with agencies, NDPB/ALBs and other sponsored organizations. In order to increase the level of strategic awareness, the research team recommended the PAMB should exist just below departmental management board level to ensure that policy development feeds directly into the formation of strategies for managing CCGE physical infrastructure assets. Policy development and then delivery are often seen as separate activities in government, and with limited overlap or consideration given to the impact on physical asset resource bases. The team encountered a sample of departments through fieldwork where a similar type of structure to the PAMB worked exceptionally well. However, this type of structure was not commonplace across government. The policy workshop identified and agreed in the order of 20–25 characteristics for the PAMB to address directly the fragmented nature of the management of CCGE assets. It necessitated bringing together the strategic and operational aspects of property asset management under one organizational unit with a clear policy, control, development and audit remit.

The PAMB would report vertically to ministers, permanent secretaries and to the OGC/HMT on property and fiscal related matters via the executive departmental management board. The expectation is that the PAMB would typically comprise in the order of 10 to 12 people including major business unit representatives with significant property holdings, the head of a consortium service provider(s) where any PFI/PPP structure operates, as well as IT, HR, finance and operational directors and representatives from the significant property centres, which in the case of the larger agencies would be the CEO or immediate alternative below that level. In line with models reviewed in the United States and Australia the research team recommended that the PAM function should be strengthened and recognized more fully at departmental management board level, with a designated board member having responsibilities and accountability for property asset management clearly identified and to act as the link between the departmental management board and the PAMB.

Under HM Treasury governance guidelines (HMT 2005) a head of department is charged with the stewardship of a department’s wider asset base and is held accountable for it to Parliament. However, depending on the manner in which departmental management boards are structured and operate, the head of department may designate and delegate the role and Lyons (2004b) proposed this should be finance directors. The fieldwork highlighted, however, that other models exist in practice within departments; the important point is that the named role has primary responsibility and is held accountable for leadership of the property asset management function, with a clear integrating mandate across departmental activities and arms-length bodies. That functional role should also include ensuring that an appropriate property asset strategy and associated plan has been developed, is updated, signed off and used as a management tool to manage the property portfolio over time within a department and also associated ALBs.

The PAM maturity matrix of excellence

A matrix of maturity for assessing excellence in PAM has been developed to act as a benchmark for the OGC, HMT and government organizations. It has a dual purpose: first, as a self-development tool to permit departments and ALBs to undertake their own assessments for continuous improvement; second, as the basis for independent audits of departments and ALBs to take place. The matrix consists of a set of levels of maturity and associated enablers and was derived from the Institute for Asset Management manual (IAM 2002), the DETR (2000) document *Building a better quality of life*, fieldwork, interviews, questionnaires and the policy workshop. The enablers identified are:

1. **Property asset management policy** dealing with the level an organization is at in terms of its policy towards PAM. This is a key enabler and includes aspects such as guidelines, KPIs and published targets.
2. **Roles and responsibilities** dealing with how an organization's property asset management decision-making structure is set up and managed, including explicit formal roles at tactical and strategic levels in the organization.
3. **Communication** dealing with how information regarding property asset management is handled in terms of data collection, and stakeholder, supply chain and management interactions.
4. **Asset management planning** dealing with the level at which an organization is at regarding formal property asset management planning. This includes the use, for example, of life cycle costing, risk management, benchmarking and meeting corporate objectives.
5. **Acquisition and disposal** deals with how acquisition and disposal of property within the organization is managed. It includes factors such as life cycle costing, health and safety, environmental issues, KPIs, risk management, procurement and social aspects.
6. **Operation and maintenance** deals with how the operation and maintenance of property assets within an organization is managed. It includes factors such as planned maintenance strategy, risk assessments, cost–benefit analysis, training, the use of O&M plans, responsibilities, ranking of property assets in terms of criticality, proactive implementation and evaluation against return on assets.
7. **Performance review and accounting** deals with how the review and accounting processes within an organization are managed. It includes the use of KPIs, property asset registers, training, financial management, roles and responsibilities as well as strategic reviews.
8. **Audit and review** deals with how the property asset management process is audited and reviewed, including skills and training needs, risk avoidance, use of technology and benchmarking of effectiveness and efficiencies.

The maturity matrix sets out transitions from 'unawareness' to 'excellence' (see Table 1 at the end of this paper). It was recognized during the research that the matrix needed further development and is the focus of a subsequent research study.

The route map to excellence

A key requirement from the study was the identification of strategic milestones to enable the OGC & HM Treasury to assess the level of embeddedness for PAM. The route map to excellence was developed through an intensive dialogue during the policy workshop. As a developmental programme the starting point is the base-lining element of the research and the anticipated end point at which OGC/HMT wished to see PAM embedded within the CCGE, with a significant number of departments and ALBs operating at or close to 'excellence' on the maturity matrix. Table 2 sets out the route map. It is linked within the maturity matrix introduced in Table 1. The key milestones identified in the research report are indicated below, with commentaries on current progress.

- In 2005 the first round of asset management plans (covering a broader spectrum than just physical assets) had been requested by HMT as part of the CSR2007 process. A further round of plans are required to inform CSR2007.
- In 2006 the maturity matrix and an agreed route map to excellence would be rolled out across central civil government. The route map was formally launched in November 2006 by the Chief Secretary to the Treasury in a publication entitled *High performing property* (OGC 2006). Further development work on the maturity matrix is set to be completed by July 2007 and launched at the OGC conference on 2 July. The route map identified the target date of March 2009 for all government organizations to set capability and skills standards against which they want to be measured, meaning that it needs to be rolled out across the CCGE during 2007–08.
- In 2007 the first formal assessment of PAM capabilities should be undertaken through an audit process of some 12–15 departments, agencies and NDPBs with major property holdings, and a random audit conducted on other smaller bodies. The OGC's recently published *Route map in high performing property* identifies that this is to take place in March 2009.
- By 2010 all government departments, agencies and NDPBs with major property holdings should have attained a profile on the maturity matrix consistent with a significant profile at Level 5 – excellence – to reflect their own circumstances and environment. The OGC published route map notes that all significant holders or users of property should have achieved Level 5 'excellence' by March 2011; this represents a core group of some 15–18 central government departments and ALBs.

Following the Lyons reports in 2004; the publication of the Leeds report on the OGC website in June 2006; a formal consultation period during the summer of 2006; and the publication of *High performing property* in November 2006; there is now an increased momentum in central government due to the impending CSR2007 review to embed property asset management across the CCGE. PAM is on the government's agenda to secure substantial monetary benefits through efficiency gains.

DISCUSSION AND CONCLUSIONS

There is an increasing international trend to adopt property asset management, as defined here, as a strategic function integrating business strategy with the operational use of property as a corporate resource. The UK central government is rolling out PAM across the civil estate; local government began addressing this some time ago.

There remain a significant number of challenges for the UK government associated not only with embedding PAM within a fragmented and highly decentralized government structure and asset base but including the implications of the costs and uncertainties surrounding the longevity of physical assets and the appropriate strategies for handling them. A few examples will demonstrate the point. First, fieldwork identified the significant impact of short-term government taskforces on space requirements for certain departments. Second, comments were made regularly during interviews that the expected lifespan of a government department could be at best two Parliaments, the most likely being no longer than one Parliament, typical figures quoted were three to five years. This was also a similar range reported in Australia. One department restructured during the timescale of the research study due to an unexpected political event. Again, this impacts on space requirements and the management of administrative as well as operational assets. Third, three generic strategies were encountered across the CCGE for handling the administrative estate in particular – leasehold, freehold and PPP/PFI. Some departments had a mix of all three and were operating with different asset ownership structures and different contractual and tenure timeframes. Fourth, some departments had the foregoing and a mix of operational and administrative assets, buildings-related and civil infrastructure, with investment requirements and whole life performance of those assets remarkably different. Finally, asset management literature typically argues that the long-term timeframe for considering property and infrastructure assets should be 25–30 years and beyond. It is, however, not quite so straightforward when confronted with the complexity of the CCGE, the influences and the timeframes noted here.

The conclusion from this research is that the only way to deal with this comprehensively is to embed property asset management as a strategic function within government departments at or just below executive management board level. With this in mind, this paper has presented three of the principal results from the report of the OGC-commissioned research forming part of the roll-out programme – the property asset management board, the maturity matrix and the route map to excellence. Lessons from the Australian experience indicate clearly that this is a medium- to long-term programme of activity. The OGC and HM Treasury have already set challenging targets for the short to medium term, not least in monetary terms but also in organizational terms. The second Lyons report notes the expectation is that central government organizations have no choice but to raise their game in property asset management and embed it within their normal ways of working.

Table 1: PAM maturity matrix (University of Leeds 2006)

Function Level	PAM Policy	Roles & Responsibilities	Communication	PAM Planning	Acquisition & Disposal	Operation & Maintenance	Performance Review & Accounting	Audit & Review
1. Unawareness	No written policy.	No staff resource active in management of assets.	No awareness of Asset Management & no dialogue with stakeholders.	Based on historical trends. Technical aspects only. Reactive	Ad hoc, informal. Price sensitive decision at line level.	Based on historical trend. Reactive maintenance. No condition assessment or performance monitoring.	Performance/cost management for major aspects only.	Reactive & unplanned.
2. Awareness	Informal guidelines setting out position on some Asset Management issues.	One or more individuals with adopted informal advocacy role at tactical level.	Some data requested routinely on Asset Management issues.	LCC for capital investment but no financial reporting. Some risk analysis. Approval procedures established	LCC, technical function, work practices, health & safety, environmental issues, O&M feasibility.	Maintenance strategy for major assets only. Asset reliability, risk assessment/cost benefit analysis considered. Training needs identified.	KPIs identified & communicated. Asset register in place. Training needs/no knowledge of financial management addressed. Process responsibilities established.	Skills & training needs identified. Well documented & prioritised processes & practices. Formal audit plans.
3. Knowledge	Formal statement setting out position on Asset Management.	Responsibility for PAM assigned to one manager.	Agreement with stakeholders on PAM objectives & targets. Data collected on most Asset Management issues.	Business oriented & performance based. Project evaluation & benchmarking. Prioritisation of investments	Full economic evaluation, LCC, performance, productivity indicators. Project management. Risk/sensitivity analysis. Integrated Procurement	Integrated financial/ O&M plans well documented. Specific costing activities. Responsibilities well defined. Project Management. Familiarity with AM practices.	Adequate skills. Well defined roles & responsibilities. Level/ cost of service regularly reviewed. System capability periodically reviewed.	Business & market oriented. Avoid unnecessary risk, use new technology, close monitoring.
4. Competence	Comprehensive internal statement, with indicators for some PAM issues.	PAM responsibilities within each business team.	Information on PAM issues reported to senior managers at strategic level & shared with key stakeholders.	PAM integral to business planning. Risk Management/ contingency plans target setting.	Value selection. Performance guarantee, support, technologies, financial, technical, risks & supplier credibility aspects.	O&M based business & performance objectives. Strategic ranking of assets. Risk Management practised. Proactive O&M.	Strategic review based on importance. Analyse trends/cause/ effect. Review support decision making. True cost, return on assets available.	System ownership embraced by staff. Participative decision making environment. Training completed.
5. Excellence	Published, with targets, reviews and promotion.	Overall responsibility with a senior manager at strategic level & regular progress reviews.	Regular dialogues with key stakeholders & supply chain, Asset Management performance major focus for reports.	Based on corporate objectives: financial/ marketing/ production. Risk Management. Industrial Relations. Modelling	Long-range strategic planning, social, environmental, technological, market forces.	Individual asset O&M strategy based on performance & evaluated against return on assets. Risk Management preventative maintenance.	Review process eminent & exemplary. Generates economic value & advancement.	Able to achieve benchmark efficiency & effectiveness. Independent audit available.

Table 2: A possible route map and action plan for implementing PAM across the civil estate (University of Leeds 2006)

	Period	Activities
Readiness for service	2006	• Engaging stakeholders. This should include heads of estates/permanent secretaries/ministers and should be carried out during the period between March and September 2006 and beyond. • Raise awareness of PAM at the QE2 Conference Centre event on 26 June 2006. • Launch road map for embedding and implementing property asset management during the period around September 2006. It is recommended that the launch does not take place until the stakeholder engagement exercise is complete. • Agree the direction, structure and process of PAM in the CSR process. • Obtain potentially the commitment from Treasury for seed-corn funding to enable an up-skilling campaign and any redundancy programme that may be required across estates functions due to continued rationalization. • Each department should produce a property asset strategy for the CSR process and this should be attached to FD and departmental plans; and should include sponsored bodies by October 2006. • By December 2006 there should be an agreed single document template for PAM plans forming part of the HMT requirement for asset management plans. • Adjustments agreed and made to departmental PSA targets, DEL and business planning processes. • Agreement that PAM forms part of the departmental capability reviews conducted by the Prime Ministers Delivery Unit.
	2007	• At the start of 2007 each organization should have achieved the milestone of the end of level two competences as described in the maturity matrix on the way to excellence in PAM. • Workshops should be held across government on the maturity matrix and discussions with Treasury Teams. • The National School for Government should commence embedding asset management in their training programmes. • PAM Plan template becomes part of the Spending Round 2007 process.
	Mid to late 2007	• An assessment should be made of the capabilities, structures and change programmes associated with PAM. There is a potential role for the NAO within this. Six to seven major departments, major agencies and six to seven NDPBs to be the main initial contributors across government. At this juncture a decision should be made on mandating the PAM process.
	End 2007	• Each organization should have achieved the milestone of the end of level three competences as described in the maturity matrix on the way to excellence in property asset management. • End of the period for 'readiness for service' in PAM. It should also be the commencement of the period of 'service delivery' for PAM.
Delivery	2008	OGC/Treasury: • Change agent role to support and challenge. • Peer review (department to department). • Priority review. • Annual stock take of whole direction of PAM in the civil estate. • Identify year-on-year targets sample basis (80:20) backwards and forward looking. Departments: • PAM fully embedded in business planning process. • Internal audit units should be undertaking annual stock takes of progress. • Department planning to meet Treasury targeted. • Shared service centres to be included within the process. • Responses to peer reviews and annual target reviews.
	2009–10	• A reassessment should be made of the capabilities, structures and change programmes associated with PAM by, for example, the NAO within in this timeframe. Six to seven major departments, major agencies and six to seven NDPBs to be the main initial contributors across government. This would also include a sample of a wider population of sponsored bodies. • Ongoing implementation and embedding of PAM. • Post implementation review/policy assessment e.g. reporting to the Prime Minister's office. • At the end of 2010 each organization should have achieved the milestone of the end of level five competences as described in the maturity matrix on the way to excellence in PAM, reflecting a profile of cells within the matrix to reflect the nature of each organization.
	2011	• Review and refresh for the next step in PAM – April 2011.

OPTIMAL AND DYNAMIC ASSET MANAGEMENT IN INFRASTRUCTURE SECTOR

Tiina Koppinen[1] and Tony Rosqvist[2]

Road, rail and water/sewerage networks are vital to the national economy. Reduction in public financing together with increasing use of networks, urge infrastructure managers to optimize their networks focusing on overall cost-effectiveness of their operations. Decision-making in asset management should be able to ensure long-term economic efficiency and optimal service levels. However, often decision-making in infrastructure management under uncertainty is far from optimal, reliable and flexible. This is why a simplified asset management decision-making method was developed for the infrastructure sector. The method aims at assisting infrastructure managers in optimizing the life cycle profiles of their assets through selection of an optimal maintenance, repair and rehabilitations project portfolio. The method applies the analytical hierarchy process and real option ideology. The developed systematic and easy-to-apply method fills the void between strategic and operative decision-making methods facilitating management of multiple investments at the local network management level.

Keywords: asset management, decision analysis, facilities management, infrastructure management, project appraisal.

INTRODUCTION

Infrastructure networks are vital to the national economy. As the economic and technical lifetime of the networks are long, numerous rebuilds, replacements and expansions take place during the lifetime highlighting the importance of Asset Management (AM). Reduction in public financing together with increasing use of the networks, urge infrastructure managers to optimize their networks focusing on overall cost-effectiveness of their operations. For AM to live up to the expectations, it has to meet four key challenges: (a) alignment of strategy and operations with stakeholder values and objectives; (b) balancing of reliability, service-level, safety, and financial considerations (Schneider *et al*. 2006); (c) ensuring optimal packaging and timing of works, and adequate competition; and (d) promoting market development (Koppinen and Lahdenperä 2004). Also, often cited objectives include maximizing the net benefit to the public, efficient use of resources, and early usage of the built facilities (Hsieh and Liu 1997). However, often decision making in infrastructure development and operation under uncertainty is far from optimal, reliable, and flexible (Zhao and Chung 2006). Approaches to municipal infrastructure management tend to be centred upon annual project execution. Simply executing existing backlog fails to consider projects in an appropriate context (Garvin *et al*. 2000).

[1] tiina.koppinen@vtt.fi

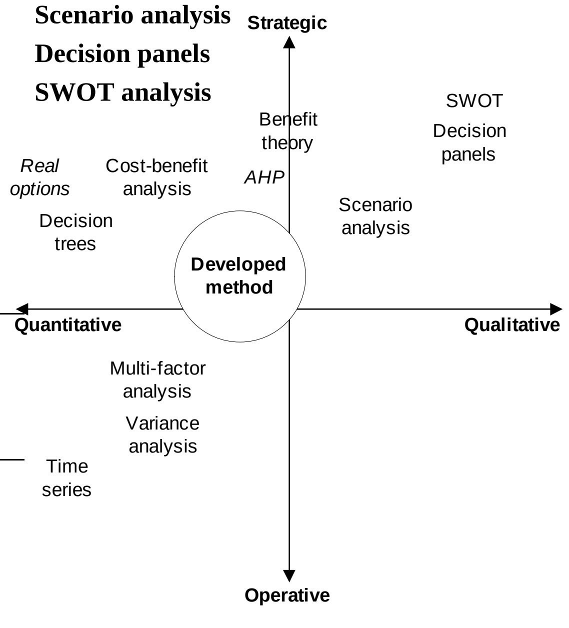
In these circumstances, it was considered important to develop a structured decision making method for infrastructure managers that would facilitate evaluation of project alternatives in order to find the most cost-effective Maintenance, Repair and Rehabilitation (MR&R) projects for implementation. This was done as a part of a research project called “Strategic framework for asset management in capital-intensive industries”. The paper outlines the work done for the infrastructure sector by starting with a list of existing decision making methods. Next, the methods are selected for the tool development and the developed, strategic framework is described. Finally, the developed, simplified Project Portfolio Selection Method (PPSM) is discussed and conclusions made.

DECISION MAKING METHODS

Different decision making methods have been developed to assist managers in decision making. Table 1 lists both strategic and operative decision making methods that aim at taking into consideration uncertainties. The Analytical Hierarchy Process (AHP) is adopted as the primary method for selection of an optimal project portfolio. AHP is easily understood and already applied in many decision making tools. AHP is enhanced with Real option thinking which best recognizes that the optimality of a certain project portfolio may depend on the level and type of uncertainty in the operating environment.

Table 1: Methods and techniques that assist decision making in uncertain circumstances

Quantitative methods	**Qualitative methods**
Decision analysis - Benefit theory/decision trees - Quantitative risk analysis - Models for stochastic dominance (FSD, SSD, TSD) - Models for information value - Markov models - Multi-goal optimization - Multi-criteria decision-making (e.g. AHP)	**Scenario analysis** **Decision panels** **SWOT analysis**
Data analysis – Time series – Multi-factor analysis – Variance analysis	
Economic quantitative methods - Analysis of uncertainties existing in investment opportunities (e.g. NPV simulation,, *Real Option theory*) - Competition theory models - Game theory models - Demand/supply models, benefit-theory - Cost-benefit analysis	



The embedded figure positions the methods in terms of their strategic- and quantitative-nature. The circle in the figure shows the void, which the developed method should fill.

Real options

Real options approach models infrastructure management processes as contingent decision making and is capable of yielding optimal solutions in light of multiple uncertainties (Zhao and Chung 2006). Real option analysis recognizes that the flexibility inherent in capital projects has value. An option to expand, defer, downsize or abandon a major capital investment allows an organization to respond to strategic and competitive opportunities rather than remaining locked into a fixed course of action. Options may be divided into two groups: flexibility and growth options (Du *et al*. 2006). However, valuation of these real options and associated financial option-based calculations are often considered overly complicated. It has been suggested that few practitioners truly understand or use the real options approach (Alkaraan and Northcott 2006). This is why an easy-to-use and reliable-enough tool is needed to assist infrastructure managers in selecting optimal projects in an uncertain environment.

AHP

The AHP, a multiple-attribute decision making technique, developed by Saaty (1980) provides a flexible and easily understood way of analysing complicated problems. AHP allows subjective as well as objective factors to be considered in the decision making process and it can handle criteria that may be conflicting. Additionally, AHP forms a systematic framework for group interaction and group decision making which is often utilized in project evaluation.

INVESTMENT PORTFOLIO EVALUATION

The asset manager must select optimal projects to the MR&R project portfolio. The optimal project portfolio depends on the operating environment. For an organization operating in a stable operating environment, the success criteria of AM may relate to reliability of service quality and speed of response set against continuous improvements in cost efficiency. However, when uncertainty in the operating environment increases, speed and appropriateness of change become increasingly relevant elements of competitiveness (Kelly *et al*. 2002). The developed method pursues to incorporate this type of consideration as an inherent part of optimal MR&R project selection. The project evaluation process is divided into two consecutive evaluations: If the project passes the pre-screening phase, it enters into the prioritization. In selecting the right asset portfolio the asset manager needs to asses, among others, alternatives' fit into the strategy, resource requirements, inherent flexibility, and resulting serviceability, operability and maintainability of the network locally and as a whole (Figure 1).

Project pre-screening

When AHP and real options are integrated, a new, simplified method for assessing investment opportunities at the local network management level is developed. Quantitative and qualitative criteria listed in Figure1 are more systematically grouped according to Figure 2: V) Value creation (~benefits); R) Resource-availability (~costs); and F) Flexibility provided by the alternatives in case of future changes (~real options). The level of Value creation is determined by whether the evaluated alternative: (1) fits into the organization's strategy; (2) contributes to the organization's capabilities promoting continuous improvement; (3) provides important stakeholders with added value; (4) enhances safety, reliability and service-level of operations; and (5) promotes market and industry development. Resource-availability is determined based on whether: (1) public financing is available; (2) other sources of funding are available; (3) in-house expertise is available; (4) industry has appropriate capabilities; and (5) market situation enables adequate supply and competition in the industry (Koppinen and Rosqvist 2007). Future flexibility is determined based on the availability and usability of real options inherent in the alternative.

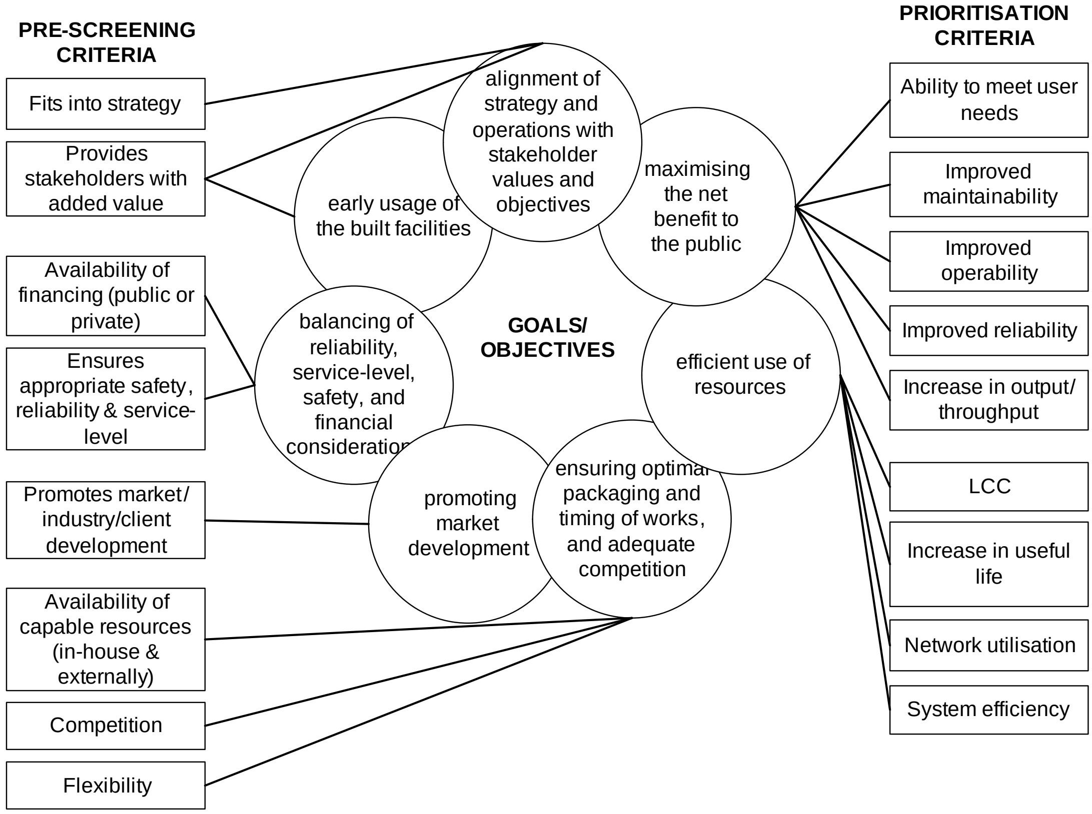


Figure 1: Turning client objectives in the infrastructure sector into the evaluation criteria

The underlying principle is to establish relative weights (w_i) of the above criteria and sub-criteria using pair-wise comparison based on AHP-method (see Table 3). The recommended scale used for making comparisons is 1–9 (Saaty 1980). Generally, the more critical the criterion is in relation to the other criteria, the higher it should be weighted. For example, the weighting of the future flexibility depends on the level of uncertainty existing/expected in the operating environment; the more uncertain environment, the more valuable flexibility is, the higher its weight should be.

As the infrastructure managers should pursue objectivity in assessing somewhat subjective factors, the sub-criteria scoring is determined based on Table 3. This system reduces effect of personal preferences. For example, R3 – In-house expertise exists: If expertise required by the alternative exists in-house, but is located in another regional office, internal co-operation is necessary in order to utilize the expertise. If earlier experiences in cooperation have been successful, the score would be 8. On the other hand, if the organization has no history of co-operation between the different regional offices, initial inefficiency may be experienced. In this case, the score should be 7.

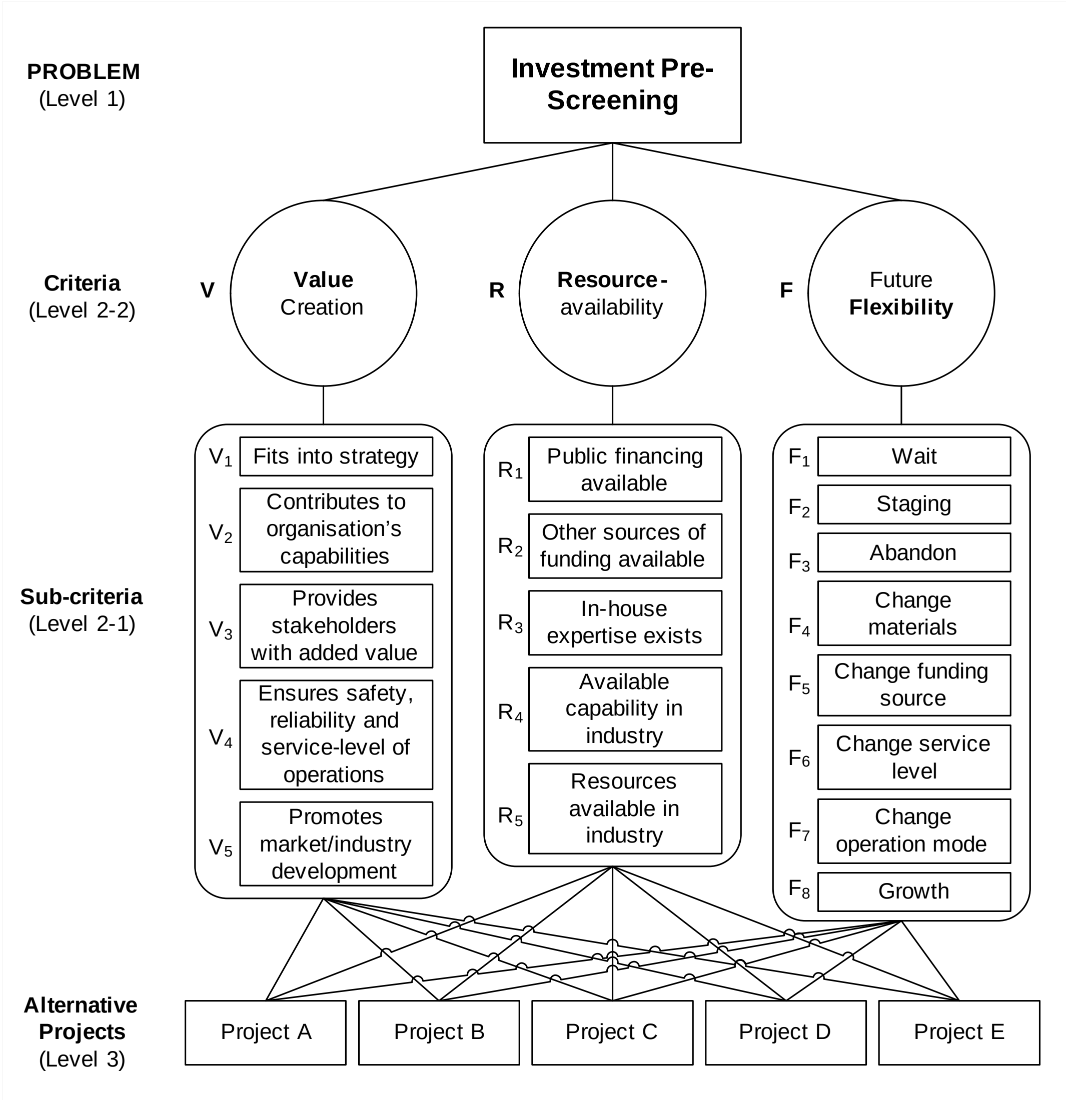

Figure 2: Investment pre-screening using AHP and taking into consideration real options

Table 2: Final importance of criteria and preferences of alternatives in pre-screening

Criteria	**Value Creation**					**Resource-availability**					**Future Flexibility**					**Total ***
Relative weights	w_V (weights through AHP)					w_R					w_F**					(sum=1)
Sub-crit.	V1	V2	V3	V4	V5	R1	R2	R3	R4	R5	F_i	F_i	F_i	F_i	F_i	
Weights	w_{V1}	w_{V2}	w_{V3}	w_{V4}	w_{V5}	w_{R1}	w_{R2}	w_{R3}	w_{R4}	w_{R5}	w_{Fi}	w_{Fi}	w_{Fi}	w_{Fi}	w_{Fi}	(sum=3)
Project A	a_{V1}	a_{V2}	a_{V3}	a_{V4}	a_{V5}	a_{R1}	a_{R2}	a_{R3}	a_{R4}	a_{R5}	a_{Fi}	a_{Fi}	a_{Fi}	a_{Fi}	a_{Fi}	A_{tot}
Project B																B_{tot}
Project C																C_{tot}
Project D																D_{tot}
Project E																E_{tot}

* $X_{tot} = w_V*(?w_{Vi}*x_{Vi})+w_R*(?w_{Ri}*x_{Ri})+ w_F*(?w_{Fi}*x_{Fi})$, i=1…5 (Flexibility: i=1…8, of which 5 most important options selected), x=a,b,c,d,e valued according to table xx; 1= X_{tot}=10

** The more uncertainties exist in the operating environment; the higher weight should be given to Future Flexibility.

Instead of complicated option-based valuation methods, flexibility provided by different real options is valued based on the option costs (OC) involved with the options, since flexibility typically comes at a price and is only valuable as a hedge against the uncertainty (Du *et al*. 2006). Here, strategic real options are determined based on the uncertainties existing in the operating environment. Score depends on the level of OC involved with the option when compared to an alternative without this option. For example: when the level of competition in the industry is uncertain, valuable real options are waiting, staging and changing of operation mode. If an alternative provides an option to implement the project in stages, and it may be expected that the competition level is significantly improved by the phase two, the staging option is valuable. Now it is assed how much more this alternative costs when compared to an alternative without this option. If OC is approximately 7% of project cost, the score would be 5, while OC of 6% would result in the score of 6.

Table 3: Valuation of the pre-screening criteria (scale 1…10)

Criteria		**Score**				
		1–2	**3–4**	**5–6**	**7–8**	**9–10**
V1	Fits into strategy	negligible	fulfils fraction of strategy	fulfils basic principles of strategy	fulfils most of strategy	fulfils strategy
V2	Contributes to organisation's capabilities	negligible	improvement trivial	improves existing capabilities	broadens capabilities	builds new strategic capabilities
V3	Provides stakeholders with added value	negligible	some	average amounts	more than average	significantly
V4	Ensures safety, reliability & service-level of operations	negligible	improved to some extent	probability of failures <7%	probability of failures <5%	probability of failures <2%
V5	Promotes market/industry development	negligible	to some extent	industry cooperation increased	industry innovativeness improved	significantly
R1	Public financing available	none	minor part	partially	adequate/ total funding	abundantly
R2	Other sources of funding available	none	one source – partial funding	two sources – partial funding	adequate funding available	abundantly
R3	In-house expertise exists	negligible	requires long-term planning and training	requires some training	requires internal co-operation	expertise readily available
R4	Available capability in industry	negligible	requires long-term planning and training	requires some training	requires industry co-operation	capability readily available
R5	Resources available in industry	negligible	requires long-term planning and much funding	requires training or waiting for completion of current projects	requires good co-ordination/ management	resources readily available
Select max. 5 strategic real options based on uncertainties in the operating environment (Fig. 2):						
F_i	n.n.	significant option costs (OC) involved	OC 10% of project cost	OC 7% of project cost	OC 4% of project cost	negligible OC involved

Finally, projects that provide x_{tot} values greater than a certain pre-determined threshold value may be selected as a promising set of projects. To visualize the above analysis, the results are drawn into a diagram shown in Figure 3. Here x-axis depicts the score of resource requirements (≈ costs), while y-axis denotes the score of value generation (≈ benefits). The size of the symbol depicts the score of flexibility. Projects in the up most, right-side square should be implemented, while projects in the lowest left-side square should be declined. Other projects above the diagonal could be implemented, if resources were available. No further analysis would be necessary. However, as resources are often deficient, these potential projects should be evaluated more thoroughly in order to implement truly the best projects. This is done through project prioritization. Projects underneath the diagonal should be omitted from the evaluation and declined unless magnitude of uncertainty and flexibility provided by the alternative justify a further evaluation of an alternative.

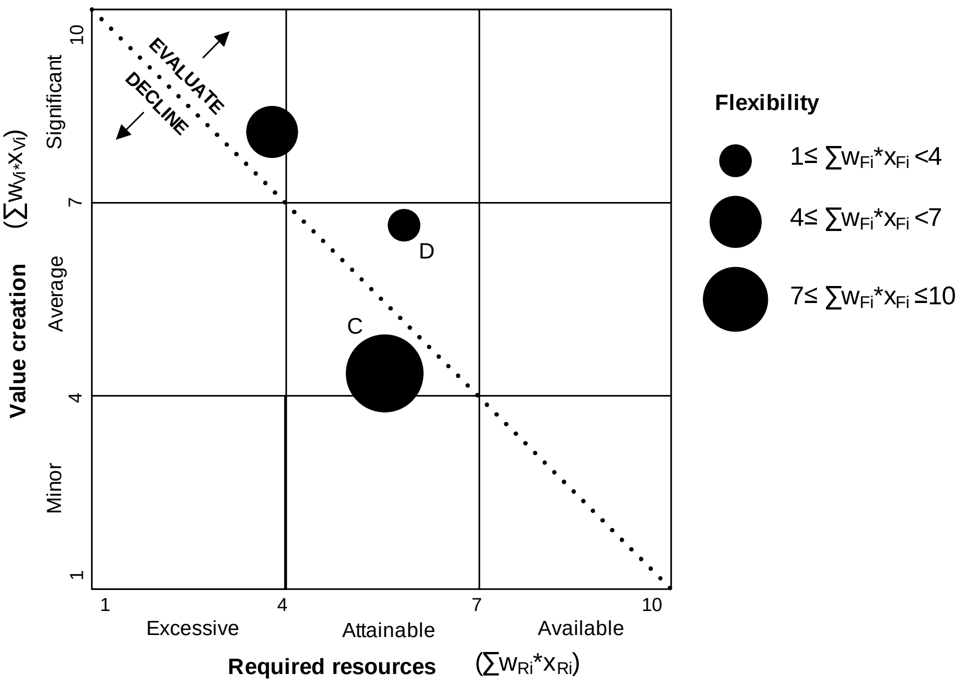

Figure 3: Selection of the potential alternatives (Koppinen and Rosqvist 2007)

Project prioritization for optimal portfolio

In order to optimize the MR&R project portfolio, a more comprehensive assessment is performed on the pre-selected alternatives (Koppinen and Rosqvist 2007). The method used is similar to the pre-screening (Figure 4), but now criteria used are divided into following groups: (1) improvement in maintainability of the asset; (2) service improvements produced; and (3) optimized life cycle cost (LCC) of the asset. The first two criteria determine the level of overall benefits of the projects, while the third criterion determines the true life cycle cost of the project (Table 4). The level of improvement in maintainability is determined by how the evaluated alternative impacts on (1) network or (2) system reliability and (3) maintainability of the network; and how it affects (4) the operation and (5) the remaining life of the network. Level of service improvement is determined based on: (1) increases in throughput; (2) network utilization level; (3) system efficiency; (4) reliability of service; and (5) ability to meet user needs. Scoring of the benefits criteria is performed based on Table 5.

The results of the prioritization are drawn into a diagram shown in Figure 5. Here x-axis depicts the LCC of the project, while y-axis denotes the scored benefits of the project. The size of the symbol depicts the flexibility provided by the investment alternative (determined in project pre-screening). Again projects above the diagonal should be selected to the project portfolio, while projects underneath the diagonal should be declined. The diagonal can be moved perpendicularly depending on the availability of resources. The idea is to position the diagonal so that the level of available resources is equal to LCC of the project portfolio (= $\sum LCC_i$, i= A, B…).

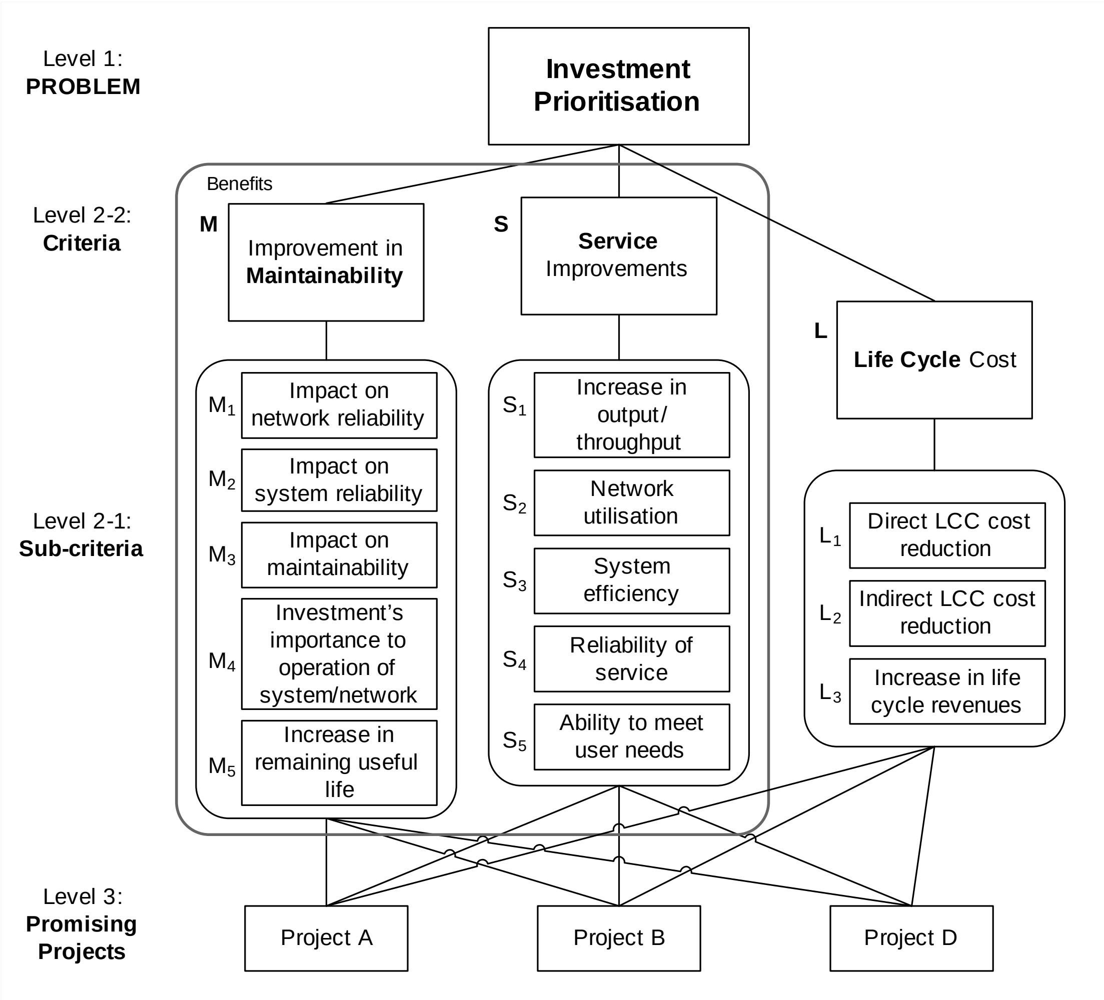

Figure 4: Investment prioritization using AHP in order to optimize the network's life cycle profile

Table 4: Final importance of criteria and preferences of alternatives in project prioritization.

Criteria	**Improvement in Maintainability**					**Service Improvements**					**Total Benefits**	**Life Cycle Cost**		
Weights	w_M (weights through AHP)					w_S					(sum=1.0)			
Sub-criteria	M1	M2	M3	M4	M5	S1	S2	S3	S4	S5		L1	L2	L3
Weights	w_{M1}	w_{M2}	w_{M3}	w_{M4}	w_{M5}	w_{S1}	w_{S2}	w_{S3}	w_{S4}	w_{S5}	(sum=2.0)			
Project A	a_{M1}	a_{M2}	a_{M3}	a_{M4}	a_{M5}	a_{S1}	a_{S2}	a_{S3}	a_{S4}	a_{S5}	A_{tot}	LCC_A		
Project B											B_{tot}	LCC_B		
Project D											C_{tot}	LCC_C		

$X_{tot} = w_M*(\sum w_{Mi}*x_{Mi})+w_S*(\sum w_{Si}*x_{Si})$, i=1…5, x=a,b,c according to table xx; $1\leq X_{tot}\leq 10$

Table 5: Valuation of the prioritization criteria (scale 1…10)

Criteria		Score 1–2	3–4	5–6	7–8	9–10
M1	Impact on network reliability	negligible	improved to some extent	probability of failures <5%	probability of failures <3%	probability of failures <1%
M2	Impact on system reliability	negligible	improved to some extent	probability of failures <5%	probability of failures <3%	probability of failures <1%
M3	Impact on maintainability	negligible	slightly facilitated	facilitated to some extent	maintainability better than average	significantly improved
M4	Importance to operation of system/network	negligible	operation slightly facilitated	operation facilitated to some extent	operation more efficient than average	strategic/ significant
M5	Increase in remaining useful life	negligible	25%	50%	75%	100%
S1	Increase in output/ throughput	none	meets partially projected increases in future demand	meets projected average increases in future demand	meets projected increases in future demand	meets projected extreme increases in future demand
S2	Network utilisation	significant over capacity or severe problems during peak utilisation	mostly inefficient	some over capacity or average problems during peak utilisation	mostly efficient	optimal
S3	System efficiency	current level or worse	increased by 10%	increased by 15%	increased by 20%	increased by 25%
S4	Reliability of service	current level or worse	failures reduced by 10%	failures reduced by 35%	failures reduced by 50%	failures reduced by 65%
S5	Ability to meet user needs	negligible	meets minor user needs	meets primary user needs	meets most user needs	meets all user needs

DISCUSSION

The developed PPSM is a generic, theoretical model for the infrastructure sector as a whole. It has not been tested in real projects, and the criteria applied aspire to be general for all infrastructure sectors. In the future research, the model will be applied to different infrastructure sectors in order to refine the model and criteria to different decision making situations. However, it is expected that in most cases a different set of criteria may be applied without changing the overall structure of the method. When different set of criteria is used, care must be taken in order to avoid double counting. Also scoring of the sub-criteria is purely theoretical and may not provide the best possible ranges for decision making in different infrastructure sectors. Thus, the scoring should be revised according to the sector-specific experiences before applying the method.

In further research, evaluation of the flexibility-level provided by the alternatives will also be looked at in more detail. Currently, flexibility is presented in the diagrams as a circle with a purely imaginative and descriptive radius. However, the model could be further developed by giving the flexibility a symbol, whose radius depicts better the true value and/or option cost of real options/flexibility.

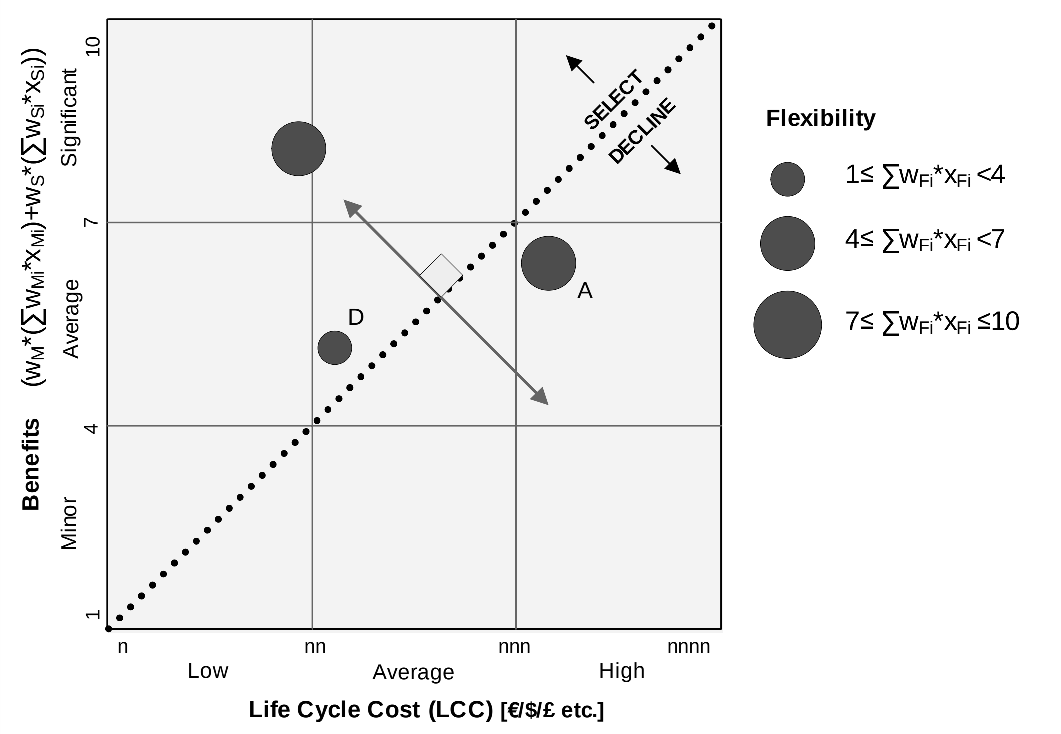

Figure 5: Selection of the project portfolio for implementation (Koppinen & Rosqvist 2007)

CONCLUSIONS

One of the biggest challenges for any public organization today is, how to prioritize projects to maximize the benefit of optional funding. The objective of the developed decision making method was to pre-screen investment options and to evaluate project alternatives in order to find the most cost-effective maintenance, repair and rehabilitation projects for implementation. (With the suggested pre-screening analysis, the asset manager can determine the order of preference of alternative projects, while the prioritization analysis determines the optimal MR&R project portfolio.) The developed method fills its intended purpose as an easy-to-apply link between strategic and operative decision making, supporting decision-making related to the management of network condition and functionality through optimal MR&R project portfolio planning.

TOWARDS EFFECTIVE LEADERSHIP IN CONSTRUCTION STAKEHOLDER MANAGEMENT

Ezekiel Chinyio[1] and Deborah Vogwell[2]

Nowadays construction clients are multifaceted and often deal with a large configuration of stakeholders in the course of a project. These stakeholders often include owners, users, project managers, facilities managers, designers, subcontractors, suppliers, process and service providers, competitors, banks, insurance companies, media, community representatives, neighbours, customers, regional development agencies and the natural environment. Stakeholders have claims, rights and expectations that impact on corporate governance, processes and outcomes, and in this regard can undermine the objectives of a construction project. The ability of a project team to identify and map stakeholders accurately informs both the relationship with the latter and project success. Meanwhile, stakeholders must be motivated proactively to behave in ways that support the objectives of a project and this can be achieved by using specific engagement strategies. A research that evaluated the practice of effective construction stakeholder management informs this article. Twelve interviews with key project stakeholders were conducted. A qualitative design was employed in the research, which was carried out by means of the grounded theory methodology. The data were evaluated by means of content analysis. The empirical findings identified the strategies and tactics for managing stakeholders; however, this article dwells on only one strand of the findings, i.e. that effective leadership of stakeholders can help harmonize their goals and prevent potential conflicts. The other findings of the research are disseminated elsewhere.

Keywords: client, corporate governance, leadership, risk management, stakeholder management.

INTRODUCTION TO STAKEHOLDER MANAGEMENT

A stakeholder is an individual with an interest or a share in an undertaking (Weiss 2006). The dimensions of interest are almost open-ended hence the checklist of stakeholders in most undertakings is often long. In construction projects, the stakeholders will often include (Newcombe 2003; Smith and Love 2004): clients (both owners and users); project managers; facilities managers; designers; shareholders; legal regulators; employees; subcontractors, suppliers and process or service providers; competitors; banks; insurance companies; community representatives, neighbours, general public; government/local authority; visitors and customers (both current and potential); regional development agencies, etc. The stakeholders in a project can be divided into (Calvert 1995; Winch and Bonke 2002):

- internal stakeholders (those who are members of the project coalition or who provide finance); and
- external stakeholders (those affected by the project in a significant way).

[1] e.chinyio@wlv.ac.uk

Similar classifications are: inside and outside stakeholders (Newcombe 2003); direct and indirect (Smith and Love 2004); primary versus secondary, social versus non-social and core, strategic or environmental (Carroll and Buchholtz 2006).

Stakeholders have power to be either a threat or a benefit to an organization (Gibson 2000). They can trigger project schemes (Orndoff 2005) and can support or obstruct an ongoing project (Vogwell 2002). Organizations often depend on external stakeholders for resources which gives the later a leverage (Frooman 1999). The argument is: stakeholders have claims, rights and expectations that ought to be honoured and not taken lightly (Carroll and Buchholtz 2006). Thus, stakes must be managed in each project to avoid any of their influences that could be contrary to a firm's objectives. Conversely, business endeavours and indeed construction projects, affect stakeholders. So it is a tit for tat affair. Businesses must recognize their stakeholders and manage them; and vice versa.

Differing stakes are a major source of conflict hence it is worthwhile to manage stakeholders in most undertakings. A research that examined stakeholder management in construction is reported in the paper. Although several findings were established in the research, size restriction warrants the discussion of one main issue in this paper, i.e. the need to develop more effective leadership in construction project delivery.

The next section reviews stakeholder theory. After that, a research that informs this paper is introduced along with its methodology. The outcome of the research with respect to leadership is then discussed before wrapping up.

ASPECTS OF THEORY

Stakeholder management involves managing relationships in order to motivate stakeholders to behave in ways that support a firm's objectives. The art of stakeholder management is about creating the most positive environment in which to develop a project (Vogwell 2002). It has been argued that corporations have a moral obligation to their stakeholders and that their policies should incorporate stakeholder inclusion with auditable board and executive level responsibilities for stakeholder relations (Wheeler and Sillanpää 1997).

Even if all stakeholders have all the good intentions, and they often do, their large number in a given project warrants their management because the pursuit of their individual objectives may not necessarily be congruent. It also demands a proactive approach in dealing with stakeholders as opposed to being reactive.

Shareholders constitute one set of internal stakeholders who have invested in a firm in expectation of rewards in terms of dividends, share appreciation and capital repayments (Doyle and Stern 2006). Shareholders have an influence on the objectives of an organization. Likewise, other stakeholders can influence the pursuit of an organization's objectives (Freeman 1984). While shareholders can influence an organization from within, most other stakeholders often influence it from the outside. The management concerns of a company are in someway sandwiched by its shareholders and stakeholders. Both shareholders and stakeholders place demands on the management of a company and it is worthwhile to address both sets of demands. The ideal is to strike a balance where the objectives of a business are achieved while satisfying stakeholders, that is, a win-win approach (Carroll and Buchholtz 2006). The discussions in this paper are however limited to stakeholder issues.

A stakeholder management approach takes many factors into account, e.g. moral, political, technological and economic interests (Weiss 2006). Three approaches are useful for dealing with stakeholders, i.e. (Goodpaster 1991):

1. *Strategic approach*: This approach allots shareholders' profit a greater priority above the interests of other stakeholders.
2. *Multifiduciary approach*: This assumes a fiduciary responsibility to stakeholders, allotting them equal stakes with shareholders.
3. *Stakeholder synthesis approach*: This approach assumes a moral but non-obligatory responsibility to stakeholders, e.g. dealing with them ethically.

Stakeholder management theory evolved from business management and aims to describe, understand, analyse and manage stakeholders. Its theory is that an organization has relationships with many constituent groups and that it can engender and maintain the support of these groups by considering and balancing their relevant interests. To any organization, therefore, the key considerations in practical stakeholder management should include the following (Carroll and Buchholtz, 2006):

1. Who are our stakeholders?
2. What are their stakes?
3. What opportunities do they present?
4. What challenges or threats do they present?
5. What responsibilities do we have towards our stakeholders?
6. What strategies or actions should we use to engage our stakeholders?

The sixth point is significant and loaded. It considers such aspects as;

- Should we deal directly or indirectly with our stakeholders?
- Should we be aggressive or defensive in dealing with stakeholders?
- How and when should we accommodate, negotiate, manipulate or resist the overtures of our stakeholders?
- How and when should we employ a combination of the above strategies or pursue a singular course of action?

It is widely acknowledged that Freeman (1984) introduced modern stakeholder theory to the business sector, and explicitly linked stakeholder interests to corporate strategy. A major purpose of stakeholder theory is to help corporate managers understand their stakeholder environments and manage them more effectively. A larger purpose is to help corporate managers improve the value of the outcomes of their actions while minimizing any harm to stakeholders. In essence, stakeholder theory concerns relationships between corporations and their stakeholders (Logsdon and Wood 2000). Stakeholder management practice is now underpinned on ethical, social and economic considerations.

Stakeholder management is useful to procurement in general and has been fostered in several disciplines, e.g. land remediation, forestry; business marketing; IT; electronics industry; hospitals; automotive industry, etc. Construction practice had embraced it and is now coming to terms with its promotion. Stakeholder management is being researched in both construction and other disciplines (Kolk and Pinkse 2006).

The key principles of stakeholder management (in Table 1 below) were first proposed by Max Clarkson who became legendary for his early support of the stakeholder concept. The principles emerged organically after an international group of management scholars, including Clarkson himself, explored the role of the large corporation in modern, highly interdependent economies. Their goal was to develop a broad concept of the firm as a vehicle for advancing the interests of multiple and diverse stakeholders. The principles thus incorporate a variety of perspectives and provide a template and guide to organizations for managing their stakeholders (Donaldson 2002).

Understanding stakeholders

Stakeholder management involves identifying and classifying stakeholders, thus facilitating both initial and subsequent engagement with them in a timely, planned and coordinated manner. This engagement involves identifying different categories of stakeholders; gathering information about them; identifying their missions in a project; determining their strengths and weaknesses; identifying their strategies; predicting their behaviour and developing and implementing a stakeholder management strategy (Cleland 1999). The classification of any set of stakeholders should identify those that are (less) critical at a particular point of time.

A twofold matrix is often used to map stakeholders on the basis of:

1. the power they can exert on a project or firm;
2. their level of interest in an undertaking.

Relatively, minimal effort is required in satisfying stakeholders with little interest in a project, whereas greater effort is required in keeping stakeholders with high interests happy (see Figure 1).

Table 1: Principles of stakeholder management (www.mgmt.utoronto.ca/~stake/Principles.htm)

Principle	**Stipulation – that managers should:**
No. 1	*Acknowledge* and actively *monitor* the concerns of all legitimate stakeholders, and should take their interests appropriately into account in decision making and operations.
No. 2	*Listen* and openly *communicate* with stakeholders about their respective concerns and contributions, and about the risks that they assume because of their involvement with the corporation.
No. 3	*Adopt* processes and modes of behaviour that are sensitive to the concerns and capabilities of each stakeholder constituency.
No. 4	*Recognize the interdependence* of efforts and rewards among stakeholders, and should attempt to achieve a fair distribution of the benefits and burdens of corporate activity among them, taking into account their respective risks and vulnerabilities.
No. 5	*Work cooperatively* with other entities, both public and private, to ensure that risks and harms arising from corporate activities are minimized and, where they cannot be avoided, appropriately compensated.
No. 6	*Avoid altogether* activities that might jeopardize inalienable human rights (e.g. the right to life) or give rise to risks that, if clearly understood, would be patently unacceptable to relevant stakeholders.
No. 7	*Acknowledge the potential conflicts* between (a) their known roles as corporate stakeholders; and (b) their legal and moral responsibilities for the interests of stakeholders, and should address such conflicts through open communication, appropriate reporting, incentive systems and, where necessary, third party review.

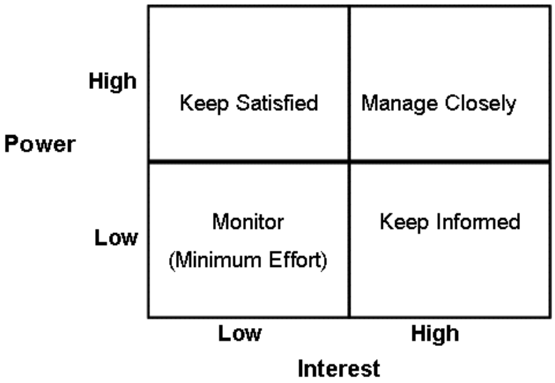

Figure 1: Power-Interest grid

In addition to the power–interest dimension Newcombe (2003) considered a power-predictability matrix. In this regard, stakeholder management should be able to identify those that can spring a surprise in terms of making a demand on or exercise power in a project. When things are progressing well with an organization and its stakeholders, it does not necessarily mean that a stakeholder cannot place a sudden and unnecessary demand on their project. Thus in running projects, organizations act in a tolerance zone which is a performance band in which the firm is satisfying the interests of all its key stakeholder groups (Doyle and Stern 2006). As projects can swing out of this tolerance band, there is a need to monitor their progress continuously.

The orientation of stakeholders' stakes can be cultural or political (Mintzberg 1995). Stakes also have the attributes of legitimacy, power and urgency and these vary in intensity (Carroll and Buchholtz 2006). In this regard,

- legitimacy is the perceived validity of a claim to a stake;
- power is the ability or capacity to produce an effect; while
- urgency is the degree to which a claim demands immediate attention.

Stakes are not static, neither is a stakeholder matrix. Thus, stakes need to be monitored regularly and major changes assessed against the matrix. The dynamic matrix is essentially not an answer to everything; rather it helps to (Vogwell 2002):

- bring order to a very complex situation;
- bring collective understanding if compiled by a group;
- suggest up-to-date strategies for management and communication of the various groups;
- manage resources and time and use these where most benefit will be derived.

Engaging stakeholders

Power differentials between stakeholders dictate measures for dealing with each other. The strategies and tactics for stakeholder management are underpinned on this differential (Kolk and Pinkse 2006). Saliency is the level of claim, attention and priority attached to these attributes and is a feature used in dealing with stakeholders (Mitchell *et al.* 1997; Gago and Antolìn 2004).

Stakeholders can be engaged through a combination of the following:

- consultation;

- dialogue;
- education;
- partnership;
- control;
- giving them information through:
  - charrette;
  - site walks;
  - workbook development.

A summary of the main methods for engaging stakeholders is as follows:

- corporate events, e.g.:
  - conference style events for building awareness;
  - workshops and plenary sessions;
  - cascade briefings;
  - obtaining slots on the agendas of existing meetings;
- exhibitions;
- one-to-one meetings;
- engagement of stakeholders as change agents;
- use of non-verbal communication:
  - posters;
  - leaflets;
  - websites;
  - newsletters/email/circulars.

Benefits of stakeholder management

Managing stakeholder relationships encourages trust, and stimulates collaborative efforts and these lead to relational wealth, i.e. increased organizational assets arising from familiarity and teamwork. Stakeholder management will improve the final outcome of projects and ensure the commitment of stakeholders (Smith and Love 2004). Companies that are stakeholder-inclusive have fared better (Wheeler and Sillanpää 1997).

Stakeholder management can deliver many other benefits and these include (Roome and Wijen 2006):

- increased process and organizational efficiency;
- waste reduction and lower costs;
- stronger market position;
- reduced risk of prosecutions;
- identification of new business opportunities;
- good public and local community image;
- foresight on upcoming issues;

- lower insurance premiums;
- easier access to financial support;
- enhanced organizational learning.

Downsides of stakeholder management
Inadequate management of external stakeholders can yield the following negative consequences (Ismodes 1997; Carroll and Buchholtz 2006):

- conflicts with the local community;
- complicated decision-making processes;
- time delays and associated cost overruns while assessing and responding to claims;
- negative publicity for the companies involved;
- difficulty in prioritizing and responding to stakeholders' claims.

Despite the numerous advantages of stakeholder management which seem to outweigh the downsides the possibility exists for the latter to manifest; and when they do manifest the consequence(s) can be drastic. It is thus feasible to treat the potential downsides as sources of risk. Thus stakeholders must be managed proactively to avoid projects going wayward. A proactive approach will either avoid the downsides or minimize them to the barest minimum.

Corporate existence and activities are conceivable in three domains (Logsdon and Wood 2000):

- governance;
- processes; and
- outcomes.

These three domains have a bearing on stakeholder management. Governance and processes have a direct relationship with the way a firm engages its stakeholders. The achievement of outcomes is then influenced by an organization's stakeholders.

A construction scheme passes through several phases from beginning to end. These have been described in many ways, e.g. conception, briefing, design, contract, physical delivery, occupation and beyond. At each stage of this journey, the stakeholders and their saliency would differ. There is a need thus to coordinate stakes from the beginning to the end of a project. How this coordination is currently done and how it can be improved is part of the issues that were explored in the research described below.

RESEARCH AND ITS METHODOLOGY

A scoping research to evaluate construction stakeholder management was carried out. The research sought to establish the current position of stakeholder management in construction. The aspects investigated included:

- the appreciation of stakeholder management;
- the support for stakeholder management;
- the approaches to stakeholder management;
- the gains and pains of stakeholder management;
- the role of coordination in stakeholder management.

Interviews with key project stakeholders were conducted on these themes from July to December 2006. The interviews were not structured and each was facilitated by an appointment and held at the interviewee's office. Twelve interviews were conducted with high-ranking officers who included directors, senior project managers, senior site managers, an architect and a users' representative. Notes were taken during the interviews; however, circumstances allowed for the audio recording of three of these interviews using an MP3 player.

The interviews were staggered, averaging two per month. This spacing of interviews enhanced the compilation of information and progressive analysis of data, given that not many interviews were recorded. The outcome of the first interview was used as a basis for conducting the second; and that sequence continued with subsequent interviews. Thus the grounded theory methodology (Strauss and Corbin 1990, 1994) underpinned the study. Findings were established and grounded as the interviews progressed. Each interview lasted one hour on average: the shortest taking about 40 minutes, and the longest 70 minutes.

The data generated were mainly verbal and non-numerical. The analysis focused on extracting and corroborating meaning from the data. Content analysis was in this wise utilized.

The opinions and anecdotes of the interviewees were analysed and interpreted to derive themes of meaning. For instance, when some of the interviewees indicated that the website was useful for keeping some external stakeholders informed, it was gathered and corroborated with other interviewees that a detached mode of communication was adequate for engaging stakeholders that have a low level of interest in a project. Content was analysed and interpreted in a similar fashion.

For this article, only one aspect of the information was extracted and analysed, i.e. relating to leadership. It is an issue that surfaced during the first set of interviews and its essence was substantiated in some of the subsequent interviews. This particular aspect of the findings informs this article while the other findings will be disseminated in another forum.

The need for effective leadership in stakeholder management

Although the research examined several issues, this paper concentrates on the aspect of coordination in the course of stakeholder management. This aspect became apparent from the very first interview. The need to coordinate the many stakes in construction was confirmed by the interviewees. Since stakes are very fluid, the level of interest in a need could change at any time. Consider, for instance, a hospital scheme being procured by means of the 'private finance initiative' (PFI); the perception of the neighbouring community concerning this hospital could suddenly change thus:

Initial perception of the scheme	*Later perception of the scheme*
'It is okay, we'll have new facilities'	'We do not like this form of procurement, it is too expensive on the tax payer'

Such a change of opinion could be orchestrated by say, a newspaper article – the media being another stakeholder, notably. Thus, stakes must be identified and their saliency monitored and managed continuously. Someone with authority (a leader) is needed to monitor and manage stakes.

This foregoing scenario is akin to risk management where risks are identified *a priori* and plans put in place upfront for their management. Uncertainty with respect to an outcome is associated with a risk event. At the stage of signing a contract, the project price and duration are usually established. Anything that undermines the completion of the project within the established price or time is a source of risk. The principle of risk management is to identify all the risks associated with any project, assess their potential impacts, mitigate them as much as possible and manage any residual risks that cannot be mitigated (Smith *et al*. 2006). The ideal is to adopt a proactive rather than a reactive approach. That way, no risk will materialize unexpectedly. If all risks associated with a project can be identified upfront and their likely impacts assessed accurately, then any eventuality can either be curtailed or managed appropriately. Likewise, stakeholders have the potential to threaten a project, i.e. they pose a risk. Thus, a proactive approach is needed for managing stakeholders.

Having begun a construction project, the involvement of stakeholders is often unavoidable. Meanwhile each stakeholder poses a certain level of risk to the project which often cannot be transferred or avoided. Stakeholders can delay a project and can even scuttle a scheme. If stakeholders with high power and high interest say this project is not going ahead then it is almost certainly not going ahead, unless they are convinced otherwise. If for instance Her Majesty's Treasury says to a particular National Health Service Trust in the UK, we are not happy with your public sector comparator and are thus unwilling to fund your hospital project then that scheme cannot proceed. If a local authority says to a construction client that the building design does not merit the granting of full planning permission, then that project cannot proceed in its current form. Suffice to indicate that the risks posed by stakeholders are consequential; however, such risks can be eliminated or reduced drastically through stakeholder management. It is possible to optimize the reduction of the risks posed by stakeholders through effective stakeholder management. The interviews in the research suggested that effective stakeholder management is a great contributor to project success and that it is worthwhile for each organization not to undermine the essence of managing stakeholders.

Contemporary construction projects could involve 40 to 75 stakeholder firms and some of these projects are promoted or funded by many establishments. In the UK, regional governments can be found in some key client groups which, is a complexity in itself (Vogwell 2002). When many stakeholders abound, it is not inconceivable for their interests to vary. For instance, one client-stakeholder may be more interested in the durability of building components; another in an iconic building; yet another in a specific location that maximizes the return to them in terms of money invested, etc. The differing aspirations of this cluster of key stakeholders have to be managed; then as they engage with other stakeholders, another dimension of complexity unfolds itself. Thus the dynamics of stakeholder interactions are much more complex than meets the eye. The potential for harbouring slightly different views is quite high. So instead of a project progressing in one direction, the different views of some stakeholders could be pulling it in different directions or slowing down its progress. It is a great risk for the interests of the stakeholders to be misaligned; it is much more complex when cliques of stakeholders emerge. With cliques the power of each sub-group is strengthened. It is thus worthwhile to have a framework for steering the different stakes so that they all move in one direction. A leader to manage this framework is equally important.

Where there are stakeholders with low interest and low power, it may be relatively easy to manage them by keeping them fully informed before, during and after relevant activities in a project. Thus, for instance, if the drainage system of a certain locality is being upgraded, the residents in that area would be informed before the works begin and given a timeframe when the works will be completed. If there are any delays in carrying out such works, the residents will be told and given a revised timetable for completing the project.

Stakeholders with 'low interest and high power' and those with 'high power and low interest' are kept informed regularly as well as consulted occasionally and their views are always considered in decision making. The risk level of these two groups ranges from moderate to high. Nothing should be taken for granted with these stakeholders, i.e. there should be no delay in attending to their needs as an issue that may seem trivial to them can develop into a significant issue easily and suddenly.

Stakeholders with ‘high interest and high power’ have the greatest potential to interfere with a project. Their positions are very important and their different views have to be sorted always in some way, as none of them should be undermined. If several of such high powered stakeholders have conflicting stakes, a means of resolving such tactfully must be sought as you would want to keep all of them on board and happy at the same time. This is where the importance of leadership becomes even more paramount, by addressing the soft skills of vision, working together, motivation, building trust among the players and ethics (Rubin *et al*. 2002). Leadership is about establishing direction, aligning people, and motivating and inspiring others (Kotter 1990).

Cleland (1999) argues that project leadership should befit the project situation because the act of leading is a continuous and flexible process. Indeed, construction projects pass through different phases and so construction professionals need different leadership styles in the different phases of the project life cycle as the stakes are highly dynamic (Bresnen *et al*. 1986). Naum (2001) suggests that leaders may have to switch from one style of leadership to another or combine elements of different styles in order to strike the right balance for each occasion.

Although the diverse leadership styles can be represented on a continuum Giritli and Oraz (2004) have generalized these into two domains: the democratic or participative type and the autocratic or authoritarian type. The leadership that is more useful for stakeholder management is not the full autocratic style but an approach that combines more emphasis on coordinating and less on controlling. It is the leadership attributes of organizing and communicating that are predominant in stakeholder management. According to Naum (2001) large capital investment projects involve making several highly complex decisions and this requires different styles of leadership; however, a participative style of leadership is much more appropriate than a directive style.

When many stakes interact and conflict with each other compromises are needed, and stakeholders may sometimes agree these among themselves. However, a leader can facilitate this agreement to ensure that all the parties involved are fully satisfied. Clear and common goals are also very vital in stakeholder management and part of the role of leadership is to ensure the emergence of common goals that are communicated to all stakeholders. These shared goals then become the basis on which a project should proceed.

Deriving common goals for a project is not necessarily a one-man task. For instance, a workshop can be used to elicit the expectations of stakeholders, and this can even be done anonymously say, by means of the Delphi technique. Participants at the workshop can also be used to map the expectation(s) of the whole set of stakeholders and to steer an optimal course for the project. This approach inadvertently gives the stakeholders more satisfaction, knowing they were part of the decision that carved a way forward towards yielding an optimal outcome. In any case, a leader is still needed to drive such a process through.

Stakeholder management is mostly carried out at a higher level and it is often approached as an inter-organizational affair. Thus the hard issues of construction are not so much under scrutiny here though they are relevant. It is the relational and soft issues that count much in stakeholder management, hence the essence of coordination.

DISCUSSION

Today, most construction clients are configurations of stakeholders (Newcombe 2003). Also, modern construction practice is characterized by large supply chains, with a leading contractor having to manage their supply chain. Effectively, there is a multifaceted client engaging a multifaceted supplier in construction. The stakes involved are thus numerous, varied and fluid. The risk of conflicts arising in such a setting is quite high. The potential for opportunism is also quite high and if everyone is looking after their own interests only, who will look after the interest of the whole? It is not a case of ‘gather the pennies and the pounds will gather themselves’. It is thus worthwhile for leadership to emerge where stakeholders abound, and the broad view of this leadership should focus on keeping the project objectives on track while balancing the achievement of each stake.

When an organization focuses on one stakeholder alone, the interests of the other stakeholders are devalued (Doyle and Stern, 2006). A fundamental responsibility of a firm therefore is to reconcile the diverging and conflicting interests of its stakeholders. Modern construction stakeholder management must be developed specifically to address any peculiarities in this sector. As a start, stakeholder management must be developed as a key competence, and this must be reflected in training curricula.

Construction clients have underperformed in terms of providing effective leadership (Latham 1994) and setting clear needs or goals (Boyd and Chinyio 2006). This has contributed in projects with less than optimal outcomes. Stakeholder management as a mutual quest can plug this gap.

Stakeholder management must be resourced and organizations may not have enough time and resources to attend to all stakeholders. The mapping of stakeholders and prioritization of the usage of resources is thus essential. A relatively lax approach can be adopted for dealing with stakeholders with very little interest while a hands-full approach is used for those with greater interest. In this regard, stakeholders with minimal interest in a project are kept informed via newsletters, websites and the like.

Since clients initiate projects, it may be worthwhile for them to steer the project’s course initially before different stakeholders come on board. The need for more effective client leadership is thus reiterated here. In the course of developing a project different stakes will emerge along the line, some with very high potency. Thus as a project unfolds, a think-tank that will coordinate the different stakes may be essential, else the risk of alienating one or more stakeholders becomes high. The think-tank can provide leadership that will harmonize the different stakes and help steer the project with minimal interruptions. It may be that this think-tank is composed of some of the stakeholders or independent experts or a combination of both.

Leadership has been studied for many centuries and can be traced to writings from the philosopher Epictetus in the first century AD (Butler and Chinowsky 2006). There are many aspects of leadership, and there is no consensus among researchers as to the definition of leadership; however, Butler and Chinowsky (2006) identified interpersonal skills and empathy as important aspects of leadership and suggested that construction industry executives should pay additional attention to these. Literature seems to suggest that soft issues are very important in leadership and the scoping study discussed in this paper has identified leadership as an important aspect of construction stakeholder management.

The research discussed in this paper involved 12 interviews; and it established the complexity of stakeholder management as well as the need for further studies into this subject matter. The interactions between construction stakeholders are very fluid and highly complex. The scoping study could not capture all the dynamics therein hence there are plans to investigate further into construction stakeholder management. An enlarged study is being designed with the aim of establishing theory in this domain. The findings of the scoping study are informing this subsequent research where leadership will be a key feature.

Although several findings were established in the scoping study, this article has discussed the aspect of leadership only. The other findings which concern strategies and tactics for stakeholder management are being synthesized for dissemination through another medium.

CONCLUSION

Several stakeholders are associated with most modern construction projects and the potential for their respective stakes to conflict with each other could be very high. Stakes are also very fluid. This warrants a coordination of the dynamic stakes and controlling their progress to avoid their adverse consequences. In this regard, effective leadership is very vital for stakeholder management; for it will provide a set of common goals for the stakeholders and coordinate their diverse aspirations towards these common goals. This is not an autocratic form of leadership but a stewarding of stakes towards maximizing overall value in a project. It is a form of leadership that emphasizes coordination and listens to what the stakeholders want and helps to steer them towards achieving the common goals of the project. A think-tank may be needed to provide this sort of leadership. Meanwhile, a follow-on research is being planned to partly study the skills needed for providing leadership among stakeholders.

ECONOMIC CONSIDERATIONS IN OUTSOURCING OPERATION AND MAINTENANCE SERVICE FOR COMMERCIAL BUILDINGS

Joseph Lai[1] and Francis Wai Hung Yik

Department of Building Services Engineering, The Hong Kong Polytechnic University, Yuk Choi Road, Hunghom, Kowloon, Hong Kong

The overblown property market in Hong Kong burst during the Asian financial crisis in 1997. After a lengthy slump, the property prices are yet to revert to their peak levels. To reduce expenditure while striving for better income, owners have increasingly outsourced operation and maintenance (O&M) services for their buildings. Whether the outsourcing is really economical hinges not only on the cost saving, but also on the change in building value, which is dependent on the performance of the contract service. Through a series of face-to-face interviews with 22 experienced practitioners playing the roles of owner, property management and O&M contractor for commercial buildings, the study examined the perceived importance of the attributes contributory to an efficient contract. Despite the difficulty of measuring transaction costs, a pragmatic model developed via analysing the opinions of the practitioners is submitted for gauging the *ex ante* and *ex post* costs variation.

Keywords: commercial property, maintenance, outsourcing, transaction cost.

INTRODUCTION

Hong Kong is the eleventh largest trading economy in the world and the second biggest stock market in Asia (HKSAR 2005). Sustainable economic development, which is central to the society, relies on having quality commercial buildings which accommodate business activities. Many of these buildings, equipped with sophisticated engineering services such as central air-conditioning, intelligent controls and IT facilities, were built in parallel to the growing economy in the past few decades. Without proper operation and maintenance (O&M), however, the value of these built assets will be undermined and the business activities affected.

Derived from statistical data (RVD 2004, 2006), the rental and price indices (100 in year 1999) of office and retail premises dropped drastically from the peak in 1997 to a trough in 2003 when the Severe Acute Respiratory Syndrome (SARS) outbreak further ruined the already weak economy (Figure 1). According to JLL (2004a, 2004b), the office vacancy rate had been significant and the anticipated negative demand of office space in Hong Kong ranked first among the major Asia Pacific cities.

Following China's entry into the World Trade Organization (WTO), Hong Kong and the Mainland China jointly signed a Closer Economic Partnership Arrangement (CEPA) in 2004 to strengthen trade and investment cooperation between the two sides

[1] bejlai@polyu.edu.hk

(HKSAR 2005). In particular, Article 13 of CEPA states the measures for further strengthening cooperation in the areas of banking, securities and insurance. Article 14, which deals with cooperation in tourism, provides that the Mainland will allow residents in Guangdong Province to visit Hong Kong individually in order to further promote the development of the tourism industry in Hong Kong (TID 2003).

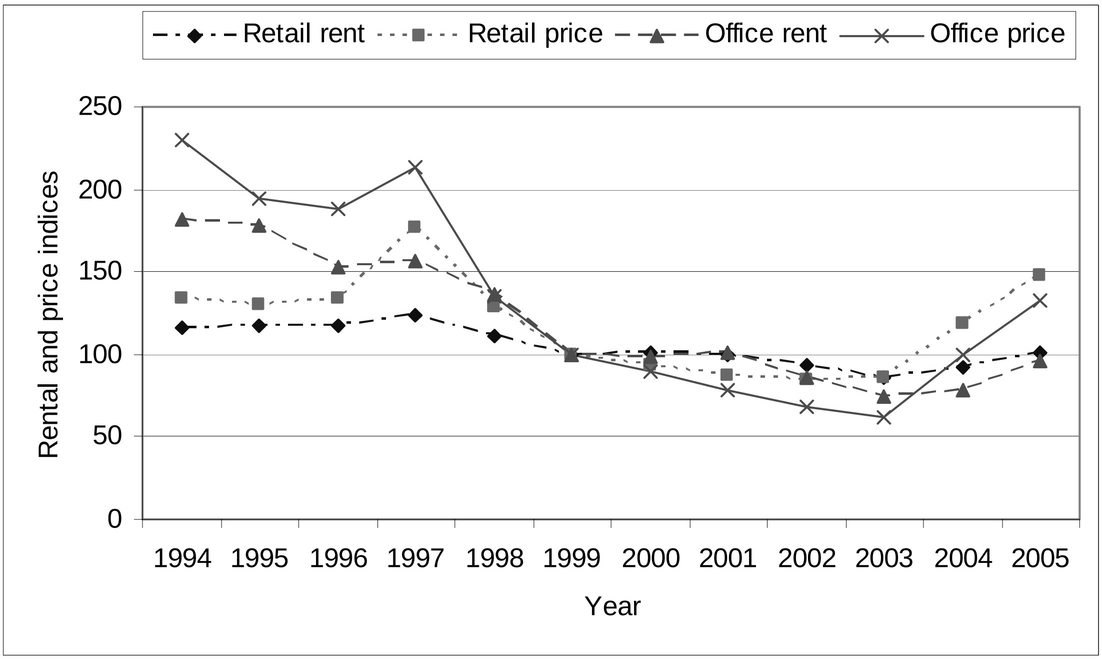

Figure 1: Rental and price indices (100 in year 1999) of commercial premises

Anticipating larger demand of commercial premises from organizations which would establish or expand their businesses to match the implementation of the CEPA, the property market started to recover (Figure 1). Notwithstanding that the Hang Seng Index also climbed to a record high of 20 001 at the end of 2006 (HSI 2007), the rental and price indices are yet to revert to their peak levels in 1997. (The Hang Seng Index, which is a compilation index of the leading stocks in the Hong Kong stock market, is the main indicator of the overall market performance.) As a corollary, owners have been unable or reluctant to invest in O&M work despite their desire to improve its quality to attract higher building income. Data compiled from RVD (2004, 2006) further reveal that the amount of new buildings has perpetually outweighed that of the demolished, giving a continuous rise in building stock (Figure 2). Confronted with these challenges, many building owners resorted to outsourcing (Yik and Lai 2005).

The number of large public and private organizations which outsourced O&M work for their buildings has been increasing, but there were cases where the work was brought back to in-house production (HKET 2005). This suggests that outsourcing may not always be beneficial, as forming and managing contracts necessitate transaction costs (Williamson 1979) and the quality of the procured service may not meet the outsourcer's expectation. Regardless of the overwhelming reports on outsourcing incidents as compared to those on in-sourcing, whether they brought along genuine benefits and more fundamentally, whether the outsourcing decisions were given rational consideration seem to be unknown.

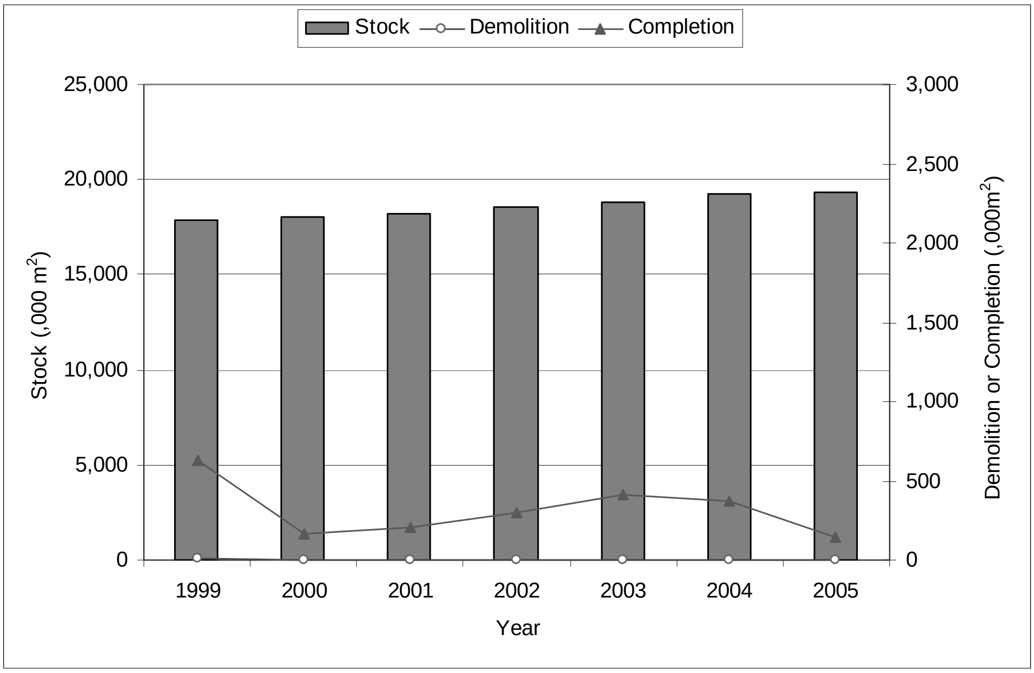

Figure 2: Commercial building stock, demolition and completion

An earlier study (Lai *et al*. 2004) found that building owners typically engage an in-house team to be responsible for some minor O&M work which is routine (e.g. daily patrol, manual logging of instrumentation readings) or which requires prompt remedial actions (e.g. burst pipe, circuit trip). Works that necessitate execution by licensed contractors (Lai and Yik 2004) or the workload of which is large but fluctuating are commonly procured through an intermediate property management company. Each of these stakeholders plays a vital role in ensuring proper delivery of the work. Their views on what attributes are critical to an efficient contract and the significance of various cost elements are essential considerations before going for outsourcing.

THE INTERVIEWS AND SAMPLES

A questionnaire was designed to collect information and opinions from O&M practitioners working on commercial buildings. The first part of the questionnaire inquired into their personal information including age, job nature and years of work experience; and the type, nature and contractual arrangement of an O&M contract work they consider representative. The second part solicited the respondents' perceived importance of a list of attributes which contribute to an efficient contract. These attributes, classified as 'economic attributes', are factors affecting the price level and thus the efficiency of the O&M contract. Subsequent to each question in this part, the respondents were asked to openly express the reasons for their response. Finally, they were asked to draw on their experience to indicate the significance of the contract sum, in-house cost and its elements including labour, material and overheads associated with the delivery of O&M work. Their comments on what major factors influence the significance of these cost items were also sought. Although for the purpose of accurate cost analysis it is more preferable to obtain the exact figures of the costs, it was only feasible to collect indications about their significance because of the following:

- Different organizations classified O&M costs into different categories, thus the cost data collected were not useful for analysis.
- The record of O&M costs was not in all cases kept in proper order.
- The interviewees refused to provide cost figures which are sensitive or confidential.

Before conducting the interviews in full swing, three pilot interviews were conducted. The comments so gathered, including those suggested to modify, add or delete some of the attributes, were taken to refine the questionnaire. For ensuring proper interpretation of the meaning of the attributes by the interviewees, the survey was carried out by way of individual face-to-face interviews during which the same interviewer explained the questions and clarified any queries before the interviewees gave their answers. Although this survey method entailed significant resources for making appointments with the interviewees and for travelling to and from their workplaces one at a time, it helped obtain quality data (Fowler 2002).

Interviewees were invited at random from members of the Building Services Operation and Maintenance Executives Society (BSOMES) and proficient practitioners with whom the project investigators had contacts. Twenty-two interviews were successfully completed where all the participants are experienced practitioners, with over 13 years of experience on average. The majority group comprises 12 practitioners working for property management companies, another six are employed directly by building owners to look after the O&M work for their buildings, and the rest are employees of O&M contractors hired by building owners or property management companies. Despite the relatively small sample size of the owner group, they are the volunteers who can provide reliable empirical information.

ECONOMIC ATTRIBUTES CONTRIBUTING TO AN EFFICIENT CONTRACT

The interviewees were asked to express their perceived importance of the economic attributes (A_E) using a five-point cardinal scale (r_i = 1 for ‘not important’ to 5 for ‘very important’). The average ratings $R(A_E)$, as shown in Table 1, were calculated by using Equation 1 where i is the contract number (1, 2, 3, …, N) and N is the total number of sampled contracts.

$$R(A_E) = \frac{\sum_{i=1}^{N} r_i}{N} \quad (1)$$

The interviewees considered ‘suitable contract pricing structure’ and ‘suitable tendering method’ as the most important economic attributes (both with $R(A_E)$ = 4.00), even though their comprehension of the various contract concepts and contract formation methods were less than satisfactory (Lai *et al*. 2006). A similarly high importance rating was given on the attribute ‘good financial status of the contractor’ ($R(A_E)$ = 3.95), which suggests the need for the contractor to finance the work upfront when there are time lags or delays in contract payment.

Table 1: Perceived importance of economic attributes

Economic attributes	**Overall**	**Owner**		**Property management**		**Contractor**	
	$R(A_E)$	$R_O(A_E)$	Rank	$R_P(A_E)$	Rank	$R_C(A_E)$	Rank

Suitable contract pricing structure	4.00	4.17	4.5 (3.5)	3.67	3 (3)	4.75	— (1)
Suitable tendering method	4.00	4.33	1.5 (1)	3.67	3 (3)	4.50	— (2.5)
Good financial status of the contractor	3.95	3.83	8 (7)	3.92	1 (1)	4.25	— (4)
Optimum length of contract period	3.77	3.83	8 (7)	3.50	5.5 (5.5)	4.50	— (2.5)
Low labour cost in market	3.68	3.67	10 (9)	3.67	3 (3)	3.75	— (7.5)
Cost saving compared to in-house production	3.61	4.33	1.5 (NI)	3.25	7 (NI)	NA	— (NI)
Good global economic environment	3.59	4.17	4.5 (3.5)	3.17	8 (7)	4.00	— (5.5)
Large contract sum	3.50	4.17	4.5 (3.5)	3.00	10.5 (9.5)	4.00	— (5.5)
Low material cost in market	3.41	3.83	8 (7)	3.08	9 (8)	3.75	— (7.5)
Amble budget allowed	3.27	3.50	11 (10)	3.50	5.5 (5.5)	2.25	— (11)
Regular budget reviews	3.27	4.17	4.5 (3.5)	3.00	10.5 (9.5)	2.75	— (10)
Large contingency allowed	2.91	2.50	12 (11)	2.92	12 (11)	3.50	— (9)

Notes:
NA: Not applicable to the contractors.
NI: Not included in the calculation of Kendall coefficient of concordance.
Figures in parentheses represent the ranks when the inapplicable attribute (marked as NA) is omitted.

Among the lower tier of attributes, ‘optimum length of contract period’ was rated as highly important ($R(A_E)$ = 3.77). A very short contract period means the transaction costs for forming recurrent contracts would be incurred frequently and the trust that can be built between the contracting parties would be weak. If the contract period is overlong, unless relevant contract provisions have been allowed the locked-in employer would find it hard or costly to adjust the service level to meet any change in the needed O&M standard. Dealing with a contractor with low incentive to provide quality service, especially at a later stage of the contract period, the employer would need to choose between inputting more effort to monitor her performance and tolerating the unsatisfactory service.

The attributes that the interviewees perceived as comparably less important include: ‘low labour and material costs’, ‘good global economic environment’ and ‘large contract sum’ ($R(A_E)$ = 3.41 to 3.68). Obviously, when the contractor can hire labourers with lower wages and purchase materials at lower costs, the employer would be more likely to receive the service on time, meeting the required quality. A better economic environment would also mean the contractors would have more market opportunities. With better job security and prospects, the contractor staff would be more devoted to their work to provide higher service quality. Meanwhile, building owners who are less pressured to cut O&M budgets would be able to procure quality service from competent contractors. For contracts with large contract sums, the contractor would be more able to maximize his profit by virtue of economies of scale and the employer would need to spend, in relative terms, less resources to monitor the contractor performance (Lai and Yik 2007a).

While the building owners rated cost saving obtainable through outsourcing as highly important ($R_O(A_E)$ = 4.33), the property management personnel only rated its importance as fair ($R_P(A_E)$ = 3.25). This is because the latter is a managing agent whose remuneration, unless provided for in the contract, is independent of the amount of money that the owners can save. To the contractors, this attribute is irrelevant given that none of the sampled contracts had incorporated any 'shared saving' conditions.

O&M stakeholders should feel much relaxed when there is an ample budget. However, this attribute only recorded a relatively low importance rating ($R(A_E)$ = 3.27). This may be attributed to the variable and loose practices of O&M budgeting (Lai and Yik 2007b). The same explains why 'regular budget reviews' carried an identical importance rating. Finally, because contingency was seldom allowed in O&M contracts to cater for unforeseen scenarios (Lai *et al*. 2006), 'large contingency allowed' was rated as the least important ($R(A_E)$ = 2.91). The different view of the contractors on this attribute ($R_C(A_E)$ = 3.50) suggests that they are often forced to shoulder contractual responsibilities which are vaguely defined (Lai *et al*. 2004) and additional works which lie in the loopholes of contract (Lai *et al*. 2006), while hoping that the contingency sum, if provided in the contract, could disburse these works.

Equation 2 is used to calculate the Kendall coefficient of concordance (W) so as to test the relative agreement of the perceived importance ratings (Kendall and Gibbons 1990) among the different groups of practitioners. The sum of the squares of the deviations (S) of the row rank sums (R_i) from their mean value $m(n+1)/2$ pertaining to the n attributes rated by the three groups (i.e. m = 3) is determined by Equation 3, where u_j is the number of consecutive members of the j^{th} tied rank. A moderate level of agreement (W = 0.608) was found among the groups.

$$W = \frac{12S}{m^2(n^3-n) - m\sum_j (u_j{}^3 - u_j)} \tag{2}$$

$$S = \sum_{i=1}^{n}\left[R_i - \frac{m(n+1)}{2}\right]^2 \tag{3}$$

$$S_r = 1 - \frac{6\sum_{c=1}^{N} d_c{}^2}{N^3 - N} \tag{4}$$

Spearman rank correlation coefficient (S_r) was further calculated (Equation 4) in order to examine the consistency of the perceived importance ratings between pairs of the three groups. The correlation between the owner group and the property management group was found to be insignificant (S_r = 0.110), reflecting their different views on the attributes. On the other hand, the correlation between the property management group and the contractor group (S_r = 0.566) and that between the owner and contractor groups (S_r = 0.700) are significant. Note, however, must be taken that they were calculated on a basis which is slightly different from that between the owner group and the property management group because the attribute 'cost saving compared to in-house production', which is inapplicable to the contractors, was excluded from the calculations.

A PRAGMATIC TRANSACTION COST MODEL

The foregoing results show that different groups of O&M practitioners have different perceptions of the attributes, which is not surprising given their differences in job natures, roles and interests. In particular, the importance of the attributes perceived by the owner and property management parties would have profound influence on their consideration in outsourcing. But the fact that these perceptions are drawn from subjective judgment of some intrinsically qualitative issues often attracts criticisms on an outsourcing decision made on such basis. A decision buttressed with quantitative justification, for instance, in terms of costs, is definitely more convincing. According to the interviewees, however, a cost model which can really help them make this kind of decision is missing, with which the result of a literature review of the current study also agrees.

In principle, whether to go for outsourcing depends not only on how much can be saved, but also on how much the ensuing building value would vary. If the building value is impaired owing to a lowered quality of the contract service, the cost for ameliorating the quality may outweigh that saved from outsourcing. Even if value is added to the building, it should be evaluated against the transaction costs that the contract incurs, as outsourcing is really economical only when there is a net gain in benefit.

The evaluation, however, is not practically simple. First, although any change in the value of the building may be determined by referring to its price or rental level, it is not solely dependent on the change in O&M service quality. Other factors, for instance, market supply and demand of the same type of building premises, may also affect the building value. Second, quantifying the benefits and impacts, some of which are non-monetary and intangible, would involve making assumptions which are arguable. Even when only the monetary cost items are considered, omission of hidden costs and inclusion of sunk costs can often lead to a false evaluation (IC 1996; Eschenbach 2003).

While it is possible to identify the costs for producing O&M work in-house before outsourcing, determining the costs for the same work carried out by contractors would not be possible until the completion of its procurement. But when considering an outsourcing decision, one can pragmatically compare the costs before and after outsourcing using the following model, which is developed through analysing the opinions gathered from the interviews.

Consider a case of total outsourcing where the O&M work is wholly undertaken by a service provider. The outsourcing decision is just if the total O&M cost after the work is outsourced is less than that before, as represented by Equation 5. IC_b is the in-house cost before outsourcing. *OC* denotes the contract sum for the outsourced work, whose magnitude largely depends on the top two attributes – suitable contract pricing structure and suitable tendering method (Table 1). *TC*, which is the transaction cost incurred for forming and managing the contract, is also an essential component in the evaluation.

Instead of total outsourcing, partial outsourcing prevails in practice (Lai *et al*. 2004) where IC_a is the resource needed to execute the portion of work retained in-house (Equation 6). *OC* can be readily obtained from the accepted tender price, but IC_a and part of TC (i.e. *ex post* transaction cost, TC_2, as will be explained later in Equation 12) can only be realized some time after the outsourcing. This is represented by Equation 7 where d is the discount rate and t is the time difference between evaluating the costs before and after outsourcing.

$$TC + OC < IC_b \quad (5)$$

$$IC_a + TC + OC < IC_b \quad (6)$$

$$\frac{IC_a + TC}{(1+d)^t} + OC < IC_b \quad (7)$$

$$IC_x = \sum_{i=1}^{N} C_{ix} \quad (8)$$

$$\frac{TC}{(1+d)^t} + OC < \sum_{i=1}^{Q} C_{ib} - \sum_{i=1}^{P} \frac{C_{ia}}{(1+d)^t} \quad (9)$$

$$\frac{TC}{(1+d)^t} + OC < \Delta C_{1,b-a} + \Delta C_{2,b-a} + \sum_{i=3}^{Q} C_{ib} - \sum_{i=3}^{P} \frac{C_{ia}}{(1+d)^t} \quad (10)$$

$$\Delta C_{1,b-a} = \left[\sum_{j=1}^{4} N_j \times S_j \times FTE_j\right]_b - \left[\sum_{j=1}^{4} N_j \times S_j \times FTE_j\right]_a + \sum_{d=1}^{D} SP_d \quad (11)$$

Summing the costs of labour, material and overhead gives the total in-house cost for performing the O&M work (Equation 8), where x is a (after outsourcing) or b (before outsourcing), and C_i represents the *i*th in-house cost element with i being '1' for labour, '2' for material and '3 to N' for overheads. Rearranging Equations 7 and 8 gives Equation 9, and then Equation 10 where $\Delta C_{1,b-a}$ and $\Delta C_{2,b-a}$ are the changes in the costs of direct labour and direct material respectively measured before and after outsourcing.

Distinct from new construction project, labour resources involved in minor maintenance work (e.g. routine inspection, cleaning and lubrication, etc.) typically overwhelm the cost of materials used. Change in direct labour cost can be determined based on Equation 11 where N_j is number, S_j is salary, FTE_j is full-time equivalent of in-house O&M staff at different levels (j; j = 1: top management, 2: managerial, 3: supervisory and 4: operational) engaged in the work; and SP_d denotes the severance payment given to the in-house staff (total number D) laid off as a result of the outsourcing. Unlike the protections under the Transfer of Undertakings (Protection of Employment) Regulations in the UK (Jeffers 1996), the Labour Ordinance provides that severance payment is calculated as two-thirds of the last month's wages multiplied by the reckonable years of service of the employee (LD 2007). Whereas changes in headcounts would also lead to variations in cost for covering their fringe benefits such as insurance, medical benefits and other allowances, they can be neglected in the evaluation in view of their relatively small amount.

As for major maintenance work which often is material-demanding while the manpower involved is relatively small, e.g. replacement of a variable speed drive costing HK$50 000 necessitates paying HK$2000 (i.e. 4%) for two technicians supervised by one engineer to complete the work in one hour, any change in direct material cost ($\Delta C_{2,b-a}$) would be significant.

O&M costs are generally regarded as overheads, i.e. indirect costs associated with some core activities of a business. To organizations whose core business is O&M work, on the contrary, O&M costs are direct costs whereas the costs that the supportive works incur are indirect. The number of overhead cost elements before (Q) and after (P) outsourcing depends on the way in which they are categorized. Exact identification of monetary overhead costs, whose classifications may vary from one organization to another, is not easy. Non-monetary overheads, for example, the time needed to accomplish some administrative tasks, is even difficult to measure. Space cost dominates the expenditure of business organizations (Davies 2000). But unless the outsourcing gives rise to dramatic organizational reform and hence downsizing, saving in space cost would not be large and so is the reduction in associated utilities, insurance and maintenance costs. Since condition-based maintenance which makes use of precious monitoring devices remains uncommon in the building sector (Pearson 2002), tools used for daily O&M work, e.g. drills, hammers, etc. are generally inexpensive. Cash infused from disposal of these tools through outsourcing, therefore, would not be enormous.

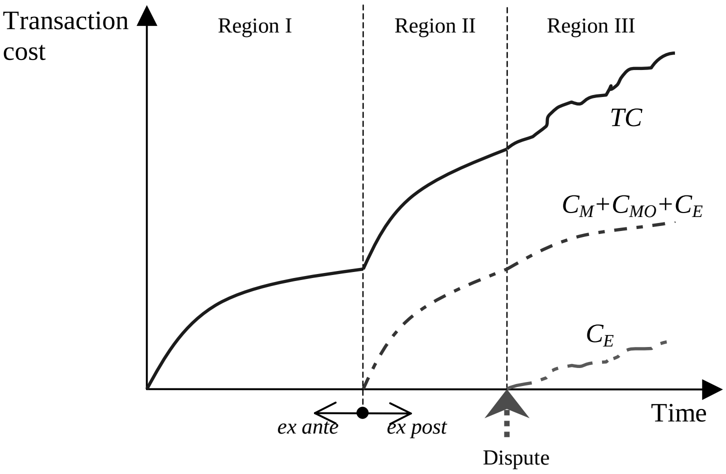

Figure 3: Transaction cost elements on a contract timeline

$$TC = \begin{cases} TC_1 = C_S + C_D + C_N \quad \text{(Region I)} \\ TC_1 + TC_2 = TC_1 + C_M + C_{MO} \quad \text{(Region II)} \\ TC_1 + TC_2 = TC_1 + C_M + C_{MO} + C_E \quad \text{(Region III)} \end{cases} \tag{12}$$

To complete the evaluation in Equation 10, one would need to further comprehend the transaction cost which includes the *ex ante* and *ex post* components. The *ex ante* resources (TC_1) associated with an O&M contract include those deployed to search information (C_S) for drafting the contract document (C_D), and to negotiate with tenderers (C_N) before contract award. The *ex post* transaction costs (TC_2) embrace those entailed in monitoring the contractor performance (C_{MO}), to measure the work done (C_M), and to enforce the contract in case of dispute (C_E). Figure 3 depicts the disposition of these cost elements along a timeline where there is dispute during the contract. Equation 12 represents the total transaction cost (TC) in different regions of the contract timeline. It has been demonstrated how the cost for monitoring O&M contracts can be measured (Lai and Yik 2007a), but the feasibility of measuring the other elements remains to be explored.

CONCLUSIONS

There are variations in the perceived importance of the economic attributes among the different groups of O&M practitioners, but they on the whole considered suitable contract pricing structure and a suitable tendering method as highly important to an efficient contract. Providing a large enough contingency sum in contract was perceived as the least important. This contradicts the theory of incomplete contracting (Hart and Moore 1988) and the reality that unpredictable scenarios always exist in real-life contracts. Further work, therefore, is needed to study what are the crucial factors that give rise to this perception and to focus on contracts incorporated that include a contingency sum to investigate the importance of such provision.

Outsourcing may help cut the O&M costs for buildings but it incurs transaction costs. The difficulty of their precise measurement has been well realized in many empirical attempts (Shelanski and Klein 1995; Masten 1996). It was neither the intention nor the capability of this study to measure the transaction costs associated with building O&M contracts. But a pragmatic model has been developed for gauging the *ex ante* and *ex post* costs variation. When more findings akin to those of Lai and Yik (2007a) are available, decision makers would become better equipped to consider whether to outsource.

A PROPOSED APPLICATION OF USING LCCA TO MEASURE COST OF SUSTAINABLE DESIGN

Wai Kiong Chong,[1] Sanat Kumar Pokharel and Cassandra Leyden

University of Kansas, Department of Civil, Environmental and Architectural Engineering, Learned Hall, 1530 W. 15th Street, Lawrence, KS 66045, USA

Economic decisions far outweigh environmental and social decisions by profit-oriented construction industry where decisions are usually made to maximize both long and short-term profits. Beheiry *et al.* (2006) had clearly stated that market forces are the best tools to advocate sustainability. The success of sustainability implementation depends heavily on the ability to measure and estimate environmental, societal and long-term economic variables, and convert them into benefits and costs. Most industrial practitioners are convinced that sustainability is important but the lack of convincing data and calculations methods hampered the application of sustainability application during the decision-making stage. It is also difficult to convince investors that increasing initial expenditure could benefit them in the long run. Life Cycle Cost Analysis (LCCA) is one of the best tools available to assess the benefit and cost of the construction. This paper reviews different LCCA methods that could measure economic, environmental and social costs of sustainable design and proposes future directions for designer's decision-making process and how LCCA could better be used to convince investors.

Keywords: sustainability, design, life cycle, cost.

INTRODUCTION

The historical tendency to focus on environmental sustainability has over-aligned sustainable development (SD) with the green movement and alienated the business executives (Beheiry *et al*. 2006). Over-aligning SD with green agendas has also prompted a natural gravitation for research to deviate away from business case for sustainability. Beheiry *et al*. (2006) examined the business impact of owner's commitment to sustainability and suggested that balancing between different sustainability strategies may yield higher return on project performance. According to Carassus (2004), fulfilling the requirements of SD would also mean mastering the ability to control the consequences of whole life cycle. Sustainability could also smooth the impact of changes on the economy. Economic analysis has to take into account recent industrial evolution and involves all stakeholders at all stages of project life cycle.

Since cost drives most business decisions, both tangible and intangible benefits are often expressed in economic terms. Only an expert with well-informed decisions and who is able to evaluate the life cycle of built environment at the design, construction, operation/maintenance, reconstruction/replacement or disinvestment stages could uphold sustainability in construction. Information on economical, environmental and societal factors is the foundation towards a successful sustainability implementation in

[1] oswald@ku.edu

construction. There are several methods of measuring the cost of sustainable design and life cycle cost analysis (LCCA) is the most prominent among them. This paper reviews different LCCA methodologies that are used to measure the costs of sustainable designs and then determines their effectiveness in measuring and presenting the benefits. It also examines the future directions to substantiate the decision-making process and convince investors about the values of sustainable designs.

LIFE CYCLE COST MEASUREMENT

It is necessary to convert economic, environmental and social benefits and externalities of sustainable design into economic cost and value, as this would allow sustainability to become measurable. Like quality, sustainability does not mean anything if it is not measurable. Transparency of business functions is critical to ensure that only genuine information will be collected and used to measure the success of sustainability implementation. Life Cycle Analysis (LCA) is a tool that measures, characterizes and evaluates resource consumption, and could incorporate a full range of environmental effects and life cycles of products, processes and activities, and measure all in scientific units. LCC is the total discounted cost of owning, operating, maintaining and disposing of a system over a period of time. LCCA is an economic evaluation technique that measures LCC (Alaska 1999). LCCA is a process of evaluating the total economic worth of a project segment by analysing initial costs and discounting future costs over the life cycle of the project segment (USDOT 2006). As such, LCC could potentially measure the costs and benefits of sustainable construction (SC), as it could be used to compare between capital and operating costs. Yates (2001) found that operating costs are typically greater than construction costs; therefore, comparing system performance requirement alternatives with respect to initial and operating costs could maximize net savings and values (Fuller 2006). Most importantly, LCCA measures the value of products and projects, and can be treated as an ideal measurement method for sustainability of construction design.

Designers can also gain insights of environmental and economic trade-offs by applying LCA and LCCA (Arpke and Hutzler 2005). There is a positive impact of LCCA application at the design, bidding and construction phases (Arditi and Messiha 1999). There is also a need of a multidimensional life-cycle approach that could provide a comprehensive and balanced analysis on sustainable design as proposed by Lippiatt (1999).

Osman and Ries (2004) used LCA to determine life-cycle impact analysis of energy systems as a useful tool to outline system configurations that could minimize environmental impacts. Blanchard and Reppe (1998) applied Global Warming Potential (GWP) and LCC to illustrate that using energy efficiency strategy and material could potentially reduce life cycle energy consumption in buildings. Junnila and Horvath (2003) suggested that practical applications of comprehensive environmental LCA could be applied to the design and management of environmentally conscious office buildings.

MODELS FOR LIFE CYCLE COST ANALYSIS

LCCA measures the total cost of facility ownership that includes costs of acquiring, owning and disposing of a built environment. According to Marshal and Petersen (1995), LCC of a project alternative can be denoted by the following:

$$LCC = I + R + E + OM\&R - S \qquad (1)$$

Where, I is the initial investment cost, R, E, OM&R and S are the PV of replacement, energy, operation, maintenance and repair costs, and the PV of salvage, respectively. The following alternative formula illustrates the discounted future costs of PV mathematically and summarizes the value into a single LCC calculation (Marshal and Petersen 1995):

$$LCC = \sum_{t=0}^{N} \frac{C_t}{(1+d)^t} \qquad (2)$$

Where, C_t is the sum of all relevant costs, less any positive cash flow as salvage value, occurring in time period t; N is the number of time periods in the study period; and d is the investor's discount rate for adjusting cash flows to PV. Building for Environmental and Economical Sustainability (BEES 2006), adopted by the National Institute of Standards and Technology, follows the LCCA calculation method as shown in the following equation (Fuller 2006):

$$LCC = I + Repl - Res + E + W + OM\&R + O \qquad (3)$$

Where I, is the initial cost; E and W, are the PV of operational expenses for energy, water and other utilities; OM&R, is the PV of non-fuel operating, maintenance and repair costs; Repl, is the PV of capital replacements cost; Res, is the PV of its remaining value at the end, or at the time of replacement; and O is the PV of finance, charges and taxes, and non-monetary benefits or costs. Salem *et al.* (2003) developed the following formula to illustrate a risk-based LCC model that integrates PV calculation method with Monte Carlo simulation as shown in the following equation;

$$LCC_N = C_i + C_{fN} + Cmo_N + Cu_N - Sv_N \qquad (4)$$

Where, N is the number of simulation iterations; C_i is the initial capital cost; C_{fN} is the cost of failure (rehabilitation); Cmo_N is the cost of operation and maintenance; Cu_N is the user cost due to failure; and Sv_N is the salvage value.

COST IMPLICATIONS OF SUSTAINABLE DESIGN

Katz (2003) and Hanscomb (2005) found that most developers and contractors have to pay a 0–2% premium for a green building, though Matthiessen and Morris (2004) insisted that this has to be done within project's limited budget. Warnke (2004) also found that "sustainable" buildings can cost up to 2% more than conventional ones. Building developers would normally share the burden of excess cost with their tenants (Yates 2001).

Investor priorities

Hanscomb (2005) demonstrated that property owners could yield a payback of at least 10 times the initial investment in 20 years time even though they had to invest an additional 2% more initially. Thus, investing as much as 2% extra for a sustainable building would make a lot economic sense for the long-term investors but not for the short-term speculators. Even the long-term investors would put economic profits above social and environmental concerns. Alternatively, if the resale values of their investments would be affected by environmental and social concerns, the treatment of both concerns at the project development phase would be different. For example, the market value of a typical US home rises 20 times than that of its energy savings PV (Lützkendorf and David 2005). A small investment to improve energy saving of homes could produce significant financial returns through higher home resale value. However, long-term ownership of properties is the only rationale why LLC would be used in a project at all.

The economic pillar of sustainable design (Cost Bottom-Line)
The economic pillar of sustainability requires both economic justification and financial benefits from implementing sustainability. Success in the construction realm has traditionally been based on cost, schedule, design changes and safety (Beheiry *et al*. 2006). This aligns more closely to the economical pillar of sustainable design. Beheiry *et al*. (2006) hypothesized that sustainable method would yield lower-risk and, therefore, more economically attractive. Preliminary results of their study implied that a correlation between corporate commitment to sustainable economic practices and better-planned projects.

Changes with zero or minimal added costs
Most of the opportunity of sustainable design that adds no additional cost to a project would have to originate from designers. For example, designers have to identify a proper building orientation that could result in maximizing thermal comfort and reducing heating demand (Katz 2005). Many of the Leadership in Energy and Environmental Design (LEED) credits do not require additional cost to comply (Matthiessen and Morris 2004). Furthermore, significant savings could be derived from energy and water use reduction, and the reuse of salvaged materials (XENERGY 2000). In addition, a study on “green school” found that every 1% additional investment yielded over 30% of returns (Katz 2005).

Commitments to higher investment costs
Green roofs, commissioning, high-performance fixtures, photovoltaic panels, system measurement and verification, certified wood and low-flow or waterless sanitary fixtures may result in higher initial construction costs. However, several studies suggested that energy and water-efficient fixtures and the use of natural gas water heaters produce desirable results when compared to conventional appliances (Arpke and Hutzler 2005). Investors may find it hard to swallow such cost increase if they are not convinced that additional economic benefits could be derived from exploiting these environmental and societal variables.

Costs and benefits involving arguable worth and values
At present, environmental and societal costs do not have tangible economic values. They remain subjective with volatile values that make conversions into economic costs rather difficult. For example, a reduction of symptoms of illnesses and employee absenteeism and an increment in worker productivity have been found in many sustainable buildings (Lützkendorf and David 2005). However, it is still difficult to measure the actual cost of such benefits, though it is easier to express that in term of values. Some researchers felt that such information and data could not be tangibly quantified, and this has been the greyest area of confirming the projected financial benefits of sustainable design (XENERGY 2000).

An area of major debate surrounds the installation of higher efficiency but more expensive heating, ventilating and air-conditioning systems. Studies have claimed that such systems have led to healthier indoor environment; however, very few studies could agree on how to quantify the health benefits. In another example, a study on several Massachusetts's schools highlighted evidences of the benefits from improved environmental quality. Their study further quantified the benefits of energy and water savings, waste reduction and reduced emission (their results may vary if different assumptions were used). However, they could not quantify the benefits from increased student learning and reduced teacher turnover (Katz 2005). Profit-oriented businesses could not rely on "values" to make decisions.

WEAKNESS OF LCCA

Most studies agreed on the framework and benefits of current LCCA measurement techniques and generally agreed upon its ability to optimize total cost vs. operating benefits and its ability to generate products with lower maintenance costs and a better life cycle (Arditi and Messiha 1999). However, Arditi and Messiha (1999) indicated the need of formal guidelines that describe utilization method, published values for different parameters used in LCCA and the development of standard software. Kalinger (1999) highlighted some of the apparent weakness in LCCA that include:

- *Study Period:* because the time scale for LCCA may not necessarily be the same as the physical life of construction components.
- *Discount rate*: the real discount rate should either be the actual cost of borrowing or the rate of return of developers' best opportunity.
- *Salvage/residual value*: Salvage is negligible at the end of service period while the residual value should be considered only if it falls within the study period.
- *Forecasting*: Major forecasting errors are caused by the valuation of intangible costs, risks, uncertainty and inflation.

The replacement period in LCCA also poses some issues. It is very difficult to predict exactly when a particular material needs replacement. LCCA relies only on LCA for most of its inputs; as such, the weakness of LCA gets carried through automatically. Horvath (2004) mentioned that the problems with boundary definition, data acquisition, data quality, uncertainty and interpretation of results to be the most significant with LCA studies. He further pointed out that applying different assessment techniques on the same material may yield radically different results if different assumptions, data sources and assessment scopes are applied. Horvath and Hendrickson (1998) also noted that there is an articulated need for LCA studies, as well as better metrics and data, for sustainable development decision making.

Performing an LCCA may greatly increase the likelihood of choosing a more responsible and economically feasible project option though there may still be several uncertainties. However, such uncertainty could be overcome by applying sensitivity analysis that could identify uncertain input values with the greatest impact, determine and control calculation variability, and simulate different scenarios to establish the break-even point and analysis. Salem *et al*. (2003) utilized a risk-based approach to predict uncertainty in LCCA by incorporating probabilities of occurrence of different LCCs of an infrastructure unit. Their study concluded that the outcome could better inform decision makers on the expected level of risk. Their analyses also appear to make LCCA more reliable. The major challenge for LCCA is to judicially address social and environmental costs of sustainable design. At present, social and environmental variables are very unstable and difficult to quantify.

EXTENSION OF EXISTING LCCA MODELS

As discussed before, the most daunting task to legitimize LCCA is to translate environmental and social values into economic cost. LCA, if carried out with required care considering all the pertinent environmental factors, could evaluate the cost of environmental impacts, which can directly be used in an economical evaluation. Thus far, there is no proven method to evaluate social costs. The social costs include missed opportunities for job training and employment, community involvement in reshaping local built environments and neighbourhood stability (Leigh and Patterson 2004). The best approach so far is to use "value" to replace cost. However, value is often meaningless to many profit-oriented organizations.

Osman and Craighill (2006) indicated the need of an extended LCA that considers social and economic impacts. While assessing the social costs, both financial and external costs need to be accounted for (Rich 2006). Therefore, the social costs structure can be modelled into:

Net Social Cost, C_{SOC} = Financial Cost + External Cost – Offsetting Benefit (5)

Where Financial Costs are the expenditures made to own or operate the system and External Costs are the broader costs borne by members of society other than those who use the system. Offset benefits, if any, must also be included. The overall cost of a sustainable design can be best represented by the following cost-benefit model, which is represented by the weighted average of individual cost impact:

$$\text{Total cost} = (\sum\text{Economical} + \sum\text{Environmental} + \sum\text{Social})\ \text{costs}$$

$$\sum\text{Economical cost} = a\,E_1 + b\,E_2 + c\,E_3 + \ldots\ldots\ldots\ldots\ldots.. + z\,E_n$$

$$\sum\text{Environmental cost} = a\,EN_1 + b\,EN_2 + c\,EN_3 + \ldots\ldots\ldots.. + z\,EN_n$$

$$\sum\text{Social cost} = a\,S_1 + b\,S_2 + c\,S_3 + \ldots\ldots\ldots\ldots\ldots... + z\,S_n$$

Where, a, b, c,.... and z are the coefficient relating to respective impacts; E_1, E_2, E_3,...., and E_n are the cost impact due to different economical factors. EN_1, EN_2, EN_3,…, and EN_n are the cost impact due to different environmental factors; and S_1, S_2, S_3,…, and S_n are the cost impact due to different social factors.

A new LCCA model for any study alternative incorporating environmental and social costs has been proposed by extending the economic cost formula from Salem *et al.* (2003), which also gives due consideration to risks as

$$LCC_N = C_{ECON} + C_{ENVN} + C_{SOCN}$$

Where C_{ECON} = PV of Net Economical Cost (same as the LCC_N in Equation 4)

C_{ENVN} = PV of Net Environmental Cost for the alternative (from LCA)

C_{SOCN} = PV of Net Social Cost for the alternative

FUTURE RESEARCH

Quantifying the social and environmental LCC to offset the increase in investment cost and establishing overall feasibility in economic terms can convince investors about the benefits of sustainable design. However, the key challenge remains on gathering reliable data for an accurate LCC. LCCA involves data from an extremely long period of time, starting from the design phase to the end of life of a building. The construction industry is extremely diverse where the designers and contractors rarely communicate with facilities managers and thus do not know what really happen to their design in the long run. Most of the LCC calculations at the design and construction stages are either assumptions or projections. Further research by the authors found that there are two potential approaches to resolve the reliability issue. The first approach is to collect LCCA data of buildings from the initial stage to the end of life. This approach will yield extremely reliable analysis but it requires an extensive amount of information and time period. The second approach is to conduct simulation using assumed or some actual data. This could potentially resolve the problem of extensive data collection while taking care of reliability at the same time.

The authors have also started efforts to identify significant factors that drive the life cycle of a building and its components. Different types of building and their components have different life cycle performance and identification is needed of the significant sustainability factors that drive building life cycle. An extended mathematical model incorporating all the pertinent cost and benefit parameters and the potential risks as devised in this paper is expected to be useful to translate the social and environmental costs of sustainable design into economic terms. The model can be a helpful decision making tool in selecting the best among different project alternatives. The validation and calibration of this model is a challenging task for the future research, which would require acquisition of real data. Further research to establish the consistency and stabilize the variables of the model is also necessary to determine more accurately the cost of sustainable design.

ACCURACY OF ESTIMATING WHOLE LIFE COSTS

Mohamed A. El-Haram[1], R. Malcolm W. Horner[1] and Sasa Marenjak[2]

[1]*Construction Management Research Unit, Division of Civil Engineering, University of Dundee, Dundee, DD1 4HN, UK*

Whole life costing (WLC) is now a requirement for all UK government tenders and private finance initiative schemes. Accurately forecasting the whole life costs of constructed projects is vital to the survival of any business. It is even more important to the companies who take responsibility for designing, constructing, operating, maintaining and ultimately decommissioning constructed projects. Whenever an estimate is generated, estimators and their clients want to know how close the figures are to reality. This paper addresses the meaning of accuracy, describes the important factors that affect it and the uncertainty inherent in making forecasts of project whole life costs. The paper also suggests how the accuracy of whole life cost prediction can be estimated and improved by taking due account of, for example, the WLC process, integration of the supply chain, education and training, use of proper tools and techniques and data which are both reliable and accurate.

Keywords: central limit theorem, estimating accuracy, life cycle, whole life costing.

INTRODUCTION

In the past 15 years whole life costing has become an integral part of building economics. There have been four main drivers in the UK: (1) the introduction of the private finance initiative (PFI) and public–private partnership (PPP) in 1992; (2) a demand from owners and clients for evidence of what their costs of ownership will be (Egan 1998); (3) the introduction of the Treasury procurement guidance note – no. 7: ‘Whole life costs’ (HM Treasury 2000) by the Office of Government Commerce which states that ‘all procurement must be made solely on the basis of value for money in terms of whole life costs’; and (4) sustainable construction initiatives. All these initiatives have the following principles in common: (a) an acknowledgment of the need for a longer term view which emphasizes a whole life approach to the management of construction projects; (b) the shift from selecting projects based only on initial capital investment to a consideration of future costs as well; and (c) the need to establish the link between the life cycle phases (design, construction, operation, maintenance and disposal/recycle) of built assets as well as the link between the whole life supply chain members.

Whole life costing includes all costs and revenues associated with the design, build, operation, maintenance and disposal of a building as shown in Figure 1. According to ISO-BS 15686, Part 5 (ISO 2006) WLC can be defined as: ‘economic assessment considering all agreed projected significant and relevant cost flows over a period of analysis expressed in monetary value. The projected costs are those needed to achieve defined levels of performance, including reliability, safety and availability’.

[1] m.elharam@dundee.ac.uk

Life cycle cost analysis is an engineering and economic evaluation tool for choosing among alternative project investments and operating and maintenance strategies by comparing all the significant differential costs of ownership over a given time period in equivalent economic terms (El-Haram and Horner 1998). It takes into consideration the building specification requirements to assess and optimize the whole life costs of a building, satisfying the client and/or user requirement. ‘It therefore provides an equitable comparison on a quantitative basis amongst competing designing Authors and authorship options within the same decision-making process, in order to select the most appropriate and cost-effective design option’ (Flanagan *et al*. 1987).

Accurately forecasting the cost of future projects is vital to the survival of any business. Whenever an estimate is generated, cost estimation analysts want to know how close the figures are to reality. Generally, the estimators will not know exact costs until the period for which the costs were estimated is completed. In construction, one measure of accuracy is the deviation from the lowest acceptable tender received in competition for a project (Morrison 1999). Ashworth and Skitmore (1999) defined accuracy simply as the absence of error, that is, the smaller the error the higher the accuracy and vice versa. According to Asiedu and Gu (1999), the accuracy of an estimate is inversely proportional to the span of time between the estimate and the event.

Traditionally, estimators do not know the exact construction cost until the project is built and commissioned. In the case of PFI projects, estimators do not know the cost of a project until the end of the concession period. In general, estimators do not know the exact whole life costs of a project until the end of its life (disposal). Naturally, each estimator will want the cost of every element to be as accurate as possible given the data they have at the time they generate it.

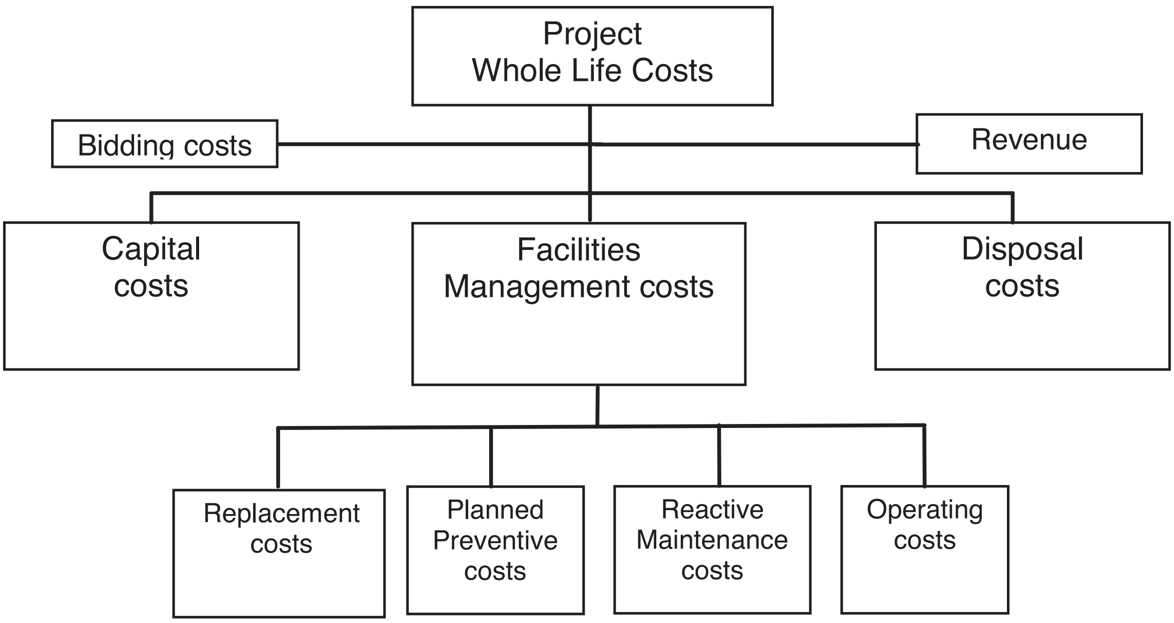

Figure 1: Main whole life cost elements

FACTORS AFFECTING ACCURACY

This section describes the significant factors that could have an impact on the accuracy of whole life costs and suggests ways that might improve the level of accuracy of whole life costing. The estimator must keep in mind the importance of the following factors:

- whole life costing methodology;
- availability of data;
- method of estimation;
- experience, skill and judgement of the estimators.

The above factors are drawn from a review of the literature (Al-Hajj and Horner 1998; Akintoye and Fitzgerald 2000) and the experience of the authors.

WHOLE LIFE COSTING METHODOLOGY

In response to the initiatives mentioned in the introduction, various methodologies have been developed to improve the implementation of whole life costing. However, their application depends on the circumstances of projects and requirements of the clients involved. The lack of an accepted industry standard methodology for implementing whole life costing has a significant impact on the accuracy of estimating whole life costs. The recent publication of ISO-BS 15686 Part 5, 'Whole life costing' will encourage a more consistent approach to whole life costing and may increase the level of accuracy. However, the Standard does not suggest methods of measurement for whole life cost elements. The authors have developed an initial framework for a standard method of measurement for whole life costs of construction projects. It defines:

- how a cost element is to be divided into the separate costs of tasks/activities/resources in the breakdown structure;
- what is included and excluded for each cost element;
- the data and information to be given in estimating the cost element;
- the units in which the cost elements and work activities are to be expressed;
- how the cost element is to be measured for the purpose of calculating cost.

The framework mirrors that used in the Civil Engineering Standard Method of Measurement and the Standard Method of Measurement for Building Works, both of which have given rise to similar methods for producing and pricing bills of quantities. An example of the proposed standard method of measurement for whole life costs is provided in Appendix 1.

Data availability

The accuracy of the output data from whole life cost modelling depends on the accuracy of the input data. Therefore, the suitability and availability of the cost data used when estimating will have an important bearing on accuracy. The data and information which are needed to estimate whole life costs include the cost of materials, manpower and equipment and/or plant that are directly required to estimate the cost of construction, maintenance, replacement, operation tasks and other whole life cost elements such as rates, security, utilities, catering and waste management.

Other data which are also required to estimate whole life cost elements include building elements' life expectancy, frequency of carrying out a task (e.g. planned preventive maintenance, cleaning, etc.), required level of performance, the physical characteristics of a building, discount rate and the period of analysis.

One of the main barriers to the successful implementation of whole life costing is the lack of available historic data on elements of whole life cost (El-Haram and Horner 1998). Even where the data exist they are neither consistent nor in a form that can be used for effective whole life cost analyses. This lack of available useful data is partly a consequence of the lack of an acceptable whole life costing data structure. One of the key steps in successfully implementing a consistently and widely used whole life costing methodology is to create or adopt a standard data structure. The objectives of a standard breakdown structure are:

- to provide the framework for defining cost which enables cost estimators to prepare whole life cost estimates;
- to identify all activities throughout the life cycle that will generate costs.

El-Haram *et al*. (2002) have developed a framework for a whole life cost data breakdown structure for the building industry. The proposed structure is divided into five levels. The top-down hierarchy of the data structure is project level, phase level, category level, element level and task level, as shown in Figure 2. Each level is broken down further. For example, level 2 is broken down into a series of phases such as capital, facilities management and disposal. The structure is supported by a pool of data and information that is related to the factors influencing the estimation of whole life costs.

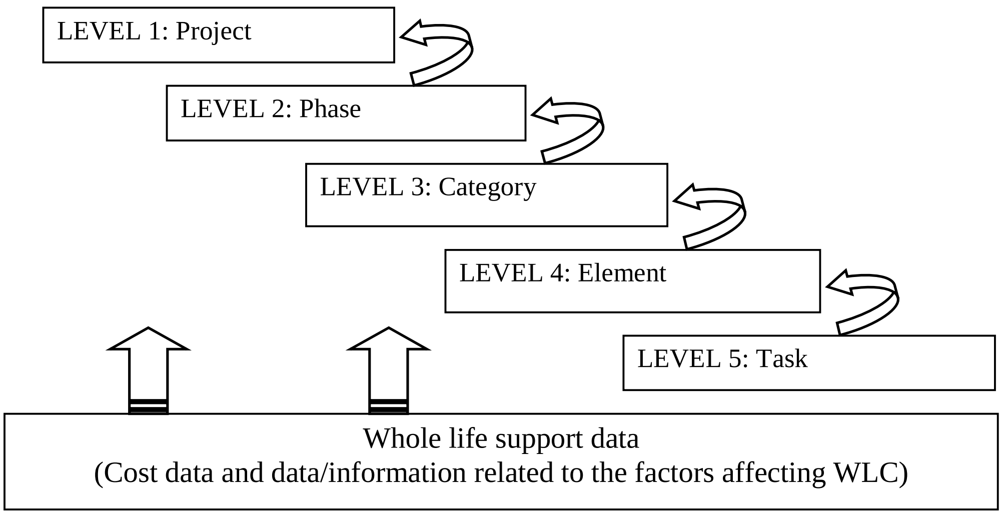

Figure 2: Levels of whole life costs data structure

The use of reliable historical data would significantly improve the accuracy of estimation of whole life costs. It is therefore highly desirable to establish a whole life cost data portal through which companies can collect and benchmark the whole life costs for every project.

Method of estimation

Various methods are available to estimate the elements of whole life costs including parametric, regression, analogous and more detailed approaches (Blanchard and Fabrycky 1991). Different estimating methods have different inherent errors. The inherent errors in the method are linked to the detail with which the estimate is produced and the variability of the cost data it employs. The choice of estimating method depends on the stage of the project, the type of each cost element (e.g. construction, replacement, etc.) and the availability of data and information. The level of accuracy of cost prediction is likely to increase and improve as the level of detail in which estimates are prepared and the knowledge about proposed design parameters increase.

Experience, skill and judgement of the estimators

Life cycle cost estimators not only attempt to estimate capital costs of construction project options which is a problem in itself, but they must also predict future costs of maintenance, replacement, operating and other related costs as well as revenues. On top of this, they must forecast the economic factors to be used: discount rate, project life and the lives of the various components used, together with their repair intervals and replacement cycles, unexpected use of the project, unusual events such as change of ownership, and the influence of future fiscal policies (Avery 1989).

Regardless of the stage of the project, estimators should compile and analyse data on all the contextual factors that can influence costs. Even cost information derived from within the same building type (school, hospital, etc.) is influenced by such factors as size, complexity, height, specification and intensity of use which combine to produce a wide range of building costs (Marenjak 2004). In addition, the estimator must make a number of adjustments to the cost data derived from one time, location and market situation to the anticipated time, location and market situation relevant to the new project. The reliability of the cost estimate and the level of accuracy of cost predictions are dependent upon the professional experience, skill and judgement of the estimator which can be improved through increasing their involvement in whole life cost estimating and through training. Estimating whole life costs is a team effort requiring the integration of the skills of all the key members including designer, builder, facility manager, end user and others. This will enhance the feedback from those who operate and maintain the facility to those who design new projects.

UNCERTAINTY

The major difficulties in applying life cycle costing in practice are related to the prediction of future behaviours and events such as:

- the behaviour of people in terms of their use of, and response to, the project (much of which will relate to non-economic issues and will be difficult to measure);
- the behaviour of materials, components, and mechanical and electrical systems;
- the future uses of the project, and the environmental conditions to which it may be exposed;
- the financial and economic conditions that influence the relationship between present and future costs;
- difficulty in controlling the total costs of ownership which are affected by administrative procedures or political decisions driven by short-term gains.

These factors are never constant, but vary from year to year. Some of them can, at least, be considered, analysed and evaluated: others cannot even be imagined at the time of estimation. The difficulties in forecasting the physical and economic life of a project stem from many factors, such as life expectancy, deterioration rate, mean time between failures, discount rate, taxation, functional, technological, social and legal regimes, location, fashion and environmental obsolescence (El-Haram and Horner 1998). Consideration of these variables can be a source of many complexities in undertaking a whole life cost appraisal. Whole life cost decisions therefore involve a considerable amount of uncertainty, which makes it very difficult to carry out economic evaluations with a high degree of reliability. Examples of the techniques used to deal with uncertainty are conservative benefits and cost estimating, sensitivity analysis, risk-adjusted discount rate, mean-variance criterion and coefficient of variance, decision analysis and simulation (Flanagan *et al.* 1987; Marshall 1991). No single technique can be labelled as best for treating uncertainty and risk. What is best will depend on many things such as availability of data, availability of resources and computational aids, user understanding, level of risk exposure of the project and the size of the investment (Marshall 1991). If the reliability of WLC analysis is to be improved, the sources of uncertainties must be dealt with as an integral part of the whole life cycle process.

LEVEL OF ACCURACY IN WHOLE LIFE COSTING

The level of accuracy varies from project to project and from phase to phase within the same project. The accuracy can change as the design progresses from the feasibility to the detailed stage. Whole life cost analysis during the feasibility and preliminary design stages may require the use of basic accounting techniques and the model may be rather simple in construction (Blanchard and Fabrycky 1991). On the other hand, whole life cost analysis during the detailed design stage may be more detailed and may rely on a more or less sophisticated cost breakdown structure. During the feasibility design stage of a building, available data are limited and the cost analyst must depend primarily on the use of various parametric cost estimating techniques in the development of cost data. The cost estimates at this level have average accuracies of ±20% to ±30% (Asif 1988; Zakieh 1991). As the building design progresses to preliminary design stage, the average level of accuracy of cost estimation is ±10% to ±20% (Asif 1988; Zakieh 1991). Finally, at the detailed design stage, all of the information about the building is known. A contractor's accuracy of estimating at this stage (tender stage) is on average ±6% to ±10% (Asif 1988; Zakieh 1991). It is very difficult to assign a level of accuracy for whole life cost estimates at the bidding stage due to the level of uncertainty. Uncertainty is inherent in making future forecasts of operation and maintenance, replacement cost and any other future costs. The expected level of accuracy at this stage is likely to be worse than the level of accuracy at tender stage for traditional projects. This means that the average accuracy of estimating whole life costs at the bidding stage is likely to be ±10% or higher. The level of accuracy of estimating whole life costs depends on the factors which are described in the previous section. However, the current level of accuracy must be accepted until a better model and more reliable data and information become available.

Illustrated example

This hypothetical example is not based on any real data and it is only presented to illustrate the level of accuracy of the whole life costs of a project. The levels of accuracy shown in Figure 3 are for demonstration only and do not necessarily represent actual levels in practice. From the literature the accuracy of estimates of construction cost at the tender stage is on average ±10%.

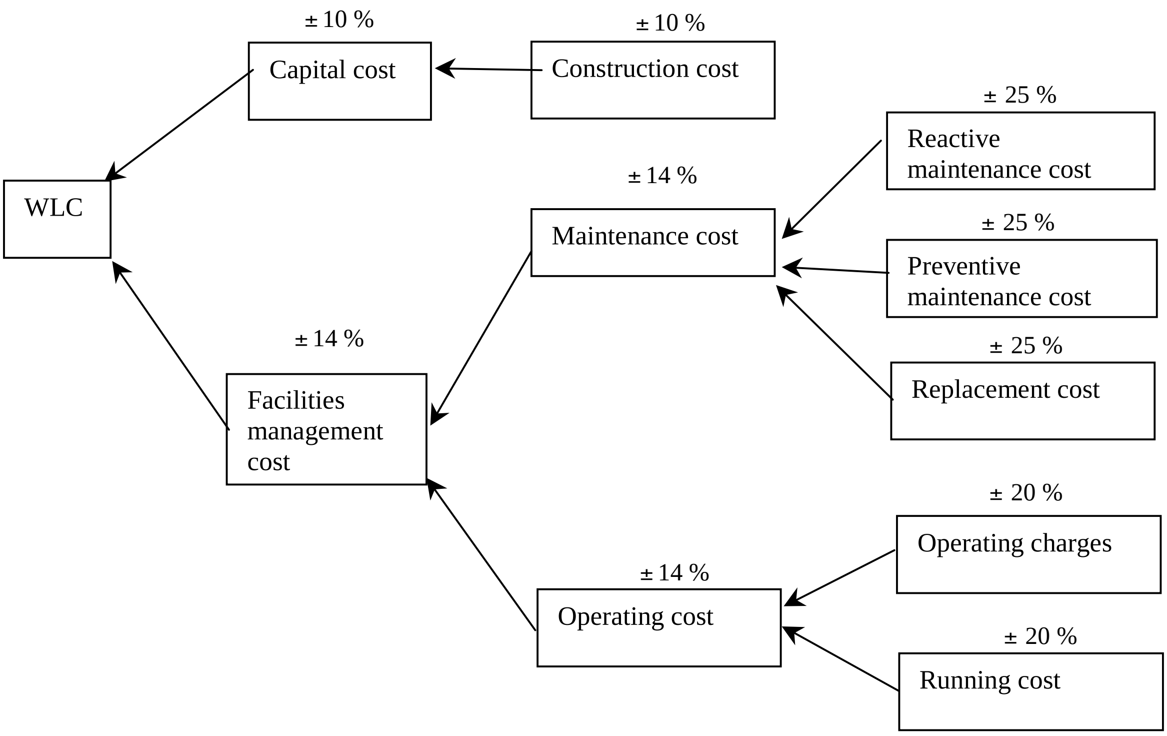

Figure 3: Illustrated example of level of accuracy of WLC

However, the authors think that the level of accuracy of estimating facilities management costs might be of the order of ±25%, while operating and running costs might be estimated to ±20%. Despite these relatively large inaccuracies, thanks to the central limit theorem (see Appendix 2), the accuracy of whole life costs is ±7%. This level of accuracy is considered to be generally acceptable, at least until better models and more reliable information are available.

CONCLUSIONS

The paper has shown that there is no quick fix that will immediately make estimators estimate whole life costs more accurately. Improved estimates will come about as a result of improvements in whole life costing methodology, integration of the supply chain, education and training, good project management, use of proper tools and techniques, sufficient resources and time, and a good reliable cost database. It could be several years before the construction industry has enough data from which better estimates of whole life costs can consistently be made. There are many issues that require further clarification to accurately estimate the WLC of a project. These include:

- better understanding of the factors that influence project costs in order to improve the estimation accuracy at each stage of a project;
- establishing the level of accuracy at each stage of a project or for each category of whole life costs;
- better understanding of how the estimator’s experience influences accuracy;

- the reliability of historical project data;
- the ways in which the choice of an estimation method and the use of cost estimation software influence estimation accuracy.

The paper has also shown that whole life costs deal with an unknown future, characterized by a variety of uncertainties. It is therefore imperative that any life cycle model incorporates the treatment of uncertainties. Fortunately and fortuitously, the central limit theorem works to the estimator's advantage. As long as there is a sufficient breakdown of costs, this law of 'swings and roundabouts' will serve to reduce the error in the final estimate of whole life costs, despite the larger levels of inaccuracy in the cost build-up.

APPENDIX 2: CENTRAL LIMIT THEOREM

The central limit theorem states that in any sequence of repeated trials the standard sample mean approaches the standard normal curve as the number of trials increases (Horner and Zakieh 1996). In these circumstances, the mean of the sum of the trials is the sum of the means of individual trials, and the standard deviation of the sum is equal to the square root of the sum of the standard deviations of each trial squared. The measure of variability of most value statistically is the coefficient of variation (CV). This is the standard deviation, expressed as a percentage of the mean. The central limit theorem (Horner and Zakieh 1996) assumes that:

- the accuracy of each cost element is independent;
- the error in the WLC model of the project is equally distributed across all the cost elements (i.e. the mean model accuracy and variance are constant for all cost elements).

Let a_i be a random variable representing the accuracy of estimation of the *i*th cost element in the WLC model, (i = 1, 2, …, n), where n is the total number of cost elements in the model. The accuracy of the estimate of a single cost element within the model is defined as the percentage difference between the estimated cost and the actual expenditure.

$$\mathrm{a}_i = \frac{EC_i - AC_i}{AC_i} \times 100$$

where:

a_i = accuracy of the *i*th cost element

EC_i = estimated cost of the *i*th cost element (say preventive maintenance)

AC_i = actual cost of the *i*th cost element.

The accuracy of estimation of each cost element has a distribution with mean μ_i and variance δ_i^2. The coefficient of variation of each cost element is

$$CV_i = \frac{\sqrt{\delta_i^2}}{\mu_i} \times 100\%$$

Assuming the a_i values are independent, then the distribution of the sum of a_i, $\mathrm{A_s}$ has a mean

$$\mu_s = \mu_1 + \mu_2 + \ldots\ldots + \mu_n = \sum_{i=1}^{n} \mu_i$$

and variance

$$\delta_s^2 = \delta_1^2 + \delta_2^2 + \ldots\ldots + \delta_n^2 = \sum_{i=1}^{n} \delta_i^2$$

Assuming that the mean model accuracy and variance are constant for all cost elements in each cost category of whole life costs, then

$$\mu_1 = \mu_2 = \ldots\ldots = \mu_n$$

$$\delta_1^2 = \delta_2^2 = ... = \delta_n^2$$

so

$$\mu_s = n \times \mu_i$$

and

$$\delta_s^2 = n \times \delta_i^2 \, .$$

It follows that the coefficient of variation of any cost category such as facilities management or the whole life cost of a project is:

$$CV_s = \frac{\sqrt{\delta_s^2}}{\mu_s} \times 100 = \frac{\sqrt{n \times \delta_i^2}}{n \times \mu_i} \times 100 = \frac{\sqrt{\delta_i^2}}{\sqrt{n} \times \mu_i} \times 100$$

Thus,

$$CV_s = \frac{CV_i}{\sqrt{n}}$$

where:

CV_s = coefficient of variation of the accuracy of the cost category;

CV_i = coefficient of variation of the accuracy of each cost element within the cost category (constant for all cost elements in each cost category);

n = number of cost elements in the cost category.

FAMILY LIFE CYCLE AND THE PLANNING OF MULTIFAMILY HOUSING

João Alberto da Costa Ganzo Fernandez,[1] Roberto de Oliveira[2] and Luiz Fernando Heineck[3]

[1]*Professor of the Construction Department, Federal Center of Technology of Santa Catarina, Brazil*
[2]*Professor of the Civil Engineering Department, Federal University of Santa Catarina, Brazil*
[3]*Professor of the Production Engineering Department, Federal University of Santa Catarina, Brazil*

The literature shows a series of studies that demonstrate the importance of the family life cycle on the housing choice process. Based on this, 935 potential apartment purchasers of Florianópolis (SC) were interviewed with the purpose of identifying the most valued architectural attributes in each phase of family life cycle and whether there is a statistical relationship between the respective phase and the relative indispensability of each attribute. With the exception of the following attributes: sunny bedrooms, individual water meter and ample kitchen, on which a consensus as to importance exists, there is a logical and distinct pattern of priorities. While childless couples prioritize the living room, barbecue on the balcony and the pool, those who have children prioritize the playground and the service bathroom. When children grow older, families start to value attributes related to space and privacy such as maid room, hobby box, two parking spaces, two master bedrooms and acoustic insulation. Buyers in the last phase of the family life cycle, the empty nest, differ from the others by the attributed importance to the independence for the service entrance and the nice view from the living room. The desired number of bedrooms is greater during the phases of family expansion and smaller during childless as well as contraction phases. The results were submitted to chi-square testing that reveals association between family life cycle and the following apartment attributes: number of bedrooms, playground, two parking spaces, service bathroom, service entrance, maid room, two master bedrooms, at most two apartments per floor, good view from the living room, pool, hobby box, hot water system, ample kitchen with table, sophisticated security system, Jacuzzi, small wash basin and individual water meter. The existence of these associations demonstrates that the variable family life cycle is relevant and may be used to support – at least in relation to those attributes – an architectural programming for a market-oriented multifamily building.

Keywords: architecture, design, family life cycle, marketing, multifamily projects.

INTRODUCTION

The first step in the architectural design process is the creation of the architectural programming or as Silva said (1991): ‘the statement of the requirements (necessities, aspirations and expectations) to be satisfied by what will be constructed’.

The Architecture College prepares the future professional to decipher and elaborate the programming for single families, not providing the necessary theoretical tools (market research) for a multifamily project. In these cases, when there isn’t a specific family and their needs aren’t knowledgeable, the architect adopts a passive posture in

[1] jganzo@terra.com.br

terms of the project, accepting the architectural programming determined by the property developer. This programme on the other hand, is based on pure intuition, market perception and on the consultation of the empirical knowledge of real estate brokers.

To reduce the chance of errors in the formulation of this programme, ingredients of flexibility considering the spatial arrangement of the project are added or subtracted many times, allowing it to adapt to the individual variations of each family nucleus. Nevertheless, according to Brandão (1997), modifications in the project resulting in the individualization of apartments in multifamily buildings imply reduced productivity owing to the increase of complexity, reduction of continuity and loss of the repetition effect.

Alexander (1979) correlates the great number of changes during the construction process with the lack of architectural quality of the original project in relation to the potential market. The absence of quality, referred to by Alexander, actually explains the inadequacy of the original project regarding the potential market segments.

Therefore, projects must be conceived considering the focus of a segmentation market. The segmentation strategies are directly linked to the increase of profit, which occurs when the economic value for the consumer is higher than the cost to create this value. ‘The objective of a segmentation strategy is to take one shot at the market and not a burst of machine gun fire’ (Engel *et al*. 2000).

The key question here is: how to correctly segment the housing market?

This work presents the potential of using the family life cycle (FLC) concept as a significant segmentation strategy for a correct definition of the architectural programming for multifamily housing projects.

THE SEGMENTATION OF THE CONSTRUCTION MARKET

The identification of the segmentation strategies adopted by the construction companies to define their standard architectural programming isn’t always an easy task. Frequently, the ways of segmenting get mixed up and interact. Sometimes, what seems to be segmentation based on income actually is a psychographic segmentation based on life style, in other situations it’s just a geographic segmentation chosen from the experience of a local construction company.

In spite of the former difficulties mentioned, a general trend towards a primary segmentation based on income/social class (demographic segmentation) and location (geographic segmentation) can be observed. Both are highly correlated: distinguished locations are directly related to higher income.

There is secondary segmentation on family size (projects of apartments with a variable number of bedrooms); sensitivity towards the marketing factor (distinguished finishing, allowed flexibility strategies and promotional prices).

However, even if some empirical segmentation is practised, the absence of more elaborated studies, mainly concerning the preferences of specific segments for certain property characteristics and specific locations, impedes the property developer from taking advantage of a well-directed project (with attributes that actually add value) or even avoiding changes during construction which may increase the final cost of the apartment.

The determination of potential segments in the construction business is decisively influenced by the location of the lots. According to Meyer and Haddad (2001), 'For all companies the opportunity to purchase a lot is the structural step of the entire process'.

Usually acquired beforehand for the market's sake, the lot, more specifically the attributes of its location, serves as a starting point for the segmentation process of the multifamily housing product and for the determination of the architectural programming. The cost of the lot will blend with the total construction area, conditioning decisively the price per unit, not depending on quantity or the size of the units.

Since the possibilities of the finishing standards are restricted to the ones considered coherent with the value of the location (primary segmentation on income), the morphologic characteristics (number and type of compartments) and general use equipment account for the role of the differential elements among the various project possibilities (secondary segmentation). This is why, traditionally, a housing offer is simplified and divided by number of bedrooms and location. In this way, the conclusion is that a primary segmentation by income emerges almost naturally because of the price and the characteristics of the lot's location.

In a regional context, Fernandez (1999)[1] demonstrated the importance of the family cycle when choosing the location of the apartments, and Oliveira (1998), through a post-occupational study, concluded that there are distinct preferences concerning the attributes of the same apartment for different stages of the family life cycle. Both studies were developed in Florianópolis, SC. Macedo (2004) reached the same conclusion as Fernandez and Oliveira while interviewing 49 residents of apartments in Maringá, PR.

The international literature presents various studies that indicate the importance of the family life cycle in the decision process of choosing a home (e.g. Rossi 1955; Speare 1970; Pickvance 1974; Clark and Onaka 1983; Schmitz and Brett 2001).

THE FAMILY LIFE CYCLE

The family life cycle is formed by the many stages of specific necessities that families go through over life's course. Regarding housing, these necessities comprise the most obvious, such as accessibility, equipment and physical space, as well as symbolic values like neighbourhood status, building facade and the quantity of natural green environment around it.

Rossi (1955) emphasizes the importance of the family life cycle affirming that the modal family voluntarily leaves the old home, impelled by changes in its size and composition, which demands a larger home.

Practically all families know beforehand the size of home they need. Some search only the neighbourhoods they find interesting. Others search areas near relatives or locations of determined social class level.

As time goes by, families become more sensitive towards the physical and social environments provided by the home's location. The need for space is the most important of all alterations caused by the life cycle, as well as the main attribute of a house. The larger the house, the larger its capacity to accommodate the needs generated by the alterations of the family life cycle. Small homes only fit the first and last stages of the life cycle. As the children grow up and spend more time away from the home, the quality of the external environment becomes more important to the family. The families ‘climbing’ the social ladder are more sensitive to the social aspects of the location. Such climb is the main motivational factor of their changes.

Clark and Onaka (1983) while analysing the results of many researches on why people move, confirmed the importance of the family life cycle as the structural element for the main reasons: for young couples, the cost of maintenance of the home and the property issue are the main reasons for the move; for families in the intermediate stages (couples with small children or teenagers), the size issue and finished quality of the home and property are the most relevant and finally for families in a more advanced stage with adult children still living in the home, neighbourhood factors and accessibility are the most important. In other words, the authors recognize that each stage has distinct necessities concerning housing.

The family life cycle stages are particularly difficult to classify and measure. The classical sociological context identifies the following phases: prenuptial; married with no children; the birth of the firstborn to the last child born (expansion phase); the birth of the last child until the departure of the firstborn; departure of the firstborn until the departure of the last one born (contraction) and after the departure of all children (empty nest) (Glick and Parke 1964).

The logical comprehension of the changing process is of great interest to the real estate market. A science that started to take its first steps in the middle of the last century (20th century) in the United States. As Wells and Gubar (1966) and Gilly and Enis (1982) confirm, the family life cycle models serve to define the potential segments, since they characterize stages and mark transitions associated with changes in the consumption pattern.

The Wells and Gubar (1966) model was a target for criticism for it considered the traditional standard post-war family, where the birth rate was high (baby boom) and the divorce rate was low. A new model proposed by Murphy and Staples (1979) includes the cycles and recycles of divorce and future marriage. However, this model only recognizes the cycles initiated by marriage. Stapleton (1980) tried to solve this problem adapting a new life cycle model to modern times, more dynamic, including in its structure the cycles and recycles of divorce or widowhood and a new marriage.

Gilly and Enis (1982) also added bachelorhood, couples that couldn’t or did not want to have children and single parents, to a very complete temporal diagram in a matrix format, with 14 stages interlacing each other.

Engel *et al.* (2000) also affirm that the homes that are not inhabited by traditional families, as the ones described by Gilly and Enis (1982), suffer the effects of temporal cycles, which are very important to marketing. As an example the American singles are quoted: they represent a quarter of the consumers of new homes. This implies changes in the projects: fewer bedrooms, less space for the dining room, more space for the kitchen (which is turning into a living room), more luxurious suites, bathrooms with a ‘spa’ and a living room with ‘high-tech’ entertainment.

As a conceptual reference, it’s worth observing the models of Pickvance and Speare created in the 1970s. Both were considered responsible for the demonstration of the relationship between the family life cycle, residential mobility and housing consumption.

The Pickvance model (1974) considers seven stages: (1) prenuptial; (2) couple with no children; (3) birth of the first child; (4) birth of the last child; (5) departure of the first child; (6) up to the departure of the last child and (7) empty nest.

According to Speare (1970), however, the FLC is composed of six stages: (1) singles, widows(ers) or divorced up to age 45; (2) newlyweds during the year of matrimony; (3) couples up to age 45 and oldest child up to age 5; (4) couples with children at school age, between 5 and 18 years old; (5) couples over 45 at the phase of family contraction; and (6) singles, widows(ers) or divorced over 45 years of age.

The author concludes in her research that though age and stage of the family cycle seem to represent the same concepts, they should not be confused. People in the same age group, but in a different stage of the family life cycle have different behavioural patterns concerning residential mobility. Similarly, people in the same life cycle stage, but in a different age group also act differently: the ones that get married later in life move less than the ones that get married earlier.

This exception suggested by Speare is relevant, since it opposes the subsequent models, which mistakenly divide the stages only by age groups, as the Burns and Gleber 1986 models. They consider five stages: (1) 25 to 34 years old; (2) 35 to 44 years old; (3) 45 to 54 years old; (4) 55 to 64 years old; and (5) over 65.

McCarthy (1976) doesn’t speak of the family life cycle, but of the inhabitant’s life cycle. For him the resident’s life cycle is divided into nine stages: (1) young and single with no children up to age 45; (2) young couple with no children; (3) young couple with a small child up to age 5; (4) young couple with oldest child between 6 and 18; (5) mature couple (husband at age 46) with oldest child at age 18; (6) mature couple with no children living at home; (7) singles, widows(ers), divorced, mature and no children living at home; (8) singles, widows(ers), or divorced with children younger than 18 living at home; and (9) other cases, such as widows(ers) that live with their married children and grandchildren.

The correct way to call them would be divisions instead of stages, since they can be mutually exclusive among each other.

Krisjanous (2001) highlights the importance of a study on the specific necessities of the empty nest for the real estate market. The increase in number of elderly couples resulting from the advances in medicine and consequently the increase in life expectancy, combined with the decrease of birth rate is causing an emerging search for real estate products that are new and adequate to the elderly. The author sub-segments the empty nest stage into three categories with distinct necessities: the young elderly (65–74 years old), the intermediate elderly (75–84) and the old elderly (over 85 years old). Burns and Grebler (1986) idealized a more pertinent solution to the population aging problem: the construction of granny flats attached to the apartment of their grown-up children.

It is evident; therefore, that the knowledge of the observable preferences of each stage of the family life cycle can provide the basis for establishing a secondary segmentation strategy to improve and better define the architectural programming.

METHODOLOGY

The attributes of the apartment preferred in each stage of the family cycle will be identified and ranked through descriptive statistics, considering the results of the research on market requests brought about by UFSC – Universidade Federal de Santa Catarina in a partnership with SINDUSCON – Industry and Construction Union, with 935 potential apartment consumers during the last five Real Estate Exhibitions that took place in Florianópolis (2001, 2002, 2003, 2004 and 2005). In these researches, a standard questionnaire was used with the objective of identifying the main desires, aspirations and necessities of the city's real estate market.

To identify how the variable 'family life cycle stage' is relevant as a segmentation element, and consequently for the elaboration of the architectural programming, the degree of association between that variable and 27 other variables that represent the attributes of the apartment were tested. The statistical tests used were the chi-square (x^2) and the concordance correlation coefficient.

According to Barbetta (1998) the chi-square test (x^2) is the oldest statistical test, as well as the most used in social research. It allows testing the significance of the association between two variables, qualitative or categorical.

When the variables are independent, there is a null hypothesis (H^o), since frequencies observed tend to be close to the frequencies that are expected. In this case, the value of x^2 must be small. However, a larger value in the x^2 statistic points to the fact that the differences between the observed frequencies and the expected frequencies shouldn't be merely casual; in other words, there is an association between the two variables.

With this test it was possible to detect which are the attributes of the apartment that have an effective correlation with the life cycle stage, and that, consequently must be observed by the project engineer while defining the architectural programming, once the probable family life cycle stage of the future residents of the property is known beforehand.

Besides the chi-square test, which possesses inferential characteristics (allows extrapolating conclusions of the sample to the universe), the contingency coefficient will be verified so as to estimate the degree or strength of the association between the two categorical variables.

All the potential apartment consumers in the city of Florianópolis in the following years (2002, 2002, 2003, 2004 and 2005) were considered as the object-population. The sampling criteria are non-probabilistic for convenience, since just one part of the object-population is accessible to collect the sample data (the visitors of the Real Estate Exhibition that are potential buyers and that agree to answer the given questionnaire).

Because of the factual impossibility of carrying out a probabilistic sampling, the results of the research must be considered with caution. Another factor that limits the explanatory power of the collected samples is selectiveness in terms of the buying potential of the public visiting the exhibition. Because it was carried out in a 'shopping centre', an environment with a well-defined socio-economic standard of the participants (middle-class, high-class), it's natural that the sampling produces this sort of inclination.

Only the interviewed people that fit into one of the five stages of the classical life cycle were considered: couples with no children, with small children, with teenagers, with adult children living at home and couples in the empty nest. The singles, widows(ers), divorced and any other situation that is outside the traditional family standard were excluded.

The research is limited by space and time variables; therefore, its results reflect the reality of the city of Florianópolis, Brazil, during the years that were researched. The transposition of the conclusions to other cities with distinct economic and cultural realities must only be an indicative character.

Since it is a descriptive research, there is no intention to determine the nature of the relationship between the variables or the factors that contribute to the occurrence of the phenomenon that was studied; these may be the subject of future explanatory research.

RESULTS

Ranking of preferences per stage of the family life cycle

Table 1 expresses the percentage of individuals, of each stage, that consider each one of the attributes (26) essential (wouldn't buy an apartment in the absence of the attribute).

Table 1: Number of cases and percentages of each stage where each attribute was considered essential

Attributes	**No children**		**Small children**		**Teenage children**		**Adult children**		**Empty nest**		**Total**	
	417	**44.60**	**176**	**18.82**	**204**	**21.82**	**96**	**10.27**	**42**	**4.49**	**935**	**100.00**

Service bathroom	50	11.99	51	28.98	59	28.92	26	27.08	10	23.81	196	20.96
Service entrance	37	8.87	37	21.02	54	26.47	25	26.04	19	45.24	172	18.40
Playground/court	30	7.19	45	25.57	37	18.14	13	13.54	2	4.76	127	13.58
Sophisticated facade	30	7.19	21	11.93	27	13.24	11	11.46	7	16.67	96	10.27
Maid's room	14	3.36	27	15.34	39	19.12	12	12.50	4	9.52	96	10.27
Two suites	20	4.80	18	10.23	37	18.14	16	16.67	4	9.52	95	10.16
Max. two apts. per floor	15	3.60	20	11.36	32	15.69	13	13.54	9	21.43	89	9.52
Swimming pool	23	5.52	19	10.80	29	14.22	9	9.38	3	7.14	83	8.88
Fitness centre	16	4.86	12	8.63	17	11.04	7	7.95	5	13.88	57	7.64
Whirlpool bath	16	3.84	17	9.66	18	8.82	6	6.25	5	11.90	62	6.63
Only one apart. per floor	1	0.24	4	2.27	4	1.96	0	0.00	1	2.38	10	1.07
Sum of the percentages		**583.05**		**805.35**		**870.75**		**879.44**		**887.30**		

The total and increasing sum of the percentages of what was considered essential shows that families are becoming more demanding as they move ahead in the family life cycle. A possible explanation is that the experience of residing makes people more critical and demanding regarding a home.

Table 2 shows the rank of each attribute for each of the stages of the FLC. The following guidelines have been extracted from recent criticisms of real abstracts. This may help to overcome some of the most frequent problems.

Table 2: The ranking of each attribute per stage of the family life cycle

Attributes	No Children	Small children	Teenage children	Adult children	Empty nest	Total
Sunny bedrooms	1	1	1	1	1	1
Individual water meter	2	3	2	2	2	2

All five stages find the following attributes a priority: sunny bedrooms (unanimous in all stages as the most important attribute), individual water meter, roomy kitchen, piped hot water and living room balcony. The first stage of the family life cycle (couples with no children) stands out from the others for attributing a higher relative value to the community function area and the swimming pool. The second stage (small children) is noticed because of the relative importance given to the playground and the service bathroom. Two garage spaces are essential for the intermediate stages of the family life cycle – teenage and adult children and the stage mentioned last is the one that values acoustic insulation the most and two suites. The empty nest stage presents rather peculiar results. In contrast to the rest, it values the independent service entrance (maybe due to cultural issues) not attributing much importance to two garage spaces.

Concerning the number of bedrooms, there is a growing demand from the couples with no children stage (mode = 2 bedrooms) up to the teenage children stage (mode = 3 bedrooms). From there on, the number of bedrooms starts to decline until the empty nest stage (mode = 2 bedrooms), as Table 3 illustrates.

Table 3: Mean and mode of the desired number of bedrooms per stage of the FLC

Family life cycle	Mean	Mode
Couples with no children	2.44	2.00
Small children	2.90	3.00
Teenage children	3.06	3.00
Adult children	2.95	3.00
Empty nest	2.57	2.00

Association between the preferences and the family life cycle stages

The statistical tests chi-square[2] and contingency coefficient (see Table 4) demonstrated associations between the family life cycle stages and the variables: number of bedrooms, playground, two garage spaces, service bathroom, service entrance, maid's room, two suites, max. two apts. per floor, beautiful view, swimming pool, hobby box, piped hot water, roomy kitchen, sophisticated security, whirlpool bath, WC in the living room and individual water meter. In other words, the degree of indispensability or priority of these variables for the people interviewed isn't mere accident, it is the product of the family life cycle stage in which the person is currently. Therefore, they are key variables in a process of segmentation per family life cycle stage.

Table 4: Association among the attributes of the apartment and the family life cycle

Attributes	$\chi 2$	p	C
Number of bedrooms	184.75	0.00000	0.41
Playground/court	84.43	0.00000	0.29
Two garage spaces	68.62	0.00000	0.26
Service bathroom	64.37	0.00000	0.25
Service entrance	64.36	0.00000	0.25
Maid's room	63.37	0.00000	0.25
Two suites	48.58	0.00000	0.22
Max. two apartments per floor	45.71	0.00000	0.22
Beautiful view from the living room	44.73	0.00000	0.21
Swimming pool	41.72	0.00000	0.20
Hobby box	34.20	0.00004	0.19
Piped hot water	33.65	0.00005	0.19
Roomy kitchen	27.65	0.00054	0.17
Sophisticated security	24.36	0.00169	0.16
Whirlpool bath	24.08	0.00223	0.16

Only one apart. per floor	12.33	0.13687	0.11
Balcony	5.03	0.75426	0.07

CONCLUSION

Families change with time, going through many stages. This process was historically called family life cycle (FLC). The work confirmed that there are associations between the family life cycle of the individual and the degree of importance attributed to some of the main morphologic, functional and symbolic characteristics of the desired apartment, among them, the number of bedrooms. In other words, the preferences revealed are not by accident, they obey the life cycle logic. Besides this statistical confirmation, the preferences of each stage were ranked and it showed that families become more demanding as they move ahead in the life cycle. With the exception of the following attributes: sunny bedrooms, individual water meter, roomy kitchen, piped hot water and a living room balcony, for all of which there is a consensus as to importance, a logical and distinct pattern of priorities is observed. The existence of two garage spaces in the intermediate stages is highly valued (families with teenage children and adult children), while a community function area is more valued in the first stages (couples with no children or with small children). Similarly, the desired number of bedrooms also follows a logical pattern. It is higher in the stages of family expansion and lower in the contraction stages.

With knowledge of the priorities of each stage, concurrent with the preferences of the stages in which potential residents of the building are (in terms of location), it is possible to create a qualified architectural programming, which will establish the conceptual guidelines for the architectural project. This adjustment of the project towards the aspirations of the market means satisfaction of the future inhabitant and success of the commercial project.

NOTES

[1] Fernandez (1999) interviewed 60 middle class apartment dwellers in downtown Florianópolis who have recently moved, with the aim of correlating locational attributes to specific preferences for each family life cycle stage. His main conclusions were: *Couples without children:* This stage emphasizes the importance of *status*. The presumed reason for this preference may be related to the need to make a social statement. The attribute of being *close to the workplace* also appears to be significant. *Couples with young children:* As one would expect, the proximity to children's schools is the most important attribute for this segment. The attribute *square closeness* appears among the five prioritized attributes, due to the lack of leisure areas in the condominiums. *Couples with young children and adolescents:* Children's development and entry into adolescence cause a change in families' priorities in relation to the location attributes. The attribute *close to school* continues to be an absolute priority, although the attribute of a well-policed area appears in third place, revealing a concern, from the parents' view, with the safety of their children who are now more independent in their daily lives. *Couples with adolescents:* In a similar vein, safety ranks as a maximum priority in this stage, displacing *proximity to the school* in the first place. The surprise in this stage is the appearance of the attribute *closeness to the supermarket*. *Couples with young adults:* This stage is characterized by parents' and children's maturity. *Proximity to the school* is no longer prioritized, because children attend or will soon attend a more distant university. It also decreases the importance of *safety*, prioritizing some quality of life attributes such as *very green surroundings* and *peaceful place*. Among accessibility attributes, the *proximity to supermarket and conveniences* underline the pragmatic characteristic of this phase of family life. *Empty nest:* The 'empty nest' stage is distinguished from the others; children have already left home, leaving the couple to experience the remainder of their lives. This segment places neither proximity to *public leisure areas* nor *very green surroundings* as priorities, instead placing more importance on the *proximity to hospitals*. The surrounding traffic of the shopping malls is less of a concern (many do not drive any more) than the comfort that these commercial outlets offer. The *conveniences* rank in second place in the preferences, reinforcing previous statements.

[2] Significant coefficient (α) = 0.005.

ECONOMIC ANALYSIS OF HOUSING DESIGN

Renato da Silva Solano[1] and Roberto de Oliveira[2]

[1]*Faculdade de Arquitetura e Urbanismo, and Engenharia PUCRS Av. Fábio A Santos, No 1660, CEP 91720-390 Porto Alegre RS, Brazil*

An economic analysis is made of two housing designs in the city of Porto Alegre (State of Rio Grande do Sul, Brazil). From the municipal approved blueprints the two designs were technically reviewed aiming at identifying possible interventions that could improve their economic performance as well as verify their principal authors' adherence to their architectural solutions. A comparison was made between the usual parametric process with the most commonly used indicators such as: construction global cost, estimation percentage services distribution participation, vertical and horizontal plans building (according to percentage participation distribution), installations and site; construction unit costs; compacity index as a key performance indicator. As conclusions, first a comparison between theoretical references and the analysed designs is presented, stressing the interventions that could be proposed to economic performance improvement for Design 1. Second, for Design 2, the repercussion on its global construction cost was analysed when the concepts of compacity index were used on the horizontal plan. In both cases the design analyses by using the shape effect have revealed that cost reductions are possible since changes could be made in the sense of reducing the number of edges and increasing the compacity index.

Key words: cost, design, estimating, housing, key performance indicators.

INTRODUCTION

This article makes a comparison between traditional Brazilian norm (ABNT-NBR 12721) cost estimation method (parametric procedures) and two other methods that are based on a building's shape. It refers only to the application of two methods in order to provide the basis for a comprehensive research. The first method deals with the amount of materials and labour costs while the second also considers the shape combined with those plan indentations that generate edges on the building; the cost impact of edges may be unperceived by the norm-based estimators, and mainly by the designers. This fact is an issue that, in the majority of projects, may lead to conflicts on the budget between designers (blueprints from office) and engineers/estimators (work on site). Literature points out the lack of designers' attention to the construction global cost (CGC) while making their decisions.

First, each of the two designs is described, then they are analysed. In Design 1 an analysis based on Mascaró's (1998) theory called Mascaró estimation method that relates design's horizontal and vertical plans, installations and temporary

[1] renato@picoralsolano.com.br

installations (such as site preparation and other related costs); after this, a study of the effect of compacity index and the balcony quality on construction costs are performed. In Design 2 an analysis of the effect of the number of edges on the general costs of construction is performed.

LITERATURE REVIEW

The comprehension of key performance indicators by designers could lead to a better understanding of impacts on construction costs of some design details. Cost analyses in early phases of the project should involve– among other measures – a search for matching the budget (within the estimation) with design propositions. The technical literature is unanimous about which design stages have the highest impact on the building's overall performance and it is the economic one that is the focus of this work (Sievert 1991; Bureau of Engineering Research 1987; Van der Mooren 1987).

Here, one of the key performance indicators is the compacity index (CI), added to the concept of economic perimeter (Mascaró 2002) that is defined as 'the perimeter of external walls passing by the internal parts of the balcony plus the perimeter of the balcony's external walls plus 50% of the external walls' and balcony's edges' (Mascaró 1998). CI is a relationship between area and perimeter, as given by the formula in row 8 of Table 1. The more compact a building is, the less cost is incurred. A circle has a CI of 100%, and square is around 85%; for rectangles, the CI starts around 60% and decreases quickly to 50% as long as the ratio between its measures increases. The study of geometric relationships goes back some decades as shown in Table 1.

Table 1: List of area comparisons by the perimeter of a closed area

Index	Equation	Author
1.Relation of shape	$\mathbf{4A/\ \pi e^2}$	Horton 1932; Haggett 1965
2. Relation of circularity	$\mathbf{4\ \pi A/P^2}$	Miller 1953
3. Relation of elongation	$\mathbf{(A/\ \pi)^{1/2}.(2/e)}$	Shumm 1956
4. Relation radial-line	$\mathbf{\sum_i(t_i\text{-}1/n)}$	Boyce and Clark 1964
5. Relation of elypsity	$\mathbf{4A/\ \pi em}$	Stoddart 1965
6. Relation of compacity	$\mathbf{A(2\ \pi f_A t^2 \eth_A)^{1/2}}$	Blair and Bliss 1967
7.Design performance	$\mathbf{100.2\ \pi(s/\ \pi)^{1/2}/c}$	March 1970
8. Compacity index	$\mathbf{2.(A\ \pi)^{1/2}.100/P}$	Mascaró 1985
9. Relation of compacity	$\mathbf{P^2/A}$	Wise 1988

Sources: 1,2,3,4,5,6, and 7 March and Steadman (1971), Martins (1999); 8 Mascaró (1985)

Notes:

A = area
C = total perimeter of the floor
S = floor area
P = perimeter of the figure
e = diameter or minor axis
m = diameter or major axis
n = number of vertices
t_i = normalized radial axes, from the centric to the vertices
t = radial axes from the centric to the small area $\eth_A$

However, those concepts are largely ignored by the majority of designers and taken for granted by the estimators because both sides operate in isolation and/or there is a lack of integration among other actors of the project's phases. Sometimes the constraint of the lot shape curbs the design towards a building's economic effectiveness owing to lack of compacity.

Another largely ignored concept is the relation of vertical and horizontal building elements. Many times designers and estimators – pressured by generalized needs of cost reductions – would like to make building cost reductions by decreasing the building's construction area. However, as it is impossible to reduce the distance between floor and ceiling (meaning the height of walls, for instance), the real final cost will not be so impacted. Table 2 shows the impact on total costs by comparing horizontal and vertical plans in the so-called 'Mascaró estimation method' (MEM). According to Mascaró, vertical plans have much more cost influence than the horizontal ones.

Table 2: MEM or relationship among horizontal and vertical plans on incurred costs (adapted from Mascaró 1998)

Element	**Percentage**
Shaping horizontal plans	26.79%
Shaping vertical plans	44.84%
Installations	24.33%
Temporary installations, site preparation and other related costs	4.02%
Total	99.98%

MEM has limitations, of course, because its use is advisable only in early design phases in order to orient the designer in relation to costs. That is the purpose of this work: to get designers, in earlier design phases, to be realistic about costs, yet not unreasonably precise.

DESCRIPTION OF THE DESIGNS

Design 1

Design 1 was conceived for the staff of a state firm foundation from user needs elicited from 5000 participants. This research indicated that 125 parking spaces were needed and also indicated the required number of elevators, the amount and dimensions of rooms of each the 96 housing units, as well as the condominium infrastructure of leisure and the building of overall systems. The land lot is in Teresópolis, and has three multi-storey buildings over columns, and the dwellings are from the second floor to the ninth floor; the water reservoir and elevator installations are over these spaces. The design of each tower can be inscribed in a rectangle of 15.75 × 27.5 metres without being constrained by the lot. It presents indentation on the façade to accommodate the core of vertical circulation and thermal devices. It also has a semi-built-in balcony on the building core that can be classified as sophisticated according to Mascaró (1998). By this is meant that the design for the balcony is elaborate. The cost impact of sophistication in design is highest when compared with second and third class. According to Brazilian norms this design is classified as similar to H8/3N (eight floors, third class of finishings, i.e. not of high quality in terms of material specification). The estimated cost using parametric method reached a construction global cost (CGC) of R$5 415 486 while with Mascaró's method it is R$5 447 072. The compacity index (CI) is 46%. The main floor plan is shown in Figure 1. As the analysis refers to estimation, details such as location in the land lot, other geometric features and other aspects are supposed unnecessary.

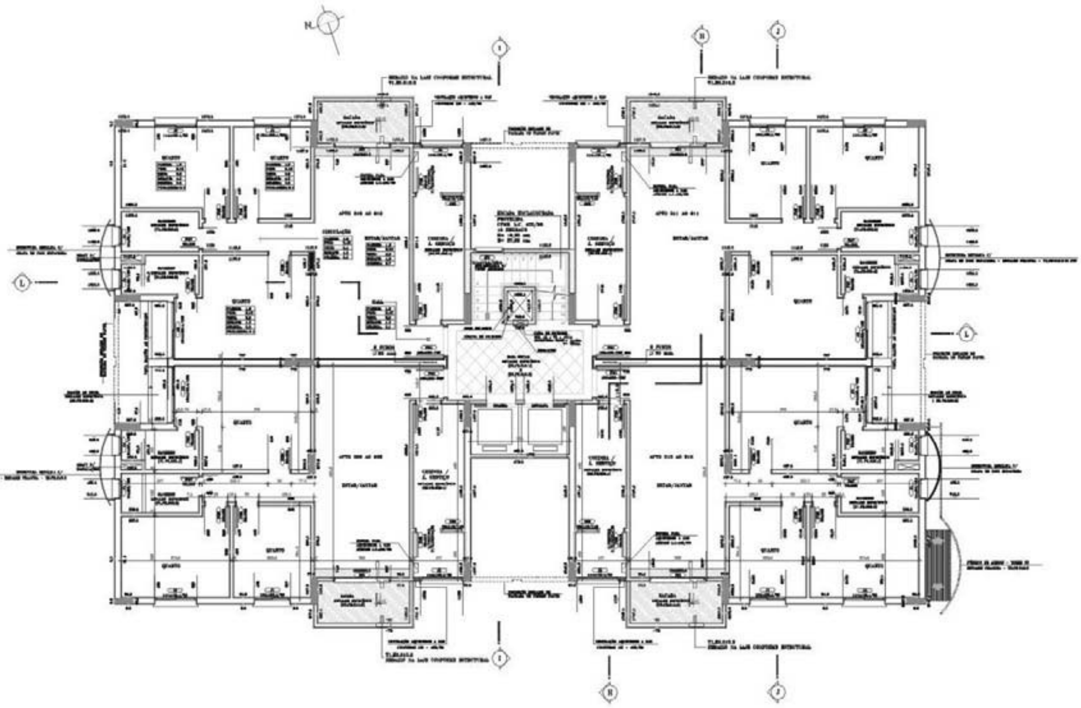

Figure 1: Design 1 main floor plan

Design 2

The conception of Design 2 was carried out by a realtor who acts in the city of Porto Alegre after consulting his/her brokers. It also is a high-rise building with an underground parking space, first floor over columns, and the dwelling units – 24 with one bedroom and 48 with two bedrooms as well as 144 parking spaces – are from the second to the thirteenth floor. According to Brazilian norms it is an H12/2N, meaning (height of) 12 floors with second class finishings. The design presents a rectangular shape in a proportion of 1:2.5 which is constrained by the lot. It also presents indentation on the façade to accommodate the core of vertical circulation. The main floor has balconies integrated with its living room. The estimated cost using parametric method reached a construction global cost (CGC) of R$6 310 000. Its CI is 64%. The main floor plan is Figure 2. As the analysis refers to estimation, details such as location in the land lot, other geometric features and other aspects are supposed unnecessary.

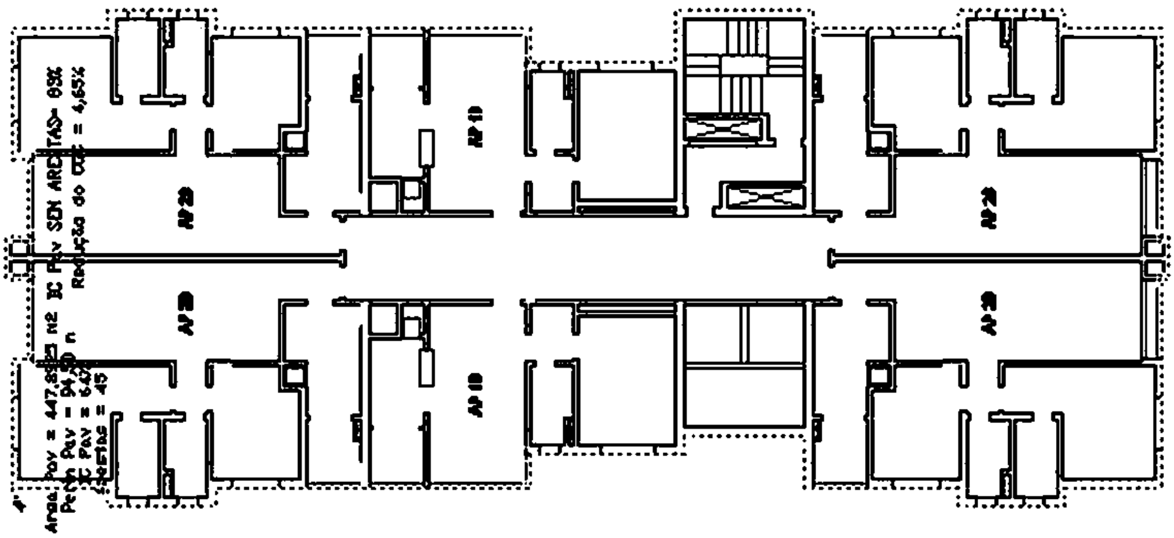

Figure 2: Design 2 main floor plan

METHOD

Design 1 analysis from economic perspective

According to Mascaró estimation method (MEM) the global cost of construction reached R$5 447 072. Table 3 shows the difference between the Brazilian norm backed methods. The overall difference is insignificant, at 0.02%.

Table 3: Differences between MEM and Brazilian norm methods

Element	% MEM	Design 1	Difference
Shaping horizontal plans	26.79%	29.8%	3.01%
Shaping vertical plans	44.84%	48.19%	3.35%
Installations	24.33%	16.92%	–7.41%
Temporary installations, site preparation and other related costs	4.02%	5.09%	1.07%
Total	99.98%	100%	**0.02%**

Following this, the influence of plan shape and the area on the total cost of the building is made using the CI (in the second column as percentage, in the third as it increases the cost also by percentage, and, in the fourth, construction costs decreasing) in eight steps named as 'action' in the first column. The first step is to downgrade the quality of the balcony, from sophisticated to simple, which results in lowering its construction cost. The other steps refer to eliminating the edges of the main floor plan in order to increase the CI and decrease the construction cost per square metre (CC/m^2). Table 4 shows those design actions, such as changing its rectangular-shaped plan, and in the last column is written the impact of the intervention.

Table 4: Actions on Design 1 towards CI and CC/m^2

Action	CI (%)	CI(+)%	CC/m^2 (–)	Comment
Original plan	46	None	None	None
01 Change for simple balcony	56	19.8	4.5%	Radical
02 Remove façade edges (rect. plan)	62	33.3	8.4%	Radical
03 Action 02 decreasing larger side	62	32.7	7.9%	Radical
04 Action 02 decreasing shorter side	60	30.0	6.9%	Radical
05 Keep only vertical circulation indentation + decreasing shorter side	51	10.7	2.6%	Radical
06 Keep only thermal devices' indentation + decreasing shorter side	55	17.8	4.0%	Radical
07 Keep only thermal devices' indentation + decreasing larger side	55	19.6	4.3%	Radical
08 Keep only vertical circulation indentation + decreasing shorter side	51	8.9	2.2%	Radical

In Table 4, the first column shows eight design measures from the original plan; the main design actions are listed. In the second column, the CI is calculated accordingly. In the third, the difference between the CI of the original plan and the one calculated as a result of each of the eight design actions. The fourth shows the difference between original cost per square metre and each one of the measures (variation of CI). In the last column comments are added to the final result for each of the eight design measures. Radical means a very marked effect on the external appearance of the building that could generate disagreement between the architect and the design consultant (in this case, engineer).

After presenting the results, and owing to the fact that the municipality had approved this design (ready for constructing), Option 1 was chosen. This choice reduced construction costs by 4.5%.

Design 2 analysis from economic perspective

This design was analysed by the CI under three options in which each one of the finishing external characteristics were kept as they were formerly proposed by the designer; only the effect of changes on geometric shape were used to evaluate the CI effect on the construction global cost indicated by square metres (CC/m^2). The shape option is indicated by the number of edges whose number directly affects CC/m^2. Table 5 shows these options.

Table 5: Actions on Design 2

Options	CI (%)	Number of edges	CGC (R$x1000)	Savings (%)
Original plan	64	45	6310	—
01 Keep plan area and adjust perimeter to 24 edges	70	24	6180	2.06
02 Keep plan area and adjust perimeter to 12 edges	75	12	6100	3.32
03 Keep plan area and adjust perimeter to 4 edges	83	4	6016	4.65

After presenting this Table to the realtor and the designer the decision made was to choose Option 2. The saving of R$210 000 on construction costs represented the sale price of two one-bedroom apartments or one two-bedroom apartment. The main reason for choosing Option 2 is because it impacts on the design only slightly while making large savings in construction costs. It is not a perfect decision, and that is why it is called an ‘option’.

RESULTS

The comparison between theoretical references and the analysed designs in the light of compacity index, vertical/horizontal shaping plans, and the number of edges has demonstrated that simple interventions in the design phase can be proposed to increase the economic performance improvement for both designs. For Design 1, using Mascaró estimation method (MEM) in which shaping of vertical and horizontal plans were considered, a negligible error of 0.02% was incurred. It means that MEM has a high level of precision, at least for this example. Following this, the action towards CI reduction has shown many design solutions that could be used, depending on owner–designer relationships and/or interests. For Design 2, the economic impact derived from the number of edges was evident and the resulting savings were exemplified by apartment’s sale price.

For both cases, the concepts of CI, vertical/horizontal shaping plans and MEM have provided the designer and owner with a clear vision of how to forecast budget conflicts with the designer and estimator. Further systematic research is called for to bring more clarification to these ideas. However, the main goal of this work is to provide two ways of balancing design propositions and their cost impacts by applying two easy and quick methods: compacity index and Mascaró estimation method.

FROM CONSTRUCTION TO SERVICES: THE CLIENT INTERFACE AND THE CHANGES IN PROJECT AND SERVICES GOVERNANCE IN PPP

Elisabeth Campagnac[1]

Laboratoire Techniques, Territoires et Sociétés, Ecole des Ponts, 6-8 Avenue Blaise Pascal, Cite Descartes F.77455 Marne –la-Vallee Cedex 2 France

Public Private Partnerships (PPP) have often been studied through the economics of contracts; the aim of this paper is to analyse them rather through the economics of services. The importance of client interface will be pointed out in relationship with the changes in project and in services governance in PPP, in France and in UK. Based on comparative research about PPP in French and UK hospitals, three main assumptions are argued. Firstly, PPPs, as complex, global and long-terms contracts, precipitate the passage from "construction" to "services". Beyond the differences in this evolution that we can observe in France and the UK, the question of client interface is of great importance in both countries. To analyse it, the economics of services are referred to rather than the economics of contracts. Secondly, in this context, the increasing difficulties the client faces when defining the performances in terms of output and outcome hypertrophies the role of benchmarking and the change of procurement process as a way to elaborate the judgement of effectiveness. This paper focuses on the experience of "competitive dialogue" in France and the UK to examine how this judgment of effectiveness in a long and complex contract lays on incremental and iterative process between the client and the providers, through more complex organisations in every side. It underlines how efficiency trends become more relational. Our third assumption is that the client interface stays very crucial in the post-contractual phase. But, while the economics of contracts insist on the question of information asymmetry for the client, the economics of services enlightens the strong interdependence between the provider and the client in the delivery of services. Therefore, it is argued that operating services by outcome mobilizes not only contracts but also conventions between the public client and the private provider and that effectiveness become more relational.

Keywords: client interface, economics of services, public private partnership.

INTRODUCTION

In most European countries, the development of Public Private Partnerships (PPP) has been accompanied by major upheavals in public commissions and considerable changes in project organisation. It is essential to qualify these changes, the forms they take and the issues they cover. The aim of this paper is to point out the importance of client interface in relationship to the changes in project and services governance in PPP in France and in UK. On the basis of comparative research about PPP in French and UK hospitals (Campagnac 2006), we will underline the place, role and characteristics of the "client interface" in the PPPs from three points of view.

[1] campagnac@enpc.fr

1. The first one relates to a theoretical point of view: it consists to clarify the status given to the "client interface" in our approach and the interest that we pay to the economics of services. The starting point is on our assumption that the PPPs, as complex, global and long-term contracts precipitate the passage from "construction" to services. We will refer here to the theory of services (Hill 1977, Gadrey 1996) and to its conceptual approach of services as the result of a co-production process between the beneficiary (here the public client) and the supplier (here the private consortium). The aim of this co-production is the transformation of a material or immaterial good belonging to the client.
2. The second one refers to the treatment of the client interface in the commissioning and to its consequences on the project's organisation. This second part will focus on the change in procurement. We will argue that, in the PPPs, the client interface has become the most strategic phase of the project. This is not only due to complexity and to uncertainty of the project but also to the conditions of its achievement from the point of view of economics of services. The increasing difficulty for the client to define the performances in terms of output and outcome is actually a characteristic of the economics of services. It encourages new offer strategy from the private consortia and militates for a complete change of the rules of game in the procurement and other criteria of judgment. For instance, the role of "benchmarking" appears as a way to elaborate the judgement of effectiveness, at different steps of the project. Through the examination of "competitive dialogue" in France and the procurement process to select the "preferred bidder" in Great Britain, we will focus on the incremental and iterative process between the client and the provider to elaborate this judgment. We will argue that effectiveness tends to become more collective and to depend on the links between the operations, between the individuals and the collective units along the line of clients specifications programming, design, build and operate, and often. So we will argue that a deep change in project governance is occurring that cannot be reduced only to the arrival of new actors in the process and their multi-rationality (investors , developers, FM operators and legal and financial advisers etc.) but which need to take in account the passage of vertical to horizontal coordination between different organisations and some lessons of cognitive sciences especially in the project design (Hatchuel 2002; Darses and Falzon 1996; Benghozi *et al*. 2002).
3. The third assumption refers to the post-contractual phase (between the public client and the facility management operator). Two main lessons can be pointed out from our research: (a) operating maintenance and services by outcome and inside a private consortium means very often a re-engineering of service; and (b) it is a very sensitive phase that could lead to misunderstanding between public and private partners. We will analyse how effectiveness in operating services by outcome mobilizes not only contracts but also conventions between the public and private actors, and how it redefines the competencies when effectiveness become more relational. A lot of PPP experiences show that many failures occur in the post-contractual phase because the dimension of "services" have not been taken in account in an appropriate way. Therefore, the post-contractual phase presupposes a long learning process between the public and private partners.

THE CLIENT INTERFACE IN PPP REFERRED TO THE ECONOMICS OF SERVICES

In the economic literature, PPPs have often been studied through the economics of contracts; we propose to analyse them here through the economics of services. We will now discuss the main differences between these two theories. The economics of services is different from the theory of transaction costs, because its assumption is based on the uncertainty about the product rather than uncertainty about the behaviour, like in the transaction costs theory. Transactions are seen as interactions productive of value and use value rather than costly frictions. The concept of "co-production of service" reflects the high uncertainty of the product.

Three main arguments militate in favour of the mobilisation of the economics of services in the case of PPPs:

- The identification of the field of application of the PPPs and the content of the activities, based on the distinction between service as process and service as result.
- The changes in terms of commission and their congruence with the "triangle of services activities", promoted by the theory.
- The redefinition of the efficiency approach in this kind of contract.

Field of application of PPPs and content of activities
No matter what specific contractual forms covered by PPP in the various countries – from the Private Finance Initiative (PFI) in UK, conceived in the early 1990s, to the "partnerships contracts" in France, launched in the 2000s – they all seem to present certain points in common, in particular those ones in breakdown with the traditional procurement :

Changes in the nature of the contract
In most cases, PPPs replace standard contracts based on separate assignments by a global contract covering the financing, design, construction, management and operation of public buildings and a proportion of the services that they provide. So a PPP contract is no more a sole construction contract but a construction plus a service contract, because it includes a more or less large part of services. Moreover, operating services is the support for public payments. The PPP is presented as a way for the administration and public authorities for getting new buildings and facilities, delivered and maintained by the private operators, and for funding them only through annual payments on many years.

Changed position and status of the public client or public sector party
The global contract is long term, paid for by public authorities and spread over time. The public sector party loses its status and function of contracting authority. Its mission is no longer to find the financing and organize the financial packaging, set out the construction programme, choose the designers, project managers and contractors, etc. Its position and function is transformed into that of a buyer which, within the framework of a *complex contract* spread over a *long period,* is called on to specify the functionalities expected from the building and services that it will place in the hands of a private consortium (cleaning, maintenance and operational services or services covering activities peripheral to public services).

Field of application
One of their main characteristics compared to the more classical concession or delegation of public services, is their field of application: the PPPs concern more the regalian public services (as Police, Justice, Defence etc.) and the most symbolic among the welfare state services (health and education, through hospitals and schools) rather than only infrastructure and public utilities, as before.

Changes in the public and private services borders and governance
The perimeter of the services activities included in the contract is quite decisive. The usual distinction is between “core services” and “non-core services”, for instance “clinical” and “non-clinical” services in the health sector. PPPs invite another distinction. Because they include construction, hard facilities management (related to the building operating and maintenance) and soft facilities management (related to the service to the person) , we would refer here to the distinction used by Curien (2002) between three main layers (infrastructure, service operating or intermediary services, and final service to the users). The redefinition of the frontiers between these three main layers is one of the main issues of the PPP. It is a complex one because it involves legal, political, social, economic and cognitive issues. Just let us keep the question of outsourcing can’t be put in the same terms for “public services” and commercial activities. (In this perspective we are interested by the distinction made by Nicinski (2001) and quoted by Villain-Courrier (2004) between “the relation of supplying a service” that could be publicly or privately managed and concerns the user in contact with the operator’s employees in a strictly commercial relationship and “ the relation of public service” that concerns the double exchange relationship between the members of the users’ community on one hand, and the users and public authority in charge to the good operating of service on the other hand. It is characterized by some derogatory dispositions.)

So, while the development of these new types of contracts in different European countries is generally linked to the imperatives of budgetary policies, limited spending and a reduction in public debt, we propose that they be considered from other points of view. Rather than simply limited to being budgetary tools, the PFI/PPP are vectors that have resulted in upheavals in public orders and project organizations structures. They also accompany the reform of “modernization” of public services in France and in UK .In other words, PPPs are far from being insignificant forms of contracts. They simultaneously translate a change in the way that orders are organized on a public policy level and a change in the management of the services associated with the concerned buildings. It could be said that there is a change in the “governance” of services.

Changes in terms of commission: The “triangle of services activities”
Theoretically, these contracts are supposed to be not a delegation but a *partnership,* laying on the idea of mutual advantages between the public and the private actors. These mutual advantages are often presented in terms of risk sharing for the private investors and referred to the financial rationale for the private partner and to the budgetary constraint, for the public client; Or in terms of service improvement and referred to the assumptions of greater management capacities by the private sector. None of these approaches could be satisfying; they need to be checked, proved and demonstrated.

That’s why we propose to focus on PPP not only as service activity but also as service relationship.

Gadrey (2003) insists on the three poles of a service relationship when he defined it the characteristics of a service activity: “ a service activity is an operation, whose the aim is a transformation of the state of an activity C , owned or used by a consumer B (or client or user) , realised by a supplier A on the demand of B, and often in relationship with him, but the outcome is not the production of a good which can circulate economically independently of its support C”.

Figure 1: The triangle of services activities

Redefinition of efficiency: outcome and service value

A second range of changes introduced by PPP concerns efficiency. In a service activity, the way to appreciate efficiency and to measure is quite different compared with an industrial production activity. It lays longer on the expected outcome than on the physical output. As in every contract by result or by targets, the object of the contract in PPPs is no more or not only tangible assets (the built infrastructure) but intangible assets (quality of maintenance, quality of delivered services). Different authors underlined the breakdown coming up with the industrial era when the most important thing was to sell goods with occasionally a free small service as a commercial argument; but the object of the transaction is now inversed: some companies sell the product at a very low price because they make profits on the long run service supply. Different authors insist too on the fact that in a service activity, it is the value that is very important and it can be appreciated in terms of direct product but in terms of indirect results. For instance, in a hospital, the service to a patient cannot be appreciated only by the cares that he or she receives, but by the real improvement of his or her health and by his or her recovery. So, the value service can be defined as the price that a client is ready to pay for the transformation that he or she judges positively (Gadrey and Zarifian 2002). It lays on a judgement about the service and its quality, and it supposes that this one succeed to be really delivered.

The situation for PPPs is more ambivalent because there is, of course, a part of tangible assets with the building construction, but the new situation is that the private partner sells to the public client a right to access to future value – maybe a share of the additional land rent – and the use of a range of services for long run. This movement is said changing the relationship to the assets: the right to use them is more important than their ownership and what is sold to the client is the permanent availability for use. This phenomenon goes with an extension of merchandising of every exchange. A real question is: what does the client buy through a service relationship? In fact, he or she can buy many things, from potentiality of gains in productivity (industrial partnership), to capacity to anticipate on the future, going through potentiality of more availability.

CO-PRODUCTION OF SERVICES AND CLIENT INTERFACE: TWO CASE STUDIES

The previous developments have put the accent on service relationship as result. This one will focus on the service relationship as process.

In this long run contract orientated to outcomes, where the transaction concerns some results to reach, the concept of co-production of the services is essential. In theory, co-production means an active attitude from the client-user: he or she has to inform the supplier and precise his or her demand as it goes along. The supplier has to adjust his or her proposal continuously. It means that the service relationship needs necessary time to construct it (contextualization, mutual adjustment, drafting of contract etc.) before technical dialogue and exchange. The role of appraisal and judgment of effectiveness become quite crucial in the process design, precisely because of the uncertainty about the "product".

What is the reality in PPPs? Firstly, it appears quite more complex because the client interface cannot be reduced to a simple interface between two individuals, but it mobilizes a great number of stakeholders on both the public and private sides, which offer a large diversity of design and appraisal criteria. For instance, in a PPP, the efficiency and effectiveness of service activities can be appreciated through various criteria such as industrial (efficiency and productivity), commercial (turns over and profit), civic (equity, contribution to common good) and financial ones (value created and risk sharing).

Secondly, it cannot be reduced to a "single colloquium" between the public client and the private consortium: in reality, the client's interface is mediated through a lot of rules, tools and calculation procedures that "instrument" the decision and could orientate it. Their role is not insignificant in the decision process.

Nevertheless, we argue that client interface tends to become more and more strategic for the success of PPP's and that through this "connection" the main issue is the co-production of services. That is why, whilst in a classical construction contract, the strategic interface for success is between design and construct, in PPPs as global and complex service contract, the strategic interface is the client interface (Campagnac 2001). We used to qualify this client interface as opening a "new service market", mobilizing cognitive and communicational changes, around the questions of complexity in decision making and uncertainty about the product.

But, in this process, it is very important to make the distinction between final service, i.e. public service, which is supposed to remain the core of the public client's activity, and the intermediary services (the different kind of facilities management), which are delegated to the private partner. The cases studies that we analysed in France and in UK through PPP in hospitals (Campagnac 2006) could illustrate each of these two points. Both concentrated on two hospital operations: a PPP/PFI operation in England (Case study A) and an emphyteutic hospital lease in France (Case study B). The two concerned operations are very different from one another in terms of size, cost and object. The case study A includes 155,000m^2 of new buildings + 109,000m^2 of existing buildings for a cost of £380 million, being €556 million; The case study B (a logistical platform for chemist and general services) concern a new building around 6,000m^2 of usable floor area at an estimated cost of €11 million. At the same time, they are relatively characteristic of PPP operations in both these countries. To understand the similarities and the differences, we compare these two operations on the basis of the interdependence resulting from the:

- *Politico-institutional and politico-legal context*: the challenge here is to link the advent of PPP in the hospital sector in both countries to health service reform modalities and changes in the rules governing public management in this sector.
- *Formal coordination procedures* instigated by the public client and the public regulation authorities, and *effective coordination and cooperation practices* of the concerned parties.
- *Contribution of the various concerned parties* to the development of the project, focussing on the interface between the concerned parties in the construction of the decision.

Client interface and complexity in decision making

The case study in the UK (Case Study A) is appropriated to illustrate the client interface face to the complexity in decision making. In the UK as in France, the development of PPPs takes place in a general context of reforms in public health system and in public management. However, the PPPs do not have the same outlines in both countries, partly because the nature of the problems met is not quite the same. Even if they face some similar challenges (budgetary and financial viability, societal evolutions, changes in models of healthcare, medical innovations etc.), they don't have the same inheritance. We can observe the differences between the national health system model, inherited from the Beveridge model on the one hand and the continental social insurance system inspired by the "Bismarck model on the other hand .The major problems for the first one are waiting lists and a lack of new construction over many years; the major problem for the second one is a very high level of expenses and increasing costs. But we can observe also the different aims of PPP in this sector in both countries.

Faced with these problems, the PFI in our case study A – one of the biggest launched in UK – combines a large hospital restructuring with a redevelopment of the buildings. It takes place in a context where the reallocation of healthcare supply between the NHS Hospital and Primary Care Trusts (PCTs), designed as a "mixed economy of care", is at the heart of the reform. In these conditions, the client interface illustrates the complexity in decision making, with a strong inter-dependence between the medical services programming (the health service process), the PFI financial process and the elaboration of commission brief. In this complex decision making process, the public client is in relationship with different public authorities with whom he or she has to negotiate at the local level (PCTs, Strategic Health Authority) or at the national one (Department of Health, PFU, Treasury etc.). He or she has to combine and manage different process: the Gateway process for *the strategic healthcare line*, the *Outline Business Case* and then the call to competition to private partners. Because of this complexity, the choice of the preferred bidder needed two years, from the "Prior Information Notice" (PIN) in July 2000 to the choice of Catalyst as preferred bidder in June 2002. The financial close was signed in December 2004. The main steps have been:

- Preliminary invitation to negotiate (PITN): from September to November 2000.
- Final invitation to negotiate (FITN) from April to November 2001.
- Best and final offer, from February to May 2002.

There were some interruptions betweens these steps due to the uncertainty in allocation of healthcares.

Compared with the French case studies, the decision making process has been also characterized by the importance of the question of risks sharing and risks management, going with the identification of services to externalize. In this case, the externalization was very large, including hard and soft facilities management, in logic of deconsolidation. If the whole process lays on many formal procedures, it supposes also a lot of negotiations between the public client, the PCTs and the local authorities, especially between the Outline Business Case and the Full Business case; the public client and the consortium. The client interface in this last aspect has been characterized by the mediation of a lot of private consultants, in order to speak a common language with the private consortium, but also in order to gather all the needed competences to discuss the project and select the preferred bidder according to different criteria. In the judgment to classify and select teams, those criteria have been the following ones: 35% for quality of Design and Build; 30% for services; 20% for legal set up; and 15% for financial.

The example of Case Study A shows that the co-production or co-design of the services are public-public (especially for the clinic services) as well as private –public (for the hard and soft FM), and follow different approaches according to each of them.

Client interface in "competitive dialogue": the change in the rules of game.
The increasing difficulties for the client to define the performances in terms of output and outcome – which is another characteristic of the services economy – militates for the client not only a global contract, but also a complete change in the rules of game of this procurement.

First of all, he or she has to justify the decision to use PPP or PFI as a contractual mode to realize the building and manage its facilities management, and for that he or she has to prove the different advantages brought by PPPs in comparison with the classical procurement. In France, those advantages concern mainly three questions: global cost or whole life cycle cost; risk sharing, results and achievements. In the UK, this previous justification is based on the public sector comparator and on the regime of best values. In fact, as many authors underline, this previous analyse hesitate between a real evaluation *ex ante* and a justification using fundamentally the same methods than the private ones coming from the experience of project financing; or still between a normative or a functional instrumentation to support the client decision.

Another change in the rules of game – which may be more relevant – concerns the client interface to propose a global project on the basis of targets to reach, specified by output and outcome. Through a case study in France, we could observe how Competitive Dialogue in France means changes as well in the design of assistance to the client (organizational and cognitive changes) as project design organization. The “Competitive Dialogue” is an original procedure from European Community Law (Directive 2004/18/EC). Its target is to optimize the public commissioning in the case of complex contracts. It introduces a long phase of discussion between the public client (and his or her representatives) and the different candidates in competition. The aim of this phase of discussions is to allow the elaboration of solutions in response to the expectations of the public client, expressed in terms of output and outcome, and also a benchmarking of the different solutions proposed by the candidates; one consequence of that is that the client’s brief henceforth is “blurred”. The schedule supposed to be clarified along a design process is characterized by three main stages:

- Principe Partenarial et Organisationnel (PPO) (*Organizational and partnership principle*);
- Proposition Prévisionnelle Sommaire (PPS) (*First projected proposal*);
- Offre Finale (OF) (*Final offer*).

The solution is supposed to be devised through a “dialogue” between the public client – with his or her assistants and different commissions – and the private consortium; at the same time, this “dialogue” has to be a competitive process that means that it has to stay quite confidential. Compared with the procedure of the “preferred bidder” the competitive dialogue is more strictly regulated and supervised. So, it needs new competencies on the public client’s side.

On the candidates’ side, it has also important impacts on the forms of cooperation inside the private partners’ teams. It was one of our conclusions of the case study in France (a hospital logistic platform in Case Study B). We had the opportunity to accompany one of the competitors’ teams during the competitive dialogue). The criteria to select the final bidder were a little different than in UK, with 15% for architectural and technical qualities, 25% for functional quality, 30% for financial quality and 30% for legal quality

We could observe different changes in comparison with a classical tender in construction market, especially these ones:

- The teams of the partner candidates are not compounded on the basis of a competitive selection but on the basis of a cooptation between the developer, the bank, the construction company, the architects and the facilities managers’ suppliers.
- Design of the global project is more collective and overall characterized by a cognitive synchronization, an iterative and loop approach, different situations of cooperation, from allocated design to co-design.
- With the multiplicity of targets in our case study – architectural quality, innovative design around the aim of high environmental quality, facilities quality for the users, increasing efficiency of industrial logistic process, optimizing the flux, but also increasing patrimonial value, economic competitiveness, financial profitability, mutualization of resources – we observed that the actors have to co-construct a common frame of reference.

> They spend a part of time to construct their internal agreements "around the table".

Therefore, we could say that this procedure – despite its limits – encourages an incremental and iterative process between the client and the provider, even if cultural gaps are strong between the public clients and private consortia. However, it also encourages, maybe more strongly, the internal cooperation inside the team. That is why we could argue that effectiveness tends to become more collective, and to depend on the links between the operations, between the individuals and the collective units along the line of clients specifications programming, design, Build and Operate, and often. In other words, we could speak of effectiveness linked with an "open cooperation" (Veltz 2005).

THE CRUCIAL ROLE OF CLIENT'S INTERFACE IN THE POST CONTRACTUAL PHASE: FROM CONTRACT TO CONVENTION

Whilst in most of the PPP contracts the stress is put on the construction risk, we would underline, based on our experience, the importance of service supply risk (mainly associated to the obligation of constant availability).

We could insist on two main points: the first one is that PPP with outsourcing of services means very often a re-engineering of services. This re-engineering takes different forms according that PPP is built in a greenfield or not. If it is applied to old buildings like for many hospitals in the UK, the re-engineering could be strong; the main dilemma in re-engineering process is once more, the multiplicity of targets and the different approaches that the private partners and the public client could have about effectiveness. For instance, it would be suicidal for the private supplier to think re-engineering only through the target of profitability, he or she has to take in to account many other criteria such as quality of services, efficiency of the team organization according to the performances indicators and contractual obligations, but also according to technological changes, new competencies required, training of employees and so on. A lot of facility managers discover the difficulty to assume both hard and soft facilities management properly in regard to their contractual commitments. The origins of these difficulties are numerous: for one part, they appear as a consequence of different rationalities between contractors and service suppliers and as the insufficient taking account of operating phase at the first stages of the project. But for another part, they come from the inexperience of private facility managers regarding the work in the public sector, in particular for all the works regarding the service to people. Most of the difficulties met are mainly relational difficulties, with the employees (overall in the first years before the agreement with the trade unions to transfer the employees of public sector to operate the maintenance and services), but also with the users (inexperience to manage the services in a public context).

The second point of our observation is that the post-contractual phase reveals the deep lack of contract fulfilment face to the nature of these difficulties. That means that the success of PPP in the post-contractual phase lay on the construction of convention, beyond the contract, between the public client and the private facility manager. Such a construction of conventions needs discussions, negotiations and common interpretation of the standards specification. So, a large communicational work is necessary to the success of the contract but we observed also that, very often, this agreement is easier if the facility managers or the SPV leader comes himself of herself from the public sector.

So one of the paradoxes of PPP could be that, launched to give to the public sector the benefits of the knowledge coming from private sector, their success would depend on the inverse process of giving the private sector the benefit of the knowledge of the public sector. The analysis of the professional trajectory and careers of PPP managers could be then decisive. But it is not exclusive of a discussion concerning the need of a crossed learning process between public and private partners.

CONCLUSION

In this paper, we argue that economics of services is very relevant to study the changes introduced by PPPs. To develop further this assumption, it is very important to get the appropriate *ex post* evaluation of the different PFI/PPP contracts. This kind of evaluation is more developed in UK than in France where the tradition of *ex post* evaluation is very weak. It has been developed especially around the notion of Value for Money (VFM). Different critics have been made to VFM. The VFM methodology has been questioned through different studies and researches concerning in particular PFI hospitals. A lot of them concluded either to the limits of VFM to evaluate really the user opinions about services and more generally all the soft project objectives, or the distortion that it introduces in the performance and measurement design (Edwards and Shaoul 2003; Edward *et al*. 2004; Pollock and Vickers 2002). Some efforts have been made afterwards to a comprehensive evaluation of outcomes compared with what was expected or to improve the procedures (for instance, HM Treasury 2003), but evaluation of such kind of contracts remains extraordinarily complex. More modestly, we have observed in most case studies analysed here and there, now or before, that the importance of co-production of services has been very often underestimated, especially, in the pre-contractual phase, with large consequences on the service operating . But it appears too that co-production of services tends to be better taken in account and it is seen, in any case, like a learning process.

A STUDY OF HOMEBUILDERS' COST MANAGEMENT ON SMALL-SCALE PROJECTS IN JAPAN

Kazuyoshi Endo[1] and Toru Onodera[2]

[1]Architecture, Kogakuin University, 1-24-2 Nishishinjuku, Shinjyuku, Tokyo 163-8677, Japan
[2]JMA Consultants Inc., Tokyo, Japan

The source of construction firm's business profit is nothing but the balance between his contract price and the amount of total cost he invests. The contents of such a cost management activity are the core of construction firm management. This study, with its focus on the small-scale works by homebuilders in Japan and by analysing their hitherto untouched internal documents, aims to clarify the actual cost behaviour and methods of their cost management activities. The results of this study indicate that the homebuilders' practical profit-making from miscellaneous expenses largely depends on the flexible use of permanently hired carpenters as well as the builder's effort to conduct effective procurement.

Keywords: homebuilders, cost management, working budget, managing construction firm.

THE BACKGROUND AND PURPOSE OF STUDY

Under any building contract system in Japan, the builder must provide the ordered building as specified in the design drawings with the contracted price. The contract price is determined by the result of not only the price negotiation with the owner but also of winning the competition with other builders. This means that such a result would not necessarily be what the builder had wished in the beginning.

It is evident that the source of builder's business profit is nothing but the balance between his contract price and the amount of total cost he invests. In order to create such a positive balance, the builder rearranges the project's budget within the amount of the proposed contract price and executes a cost management activity.

The contents of such a cost management activity is nothing but the core of construction firm management, under which the builder does not need to disclose specific processes and results of individual projects, and the owner principally cannot request such disclosure by the builder in Japanese contract conditions. Therefore, the accumulation of the builder's work experience is stored inside his firm, and there have been little efforts made toward objectively examining what has been written and what has been done.

This study, with its focus on small-scale works by homebuilders and by analysing their hitherto untouched internal data, aims at clarifying the actual facts and methods of their cost management activities to compile a basic resource of related information that would facilitate better understanding of homebuilders' cost behaviour and management of construction firms' business.

THE OBJECTIVES OF THE STUDY AND METHODS USED

This study analysed traditional wooden detached houses, which held about 25% of the Japanese annual housing construction number of houses. The houses analysed in this paper are still the main system of housing in Japan. The scales of the homebuilder who supplied it were various, but intended for comparatively small homebuilders in this study.

This study took up, for comparative purposes, three typical homebuilders as locally accessible construction firms, as shown in Table 1. In selecting the three firms, consideration was extended to their in-company status of developing and storing related data and documents. Here is an outline description of the three homebuilders:

- Firm A: a local firm specializing in custom-made wooden houses. Fabrication of framework materials is mostly done in-house, with some partly depending on procurement of pre-cut materials. As they largely depend on manual carpentry, the main workforce consists of regularly hired carpenters.
- Firm B: a firm specializing in house and store interior work. It is also experienced in serving as a subcontractor for certain general constructors and in manufacturing furniture. It operates its own fabrication unit, where carpenters are hired as regular personnel, who are multi-skilled in line with the firm’s main business line.
- Firm C: another local firm specializing in custom-made wooden houses. It has also participated in projects of building condominiums and hospitals. With no in-house fabrication facility, subcontractors who work almost on a full-time basis for this firm provide part of its carpentry work. Major materials are fabricated by hand. In addition, to maintain an antenna-shop, the firm displays a “model house” at a major model-home park. This strategy leads to a relatively higher probability for the firm to face some major housing makers as well as other rival builders.

The authors have been able to obtain needed cost management data in a total of 27 itemized data from the above three homebuilders. With each of the selected 27 projects, the collected data such as detailed cost estimates presented to the client, working budget documents, account books for specific projects, and cost estimates submitted by the vendors were entered into spreadsheets so as to better analyse the actual composition of and changing trends in contract costs and prices.

Table 1: Homebuilders selected for the study

Firm	Location	Amount of annual sales (million yen)	Annual no. of new homes built	No. of all workers (regular staff incl.)	Major line of business
A	Tokyo Metropolis Suburban	220	7	12(8)	Wooden house, custom-built
B	Tohoku pref. govt. city	150	1	9(6)	Refurbishment
C	Shikoku pref. govt. city	800	20	40(12)	Wooden house, custom-built

COST DATA RELATING TO SMALL-SCALE CONSTRUCTION PROJECTS STRUCTURE OF THE DOCUMENT

Here are descriptions of each of the four cost-related documents.

Detailed cost estimates presented to the client
According to the commonly used contract clause, the contracted builder is to submit detailed cost estimates as a price list for approval by the client. Actually, however, the commonly used practice is that such a breakdown is to be shown by the builder even during the pre-contact negotiations as evidence of his contract pricing intention. Thus, every detail of the cost information as shown in this paper should represent the breakdown, which is finally attached to the contract resulting from pre-contract negotiations.

Working budget document
This is an in-house document for each homebuilder, prepared for securing the eventual profit from the project. There are different motives for developing such budget documents, as shown below:

- The budget document is prepared prior to the cost estimates being presented to the client and reflects the builder's concept of cost management and/or some technical characteristics of the project itself.
- The cost estimates for the client and the working budget document are consolidated by using suitable software etc.
- The working budget document is prepared independently from the cost estimates for the client.

Account book for specific project
This document represents the aggregate on the part of a homebuilder of the actual generated labour costs, materials costs and payments to related suppliers.

It is to be used for managing ongoing costs and for verifying the generated project costs.

Cost estimates collected from vendors
This is a batch of cost estimates presented by the suppliers and/or vendors on which the date of estimation made and the time limit of validity must be shown.

The builders will select qualified vendors by checking against this document and may refer to or quote from the document when they prepare detailed cost estimates for the client. Thus, the date of preparation of this document may vary widely from a date prior to that of preparing such documents as detailed cost estimates for the client and working budget statements to a later date after starting the project work.

FACTUAL ASPECTS OF COST ESTIMATION ON SMALL-SCALE BUILDING PROJECTS

Ratios of miscellaneous expenses at each phase of the firm's cost management
Our hearings made us believe that smaller homebuilders like the three firms would have to set an optimum ratio of miscellaneous expenses including profit at a level of 20–30%.

Percentage figures in Table 2 represent ratios of miscellaneous expenses for each of the detailed cost estimates, working budget statements and account books for specific projects, respectively.

While the average ratio of miscellaneous expenses throughout the 27 projects by the selected three homebuilders is 7.2%, it can be observed from the table that 17.5% is secured for the working budget and 22.4% for the actual payment in the account book. Through the listening sessions, it has become clear that negotiating clients may pick up miscellaneous expenses as a target for a discount subject, and that figures in terms of miscellaneous expenses would serve as a disadvantage in competing with other contractors. Because of this situation, the usual practice to avoid such disadvantages is for the contractor not to specify the real amount of essential miscellaneous expenses on their proposals in an effort to “downsize” this cost account.

Table 2: Percentage variation of the ratio of miscellaneous expenses at each phase of the contract activities

Firm	Detail cost estimates presented to the client				Working budget statements				Account book for specific project			
	Simple average %	Max. value %	Min. value %	Standard deviation %	Simple average %	Max. Value %	Min. value %	Standard deviation %	Simple average %	Max. value %	Min. value %	Standard deviation %
A	9.4	14.7	5.4	2.7	21.7	28.2	9.5	6.1	22.5	27.7	19.1	3.5
B	7.4	14.3	0.0	4.1				*	24.5	39.9	5.0	9.1
C	1.8	2.1	1.5	0.2	9.0	18.4	-4.6	9.9	13.5	18.7	10.1	3.5
All	7.2	14.7	0.0	-	17.5	28.2	-4.6	-	22.4	39.9	5.0	-

*Within Firm B, no records as working budget statements are filed because the field foreman undertakes the planning of the working budget by himself

The generality of the data in Table 2, however, requires special attention because the three homebuilders selected for this study do well in preparing the related costing data as well as in maintaining good filing of such data. In addition, it seems that the density of their cost management activities is substantial.

PROJECT BY PROJECT ANALYSIS OF THE STUDY DATA

This section is a report of the analysis of one project each from the three selected homebuilders, from which the characteristics of its cost management programme seemed to be relatively clear. In this article, we analyse it from the limitation of pages about three typical projects.

Firstly, some explanations about the terms used in Table 3 and elsewhere: [Plus-minus ratio] means increase/decrease of monetary value on each line item, and [Shared ratio by type of work] is the shared ratio by each account against the total figures. It should be noted that collective calculation was made on such “combined” works as undertaken by the same suppliers or vendors.

Result of analysis of Project A6 (Firm A)

Project A6 built by Firm A is a conventional detached house with a design build contract. Cost estimates presented to the client were prepared in June 2004. Its contract price was 20-million yen or unit price per square metre was 214,000 yen (including consumer tax). This firm has rich experiences in building this type of houses. The contract price includes design fee, which represents 3.0% of the total price.

The detailed cost estimates presented to the client were prepared based on the detailed calculation of cost data. Cost accounts were so arranged after what the respective suppliers had classified in their quotations. The working budget document largely follows the same pattern as in the respective cost estimate documents in the detailed cost estimates, working budget statements and account books for specific projects.

Table 3: A comparative analysis of ratios distributed according to subcontracted works for detailed cost estimates, working budget statements and account books for specific projects (for Project A6)

Type of subcontracted work	Cost breakdown in the					
	Detailed cost estimates (Col. 1)		Working budget (Col. 2)		Account books for specific projects (Col. 3)	
	Yen	%	Yen	%	Yen	%
Demolition work	1,085,763	5.4	1,018,584	5.1	1,016,400	5.1
Temporary set-up work	1,125,993	5.6	428,892	2.1	336,554	1.7

Miscellaneous expense (including profit)	3,518,020	211.3	-	236,830	4.6	3,754,850	225.5

Table 3 represents detailed cost-estimating figures as spread in the detailed cost estimates, working budget statements and account books for specific projects, respectively. Analysis by each of these phases is discussed below.

Comparison between the cost estimates presented to the client and the working budget statements
The ratio of the miscellaneous expenses in the detailed cost estimates does not exceed 8.3%. Among all elements, the largest ratio is 30.2% for carpentry, half of which is 15.6% for cost of materials.

All cost accounts on the working budget documents are shown with lower listed values. The ratios of such reduction are particularly larger in the temporary work accounts. This may be due to such builders' on-the-spot ideas as (1) plans to have the lease costs (as included in the detailed cost estimates for the clients) to be replaced by their in-house inventory stock, and (2) use of regular carpenter-employees, etc. Most other cost accounts are seen to be listed as somewhere over 10% discounts.

According to the project-level breakdown of cost estimates on Table 3, ratios for carpentry (with a substantial share in the contract price) are even higher than the temporary work ratio (particularly evident in the material cost accounts with 16.0%). These increased ratios resulted in the remarkable jump in the miscellaneous expenses boxes on Table 3 from 8.3% on column 1 to 25.9% on column 2.

Comparison between the working budget statements and the account books for specific projects
The next analysis was to compare the data recorded on the working budget against the actual paid amounts in the account books for specific projects. It can be noted that the data for carpentry and some others on fieldwork ledger (Column 4) resulted in larger figures than working budget (Column 3). The listening sessions in this regard clarified some reasons such as: (1) overlooking of data; (2) incorrect forecasting; and (3) debit/credit adjustments with concerned suppliers, etc. From a wider perspective, however, amount of actual spending is seen staying within the limit of the working budget, and such excess payments on the individual work accounts are embraced in the total picture. Thus, the high ratio of the miscellaneous expenses at 27.1% (even compared to Column 3) can stay on Column 4.

Comparison between the detailed cost estimates and the fieldwork ledger
Here, reduction in ratios is remarkable in both the temporary work and design fee. While the reason for such reduction in the temporary work is pointed out above, the reduced ratio for the design fee is due to the builder himself who could replace the design work and not pay the intended design agent since he is a Certified Architect under the Japanese law. The ratios of tile work and the furniture work indicate that the actual payments exceeded the initial cost estimates. Thus, the necessary level of the miscellaneous expenses ratio is secured.

Result of analysis of Project B2 (Firm B)
Project B2 was a house-refurbishment project under Firm B's Design-Build with a total contract price at 4,516,350 yen. Firm B, too, has rich experiences in this type of projects. Usually, the refurbishment project is liable to the existing conditions of the contracted house, and therefore many cases have had to conclude the contract even before they can confirm the scope of contract work and other details.

Firm B reflected considerable differences between the figures in the detailed cost estimates and the data on the working ledgers. Nevertheless, it is usual that the initial contract price tends to remain unchanged unless otherwise necessitated for greater reasons. This means that cost management of these refurbishment projects has to face such restraining situations.

Comparative analysis for Firm B was made only between the Cost estimates for the client and the working ledger because no other formal documents are filed as the field workers executed the working budget planning on the spot.

Comparison between the cost estimates presented to the client and the working budget statements
Table 4 shows the results of comparing the detailed cost estimates with the actual paid figures of the account books for specific projects. As for the actual payments, the majority of project types turned out to be widely reduced, and the carpentry costs including carpenters' labour costs were found to have increased. This was the result of the expanded use of the permanently employed carpenters to cover other types of work wherever possible.

Table 4: Comparison of the detailed cost estimates and the account books for specific projects (for B2 project)

Type of subcontracted work	Cost breakdown in the					
	Detail cost estimates for the client		Working budget		Account book for specific project	
	Yen	%	Yen	%	Yen	+/- %
Temporary set-up work	262,605	5.8	0	0.0	-262,605	-100.0
Demolition work	189,000	4.2	0	0.0	-189,000	-100.0
Carpentry	2,695,159	59.7	2,970,634	65.8	275,475	10.2
Steel doors and windows installations						
Roofing work	301,980	6.7	262,500	5.8	-39,480	-13.1
Wooden doors and windows installations	64,050	1.4	33,180	0.7	-30,870	-48.2
Painting work	119,910	2.7	21,000	0.5	-98,910	-82.5
Interior work	189,735	4.2	189,735	4.2	0	0.0
Electrical installations	153,300	3.4	0	0.0	-153,300	-100.0
Design fee	157,500	3.5	0	0.0	-157,500	-100.0
Special discount	-36,889	-0.8	0	0.0	36,889	-
Miscellaneous expenses (including profit)	420,000	9.3	1,039,301	23.0	619,301	147.5
Total	4,516,350	100.0	4,516,350	100.0		

Particularly, a 100% reduction is seen in the temporary set-up work, demolition work, electric installations and design fee. There are some varied reasons for this: cost of temporary set-up work and demolition work were either undertaken by the firm's permanent-hire carpenters or were included in other types of work undertaken by the subcontractors, thus not requiring any payments for that matter. While it was not made clear why the cost of electrical installation work was reduced, it could have resulted from some account-offsetting transactions dealing with some past debit/credit records. Then, the design fee was absorbed into miscellaneous expenses because the work itself was done within Firm B. Thus, the overall cost reduction ratio went up from 9.3% for the detailed cost estimates to 23.0% over for the account books for specific projects.

Result of analysis of Project C3 (Firm C)
This is a private house as Design-Built by Firm C in 2004. A conventional wood-house building method was used. They adopted the standard specification for its model house. The contract price was 25-million yen at a square metre unit price of 170,000 yen. They offered 10.4% discount in the detailed cost estimates.

Discount	2,600,218	-	-	-	2,600,218	-
Miscellaneous expenses (including profit)	2,845,200	599.5	333,641	10.1	3,178,841	669.8

Comparison between the cost estimates and the working budget statements
The ratio of the miscellaneous expenses in the detailed cost estimates is notably low at 1.9%, while the relative percentage of carpentry compared with the case of Project A6 is pretty high at 48.2%.

Comparison of the detailed cost estimates with the working budget shows figures that are widely reduced throughout all types except the painting work. In terms of money size, a reduction of over 1-million yen is seen for carpentry and wooden doors and windows installations. Reduction ratios of 30% and over are also seen in the temporary set-up work, plaster work, interior work, and plumbing work.

Thus, the above situation led to a large 13.3% increase in the ratio of the miscellaneous expenses because of the reduced price in the working budget exceeding the amount of price discount on the detailed cost estimates document.

Comparison between the detailed cost estimates and the account books for specific projects
As shown in Column 6 of Table 5, the only increase in cost was some 1,260,000 yen on the painting work, miscellaneous work and the design fee, and all other types of work realized more than a 10% reduction, particularly with larger percentages for the temporary set-up work (75.6%), water-proofing work (54.0%), masonry (55.2%) and wooden doors and windows installations (82.7%).

Summary of the project analysis
The analysis in this study confirms the fact that the usual practice on the part of these homebuilders is to intentionally split what is supposed to be handled as miscellaneous expenses into other types of work so that the miscellaneous expenses on record would appear to be low on the detailed cost estimates.

In the process of developing the budget, homebuilders have to be sure at first of a required amount of miscellaneous expenses, then have the budget allotted to each and all types of work, so as to be able to ensure the actual payments don't exceed the set limitations. It should be noted that in this process the extent of builder's compliance to the figures in the detailed cost estimates would depend on how well the entire project is being managed. Thus, there would be some discontinuing portions to be found between the detailed cost estimates data and the data of the working budget and other ensuing phases.

One of the factors that would enable the builders to realize the above processes is the builder's effort to come up with some "break-through contrivances" within the scope of his contract. For instance, there were cases where what would have been given to subcontractors on minor portions of small-scale projects were actually taken care of by in-house carpenters. This should enable the homebuilder to (1) save some expenses meant for subcontractors and (2) enhance the project's productivity through the use of in-house carpenters who would otherwise have been left on an idle-time situation. This is an example of homebuilders' planning flexibility, realized by permanently employing their own carpenters.

The second factor seems to be that many detailed cost documents directly use the listed prices or catalogue prices of necessary parts, equipment and supplies to be procured, thus creating balances from the actual procurement payments based on the actual selling prices. This status is apparent in handling the miscellaneous expenses on the part of homebuilders. Here again, the result of such saving efforts could depend on how well the homebuilders would pursue their own procurement actions and how good their "break-through contrivances" were.

However, if such "in-house contrivances" on the part of homebuilders can be empirically foreseen, we should then be able to point out some "fictional characteristics" in their detailed cost estimation documents. Thus, the owners may embrace some feeling of opacity in reviewing construction cost data as presented to them in our observations.

GENERAL CONCLUSION OF THE STUDY

In this paper, the actual cost data on the part of private homebuilders was analysed and the hitherto unknown situation surrounding their cost management methodologies was disclosed.

We can now say that homebuilders' cost management processes are rather amorphous (not uniform) and that considerable variances are seen depending on individual company practices and policies, specific conditions existing for individual projects and works. It was confirmed from not only the analysis of the document but also interviews to the managers. Much of their management was based on experience.

The results of this study, however, indicate that the homebuilders' practical profit-making from miscellaneous expenses largely depends on the flexible use of permanently hired carpenters as well as the builder's effort to conduct effective procurement. With the actual situation as observed above, it is apparent that homebuilders, in dealing with miscellaneous expenses, are now facing some difficulties or issues.

It is becoming difficult for homebuilders to keep hiring in-house carpenters due to several factors, such as wider use of pre-cut materials in the framework process, increased use of metal hardware, fitting works and interior works (which were usually taken care of by carpenters) being replaced with the purchased parts and other materials, etc. – all of which are shrinking the carpenters' sphere of work. Also making their status more difficult is the imminent possibility of the aging of skilled workers and of their mass retirement. Although it was not observed in this study, we know that some comparatively large-scale homebuilders keep overheads low by sending carpenter construction out to the subcontractor cheaply.

As to the need for workers' contrivance in the procurement process, its profit-squeezing flexibility is being pressed under such conditions as increased versatility of material distribution channels, price information is becoming more easily obtainable on the part of owners, etc.

Based on the result of the study, the authors intend to extend the study on finding a new style of the small-scale production in Japanese housing market, and also examining the possibility of a new business model.

USING KNOWLEDGE OF THE BUSINESS CYCLE TO FORECAST BUILDING COSTS

Johan Snyman[1]

Medium-term Forecasting Associates, Building Economists, P O Box 7119, Stellenbosch, 7599, South Africa

Quantity surveyors in South Africa find forecasts of building costs useful when estimating. Builders' input costs comprise labour, materials, plant and fuel. Tender prices include these cost items plus the profit margins of building contractors. It is known that the profit margins of building contractors fluctuate over the course of the business cycle. This is why it is important, when forecasting building costs, to first determine the expected course of the business cycle. Experience shows that building contractors widen their profit margins in the upswing phases of the business cycle and shrink them during building recessions. This is one of the main reasons why tender prices fluctuate. Several other factors influence tender prices, *inter alia,* changes in input costs, productivity changes due to bottlenecks in the supplies of labour and materials, fluctuations in the degree of competition in tendering and the availability of work on hand. Knowledge of the cyclical features and trends in these cyclical economic indicators are useful when making informed forecasts of building costs, especially when they are integrated in a structured way.

Keywords: building cost, estimating, forecasting, price, profitability.

INTRODUCTION

Different people understand different things about building costs. This is due partly to the fact that all humans interpret what they see or hear in terms of their own experience and their own interests. A police officer on the beat is perceived as a threat by a burglar, but as an angel by the person being hotly pursued by muggers. It is important, therefore, to explain exactly what building costs mean in the context of this paper. Lay people often use the term building costs in a generic sense. Sometimes they speak of it as being building contractors' input costs. Other times they mean tender prices, i.e. builders' output prices. In this paper, a distinction is made between input costs and tender prices. Builders' input costs comprise labour, materials, plant and fuel. Tender prices include these cost items plus the profit margins of building contractors. It is known that profit margins of contractors fluctuate over the course of the business cycle. Other factors contributing to fluctuating tender prices include, *inter alia*, movements in wage rates and building materials prices, bottlenecks in the supplies of labour and materials, together with fluctuations in the productivity of labour and management. It is shown that fluctuations in the business cycle contribute to fluctuations in builders' input costs and tender prices. This interaction is at the heart of the dynamics of price formation in the South African building industry. The objective of this research is to promote a better understanding of these concepts and to improve forecasting in this particular field of economics.

THE BUSINESS CYCLE

The business cycle has four distinct phases: the upswing or recovery phase, the peak, the downswing phase and the trough. Business cycles are said to be recurring, but not periodic (i.e. not perfectly regular). A distinction is often made between classical business cycles and growth cycles. When gross domestic product declines in *absolute terms* from peak to trough, it is known as a classical cycle. Growth cycles are identified by variations in the *rate of growth* of gross domestic product. As economies developed rather rapidly in the post-war period, growth cycles predominated. The duration of business cycles in South Africa normally vary from three to five years, measured from peak to peak or from trough to trough (SARB 2006:S-153). Sometimes, however, they can last for most of a decade, as was the case in the USA during the 1990s. In the charts to follow, the shaded areas represent the upswing phases of the business cycle in the South African economy, as dated by the SA Reserve Bank. These shaded areas form the backdrop to movements in certain cyclical indicators described in greater detail below.

BUILDING COSTS AND FORECASTING IN GENERAL

Quantity surveyors find building cost forecasts useful when estimating. From the large body of research on building costs and forecasting, undertaken during the past four decades, several important studies have been selected. Though this list does not purport to be comprehensive, these studies indicate to some extent the progressive development of the field. Kilian (1972) showed that shortages of labour and materials created serious bottlenecks and contributed to rising building costs. Swart (1974) studied price formation in the South African housing industry. Bowen (1980) investigated the feasibility of producing an econometric cost model for framed structures by means of regression analysis.

Tysoe (1981) analysed various construction cost and price indices in use in the UK and how these could be applied to enhance cash flow projections. Flanagan and Norman (1983) investigated the accuracy and monitoring of quantity surveyors' price forecasting for building work. They developed a simple feedback mechanism to improve forecasting performance. Bowen and Edwards (1985) assessed the state of cost modelling and price forecasting prevailing in the South African building industry and concluded that expert systems, a form of artificial intelligence, held exciting possibilities for the future.

Taylor and Bowen (1987) examined techniques and applications related to the forecasting of building price levels. They found that of the more simplistic methods, the classical decomposition (time-series) method permits the introduction of judgement, but fails to model the changing process adequately. The Box-Jenkins modelling system yielded superior results in their study. Snyman (1989a, 1989b) described the various phases of the business cycle and, using time series data, explained in a pragmatic way how the business cycle influences building costs.

Fellows (1991) evaluated the accuracy of building cost and tender price indices and demonstrated that stochastic time series forecasting is a useful approach. Hindle (1991, 1993) focused on fluctuations in the demand for construction caused by business cycles, and on pricing policies and tendering strategies employed by building contractors. Blair *et al*. (1993) analysed the forecasting problem in terms of time series methods and noted that construction cost escalation remains a risk factor to be shared by the contractor and the owner. Bowen (1993) undertook a communication-based examination of price modelling and price forecasting in the design phase of the traditional building procurement process.

To improve forecasting of building demand levels and building costs, Snyman (1994) developed leading indicators for the South African building industry. Akintoye and Skitmore (1994) found that construction price appeared to be an important elastic influence in housing construction, but not so in the case of commercial and industrial construction. Ming *et al*. (1996) investigated how an Australian building firm's profits changed as market conditions changed. Akintoye *et al*. (1998) examined macroeconomic leading indicators of UK construction contract prices. They found that the unemployment level, construction output, industrial production and the ratio of price to cost indices in manufacturing are consistent leading indicators of construction prices. The approach put forward in the current paper is based on the understanding that fluctuations in the business cycle cause movements in builders' input costs and in tender prices. It is based on a judgemental forecasting approach in which knowledge of the cyclical features of key building cost indicators is paramount.

BUILDING COST INDICATORS IN USE IN SOUTH AFRICA

There are two building cost indicators commonly used in South Africa. The first of these is a composite index of building contractors' input costs: labour, materials, plant and fuel. It is a weighted index of the prices of units of inputs and does not make any allowance for changes in builders' profit margins or productivity. It is colloquially known as the "Haylett Formula" and forms the basis of the Contract Price Adjustment Provisions used in the South African building industry (readers from the UK will recognize its similarity to a "Baxter Formula"). This system of indexation relies on a number of Work Groups that relate to various trades in the building industry. These indices are published by Statistics South Africa, Pretoria.

The second index commonly used is the BER Building Cost Index, compiled by the Bureau for Economic Research at Stellenbosch University. This quarterly index is based on an analysis of accepted tenders. Twenty-two representative items, common to all buildings, are extracted from accepted bills of quantities. Current rates are then compared to base rates to yield a useful index of trends in tender prices. This tender price index therefore measures the market prices of building projects because it includes the profit margins of building contractors. Indeed, this special feature distinguishes it from the Haylett indices described above. As an aside, it should be mentioned that the BER Building Cost Index is somewhat of a misnomer in that it measures builders' output prices, rather than their input costs. One can see that a particular builder's output price is a client's input cost, thus making the name more appropriate. The BER refers to it as a building cost index for historical reasons, for marketing purposes, and for representing the cost to clients. Figure 1 depicts these two key building cost indicators during the period 1975 to 2006.

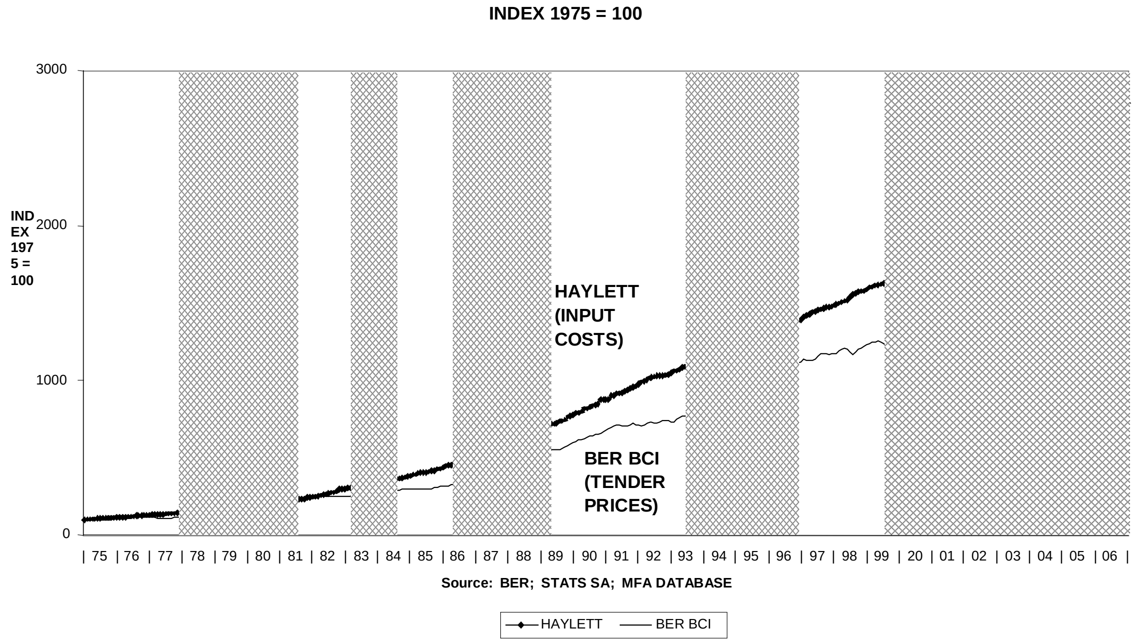

Figure 1: Haylett and BER building cost index comparison

FORECASTING BUILDING COSTS

In subsequent paragraphs, various cost factors will be considered. To forecast the future course of labour costs, one requires knowledge of labour rates, the bargaining power of labour unions, general inflationary trends, as well as the availability of skilled and unskilled labour. Similarly, to forecast the expected course of building materials prices, one needs to acquire knowledge of the degree of competition amongst building materials manufactures and merchants, their pricing policies and the way that increases in energy and transport costs affect them. Thus, the forecaster needs a profound knowledge of labour and product markets. Figure 2 depicts the cyclical indicators representing the availability of labour and materials, as derived from qualitative business surveys compiled by the Bureau for Economic Research at Stellenbosch University. Respondents are asked whether they experience shortages in the supply of labour and materials. Observe that the percentage of respondents reporting bottlenecks increases during growth phases in the economy and that supply conditions improve during recessions.

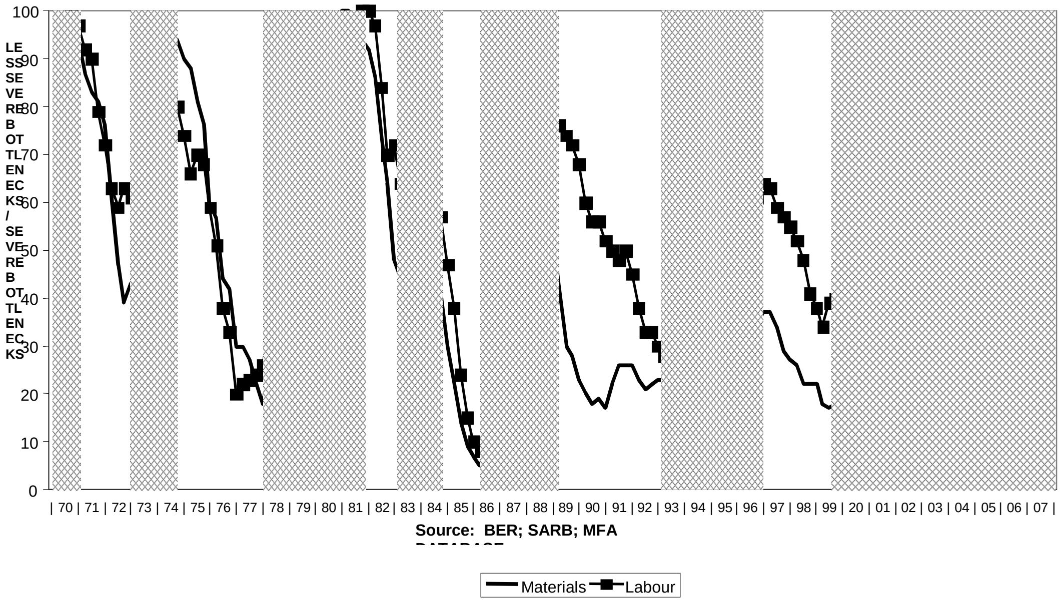

Figure 2: Labour and materials shortages

South Africa is a developing economy and many plant items are imported. In determining the future course of local plant and equipment prices, the single most important factor to consider is the exchange rate of the rand, South Africa's currency unit. The rand exchange rate has been volatile during recent years. This is the case because of fluctuations in trade and capital flows, leading to a heavily traded currency that is also subject to speculative pressures. Even though buildings are not exported, the South African building industry cannot escape the destabilizing effects of fluctuations in the rand exchange rate. Given a weaker rand, the suppliers of construction plant and equipment items have little choice but to raise local selling prices. When the rand strengthens against a basket of currencies, they are in a position to curtail local price adjustments (Kilian and Snyman 1981; Snyman 2006). This well-established pattern is shown in Figure 3 that depicts the annual percentage change in the index of construction plant, as compiled by Statistics SA. Also shown is the annual percentage change in the real effective rand exchange rate. This is a trade-weighted index, adjusted for inflation, as compiled by the SA Reserve Bank. The movements in plant prices are read off the left-hand scale. Please note that for the sake of easy comparison, the rand exchange rate fluctuations have been *inverted* and are to be read off the right-hand scale.

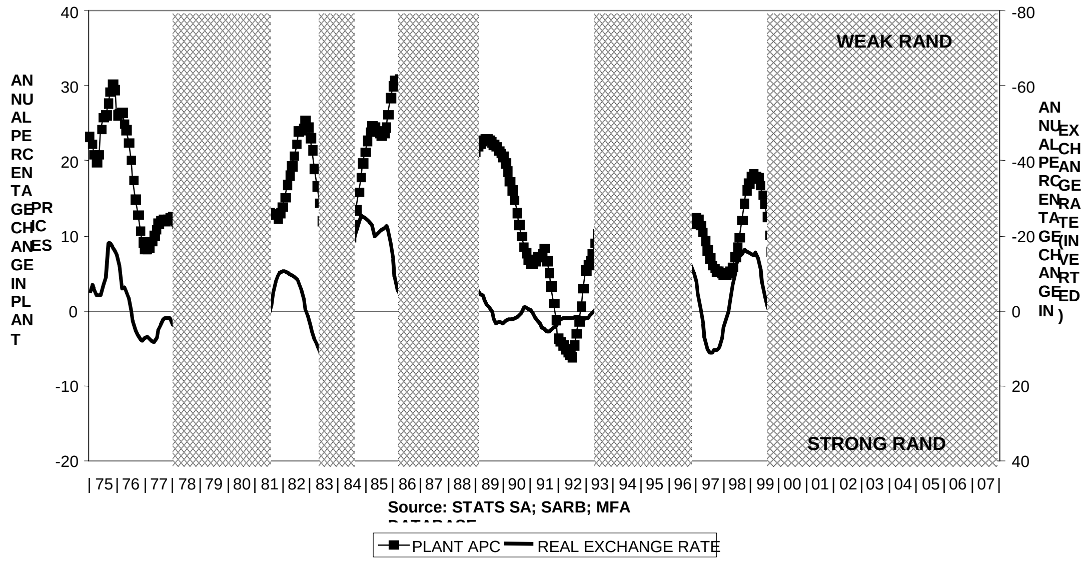

Figure 3: Movements in plant prices and the real effective rand exchange rate

Observe that the rand was weak in 1975, 1981/82, 1984/85, 1988/89, 1996, 1998/99 and 2000/01. Generally speaking, these were years of economic recession. During these periods, plant prices rose rapidly – in certain cases (1975, 1985 and 2001/02), by as much as 30% per annum. It is also evident in the chart that in two instances the annual rate of change of plant prices became negative. Thus, in 1992 plant prices were lower than in 1991. In similar vein, plant prices in 2003/04 were lower in absolute terms than in 2002. Both these events occurred in conjunction with a stronger currency after a period of rand weakness. Thus, it can be expected that price formation in the market for construction plant and equipment will remain subject to the vagaries of the rand exchange rate in coming years. This knowledge assists one in forecasting trends in construction plant prices.

Next, the focus shifts to the BER Building Cost Index. This index has been the subject of periodic scrutiny to ascertain its validity (Brook 1974; Kilian 1980; Snyman 1980; Brook 1985; Segalla 1991, Marx 2005). This tender price index has a database starting in 1962 with a rather interesting cyclical history presented in Figure 4 in the form of annual percentage changes.

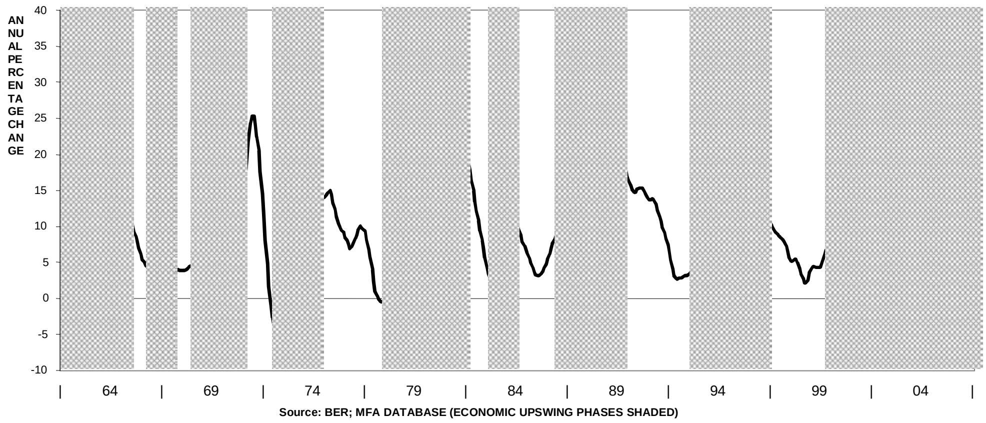

Figure 4: BER building cost index annual percentage change 1962–2006

The cyclical features evident in Figure 4 can be summarized briefly as follows.

- During the upswing phase of the business cycle (i.e. the shaded area), the index of tender prices rises more rapidly.
- During the downswing phase of the business cycle, the index rises less rapidly.
- During two severe recessions (1971/72; 1976/77), the index actually becomes negative on a year-on-year basis.
- The index usually rises more rapidly in the long upswing phases than during the shorter growth phases.
- The annual percentage change usually peaks towards the end of a growth phase in the business cycle.
- In recent times, from about 2000 onwards, the index has reflected a rather unstable rate of change. This can be ascribed, in part, to instability of the rand exchange rate, as explained above. This upswing phase is the longest on record and differs from previous ones in that it is characterized by an inflation-targeting monetary policy and responsible fiscal policy (small budget deficits).

Having considered the cyclical behaviour of tender prices, the following list summarizes the causal factors. During an upswing phase in the business cycle, building demand is usually buoyant, with several consequences (Hillebrandt 1974; Bon 1989; Snyman 1989b), given below.

- Labour rates, building materials and plant prices tend to accelerate.
- Discounts on building materials prices, offered by building suppliers to contractors, are reduced.
- Due to the perennial shortage of skilled labour, the flow of work is interrupted, bottlenecks are experienced on site, labour piracy is commonplace and management is over-extended. Consequently, labour productivity declines, with a concomitant rise in actual labour costs (as distinct from wages).
- As building contractors are forced to meet completion dates, they are obliged to employ more people. However, in the short term the supply of labour is at a premium because training programmes are abandoned in recessionary periods. Many unskilled workers are now pressed into skilled jobs. The inevitable result is that the average level of skills and the quality of building work both tend to decline.
- Given the oligopolistic nature of the market for building materials in South Africa, as well as the long lead times for new investment to create additional production capacity, acute shortages of building materials develop in the short term.
- Given the abundance of new building work, contractors avail themselves of the opportunity to widen their profit margins to recoup losses and/or to maximize current profits.
- The operational and financial risks facing building contractors (Hillebrandt 1974: 162–6) tend to increase because of prevailing bottlenecks and the need

for additional capital for expansion. Actual profits are rarely equal to planned profits because of extended project durations and cost overruns.

- Probably the single most important factor influencing the course of tender prices is the degree of competition in tendering, described in greater detail below.

All of these cyclical factors combine to propel tender prices sharply upward during a growth phase of the business cycle. Naturally, during a building recession, these factors work in the opposite direction to contain excessive tender price increases. Competition in tendering, operating as a powerful economic force, requires special attention in this regard. Figure 5 depicts the degree of competition in tendering, as derived from business surveys conducted by the Bureau for Economic Research at Stellenbosch University. Building contractors are asked to say whether they experience competition in tendering as "keener", "the same" or "less keen". The indicator in Figure 5 represents the perceptions of respondents who experienced keener competition. Observe that the degree of competition in tendering eases during an upswing phase of the business cycle. In contrast, when building work becomes scarce during severe recessions in the building industry, competition intensifies.

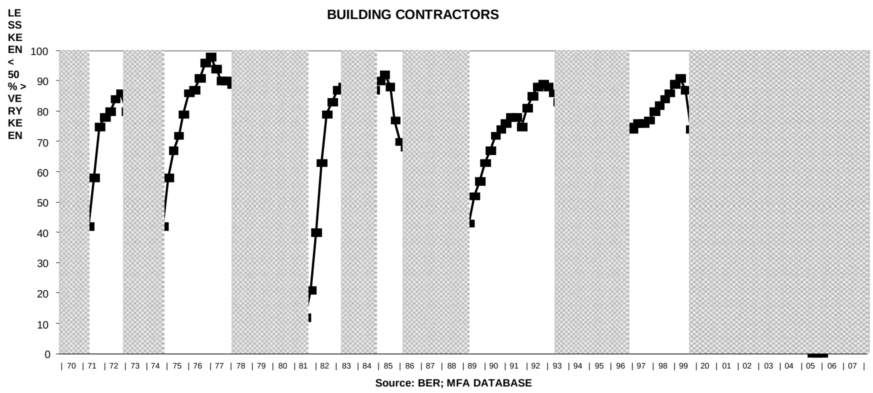

Figure 5: The degree of competition in tendering

When this indicator is inverted, and is compared to movements in tender prices on the same time scale, an inverse relationship becomes evident. Figure 6 depicts the annual percentage change in tender prices (similar to Figure 4) with the cyclical indicator of the degree of competition in tendering superimposed on it. The movements in tender prices are read off the left-hand scale with competition being read off the inverted right-hand scale. This is done to highlight the coincidence of turning points in these two cyclical indicators. Despite their diverse nature, the picture that emerges is one of fairly regular cyclical behaviour. When competition in tendering eases, tender prices rise more rapidly; when competition intensifies, tender prices rise less rapidly. This knowledge assists one in forecasting the course of tender prices.

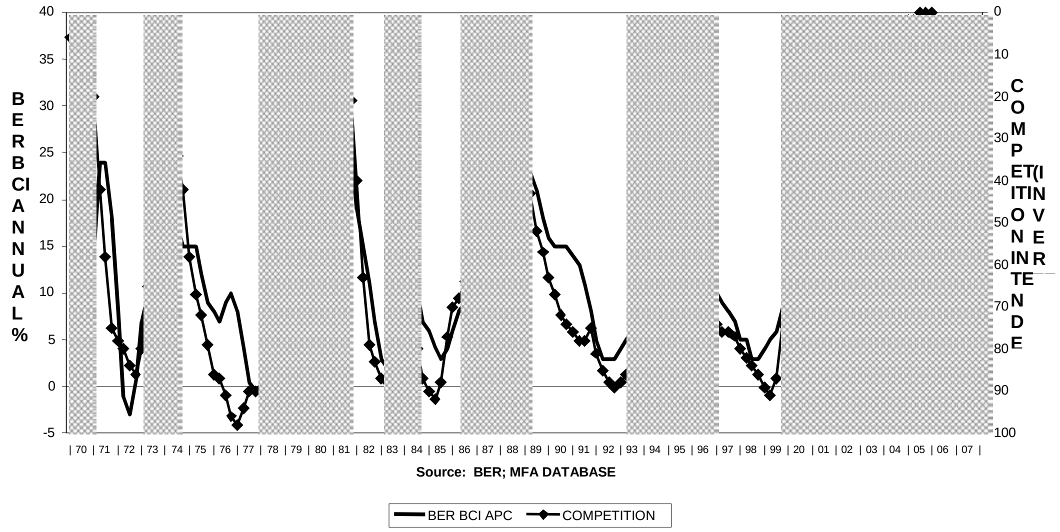

Figure 6: Comparison BER BCI annual percentage change and competition in tendering

It has been emphasized that fluctuations in tender prices are strongly influenced by fluctuations in the degree of competition in tendering. Competition in tendering affects profit margins in a direct manner: the less work available to tender on, the keener the competition for any particular project. Conversely, the more work available, the less keen the competition. It has been shown that the business cycle influences the degree of competition in tendering. It follows logically that the business cycle also influences the profitability of building contractors.

To gauge the effect of the business cycle on profitability and productivity trends, a cyclical indicator is compiled by comparing movements in tender prices with input costs. The BER Building Cost Index is an analysis of accepted tenders and includes profits of building contractors. The Haylett Index is a composite index of builders' input costs. It does not include profits. By dividing the tender price index (inclusive of profits) by the Haylett Index (exclusive of profits), one can derive the trend in the profitability and productivity of builders.

A number of features are noteworthy. First, observe that the derived indicator has dropped over the long term (1970–2000). This can be ascribed to long-run productivity improvements. Second, it is evident that profitability generally improves during a growth phase in the business cycle. It deteriorates during a recessionary period. These short-run fluctuations are due to changes in profit margins of builders who are faced with keener competition in recessionary phases of the business cycle. A similar trend is evident in census data relating to profitability in the South African construction industry and a comparison with the market conditions index derived above presents an opportunity for future research.

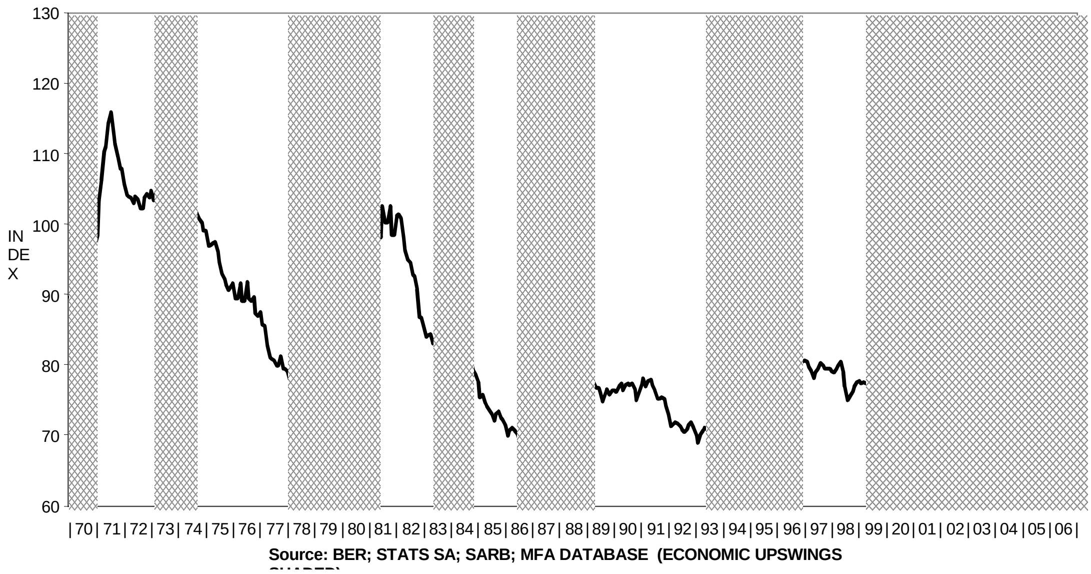

Figure 7: Profitability indicator (output prices divided by input costs)

CONCLUSIONS

When making informed forecasts of building costs, it is important to consider the course of the business cycle. This is necessary because the upswing and downswing phases of the business cycle affect the course of building costs in different ways. In growth periods in the economy, there is usually plenty of work for builders to tender on. The degree of competition in tendering eases and this allows building contractors to widen their profit margins. Yet, actual profits do not necessarily equal planned profits because building contractors normally experience cost-raising bottlenecks in the supplies of labour and materials. During recessions, the opposite would apply: bottlenecks would ease, productivity would improve, competition would intensify and tender prices would rise less rapidly. It has been shown that business cycle surveys can be useful when forecasting builders' input costs and tender prices. Thus, knowledge of trends in cyclical indicators representing the availability of labour and materials, competition in tendering and the profitability of building contractors can assist building economists in improving their ability to forecast building costs in South Africa.

THE PRACTICE OF CONSTRUCTION MANAGEMENT

J.J. Smallwood[1]

Department of Construction Management, Nelson Mandela Metropolitan University, PO Box 77000, Port Elizabeth, 6013, South Africa

International literature indicates that supervision, communication, motivation and leadership are the top ranked skills required for practising construction management – the discipline of managing a construction business and/or project(s). Whereas operational and middle management require more skills and knowledge in operational programming, labour forecasting and organization, top management requires more skills and knowledge in competitive tendering, costing and estimating, and analysis of project risk. The research reported on in the paper constitutes phase 2 of the study 'The practice of construction management'. The findings include that administration, oral communication, controlling, coordinating, decision making and leadership are skills ranked among the top 10 for all levels of management. Other findings include that contract administration, contract documentation, cost control, building methods and quality management are subject areas ranked in the top 10 positions for all levels of management. The paper concludes that the most frequently used subject areas reflect the focus at the respective levels of management: top – the management of the business of construction; middle – the management of a number of projects, and operational – the management of specific projects.

Keywords: construction management, discipline, knowledge, skills.

INTRODUCTION

Drucker (1955) states the three jobs of management as: managing a business; managing managers; and managing worker and work. He contends that although the three jobs can be analysed separately, studied separately, appraised separately, and despite each having a present and a future dimension, management cannot separate them nor can it separate decisions on the present from decisions on the future. Clearly, management is concerned with the business environment and work per se, and furthermore, it is concerned with planning – decisions regarding the future.

According to Fellows *et al.* (1983), construction management can be viewed in two dimensions, the management of the business of construction and the management of projects per se. They emphasize that in practice, the two dimensions are interdependent. Lavender (1996) emphasizes that the differences between managing the business of construction and projects should not be overstated, but that they should be noted. Whereas the former is ongoing, projects are unique, of a temporary nature, entail a series of deadlines and targets and the establishment of a project team.

Frederick W. Taylor, while working in the steel industry during the early 1900s identified the need for a systematic and scientific approach to industrial management. He proposed that managers realize order and system to their work in the form of 'scientific management', and suggested that managers should condense the great mass

[1] john.smallwood@nmmu.ac.za

of traditional knowledge to a science by classifying, tabulating and reducing it to rules, laws and formulae. He recommended that managers plan the work of the people reporting to them and devise means of coordination and control. His plan called for managers to motivate their people by selecting, teaching and developing the workers and 'heartily cooperating with them'. Effectively, he identified the need to systematize management, analyse the work to be done, measure it, and assign portions thereof to the people best able to execute it (Allen 1958). Allen (1958) contends that although Taylor did not provide the whole answer to 'What is a manager?' he enabled us to take a long stride forward.

Henri Fayol's book *General and industrial management* published in 1916 in French is regarded as the first attempt to derive general principles of management (Lavender 1996). He identified six key activities that take place in an industrial organization: technical such as production; commercial such as purchasing and selling; financial such as obtaining long-term and working capital; security in the form of taking care of the organization's property; accounting such as compiling and maintaining financial information; and managerial. Fayol then identified five processes relative to the managerial activities: forecasting and planning; organizing; commanding; coordinating; controlling (Lavender 1996).

Allen (1973) subdivides the order of management work into functions – planning, organizing, leading and controlling, and suggests a fifth in the form of coordination. Allen (1985) elaborates on management as an art, science and profession in his book *The management profession*.

Based upon his interpretation of the term 'management', Allen (1983) evolves a succinct definition for a professional manager: 'A management leader who specializes in the work of planning, organizing, leading and controlling through the systematic use of classified knowledge, concepts, principles and a common vocabulary, and who subscribes to the standards of practice and a code of ethics established by a recognized body.'

The nine recognized functions in an organization provide further insights relative to the knowledge and skills required by construction managers: general management; production; procurement; marketing; financial; human resources; public relations; legal; and administration and information technology. Generally, the organization structures of contracting and related organizations, dependent upon size, are structured according to these functions. Successful management of the business of construction, which includes managing projects, is dependent upon effective integration of these functions. Furthermore, although the production function mostly takes place on projects, it is merely one of the functions and is dependent on the others, and vice versa.

Given that the environment within which construction management is practised changes, the debate surrounding the content of construction management undergraduate courses, and a pending scoping exercise by the Building Construction Standards Generating Body, the study 'The practice of construction management Phase 2' was initiated to investigate the frequency of use of knowledge areas and skills.

Research of this nature is important as the findings inform tertiary institutions presenting construction management programmes, and related councils and institutes, which are the custodians of knowledge, and responsible for the development of initial skills, registration of practitioners, maintenance of standards and continuing professional development (CPD).

REVIEW OF THE LITERATURE

Functions and activities of management work

Allen (1973) identifies two classes of work – mechanical and human. He then subdivides the class of human work into the orders of management work and technical work. Technical work entails physical and mental effort by the person doing the work. Management work also entails physical and mental effort, but by a person in a leadership position to realize results through other people. He then subdivides the order of management work into functions – planning, organizing, leading and controlling, and suggests a fifth in the form of coordination. The functions of management work are then subdivided into activities:

- Planning: forecasting, developing objectives, programming, scheduling, budgeting, developing procedures and developing policies;
- Organizing: developing organization structure, delegating and developing relationships;
- Leading: decision making, communicating, motivating, selecting people and developing people; and
- Controlling: developing performance standards, measuring performance, evaluating performance and correcting performance.

Certain activities are subdivided into segments:

- Developing objectives: establishing key, critical and specific objectives; and
- Developing organization structure: establishing functional and divisionalized organization structure.

Knowledge and skills

According to Fryer (1990) in 1971 Robert Katz identified three broad classes of skills: human, technical and conceptual. Human skill is the manager's ability to work as a group member and build cooperative effort in the team, communicate and persuade. Technical skill includes proficiency in some aspect of the organization's work, analytical abilities, and specialized knowledge and techniques. Conceptual skill is the ability to adopt a holistic perspective relative to the organization. Katz argued that human skill is important at all levels of management, but especially at operational level, as such managers have wide-ranging and frequent contact with people. Operational management also relies heavily on technical skill, but this is less important for top management, which depends more on conceptual skill. Katz further argued that many management tasks require the use of several skills – for example, resolving a technical problem may require more than technical skill as it may affect people.

Fryer (1990) focuses on interpersonal, informational and decisional skills due to Mintzberg's contention that managers perform an intricate set of overlapping roles, namely interpersonal, informational and decisional. In terms of interpersonal skills, construction managers ranked human skills highest during a study conducted by Fryer (1990) in 1977 to investigate the development of managers in the construction industry. Relative to social skills, site managers and contracts managers stressed the need for keeping people informed, getting them involved in tasks, fostering cooperation and teamwork, communicating clearly, dealing with people as individuals, and showing an interest in people.

Phase 1 of the study 'The practice of construction management' entailed a national postal survey of non-student members of the South African Institute of Building (SAIB) (Smallwood 2000). The objectives of the study were to determine, based on frequency of use, the importance of skills and areas of knowledge per level of construction management. Respondents were asked to identify the frequency at which skills and knowledge pertaining to subject areas are required, using the range of responses: frequently, sometimes, rarely or never.

It is significant that all five functions of management work are represented in the top 10 ranked skills of operational, middle and 'all' levels of management: controlling, coordinating, planning, leadership and organizing. Planning and organizing are not included in the top 10 ranked skills of top management (Table 1). It is notable that the importance indexes (IIs) for the top eight ranked skills for all levels of management are above the midpoint value of 1.50 indicating prevalence in terms of use. Effectively, costing is more important to top and middle management, whereas interpersonal, organizing, planning and plan-reading skills are more important to operational and middle management.

Table 1: Importance of skills per level of construction management based on frequency of use (Smallwood 2000)

Skill	Level of management							
	Operational		Middle		Top		All	
	II	Rank	II	Rank	II	Rank	II	Rank
Communicating (oral)	1.29	2	1.69	3	1.80	1=	1.59	1
Controlling	1.27	3=	1.71	1=	1.76	3	1.58	2=
Decision making	1.22	8=	1.71	1=	1.80	1=	1.58	2=
Coordinating	1.24	6=	1.63	6=	1.75	4=	1.54	4
Administrative	1.22	8=	1.63	6=	1.75	4=	1.53	5=
Planning	1.27	3=	1.68	4	1.63	13	1.53	5=
Leadership	1.20	10=	1.59	10=	1.73	7	1.51	7=
Organizing	1.25	5	1.64	5	1.64	12	1.51	7=
Communicating (written)	1.15	14	1.58	13	1.75	4=	1.49	9
Interpersonal	1.20	10=	1.59	10=	1.61	14=	1.47	10

Respondents were also required to respond regarding the importance of subject areas based on the frequency of use of related knowledge (Table 2). Given that cost, quality and time are the traditional project performance measures and parameters, it is significant that cost control, quality management and planning (programming) are ranked in the top 10 subject areas for the operational, middle and top levels of management, with the exception of planning (programming) for top management. It is notable that relative to the 'all' levels of management there are only two subject areas for which the IIs are above the midpoint value of 1.50, namely construction methods (building) and cost control.

Contract administration, contract documentation, cost control, construction methods (building) and quality management are in the top 10 ranked subject areas for operational, middle and top levels of management. Customer service is only common to middle and top management; measuring quantities, programming and subcontractor management are common to operational and middle management.

Table 2: Importance of subject area per level of construction management based on frequency of use of knowledge (Smallwood 2000)

Subject area	Level of management							
	Operational		Middle		Top		All	
	II	Rank	II	Rank	II	Rank	II	Rank
Construction methods (building)	1.22	1	1.80	1	1.59	6=	1.54	1
Cost control	1.15	3	1.75	2	1.64	2=	1.51	2
Quality management	1.14	4	1.63	6	1.59	6=	1.45	3
Contract administration	1.08	5=	1.66	3=	1.58	9	1.44	4=
Subcontractor management	1.19	2	1.58	8=	1.54	12=	1.44	4=
Contract documentation	0.98	10=	1.66	3=	1.59	6=	1.41	6
Planning (programming)	1.07	7	1.61	7	1.47	17	1.38	7
Customer service	0.85	19	1.56	10	1.71	1	1.37	8

Productivity	0.90	14	1.53	12	1.46	18=	1.30	10

RESEARCH

Sample stratum and methodology

A survey 'The practice of construction management Phase 2' was conducted among non-student members of the Chartered Institute of Building (CIOB) (Southern Africa) to determine the frequency at which 78 knowledge areas and 45 skills are used relative to the three levels of management. The primary objective of the survey was to provide 'current' data for reference by the Building Construction Standards Generating Body (SGB) during a management scoping exercise.

A questionnaire was mailed to members, and also circulated electronically to those members with e-mail addresses. Ninety-one responses were included in the analysis of the data from a net sample frame of 648, which represents a response rate of 14% (91 / (656 – 8)].

Analysis and presentation of the data

Given that respondents were required to respond in terms of a frequency range: never, monthly, fortnightly, weekly and daily, it was necessary to compute an importance index (II) to enable a collective comparison of responses to and a ranking of the respective subject areas and skills. The II is calculated as follows:

$$II = \frac{1n_1 + 2n_2 + 3n_3 + 4n_4}{n_o + n_1 + n_2 + n_3 + n_4}$$

where n_0 = unsure/never, n_1 = monthly, n_2 = fortnightly, n_3 = weekly and n_4 = daily.

The skills and subject areas are presented in and ranked in terms of descending frequency of use. The five ranges of II values indicate that the skills and subject areas can be deemed to be used as follows:

- $3.2 \leq 4.0$: weekly to daily/daily;
- $2.4 \leq 3.2$: fortnightly to weekly/weekly;
- $1.6 \leq 2.4$: monthly to fortnightly/fortnightly;
- $0.8 \leq 1.6$: never to monthly/monthly; and
- $0.0 \leq 0.8$: never to monthly.

Findings

Respondents were involved with the following types of construction: commercial (73.6%), industrial (51.6%), domestic (42.9%) and infrastructure (23.1%).

The 0–2 floors (67%) height category predominated in terms of the level of structures respondents were involved with, followed by ground (49.5%), below ground (27.5%), 0–10 floors (25.3%) and 0–20 floors (12.1%).

The average number of years worked in the respective levels of management by respondents increased with the seniority of the level: operational (4.3), middle (6.7) and top (9.3). There are 65.9% of respondents currently working at top management level and 25.3% and 5.5 % at middle and operational level respectively.

Tables 3 and 4 indicate the mean frequency of use of skills and subject areas for all levels of management in terms of IIs, respectively.

Oral and written communicating predominate among skills in terms of the mean for all levels of management, followed by decision making, organizing, administrative, leadership, coordinating, planning, numerical (maths), plan reading, interpersonal, motivating and controlling (II values $> 3.2 \leq 4.0$) (Table 3). However, it should be noted that leadership and controlling are more important at top management, plan reading is substantially more important at operational and middle management, and interpersonal and motivating are more important at middle and top management.

Other frequently used skills are: supervisory, computer, technical, negotiating with subcontractors and costing (II values $> 2.4 \leq 3.2$). However, it should be noted that computer skills are substantially more important at middle and top management, and negotiating with subcontractors is substantially more important at operational and middle management.

Other important differences include: measuring quantities is more important at operational management; team building, estimating and procedures development are more important at middle and top management; financial, marketing and entrepreneurial are more important at top management.

There is only one skill that is never used by the majority of all levels, namely negotiating with unions at operational management.

Mathematics predominates among subject areas in terms of the mean for all levels of management, followed by building methods (construction), materials, customer service, subcontractor management, cost control, quality management, contract administration, productivity, ethics and materials management (II values $> 2.4 \leq 3.2$) (Table 10). However, it should be noted that building methods (construction), materials, subcontractor management, cost control, quality management and materials management are more important at operational and middle management; customer service and ethics are more important at top management; and productivity is more important at operational management. Other notable differences include the importance of measuring (quantities) and surveying (land) at operational management, and negotiating, management (business), financial management, public relations, property economics, marketing, entrepreneurship, accountancy, cash flow forecasting, economics, company law, property development, property law and tax at top management.

There are 11 subject areas that are never used by the majority at operational management, two at middle management and two at top management.

SUMMARY

Tables 5 and 6 provide a summary of the top 10 skills and subject areas for all levels of management in terms of ranks emanating from Phases 1 and 2 of the ‘Practice of construction management’ studies reported on in the review of the literature and the research sections above, respectively.

Table 5 indicates that relative to skills, 65 of the 80 ranks (81.3%) presented are within the top 10 of their respective studies – there is limited discordance between the findings of the two studies. Although the II values have not been presented due to the use of different scales, it should be noted that the differences between the highest and lowest ranked mean skill II values are:

- Phase 1: 0.15 on an II ranging from 0.00 to 3.00 (5%); and
- Phase 2: 0.63 on an II ranging from 0.00 to 4.00 (15.8%).

The ranking of communicating (oral), communicating (written), decision making, administrative, leadership and interpersonal, in particular the two communicating skills, amplifies the importance of the management function of leading. Furthermore, it is notable that the other four functions of management work are ranked within the top 10: organizing; coordinating, planning and controlling.

Table 5: Mean frequency of use of skills for all levels of management for Phases 1 and 2 in terms of ranks

Skill	Levels of management							
	Operational		Middle		Top		Mean	
	Phase 1	Phase 2	Phase 1	Phase 2	Phase 1	Phase 2	Phase 1	Phase 2
Communicating (oral)	2	1	3	1	1=	1=	1	1
Communicating (written)	14	2	13	2	4=	4	9	2
Decision making	8=	8	1=	4=	1=	3	2=	3
Organizing	5	6	5	4=	12	6=	7=	4
Administrative	8=	7	6=	8	4=	5	5=	5=
Leadership	10=	11	10=	10	7	1=	7=	5=
Coordinating	6=	4	6=	11	4=	8	4	7
Planning	3=	9	4	4=	13	11	5=	8
Interpersonal	10=	13	10=	9	14=	9	10	11
Controlling	3=	10	1=	15	3	10	2=	13

Table 6 indicates that relative to knowledge areas, 52 of the 80 ranks (65%) presented are within the top 10 of their respective studies – there is a degree of discordance between the findings of the two studies. The differences between the highest and lowest ranked mean knowledge area II values are:

- Phase 1: 0.32 on an II ranging from 0.00 to 3.00 (10.7%); and
- Phase 2: 0.82 on an II ranging from 0.00 to 4.00 (20.5%).

The ranking of construction methods (building) indicates the importance of technical knowledge. The rankings of cost control, quality management, planning (programming) and productivity reflect the status of the traditional three project parameters: cost, quality and time. The ranking of customer service reflects the status of client satisfaction – client satisfaction was ranked first among 11 project parameters during a study conducted among project managers (Smallwood and Venter, 2002). Furthermore, client satisfaction is essentially a function of performance relative to the traditional project parameters of cost, quality and time. The relevance of the other subject areas is as follows. Construction management includes the management of projects and therefore contract administration and contract documentation are important. Furthermore, both require communicating. The greater percentage of all projects is undertaken by subcontractors, and construction managers invariably interact with project managers.

CONCLUSIONS

Construction managers, certainly members of the CIOB (Southern Africa), spend a limited number of years at operational management level, and more at both middle and top management level.

The most frequently used subject areas reflect the focus at the respective levels of management: top – the management of the business of construction; middle – the management of a number of projects; operational – the management of specific projects.

Based upon their frequency of use and current tertiary education, the question arises as to the extent to which tertiary institutions and CPD address a number of skills and subject areas. The skills are: interpersonal, entrepreneurial, initiating, team building, conflict resolution, procedures development, systems development, design management, research, design (temporary works, and negotiating with the community. The subject areas are: customer service, entrepreneurship, ethics, management systems, procedures, total quality management, risk management, procurement systems, dispute resolution, benchmarking, service management, facilities management, design management, design (temporary works), research, worker participation and re-engineering.

Table 6: Mean frequency of use of knowledge for all levels of management for Phases 1 and 2 in terms of ranks

Knowledge area	**Levels of management**							
	Operational		**Middle**		**Top**		**Mean**	
	Phase 1	**Phase 2**	**Phase 1**	**Phase 2**	**Phase 1**	**Phase 2**	**Phase 1**	**Phase 2**
Construction methods (building)	1	1=	1	2	6=	9=	1	2
Cost control	3	9	2	4	2=	15	2	6=
Quality management	4	8	6	7=	6=	20	3	6=
Contract administration	5=	16	3=	3	9	12	4=	8
Subcontractor management	2	4	8=	6	12=	25	4=	5
Contract documentation	10=	18	3=	9	6=	22	6	15

Project management	18	27=	3=	10=	12=	16	9	20
Productivity	14	5	12	14=	18=	23=	10	9

RECOMMENDATIONS

Construction management undergraduate programmes need to focus on management and more specifically the management of resources within defined parameters such as cost, environment, health and safety, productivity, quality and time. However, to be able to manage resources within defined parameters requires technical expertise relative to the construction process. The findings clearly indicate the need to empower graduates to improve the construction process – customer service, health and safety, productivity and quality management. These findings correlate with the contention of Harriss (1996) that the Royal Commission in New South Wales would say that undergraduate construction management education has not added value and produced a healthy industry in Australia. Given the aforementioned findings, complementary issues need to be addressed: benchmarking, constructability, partnering, procurement systems, re-engineering and value management. Furthermore, given that construction managers spend a limited number of years at operational management level, and more at both middle and top management level and those construction managers in small and medium sized organizations need to fulfil a range of functions, construction management programmes need to empower graduates to manage the business of construction.

Councils should benchmark tertiary education programmes in terms of skills and subject areas and assess applicants applying for registration accordingly. Institutes should follow suit and engender the delivery of appropriate education and training by the providers thereof, to assure that applicants applying to upgrade their membership, and non-applicants applying for membership, will complement the discipline, practice and profession of construction management. Furthermore, institutes should evolve the requisite CPD where inadequacies in education and training have been identified, or where changes in the construction environment require such CPD. Practitioners should objectively assess their current ‘basket’ of skills and level of knowledge relative to subject areas. Tertiary institutions should assess whether they address the subject areas, and the development of the skills, and if so, the extent to which they do.

ADOPTION OF PCM TO IMPROVE GENERAL CONTRACTING: THE ITALIAN CASE

Aldo Norsa[1] and Ernesto Antonini[2]

[1]*Università Iuav di Venezia, School of Architecture, Venice, Italy*
[2]*University of Bologna, School of Architecture, Cesena, Italy*

Since 2001, Italy has interpreted in an original (but somehow awkward) way the third type of European tender procedure, introducing (through law 443 known as "*legge obiettivo*") the role of "*contraente generale*", improperly translated as general contractor. As the first case study suggests, the Italian way – compared with what the best European practice proposes – lacks a clear transfer of risks and allocation of tasks. After a brief analysis of the alternatives, the authors suggest how to improve the Italian practice (according to the European directives) and make it fit better with the PPP approach, which is the correct framework for the "*contraente generale*" variant. Both clients and contractors should adopt project-construction management (PCM) services to assure the effectiveness of all phases of the delivery process.

Keywords: client, contract law, international comparison, PPP, procurement, project-construction management

INTRODUCTION

During the past five years, Italy has tried to fill its "infrastructural gap" with a new type of procurement of public works exceeding the amount of 250 million euros, thus introducing the so-called "*legge obiettivo*" (law 443/2001, completed by decree 190/2002), which complements law 109/1994 (known as "*legge quadro*" or "*legge Merloni*") governing the award and execution of all public works contracts, including concessions and project finance initiatives, as well as the "code" extended supplies and services that fits in the new European directive framework. This piece of legislation – applied to an original list of 228 "strategic works" established by the past Government at the end of 2001 – was conceived as a sort of "fast track" for selected projects and was intended to accelerate and facilitate their delivery.

As far as this paper is concerned, it is interesting to remark that the *legge obiettivo* has introduced and disciplined the "*contraente generale*", an entrepreneur whose tasks are modelled according to the European directive 93/37 interpreting the "third type" of tendering procedure, i.e. a figure that is responsible for "the realization, by whatever means, of a work corresponding to the requirements specified by the contracting authority" (EC Directive 2004)

In English, the common translation suggested for *contraente generale* (and currently used in the Italian context) is "general contractor" but this apparently obvious correspondence does not help much as some observers think that "main contractor" better explains that the "realization by whatever means" implies not only the capacity

[1] norsa@iuav.it

to deliver all sorts of works but also to coordinate the activities on site of a number of specialized contractors.

As a matter of fact, the available literature offers an array of opinions but lacks a clear or univocal definition: the notion of *contraente generale* still remains controversial on the ground of international comparisons, especially in terms of risk allocation between public client and contractor, as discussed in a previous paper by the same authors. (Norsa and Antonini 2006)

The point is that the *contraente generale*, as defined in the Italian law, has the task of designing, building and partially pre-financing a work. Its contract is thus a variation of the engineering, procurement and construction (EPC) formula: it combines a “turnkey contract”, implying delivering on schedule at a fixed price with the specified quality, with a design, build, finance and transfer (DBFT) scheme in which the facility is transferred to the awarding authority upon completion and acceptance of the works.

The main difference lies with risk allocation as far as financing is concerned: although the *contraente generale* is required to finance the project in an initial phase, he does not assume any of the risks typical of a “concession” or a “PPP” based on the EU directives. In the Italian variation, he does not operate or manage the facility: his task is limited to the design and EPC phases. This will be examined in greater details in a “case study”.

PROCUREMENT SYSTEMS: HOW DOES CONTRAENTE *GENERALE* FIT?

Until now, not one of the 228 “strategic infrastructure” projects approved in 2001 (see chapter below) has been completed: it lacks any element to carry a deeper analysis on the new *contraente generale* scheme, based on its practical application.

Waiting for such feedback, the paper will try to discuss the profile of the *contraente generale* by comparing it with the most suitable categories issued from the internationally recognized building procurement system classification.

For the purpose of international comparison, it is useful to remind that, in the selection of the most suitable building procurement system, the approach devised by Perry (1985) appears most appropriate from the point of view of classification, as suggested by Mastermann (2002). The structure of this classification is sketched in Figure 1, which provides an overview of the entire range of building procurement systems currently in use.

Based on this classification, the possible options for our purpose are the following:

1. *Separated procurement systems or conventional systems*, where the main elements of the project-implementation process, i.e. design and construction, are the responsibility of separate organizations, e.g. design consultants, quantity surveyors and contractors. The client has all of the members of the project team to deal with and is responsible for the funding and the eventual operation of the facility.

2. *Integrated procurement systems*, where one organization – usually but not exclusively a contractor – takes responsibility for the design and construction of the project so that, in theory at least, it is the only one with which the client deals. “Design and build”, “develop and construct”, “package deal method” and “turnkey approach” are the main systems in this group. In the latter case

the contractor may well provide or arrange funding for the project and be responsible for the subsequent operation of the facility.

3. *Management-orientated procurement systems*, like “management contracting”, “construction management” and “design and manage” where the management of the project is performed by an organization working with the designer and other consultants to produce the design and manage the physical operations which are carried out by works- or package-contractors. When using such systems, the client will need to have a greater involvement with the project than when employing any of the other previously described methods.
4. *Discretionary systems*, where the contracting authority lays down a framework for the overall administration of the project, within which it has the discretion to use the most appropriate of all the procurement systems outlined above.

How does the approach involving the *contraente generale* fit within these options?

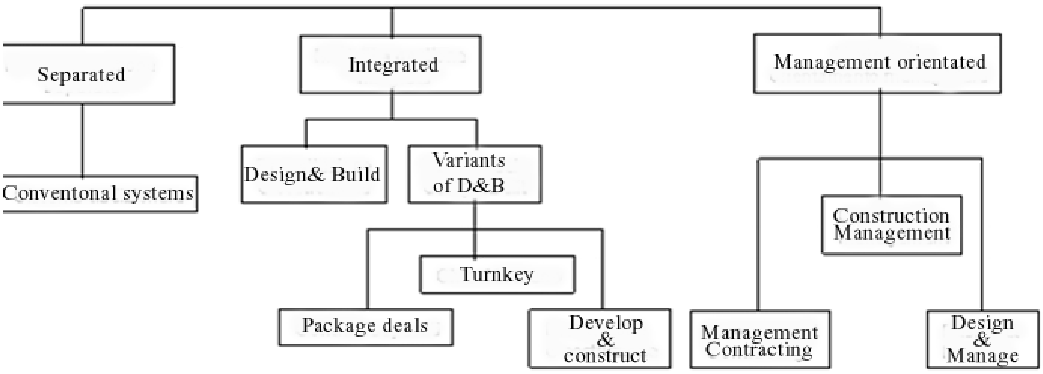

Figure 1: Systems for the management of design & construction of building projects (Mastermann 2002)

The most appropriate option to study is the second, the integrated procurement system, in order to verify how a *contraente generale* can meet the typical requirement of this process. It incorporates all the methods of managing the design and construction of a project where these two basic elements are integrated and become the responsibility of one organization, usually a contractor. Its main variant, the “design and build” procurement system, the arrangement whereby the contracting organization takes sole responsibility, normally on a “lump sum fixed price” basis, seems the model that better fits the *contraente generale* profile, although Mastermann suggests that the excellent performances in time and cost of this model depend on the typical “single point responsibility”. This advantage can only be really achieved if performance criteria are used in the formulation of the client’s requirements but unfortunately none of this kind of specifications are clearly stated by the Italian *legge obiettivo*.

As shown in Table 1, the Italian CG scheme fits (✓) only two on the three main features of a “classic” D&B scheme. Like in the generally adopted D&B model, in the GC too the contracting organization takes sole responsibility of the project and the contract is established on a lump sum fixed price. The Italian scheme does not prescribe (✕) the use of performance criteria to specify the client’s requirements.

This lack seriously jeopardizes the coherence of the framework, because it does not allow the client to make a clear evaluation of the design options proposed by the contractor.

Table 1: Comparison between D&B main features and Italian CG scheme

	D&B	Italian CG
Contracting organization takes sole responsibility	✓	✓
Lump sum fixed price	✓	✓
Client's requirements expressed by performance criteria	✓	✕

The "turnkey" is the other variant of integrated procurement systems that could be applied to the *contraente generale*. In this case, one organization, generally a contractor, is responsible for the total project from design through to when the key is inserted in the lock, turned and the facility is operational. As shown in Figure 2, the responsibility of the contractor can extend to include the installation and commissioning of the client's equipment and sometimes the identification and purchase of the site, recruitment and training of personnel, arranging of funding for the project and its operation.

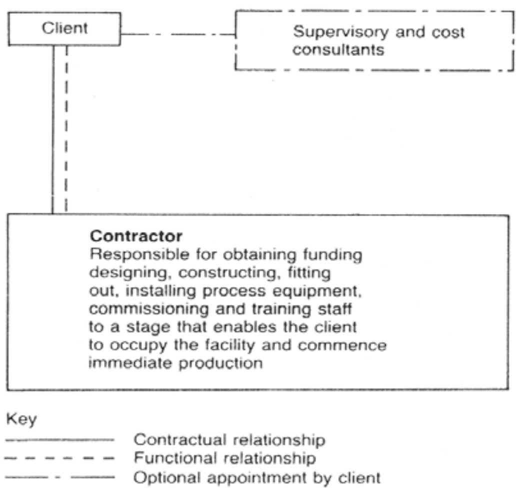

Figure 2: Functional and contractual relationship: the turnkey system (Mastermann 2002)

Because of the explicit exclusion of operating the facility, the "turnkey" system as usually adopted in international procurement does not meet the profile drawn by the Italian ad-hoc legislation. Table 2 summarizes the only partial coherence between the CG and the turnkey scheme, as internationally adopted. The CG model fits some main features of the turnkey framework (✓), but it does not fit it (✕) in order to include the operation of the project into the contractor responsibilities. It means that the contractor is only involved in the construction phase. Subsequently, the client must provide a set of specific means to check the serviceability of the project and, despite it, it remains highly exposed to the risks of unaccomplished performances.

Table 2: Comparison between turnkey main features and Italian CG scheme

	Turnkey	Italian CG
Contractor is responsible for the total project	✓	✓
Contractor's responsibility includes the installation and commissioning of client's process or other equipment	✓	✓
Contractor's responsibility includes the arranging of funding for the project	✓	✓

Contractor's responsibility includes the operation of the project	✓	✕

Another possible reference could be the third option: the management orientated procurement systems, i.e. processes whereby an organization, normally construction based, is appointed to the professional team during the initial phases of a process to provide construction management expertise under the direction of a contract administrator.

Within this framework, the "design and manage" variant seems to meet the *contraente generale* model closer than others. In this procurement system – as sketched in Figure 3 – a single organization is appointed to both design the project and manage the construction operations using package contractors to carry out the actual work. Reimbursement is by means of a lump sum or percentage management fee, with the actual cost of the works packages together with any common services being paid to the contractor when responsible for the management of the project.

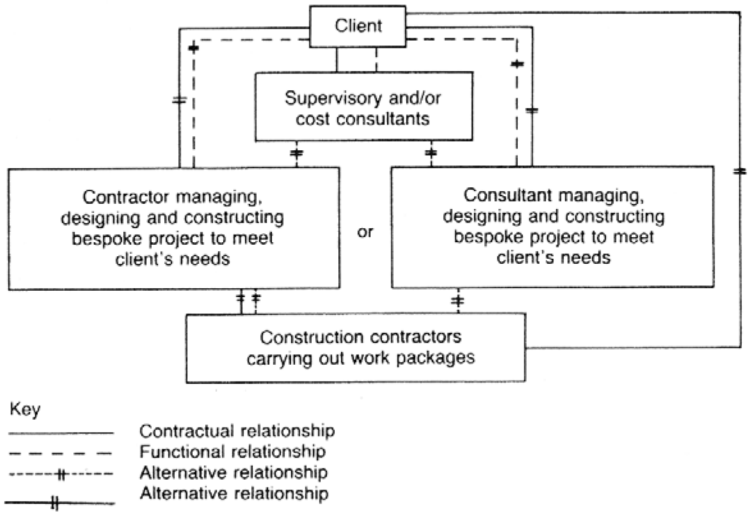

Figure 3: Functional and contractual relationship: design and manage (Mastermann 2002)

It must be noted that the appointment of an independent quantity surveyor is not envisaged by the Italian scheme, although this activity is considered compulsory by the international reference model.

Moreover, in a constructor-led design and manage approach the question of quality control is a vexed one, with the responsibility for this function nominally being allocated to the design and manage contractor but in reality usually devolving upon quality controller, independently appointed by the client.

How critical the question remains is shown by a recently published comparative analysis on 12 PPP cases in Europe, in which the key role played by means and measures of control established along the entire process is highlighted (Bougrain *et al*. 2005).

Also in this third case, depicted in Table 3, the Italian CG scheme accomplishes (✓) only with some features of the reference model: the main lack (✕) concerns the appointment of an independent quantity surveyor, which is not prescribed in the Italian scheme. It means that the client must directly provide the management of all the financial aspects of the scheme, without the support of any "third" advisor. If this solution is unadvisable in principle, it seems especially critical for the Italian public clients, which generally have very little experience in these topics.

Table 3: Comparison between D&M main features and Italian CG scheme

	D&M	Italian CG
A single organization is appointed to both design the project and manage the construction operations using package contractors to carry out the actual work	✓	✓
Lump sum fixed price	✓	✓
The client appoints an independent quantity surveyor to oversee the financial aspects of the scheme	✓	✕

"Quality control" is still an unspecified function and it is not clearly established by the *contraente generale* scheme. It remains ambiguous how the Italian legislator has intended to reinforce the client's position against the contractor, a goal that is generally achieved establishing means and measures of control during and after the construction phase. Thus resorting to professional services internationally known as project/construction management (PCM), as proposed in the Conclusions below.

The comparison between the CG scheme and the possible reference models could be summarized as follows:

- Compared to the reference models, the CG scheme establishes a "hybrid" procurement system in which the contractor assumes the sole responsibility for the total project and is appointed by the client to both design the project and manage the construction operations (like in a D&M typical scheme), and partially arrange the funding for the project (like in a turnkey system).
- The lead role of the contractor should be fortified by the application of this framework, with a subsequent expected improvement of the process efficiency, despite no evidence available at present to confirm this presumption.
- Nevertheless, the achievement of this goal seems to prevail over the need of a well-balanced risk allocation between client and contractor. In fact, the CG scheme lacks a number of measures usually adopted in the reference models to transfer some risks to the contractor, like the responsibility for the operation of the project or to improve the effectiveness of the client control on the project progress, through the appointment of independent surveying.
- Because of its hybrid profile, the CG scheme partially overlaps both the traditional general contractor and the PPP schemes currently in use in Italy. It may cause several improper analogies due to the similarity of some figures (i.e. the fund arranged by the CG to pre-finance the project and those provided in a PPP framework) and subsequent doubts and snags in the project progress.
- Except the partial pre-financing of the project (with its dubious nature), the CG scheme seems to introduce very few real innovations in the traditional "general contractor" model.

THE *LEGGE OBIETTIVO*: TIME FOR AN ASSESSMENT

Despite it, the procurement innovation introduced with the *legge obiettivo* was welcomed at first in Italy with positive comments focused on its expected effect to push forward an extensive and much-needed infrastructure programme.

However, based on the experience so far, the implementation of the "strategic infrastructure programme" has deceived: it has been neither quick nor effective as had been originally hoped. In addition, the limited application of the *contraente generale* formula has hindered a sufficient base of case studies from which to draw conclusions about its effectiveness.

The turning point came in May 2006 when a new Government took office as a result of general elections, bringing with it a critical attitude against the pretended advantages of the reforms endorsed by the previous Cabinet, especially focusing on the shortcomings of the *legge obiettivo*.

The main problem is with limited resources. At the end of 2001, the previous Government had approved a long list of 228 strategic infrastructure projects that needed more than 173 billion euros to be implemented but, in fact, only 37 billion had been allocated. Consequently, so far only 19 tenders have been published (involving a total investment of 16.7 billion) and 15 awards to *contraenti generali* have been finalized (at a total expected cost of 13 billion). In only four cases are the works effectively under way, while the largest of all contracts (the realization of the Messina Straight Bridge) has been declared no longer a priority and is waiting for a settlement with the winning consortium, led by Impregilo.

According to many observers, the supposed “new market” shows symptoms of “pathology” similar to the traditional one, which is responsible for the weakness of the Italian civil engineering contractors when compared with most European competitors:

- The “bulimia” of a Government (in power between 2001 and 2006) that announced unrealistic plans and created expectations among the construction industry that could not be satisfied (ANCE 2005).
- The ineffectiveness of the public administration, which has resulted in all sorts of delays. As an example, according to a survey by Ecosfera (2006) on a sample of projects managed under the *legge obiettivo*, the completion of the preliminary designs took an average 671 days instead of the planned 341.
- The lack of selection to the point that 42 subjects already qualify as *contraenti generali*, thus increasing and exacerbating the competitiveness as proved by the fact that the 15 mentioned tenders have been awarded with an average reduction of 12.4% of the prices (for sole construction).

This shows in the economic results. According to *Edilizia e Territorio*’s (Classifiche 2006) annual survey of the balance sheets of the most prominent Italian civil contractors, in 2005 the top 50 groups showed a limited 0.50 profit/turnover index. A more extended Mediobanca (2006) study on the top Italian firms shows that the 2005 turnover increased 1.6% on average mostly due to exports, as domestic activity decreased by 2.1%. Not surprisingly, Impregilo ranks only 25th in the annual listing of the top European groups!

A CASE STUDY

Out of the four projects in actual progress under the *legge obiettivo*, the Sicignano-Atena lot (30 kilometres, see Figure 4 below) of the reconstruction of the Salerno-Reggio Calabria motorway has been the first public work in Italy let out under the new *contraente generale* scheme.

Figure 4: The Sicignano-Atena lot of the Salerno-Reggio Calabria Motorway in southern Italy

The call for bids was published in September 2002, just a month after the mentioned Decree 190 took effect, and the contract was definitely awarded (after a legal settlement) in October 2003 to CMC, the biggest European cooperative construction firm that ranks fourth among Italian contractors.

The awarding authority is Anas, the national agency for roads (and motorways): it agreed to pay CMC 445 million euros (instead of 512.6 as stated in the call for bids), 30% of which was pre-financed by the contractor and reimbursed at the completion of 90% of the work. The duration of the contract was settled in 1.095 days.

The contract basically includes the executive design of the entire project (based on a previous scheme design draw up by Anas in five separated lots), the arrangement of funding for the pre-financing, the executions of the works and the management of the expropriation procedures on behalf of Anas. Figure 5 shows the milestones of the process.

The way this project has so far been managed, starting from the provision of the financial resources, provides interesting insight. A review of the whole process allows us to discover interesting elements and confirms the lack of definition of the contractor's task and responsibility that still marks the Italian *contraente generale* scheme.

As explained by Francesco Francesconi of CMC (Norsa 2007), the first step that his company took was implementing the usual financial scheme. The project, at the level of definition that the design process had reached, was submitted to the corporate sector of a primary Italian bank and presented as a "normal" contract concerning the sole execution of works. The bank understandingly rejected the request. According to Francesconi, this happened because on both sides (bank and contractor) there was insufficient knowledge of the topic: the subject was new to the point that the question had proved inappropriate and inevitably the answer inadequate.

Consequently, a different bank was consulted, with enough experience in *project financing* to appear as a more suitable partner. After careful study, it classified the proposal as “a project-financing scheme without management risk” in which CMC had chosen to avoid the creation of a special purpose vehicle (SPV), which is usual when project financing is at stake.

In this framework, the bank submitted the proposed programme to the due diligence procedures (legal, technical, insurance) typical of the project financing format. As expected, this assessment confirmed that the project could be considered “accepted” by the client only after its final approval. That is, based on a specific clause of the call for bid, two years after the transfer of the completed works to the awarding authority. It means that the intermediate payments connected with partial deliveries do not include any approval by the client.

Consequently, the right to be paid could be pretended by the contractor only after the client final approval, with the obvious risks connected to the possible contract resolution or unconformity of the works.

It needed to devise a financial solution able to limit the contractor’s exposure to this risk, especially about the possible request of reimbursement by the client of all the amount it paid as advance to the contractor, before the final approval.

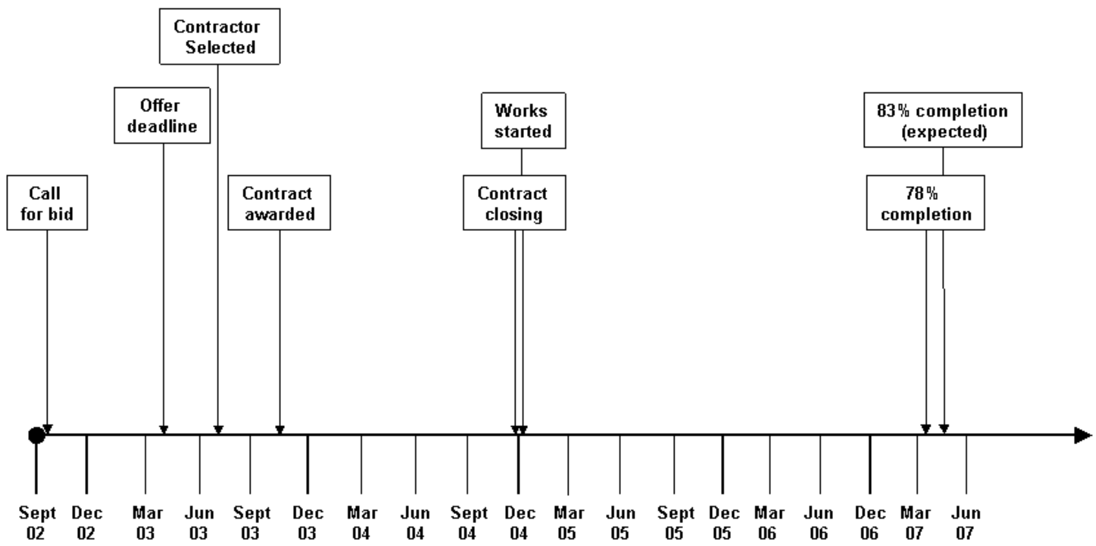

Figure 5: Sicignano-Atena project: the building process milestones

After a long discussion with the bank, a financial scheme was finally identified, but this negotiation postponed the “closing” till December 2004, beyond the deadline (established in 360 days from the project approval) prescribed by the awarding authority for the project kick-off. The latter needed thus a new administrative round to modify the deadline, which caused a further delay and in turns pushed away the slot on which the business plan had been established, with additional modifications to be brought into the business plan and subsequent additional warranty required by the bank.

All this delayed the operation by six months, basically due to the ambiguous nature of the *contraente generale* contract, at least from the bank's point of view, which does not accept to consider such operation like a traditional construction contract because of the relevant financial services included in the contractor package, but interprets it as a sort of "project financing", without operation of the facility but, instead, the need to obtain the pay-back in the shortest period.

CONCLUSIONS

In Italy, the application of the *legge obiettivo* has so far proven controversial. The new scheme was expected to accelerate the construction process in the public works sector and to provide financial resources from the private investors, to lighten the expenditure of public money or, better, to spread it over a long period.

In fact, the contribution of private funding as established by the CG scheme is just a down payment by the contractor to be refunded by the client just before project completion. If not for its greater amount, it is very similar to the bail bond usually request by the client in the classical "general contractor" scheme and is clearly deemed as a guarantee by both the contractors and the banks, as observed in the case study above. Its reimbursement in so short a period cannot produce any substantial effect on the project financial structure, but for the count accounting to be set forward in the annual state budget.

Coupled with an excessive number of projects submitted on this scheme just for "political" reasons (see "The l*egge obiettivo*: is time for an assessment" above), this trick soon revealed its frailty. Moreover, the lack of funding seriously limited the application of the scheme and it hampered gathering any further expected advantage.

In addition, the traditional procedures have not been accelerated in the few cases in which the scheme has been applied, because the variants have revealed several "hidden faults" jeopardizing the effectiveness of the law. And also because –as highlighted above - the CG model has been forced far over the limits of the available resources to a quantity of projects without coherence and without strategic (as well as social) value. (Cipe 2006)

Financial constraints severely limit the application of this law and impose a thorough reassessment of the priorities assigned to the infrastructures that have been announced (and sometimes have already been the object of tenders).

While radically changing this policy, the new Government should focus on the notion of "infrastructure" including both facilities and services, and should therefore inspire its action to two guidelines: liberalization and effectiveness.

As far as the *contraente generale* system of procurement is concerned, some specific suggestions can be made on a technical ground according to the state of the art as it has been previously sketched.

First of all it must be recognized that whenever a public client requires "pre-financing" from a bidder, it is an obvious case of the PPP scheme in which PPP should extend to the phase immediately following construction, i.e. operation of the facility. This seems essential to not only assure that quality is delivered and monitored but also that the contractor has a larger (and longer) payment on which to rely in order to make pre-financing "bankable". This is especially advisable if Italy wants to favour the growth of few general contractors large (and strong) enough to compete with counterparts from other European countries. In this aim, it is essential that Italian public clients improve their management skills, considering that "a strong demand is a prerequisite for a strong offer" (Norsa 2005)

To implement any approach of public private partnership, contracting authorities must resort to the services of professional PCM to help them govern the whole process. Contractors must do the same, as their internal management skills can rarely match those of professional organizations.

This is not only a guarantee that the works are delivered in time, at cost and with quality satisfying the performance requirements, but also needed to accelerate the evolution of the construction market to an essential component of the "service economy" where private partners offering both capital and managerial skills can thrive.

A SYSTEMS APPROACH TO SUPPLY CHAIN INTEGRATION IN CONSTRUCTION

Ruben Vrijhoef[1] and Hennes de Ridder

Delft University of Technology, Faculty of Civil Engineering, Department of Building Processes, PO Box 5048, NL-2600 GA Delft, The Netherlands.

By nature, construction has been dominated by project-based production, involving relatively many independent firms joining in constantly changing one-off coalitions. As a consequence, the construction supply chain is relatively fragmented, the production environment is relatively unstable, and as a result, the industry performance has been low, particularly compared to other industries. Application of supply chain integration has been deemed as a major solution to resolve many problems of construction. This may concern client-led integration strategies, as well as supplier-led integration strategies. A systems approach could help to build a model of supply chain integration to enable construction parties to develop repetitive and integrated strategies in the supply chain. When applying a systems approach, the supply chain must be viewed, engineered and built as a 'systems of systems'. In order to build this model eventually, the work presented applies the ideas of 'management research as a design science' and 'constructive research', rather than 'analytical research'. First, a generic model will be built applying 'theoretical 'building blocks' from four theoretical perspectives: economic, social, organizational and production system. Next, the generic model will be specified and validated by adding empirical 'building blocks', i.e. practical examples of supply chain integration inside and outside construction, and thus confronting the generic model with practice. The result will be tested and generalized by inviting expert opinions about the general validity and capabilities of the model to actually help building construction supply chains as integrated systems. The work will result in a set of guidelines for different parties in the construction supply chain to shift from a project-based approach towards a repetitive approach to their business. On an inter-firm scale, this must lead to a move from project delivery by occasional coalitions of dispersed firms towards integrated product development within 'extended enterprises' of aligned firms.

Keywords: construction, integration, modelling, supply chain, systems engineering.

INTRODUCTION

In construction, the production system, and the supply chain in particular, have been deemed to be disintegrated and inefficient. A more integrated approach to construction has been coined very often as a solution for the many problems and deficiencies existing in construction. On the other hand also the restrictions of integration in construction have often been discussed, because of the temporary nature and dispersed structure of the industry.

In essence, construction can be typified as a specific kind of project-based industry dominated by a project-based and capability-oriented production system. The construction process has been observed as a make-to-order, design-to-order, or even concept-to-order kind of delivery process (Winch 2003). The industry mainly delivers

[1] r.vrijhoef@tudelft.nl

one-off engineer-to-order products (ETO), rather than repetitive assemble-to-order (ATO), make-to-order (MTO), or make-to-stock (MTS) products as delivered by manufacturing types of production systems (Wortmann 1992). Both types of systems are fundamentally different, and 'treating construction as a type of manufacturing obviously neglects design, and arguably subordinates value generation to waste reduction, which inverts their proper relationship'. However, 'certain aspects of construction should move into the realm of repetitive making' (Ballard 2005). Production system types of different industries could be dominated by either (one-off) designing or (repetitive) making (Figure 1).

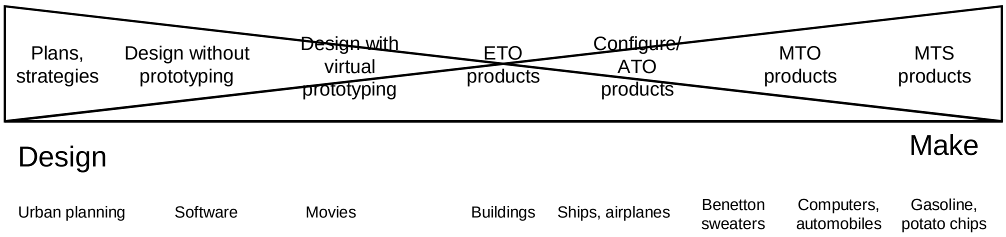

Figure 1: Production system types (Ballard 2005)

The fact that construction is predominantly a demand-driven process and design is often disconnected from production leads to various problems of production. The producer is not the designer, and production is mostly based on craftsmanship mainly taking place outdoors. Moreover production involves many crafts and relatively small firms. This causes problems originating upstream the supply chain to persist and often become worse downstream, because of the mechanisms of causality and interdependence within the supply chain.

This notion leads to the main idea of the work presented aimed at the development of a model for integrated construction supply chains. This touches on the basic peculiarities of construction as a disintegrated industry, and the negative effects of this on the performance of the construction supply chain. The premise here is that the construction supply chain would function better when approached and (re)built as a single entity, an extended enterprise. In a way, the broader issue here is whether construction could or should develop itself towards the standards and practices of a 'normal', more integrated, supply-driven industry.

In contrast to most previous construction management research, this research explicitly aims to build a multi-theoretical and multi-aspect model and guidelines to enable the integration of multiple firms and repetition of multiple projects. This paper gives an overview of the status of the research that is currently underway. In particular, the paper gives an insight into the 'building blocks' found in theory and practice, to be used in the process of model building further on in the research.

VIEWING THE SUPPLY CHAIN AS A SYSTEM

Systems theory views the world in terms of collections of resources and processes that exist to meet subordinate goals. Two aspects of systems theory are of particular importance for supply chains: synergy and entropy. Synergy means the parts of a system working together can achieve more than the sum of achievements that each one would achieve separately. Entropy refers to the necessity of feedback across the chain to prevent debilitation of the system (New and Westbrook 2004). Hassan (2006) suggested the application of system engineering to the design and formation of supply chains. The structurist character of systems thinking can be helpful building the structure and operations of the supply chain in a systematic manner, ensuring its effective functioning.

In terms of systems typology, supply chains are human activity systems and social systems, consisting of actions performed by individuals and groups of individuals, i.e. firms (Checkland 1981). Supply chains can be characterized as networks between economic actors (e.g. firms), engaged in a voluntary relationship to produce and deliver a product or service. Rouse (2005) considers the nature of firms as systems, and supply chains as 'systems of systems'. This is essential to fully understand and thus be able to find integrated solutions to improve firms and systems of firms (i.e. supply chains). Rigby *et al.* (2000) underline the importance of systems thinking for organizational change and improvement, but warn of the risk of underestimation of the complexity of reality when translating this reality into a mental model. Systems approaches are not fully capable of capturing 'soft factors' such as power, trust and human factors.

UNDERSTANDING THE CONSTRUCTION SUPPLY CHAIN

Industry structure

Often the construction industry has been characterized by complexity, referring to the demography of the industry (many SMEs and specialist firms) and the organization of construction, including the configuration and coordination of construction supply chains. Indeed construction as such is a less structured industry compared to other industries, with a vast network of actors of different kinds around a project, i.e. the development and construction of a built object (Figure 2).

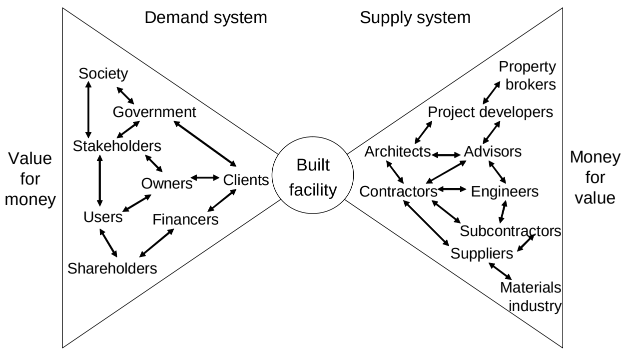

Figure 2: Demand and supply systems in construction (Vrijhoef and De Ridder 2005)

Make-to-order delivery and craftsmanship

Construction supply chains are make-to-order supply chains, where project management and engineering are important issues. The fact that construction is often a demand-driven make-to-order process and design is often disconnected from production leads to various problems of production. The producer is not the designer, and production is very much influenced by craftsmanship. Moreover production involves many crafts and many relatively small firms. This causes problems originating upstream the supply chain to persist and often become worse downstream, because of the mechanisms of causality and interdependence within the supply chain.

One-of-kind and onsite production

Most production in construction is one-off and done on site. The 'factory' is organized on site, and mostly very few materials and components of the end products are prefabricated or preinstalled off site. The logistics in construction are converging, meaning relatively many suppliers are directly involved for the production of an end product for one or very few customers. On the other hand, buildings are physically, economically and socially linked with their environment in terms of use of space and surface, availability of resources and capital, local design and construction practices.

Role of the client and user

In most construction projects the end-customer is at the start as well as the end of the entire process, and therefore the customer and end-users play a dominant role in construction. This also causes the make-to-order mechanism and the need for reactivity in construction supply chains. This is the reason why in construction products are rarely ‘launched’ and ‘marketed’ as in other industries, and why construction is different from most other industries, e.g. consumer goods. Most contractors are not manufacturers of integrated end-products. Most products are not standard, and processes are not repetitive, and often cause high levels of waste (Vrijhoef and Koskela 2000).

AIMS OF SUPPLY CHAIN SYSTEMS ENGINEERING

Supply chain integration as a goal of supply chain systems engineering

One can understand that low levels of integration and repetitiveness in construction lead to problems and underperformance of the construction supply chain as a production system (e.g. Vrijhoef and Koskela 2000). One way of resolving this is to apply concepts that increase integration and repetition within and between project supply chains, such as in partnering arrangements (e.g. Bresnen and Marshall 2000). Previous work points out the need for more alignment and more structured ways of working in the construction supply chain. Systems engineering can help in a sense that systems engineering’s goal here is supply chain integration, and to ‘engineer problems out’ of the supply chain, i.e. the production system (Hassan 2006).

Improving the supply chain by supply chain integration

Stevens (1989) points out the importance and possibilities of supply chain integration for companies to react to market conditions and reduce cost levels. In order to do so, ‘virtually all firms and functions’ in the supply chain should be connected, operating as it were a ‘factory without walls’. However, in many cases, it is simply impossible to fully integrate an entire supply chain (Fawcett and Magnan 2002). This is particularly true for temporary and fairly disintegrated construction supply chains.

This also means supply chain integration can contribute substantially to the overall performance improvement of construction, enabling the industry to deal with the diversity of demand, and reduce the instability of the production environment. It also improves the efficient integration of construction inputs and new technologies, and harnesses the delivery process against the impact of economic and social turbulence. This more centralized mode of process control calls for central roles to be played by the supply chain: the system integrator. This role could be divided in two partial roles: the demand system integrator and the supply system integrator (Figure 3). For instance the client organization responsible for the procurement could take up the demand integrator role; the main or prime contractor could take up the supply integrator role (Vrijhoef and De Ridder 2005).

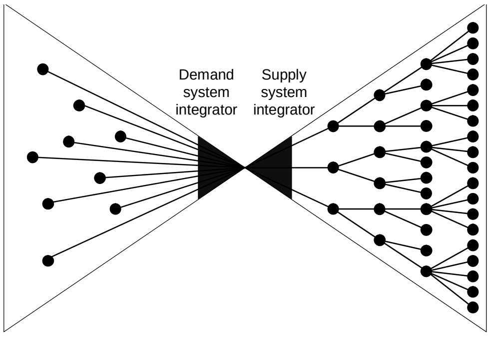

Figure 3: The role of the demand and supply system integrator (Vrijhoef and De Ridder 2005)

RESEARCH APPROACH

The research presented follows the ideas of theory building from case studies as introduced by Eisenhardt (1989). The approach is semi-inductive starting from theory and case studies (building blocks), shaping hypotheses, and from there building a theory (model). This corresponds with the ideas of 'constructive research', which combines the analysis of existing phenomena and building new concepts at the same time. This kind of research is aimed at designing 'solution-oriented research products', rather than deducing 'analysis-based explanations', while viewing management research as design (or engineering) science (Van Aken 2005).

The research approach could be summarized as an engineering approach, i.e. engineering a supply chain integration model as if it were a system that should be functional and useful. This engineering process starts by building the generic supply chain integration model using the theoretical 'building blocks' found in the four theoretical perspectives presented below: social, economic, organizational and production. The generic model built from the theoretical building blocks will next be validated by confronting it with empirical evidence from case studies of supply chain integration, outside and inside construction.

In the research, the case studies within construction aim at describing the supply chain integration strategies applied by different parties, i.e. firms along the construction supply chain, e.g. clients, architects, contractors and suppliers. The case studies cover a number of types of construction rather than one specific type of construction. In a later phase of the research, guidelines for supply chain integration for different types of construction are derived from the model, based on the discussion of the case study analysis results with experts.

THEORETICAL BUILDING BLOCKS

Supply chain viewed as a social system

In construction the relations between firms are typically maintained for the duration of the project. Supply chains are directed not merely towards minimizing transaction costs, but also towards enhancing the transfer of expertise and systematic feedback on planning, design, construction and maintenance between parties, and ultimately towards striving for joint value maximization. Increased cooperation and integration between supply chain parties enables delivery of a total product with quality guarantees to the market. Bounded rationality and differences in know-how between firms would be resolved by joint product development. Opportunistic behaviour is then replaced by mutual trust, which obviously is necessarily for an open dialogue (language) and optimal knowledge sharing.

On an industry scale, Dubois and Gadde (2002) distinguish tight couplings in individual couplings in projects and loose couplings in the permanent network within the industry as a 'loosely coupled system'. The pattern of couplings influences productivity and innovation, and the behaviour of firms. In terms of organizational behaviour, cultural and human issues such as trust and learning have been indicated as having major implications for construction supply chains (Love *et al*. 2002). The social systems approach therefore lays the socio-organizational basis for improved inter-firm relationships within the supply chain.

Supply chain viewed as an economic system
In economic terms a supply chain is a series of economic actors, i.e. firms buying from and selling to each other. From an economic perspective the choice of a coordination mechanism or governance structure is made by economizing on the total sum of production and transaction costs (Williamson 1979). Transaction cost economics (TCE) provides an explanation for the existence and structure of firms and for the nature of coordination within a supply chain (Hobbs 1996). When transaction costs are low, contracting is used (i.e. market structure), while internalization will prevail for high transaction costs (i.e. hierarchy). Intermediate modes are often referred to as hybrid modes (Williamson 1991).

TCE recognizes that transactions do not occur without friction. Costs arise from the interaction between and within firms as transaction costs: information costs, negotiating costs and monitoring costs (enforcement costs) (Hobbs 1996). Transaction costs would be zero if humans were honest and possessed unbounded rationality. Transaction costs for a particular transaction depend on the three critical dimensions of transactions: asset specificity, uncertainty and frequency (Williamson 1985). Besides these key concepts underpinning TCE (bounded rationality, opportunism, asset specificity, uncertainty and frequency), Milgrom and Roberts (1992) add two other items: difficulty of performance measurement, and connectedness to other transactions. Both are relevant from a supply chain viewpoint, and influence the possibilities to reduce transaction costs. Obviously improved collaboration and communication in the supply chain will reduce transaction costs.

Supply chain viewed as a production system
The supply chain is aimed at the delivery of a product or service to an end market or a single customer. This implies a production process which is purposive. The management of the production process needs to ensure the purpose of the process is achieved effectively and efficiently by addressing the transformation (conversion), flow and value aspects of production in an integrated manner (Koskela 2000). In terms of the firm, both primary and support activities are aimed at the delivery of customer value, and as a result revenues and profit for the firm (Porter 1985) (Figure 4).

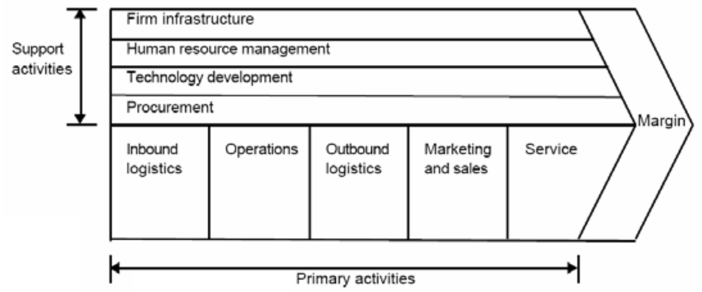

Figure 4: Value chain (Porter 1985)

Supply chain viewed as an organizational system

Firms as well as supply chains are organizational systems built from various vital elements that make them function as they do. By viewing organizations as systems of flows, Mintzberg (1979) identifies four system representations of organizations together making up the structure and infrastructure of organizations: the organization as a system of formal authority, regulated flows (material, information), informal communication, work constellations and ad hoc decision processes.

Typically, the supply chain is a ‘system of systems’, or a ‘superstructure’ of organizations. Firms along the supply chain perform distributed production activities and business functions. This raises the issue of core competences of firms (Prahalad and Hamel 1990), together making up an ‘extended enterprise’. In construction this relates to the idea of the ‘quasi-firm’ coined by Eccles (1981).

EMPERICAL BUILDING BLOCKS

Based on the theoretical building blocks, first a generic supply chain integration model will be built. The generic model will next be specified and validated by adding empirical ‘building blocks’ from a few case studies of supply chain integration outside and inside construction. These case studies include multiple cases including the four cases below, i.e. two companies outside construction (truck manufacture and shipbuilding), and two construction firms (housing and commercial building). For reasons of limited space in this paper, below the four cases are described very briefly.

Two examples of supply chain integration outside construction: truck manufacture and shipbuilding

In the early 1990s the Dutch truck industry went into a crisis. After drastic reforms most companies recovered, and are currently doing quite well. One of the measures was to reform and integrate the supply chain. Suppliers have been integrated in product development, planning and logistics. In respect of the clients, in Europe, an integrated dealer network has been established, which ensures direct follow-up of defects to trucks, and 24-hour on-road maintenance.

In the Dutch shipbuilding industry, a few producers have improved their businesses drastically. They are globally leading companies in limited product categories. For those products they have introduced strict standardization and modularization, and imposed this on their suppliers. This has improved the profitability and quality dramatically. Some suppliers have become ‘external business’ units, guaranteeing the close links.

Two examples of supply chain integration inside construction: housing and commercial building

In the Dutch housing sector, a few builders have transformed their business and become suppliers of completely pre-engineered houses. They deliver houses from their catalogues to be built in one week. The different types of houses can be customized completely according to clients' wishes. The fully integrated in-house production and pre-installation of the houses ensure a smooth process, and prevent delays and quality problems. In addition to the delivery of the house itself, they arrange for the permissions from local governments, mortgage and other additional issues.

In the Netherlands, many project developers have moved their business towards the 'front end' of the supply chain. They have acquired land and existing buildings to be developed and redeveloped. Additionally they deliver all services desired by their clients including finances, maintenance, facility management and operations such as security and restaurants of offices. Some project developers have integrated the supply chain to such an extent that they actually became their own clients, in order to find users of their projects after completion.

Comparing supply chain integration outside and inside construction

When broadly comparing the examples of supply chain integration inside and outside construction, one sees differences as well as similarities. Differences can be found in the possibilities to pre-engineer products, and integrate the supply chain. Outside construction the levels of pre-engineering and integration are higher, because levels of repetition are generally higher. Similarities can be found in the mechanisms to integrate design, follow up clients, and offer additional services to clients. Apparently these issues are generally valid and play a role in most industrial sectors delivering products to customers.

However, the characteristics of industries vary from industry to industry. The production system of each industry has been shaped by the industry characteristics and history. Project production systems in project-based industries such as construction are aimed at a product mix that is 'one of a kind or few', process patterns are 'very jumbled', processes segments are 'loosely linked', and management challenges are dominated by 'bidding, delivery, product design flexibility, scheduling, materials handling and shifting bottlenecks' (Schmenner 1993). The fragmentation of the construction industry has been identified for decades as a major point of the complaints about the state of practice (Turin 2003), reflected most characteristically by the predominant one-off approach in construction projects, or 'unique-product' production (Drucker 1963).

IMPLICATIONS OF SUPPLY CHAIN INTEGRATION

Implications from a demand system perspective

Traditionally, clients have played an important and dominant role in construction (Cherns and Bryant 1984). Also with regard to supply chain integration, the client's role can be rather critical, while he makes the initial decision to procure construction works and the way in which procurement takes place (Briscoe *et al*. 2004). Clients who have the power to shift their procurement strategies vis-à-vis the market are in a position to align the supply chain effectively, and implement supply chain integration successfully (Cox and Ireland 2001). In these cases, procurement strategies must therefore be aimed at establishing long-term relationships in the supply chain. Some advanced and professional clients with 'buying power' have created multi-project environments and manage their procurement through a portfolio approach (Figure 5), aimed at the increase of repetition and creating similarities between multiple projects, and thus increasing the degree of project certainty and 'supply chain stability' (Blismas *et al*. 2004). Often these clients have successfully introduced a strategic long-term approach to procurement, which has proved to be particularly effective for certain sectors in construction (Cox and Townsend 1998).

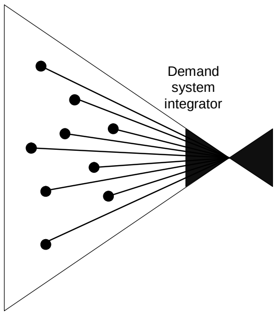

Figure 5: The role of the demand system integrator (Vrijhoef and De Ridder 2005)

Implications from a supply system perspective

On the supply side, parties have evolved towards more integrated arrangements through project-independent collaboration with other parties in the supply chain as well as internalization of neighbouring activities or businesses. In both cases operational and competitive advantages, through higher levels of productivity and efficiency as well as delivering better client value are the drivers for this kind of supply chain integration. Normally this development is led by a focal firm, the system integrator; this could be a main contractor, but also an architect or engineering firm (Figure 6).

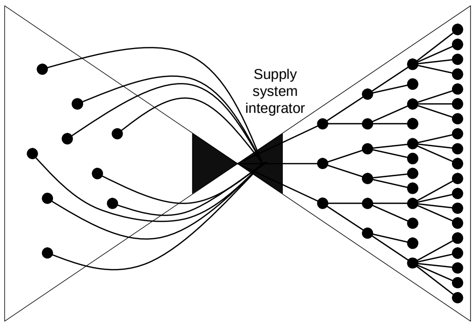

Figure 6: The role of the supply system integrator (Vrijhoef and De Ridder 2005)

CONCLUSIONS

Theory as well as examples from other industries claim and demonstrate the value of supply chain integration. This is also true for construction. Owing to the characteristics of construction, a specific model for supply chain integration in construction must be adapted and built, including guidelines for firms along the supply chain in different types of construction. A systems approach as proposed in this research is helpful to build the integration model and improve construction supply chains. This exercise includes a 'building exercise' using theoretical building blocks (concepts) and empirical buildings blocks (cases) leading to a 'change model' of 'organizational rebuilding' of existing construction supply chains. In order to do so all functions along a supply chain in fact need to be deconstructed, followed by reconfiguration of the functions and the interfaces between these functions. By doing this, the endemic problems and irrationalities should be 'engineered out' of the construction supply chain, eliminating existing problems including their negative symptoms. The side effect must be that the control of different functions will get more aligned and centralized, transforming the supply chain into an integrated structure, i.e. extended enterprise.

Although the application of supply chain integration to construction is a fundamental and potentially strong solution to improve the performance of construction practice, the take-up by the industry is not widespread. Apparently, the possibilities in construction are restricted compared to other industries. This includes the possibilities for product development, standardization and prefabrication, and achieving economies of scale for a large market. These characteristics are the main reasons why supply chain integration in construction has been slow, and thus needs intelligent solutions.

RELATIONSHIP MANAGEMENT: A CASE STUDY OF KEY ACCOUNT MANAGEMENT IN A LARGE CONTRACTOR

Hedley Smyth[1] and Tim Fitch

The Bartlett School of Graduate Studies, University College London, (Torrington Place Site), Gower Street, London, WC1E 6BT, UK

Relationship management theoretically arises from relationship marketing, which includes key account management (KAM) as a concept. Relationship management is distinct from relational contracting, which induces behaviour derived from changes in market structure, whereas relationship management is behaviourally proactive. The main relationship marketing tenets are provided, showing development into relationship management, specifically in construction. Relationship management has been partially applied in construction. However, several large contractors are applying elements. Investment and resource allocation, and organizational behaviour have posed constraints, particularly concerning service continuity in construction. In construction particular issues are posed at the project-corporate interface, requiring contractors to become more interventionist, along the lines of portfolio management, especially for KAM, which is explored through an in-depth case study of a major UK contractor as it is being implemented. The method combines external observation with action research. Emphasis is placed upon analysing the KAM concept contextually, in terms of both projects and behaviour in the form of individual and organizational behaviour in order to explore causality in practice from the formation and implementation of the policy.

Keywords: management of the firm, marketing, organizational behaviour, relational contracting.

INTRODUCTION

Enterprise management has moved towards emphasizing process management above structure over the last 20 years. Construction has made some moves away from adversarial behaviour towards more collaborative practices. There remains a primary emphasis upon structural approaches to the market (Smyth 2006), which includes relational contracting. A relationship approach is process-orientated approach. Relationship marketing and management are therefore process-orientated (Pryke and Smyth 2006). A concept of relationship management is the key account handler (KAM), which seeks service improvement for the client, and repeat business for the contractor from having a single role responsible for client management.

The *aim* of this paper is to explore the concept and application of KAM in construction. The *objectives* are to locate KAM within relationship marketing, examining how this has been developed in theory and practice into relationship management (RM) in construction. A further objective is to clarify the distinction between relationship management and relational contracting (RC). The final objective

[1] h.smyth@ucl.ac.uk

is to explore how relationship marketing and management are being applied in a leading construction firm.

The findings in general terms add support for the *relationship paradigm* concerning the Management of Projects (MoPs) (Smyth and Morris, 2007; Pryke and Smyth, 2006). The findings specifically add support for the application of RM in construction, hence demonstrating in practice differences between RM and RC, which is of normative significance because adherence to the concept RC has imposed artificial constraints upon the scope for developing firm and project management in construction practice (see Table 1). More specifically, KAM is shown to provide a means to address one considerable obstacle to increased client satisfaction on the one hand, and deliberate and differentiated service delivery by contractors on the other hand, by addressing consistency and continuity of service on projects and programmes.

Table 1: Features of relational contracting and relationship management

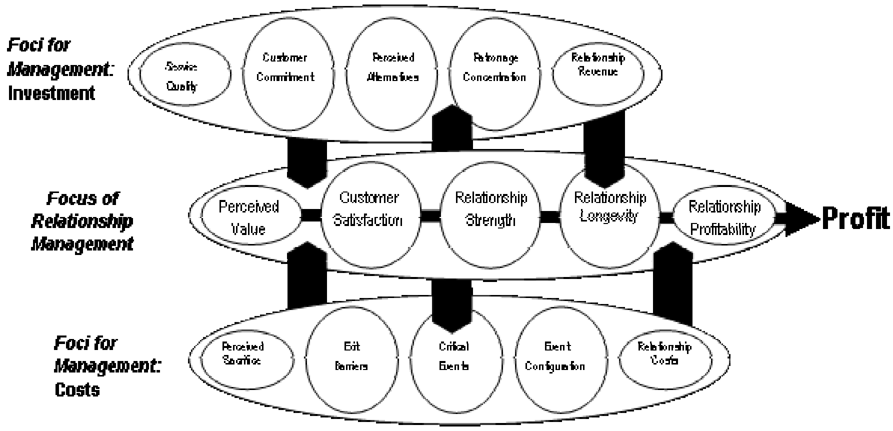
Relational Contracting (RC)	**Relationship Management (RM)**
Market driven	Organizationally driven
Structural change to induce behavioural change	Process changes to improve performance and induce structural change
Governance through client procurement requirements	Aggregated behaviour through contractor strategic choice
Top down	Bottom up
Contractor reactive	Contractor proactive
Project commitment	Corporate commitment across projects
Low investment	High investment
Ability to move from Relational Contracting to Relationship Management	

RELATIONSHIP MARKETING AND RELATIONSHIP MANAGEMENT

In marketing, there has been a *paradigm* shift since the mid-1980s from the transaction approach of the marketing mix towards a proactive paradigm of human agency called relationship marketing, in essence a way to restore the sole trader-customer relationship for large organizations through strategy and systems. The marketing mix paradigm was seen as appropriate for mass-market consumer goods, whilst relationship marketing was increasingly perceived to be appropriate for business-to-business transactions, especially for intangible services. Dominant schools of thought have had different emphases, for example the pioneering Nordic School (e.g. Grönroos 2000; Gummesson 2001), the founders of the largely Anglo-Saxon IMP Group (e.g. Christopher *et al*. 2001; Ford *et al*. 2003) and the more pragmatic North American stream (e.g. Berry *et al*. 1983; Reichheld 1996), common themes being investment in and value from relationships (Ford *et al*. 2003), and a market orientation pursued through networks of relationships (Gummesson 2001). The business purposes typically included:

- Increasing customer loyalty, hence relationship strength and longevity by increasing customer satisfaction.
- Increasing profitability through adding relationship and service value, and reducing sales plus other transaction costs.

Concepts and practice have broadened since the beginning with relationship marketing being perceived as both an alternative as well as being complementary to the marketing mix (Kotler *et al*. 1996). Developing relationship marketing requires a range of conceptual tools. For example, Gummesson (2001) identified 30 different types of relationship within four categories that required management, and Storbacka *et al*. (1994) developed a model to guide its management (Figure 1).



.

Figure 1: A simplified model of relationship management (Source: Pryke and Smyth 2006, adapted from Storbacka *et al*. 1994)

In order to deliver customer satisfaction, it was quickly recognized that managing relationships required actions that went beyond marketing. Gummesson (2001) asserted everyone was a part-time marketer and some organizations eliminated marketing departments in response. Relationship marketing was developed into a management approach for what were complex, intangible services that operated in uncertain and high-risk contexts (cf. asset specificity and bounded rationality in transaction cost terms). Hence, relationship management was developed, as implied within Figure 1.

Managing critical events, sometimes called *moments of truth*, at the customer-supplier interface and with other stakeholders is important. A management tools to address this issue is the concept of the key account manager (KAM) (e.g. McDonald *et al*. 1997; Kempeners and van der Hart 1999). Having a primary single point of contact, the KAM, permits the supplier to provide consistency and continuity of service. Applying the KAM concept within RM needs clarity and precision. The transactional approach of marketing mix manages sales through a single point of contact, sometimes depicted as a butterfly or bowtie diagram with sales and procurement being the primary economic interface, whereas RM is multi-faceted and cross-functional, recognizing a series of interfaces (Figure 2). In order to ensure consistency over a series of transactions and continuity for service delivery, a KAM manager acts as the internal manager to muster the service across the supplier interface with the customer, who preferably identifies a counterpart in order to improve collaboration.

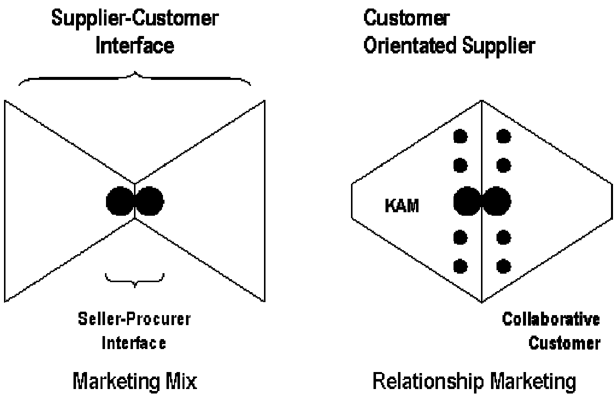


Figure 2: Customer interfaces and the location of KAM

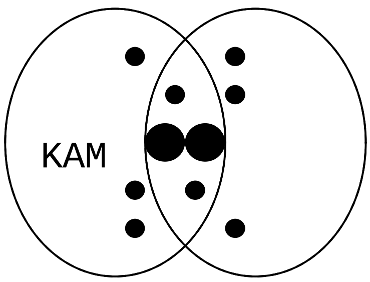

Figure 3: KAM within a network of transaction relationships

Initial contact may be transactional; developing into RC as relationships develop, it can transition into relationship marketing, then RM, the boundaries of the firms becoming less distinct behaviourally – a more organic network of relationships (Figure 3). Those personnel located within the overlap have intensive contact and constitute the decision making unit (Smyth 2000). To work consistently, RM becomes embedded as a core competency (cf. Pralahad and Hamel 1990), hence as social capital, which has the feature of appreciating with use, unlike most financial assets, as well as being a set of business systems. Implicit in the KAM concept within relationship marketing is the notion that some accounts are non-key, thus key accounts will tend to constitute the core business in volume in relation to service expertise (e.g. McDonald *et al*. 1997; Spencer 1999; Ojasalo 2001) and/or non-key customers are managed transactionally; however, in firms adopting RM all customers are considered key for the business unit or company.

The introduction of KAM can increase transaction costs, however, any increase is conceptually offset through efficiencies in sales costs as a result of repeat business, efficiency through effective learning and productive responses made through relationship strength and longevity, and by profits derived from added relationship, hence service value. RM generally and KAM specifically provides a focus for collaborative working, such as partnering and SCM, but this again raises issues concerning a further raft of investment, costs and returns.

RM requires resources to be allocated for investment in the strategy and systems for operation and in the norms (organizational culture) and codes of conduct as a core competency within the resource base view (Barney 2003). However, a conceptual distinction has to be made between RC as a branch of transaction cost theory and RM as a competency for inducing more cooperative forms of behaviour. RC is a top-down approach with a reactive response in behaviour hence action. RM is bottom-up, proactively soliciting behavioural changes in aggregate behaviour. Once a significant number of firms engage with this, there is opportunity to change governance and market structure. Changes in market structure are likely to be seen as greater differentiation of services and therefore increased numbers market segments defined by service configurations – ultimately to segments of one firm in idealized terms (Gummesson 2001; Smyth 2000 in construction). Relationships can be developed to a more sophisticated level and actively managed within RM in ways that go beyond RC, although RC can act as a basis for transitioning into RM (Smyth and Edkins 2007).

This section has set out the main tenets of relationship marketing and RM, and the KAM concept. The distinction between RM and RC has also been made.

APPLICATION IN THE CONSTRUCTION FIRM

Relationship marketing is more theoretically aligned than the marketing mix to most of the characteristics of construction and contractors (Smyth 2000, 2006). However, practice does not support this conceptual proposition to date, a primary reason being the tendency to minimize investment and transaction costs in lumpy and uncertain markets where individual firms lack market dominance and leverage with clients and their customers (Gruneberg and Ive 2000; Smyth 2000; Cox and Ireland 2006). Contractors tend to seek structural solutions to marketing issues, resulting in contractors offering undifferentiated services organized by procurement route and building types (Smyth 2006). However, this does not mean relationship marketing cannot be applied to construction. Indeed, it has been argued that firms can chose to invest and allocate resources to relationship marketing and management (cf. Barney 2003), recognizing that this exposes firms to higher risks in the short-to-medium term (Smyth, 2000). Additionally, client drivers have required changes in working practices amongst contractors to the extent that RC has been adopted for projects and client programmes; however, there is piecemeal evidence of contractors going beyond a top down approach of RC applied on a project-by-project basis, towards a more behavioural approach (e.g. Smyth 2000; Kumaraswamy and Rahman 2006; cf. Smyth and Edkins 2007).

In order to implement RM into construction, contractors need to adopt a corporate strategy, managing their projects as a programme (Pellegrinelli 1997; Maylor *et al.* 2006). A separate model is needed for RM at the project level (Figure 4), which places greater investment emphasis upon the corporate-project interface and managing project transaction costs and supply chains. However, the project level requires integration into the corporate structure through investment and support systems particularly to inject quality, commitment, developing alternative solutions and support for managing critical events, whilst yielding converting project relationship value and revenues into corporate revenues and profit (Pryke and Smyth 2006).

The KAM function plays a significant role at the corporate-project interface in construction, taking responsibility for all projects for a client, concurrent and sequential, and thus is responsible for chunks of the contractor's total programme. This bridges the corporate level and project level. If a KAM has responsibility for a series of clients, this may constitute a segment of the contractor's market. Such accounts and segments may cut across procurement routes and building types, thus challenging the traditional corporate solutions to marketing as primarily structural ones (cf. Smyth 2006).

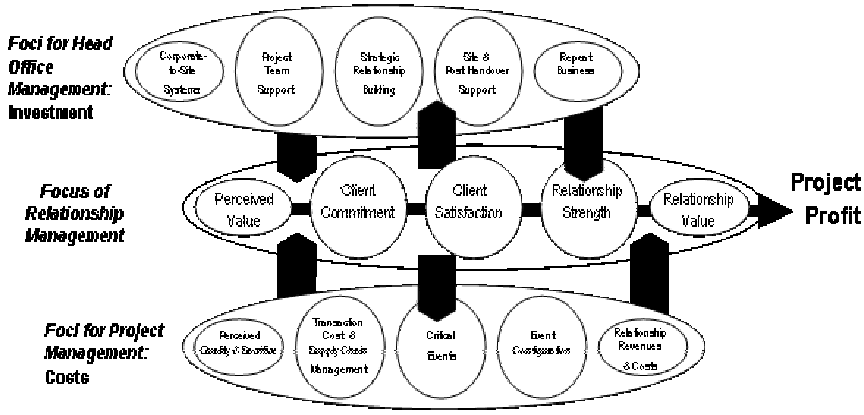

Figure 4: A simplified model of relationship project management (Source: Pryke and Smyth 2006)

A KAM can be a senior sales person (business development director), a contracts manager or a board director, depending upon strategy and client importance (cf. Kempeners and van der Hart 1999). It is the responsibility of KAMs to increase client satisfaction, thus increase the chances for repeat business as well as increasing market reputation by adding value through relationships (Pryke and Smyth 2006). Therefore, actions to add value to the services on the one hand, and problem solving to address critical events or moments of truth on the other hand are amongst the most important for the KAM function. A vital and neglected part of delivering client satisfaction in construction has been identified as consistency of service within projects and continuity of service across projects for clients (Smyth 2000; cf. Wilkinson 2006). Consistency refers here to the service character and quality received on a project and continuity that the character, hence quality is maintained across projects so that the experience received by a client on one project is the same or similar on others.

Two models have been identified at the project level for consistency (Smyth 2000; Pryke and Smyth 2006):

- Relay team.
- Account handler.

The relay team model is most suited to construction for transaction cost management. Resources are allocated to projects to maximize efficiency from the contractor view point, which may include changes in key personnel at each stage of the project from tendering presentations to completion on site, each change constituting a leg of the relay. However, this does not necessarily maximize effective service delivery. Ideally, the baton represents consistency and continuity whereby expectations of the client, promises made to the client, technical and process project information is handed on at the changeovers with some overlap (cf. Winch 2000). In practice, many contractors figuratively make changeovers that either “drop the baton” or personnel do not “carry one”. The result is that client requirements and hence satisfaction suffers. The relay team works where the baton is passed and client are aware of the changes in personnel in advance and the reasons for the changes (Smyth 2000).

The account handler model has a single person of contact for the client and is ultimately in charge (overseer) throughout the project. This is similar to, and might be performed by the KAM, but the role can be project specific, reflecting the project rather than programme as the management focus within many contractors, in other words, the 'account' and project are synonymous. Applying RM, the account and the client programme (segment of the contactor's total programme of projects) are synonymous, the KAM managing at this level. An RM strategy decision is whether to have a layered approach, whereby the KAM operates at the programme level, with account handlers or relay teams at project level, decisions depending upon factors such as project complexity, transaction cost management and linkages to other strategic and functional areas, such as procurement and estimating. Heads of all key functions – responsible board director, KAMs, estimating, account handler, supply chain managers, contracts director and project manager as roles which are not necessarily mutually exclusive – will constitute the decision-making for any particular project on the contractor side, together with complementary roles among the client and their design team (Smyth 2000).

The level of investment in systems and support from the corporate centre of the firm under RM is more than the requirement to satisfy continuous improvement of project partnering and strategic partnering (client programme and segment of the contractor programme), supply chain management and other approaches that come under RC. To make RM work aggregated behaviour (norms or organizational culture) and behavioural codes of conduct (prescribed procedures) need to be in place that go further than reaction to new formal and informal contracting agreements under RC. KAMs have an important role in modelling and guiding the implementation of appropriate behaviour for their projects and clients. It has been found that contractors still have to address the behavioural issue, tending to leave appropriate behaviour to the responsibility of individuals rather than proactive management by the firm (Smyth and Edkins 2007) – they have been practically influenced by transaction cost management and arguably adopted limited horizons through transaction cost theory in the form of RC rhetoric and fashion (cf. Green 2006).

The concepts and application of different approaches to relationship development and management in projects has been a major stimulus in the identification of a *relationship paradigm* for the MoPs (Pryke and Smyth 2006; Smyth and Morris 2007). This section has explored how RM and KAM can conceptually be applied in construction, clarifying the distinction of this approach from other approaches, in particular RC. However, conceptual possibility becomes relevant to practice upon application.

METHODOLOGY AND METHODS

Two paradigms are being applied: marketing-based RM, and a relationship approach within the management of projects (Pryke and Smyth 2006). Management by definition concerns causal powers for generating particular outcomes or events. Management has socially constructed prescriptive agendas. The prescription is needed because outcomes are contingent upon fertile conditions in the overall operating context (social, political and environmental), the social conditions for the object (social, technical and socio-technical in the case of construction projects). Therefore a methodology is required that is not merely instrumental in identifying general patterns, but can offer explanation between the socially constructed theory for both general and specific events (Smyth *et al*. 2007). Critical realist methodology satisfies these criteria, recognizing the context specificity, which renders events or outcomes dependent upon contingent conditions (Sayer 1992; Smyth and Morris 2007 in construction). Following Danermark *et al*. (2002), this research covers the first two stages of a six-stage research process six stage research process, the literature review emphasizing extensive research, intensive research being needed to substantiate conceptual possibilities following implementation. An action research method is being used to help through combining participation and observation (see Dunnette 1976). It is typically associated with the interpretative methodology within ethnography, and is sometimes associated with empiricist approaches. It is suited for this study because it engages at a fine grain of analysis, so that both the general and particular are identifiable. The case study deals with the initial stages of KAM implementation and later consideration will be necessary to assess whether customer satisfaction and benefits are realized.

CASE STUDY

KAM is a conceptual possibility, yet only takes on complete relevance once seen in the field. Yet there have been attempts to apply KAM. These have been short lived because partial implementation will not work in the long run, hence the need for RM, and because the commitment must be embedded into firms as a core competency (Pralahad and Hamel 1990). However, several large contractors are beginning to consider and adopt RM.

Some empirical context is needed in which to locate the detailed case study. One medium-to-large sized UK firm appointed a board level marketing director as KAM, who spent two days every week looking after the interests of its key client portfolio (a supermarket chain), liaising internally with those responsible for projects and externally with clients to ensure actions were aligned to expectation, to add value that arose through a series of innovations in working practices that directly benefited the client. In this case, RM was embodied in an individual, rather than being embedded and owned by the firm, consequently the function was lost when the individual ceased to work for the firm (Smyth 2000).

A second case involved a niche market leader in partnership housing in the UK, the KAM function again being led by the marketing director. This firm experienced considerable success embedding RM into the firm short-term, the approach not being robust enough to withstand on the one hand becoming complacent about some basic tenets of the execution of project management, and on the other hand withstanding structural change imposed by the parent company on the niche market contractor.

A third case involved a major internationally owned contractor appreciating the benefits of the KAM function, appointing project managers into the role for key UK clients, yet failing to appreciate how KAM fitted into RM. The consequence was a failure to resource the KAM role, thus the KAMs took their focus off the client and were fighting for internal resources to achieve their set objectives.

The action research case of the detailed case study centres upon a large the national business of an international UK contractor. One of the management studied RM within a part-time interdisciplinary masters programme around MoPs. He influenced both board and senior management of his employer to explore application. A consultancy and training involvement for the firm developed on RM, and a monitoring process set up, initially to cover a one-year implementation period.

The organizational structure was traditional, following typical hierarchical lines of communication and accountability. The Customer Directors acted as the sales force, serving a business organized on a project-by-project basis with co-ordination occurring at the level of the Operations Directors. Clients were categorized into green, amber and red according to priority, which was predominantly based upon (potential) profit margins, yet the criteria were not always clear to the Customer Directors.

The new strategy was to introduce RM with the Customer Directors (CDs) acting as KAMs with the aim to increase customer satisfaction, improve repeat business, especially through cross-selling and raise net margins to 3–4%, except where certain clients were identified as giving rise to other explicit strategic benefits, such as covering a base-load of overheads, being efficient payers to increase return on capital employed, and provided sector track record and reputation to use to secure other clients. The implementation phase is reported here, the extent of benefits to customer will become apparent at a later stage.

A new structure has developed, in two phases. The first phase involved giving the KAM function authority, placing CDs in a separate line of authority and developing cross-functional working. The second phase, having embedded the CD function was to create Sector Directors (SDs) to be responsible for clients whose business is transport and energy, rail, retailing, and facilities management for example (Figure 5). The result is less hierarchical and more organic, depicting the growing horizontal as well as vertical communication and accountability (cf. Millman 1996). This is a snapshot and the picture continues to evolve and become formalized.

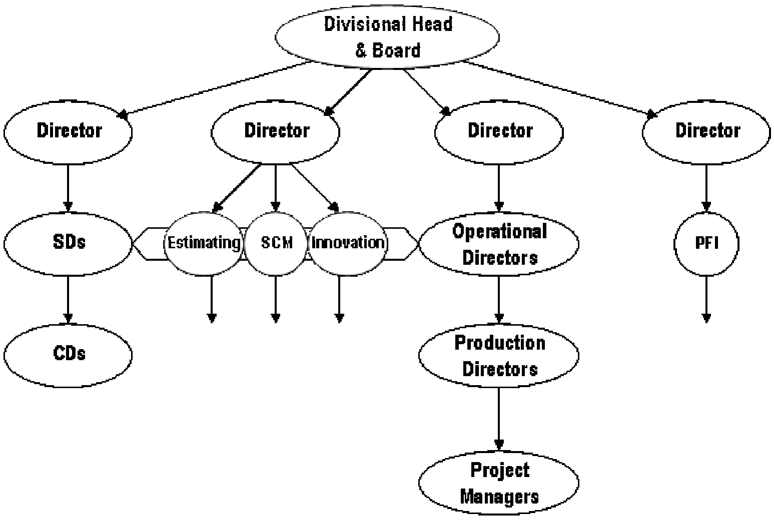

Figure 5: Simplified model of current organizational structure and KAM function

The KAM function therefore operates at two levels: SDs and CDs under a Board Director (cf. Kempeners and van der Hart 1999). Under the KAM function *Sector Plans* are being developed by SDs (cf. market segment planning), *Customer Account Plans* have been developed for individual clients (cf. sales planning), and *Relational Development Plans* within clients have been developed with a specific remit to build relationships and add service value (cf. relationship marketing sales tactics-cum-process plans, which contrasts with the former marketing mix-style *Tender Approval Form* as the project strategy at the tender stage). However, SDs and CDs require more than business development skills, requiring for example developed management skills (Millman 1996), and a detailed understanding and knowledge of technical, product and service issues (McDonald *et al*. 1997). The developed management skills include the ability to work across functional departments and roles. The SDs and CDs are charged with that role. Currently, there are two aspects. First, Sector meetings are chaired by the SDs and involve the Operational Directors, CDs are charged with responsibility for communication opportunities in the business development pipeline, updating *Relational Development Plans*, determining relationship ownership amongst the CDs, rating clients, plus actions to be taken. Rating clients uses the green, amber, red approach based upon (potential) net profit margins, but has yet to be developed into a more sophisticated model based upon relationship value over the client life cycle and margins derived from the added value component. Second, cross-functional working is also engaged with Estimating. This is seen as a vital role in determining profitable value added opportunities. This currently happens on a reasonably informal basis, which may evolve into a formal approach in time. Yet to develop is the cross-functional working with SCM and Innovation, which should prove to be significant for adding value, improving service and client satisfaction in the medium-term. All these aspects are vital components for achieving consistency within a project and continuity of service for a client programme.

Table 2: Summary of case study implementation

KAM Roles	KAM Functions	KAM Outcomes
Board Director	Develop roles	
	Create functional authority	Devise systems and support
	Manage KAM roles and functions	Raise net margins to 3–4%
Sector Directors (SDs)	Embed KAM function	Implement systems and support
	Sector Plan development	Increase customer satisfaction
		Improve repeat business
	Customer Account Plan management	Raise net margins to 3–4%
		Increase customer satisfaction
	Sector Meetings	Increase cross-selling
	Manage Commercial Directors	Increase customer satisfaction
Customer Directors (CDs)	Business Development (relationship marketing)	Improve repeat business
	Relational Development Plans	Increase customer satisfaction
	Cross-functional working	Increase customer satisfaction
	Manage RM-Client programme and project interfaces	Increase customer satisfaction
Operational Meetings	Attend Sector Meetings	Increase customer satisfaction
	Deliver added service value in programmes and projects	Increase customer satisfaction
		Raise net margins to 3–4%
		Improve repeat business

This represents a significant shift in emphasis from "just getting the job done" or task-orientation (Handy 1997) towards tailoring services to meet client expectations that are within the power of the contractor to deliver. In essence, reverses the 80:20 Pareto rule from suppliers having 80% focus on cost of production and delivery and to an 80% focus upon service quality, as it is this less or intangible service element that has been found to constitute 80% of customer satisfaction (e.g. Ford *et al*. 2003). Pratt (1999) identified the same 80:20 mismatch in construction, which in this contractor is beginning to address in a comprehensive way. This case reports upon the implementation of KAM to date; however, it is expected that the strategy will evolve and how clients respond remains to be seen, and the ways in which the are perceived to benefit has yet to come through the KAM system.

CONCLUSION

The paper has shown that relationship marketing and management are conceptually possible for adoption into contracting and has shown that it is being applied by way of a detailed case study using action research methods within a critical realist methodology. The paper has presented the initial findings concerning implementation, further study being required over a longer timescale to assess the tangible benefits of adopting relationship marketing and management. Both the concepts and application provide clarification to frequent confusion and misunderstanding concerning the scope and limits of RC and the potential for relationship marketing and management.

MANAGING HUMAN RESOURCES WITHOUT HUMAN RESOURCES MANAGEMENT DEPARTMENTS: SOME EXPLORATORY FINDINGS ON A CONSTRUCTION PROJECT

Paul W. Chan[1]

School of the Built Environment, Northumbria University, Ellison Building, Ellison Place, Newcastle upon Tyne, NE1 8ST, UK

There has been a growing interest in human resources management (HRM) in construction. The dominant discourse has, however, concentrated on criticising the industry's lacklustre approach towards HRM, with writers promoting the use of more formal methods of managing human resources in construction. Yet, little has been done to fully explain how informal HRM practices can work in construction. This study arose from an opportunity to investigate this within a medium-sized contractor, which did not have a HR department. Through a series of 19 interviews and documentary evidence collected, the recruitment, employee deployment and development practices of the case study organisation are examined, providing evidence that informal HRM can be effective.

Keywords: case study, deployment, development human resources management practices, recruitment.

INTRODUCTION

There has been growing interest in human resources management (HRM) in construction over the last decade. Textbooks have been introduced on this subject, including Langford *et al.* (1995), Druker and White (1996) and more recently, Loosemore *et al.* (2003). Following the Latham (1994) and Egan (1998) agenda, the UK construction industry has also seen the promotion of the Respect for People (RfP) initiative (Movement for Innovation (M^4I), 2000). This greater emphasis placed on human resources and human relations in construction indicates a movement beyond the dominance of the technical rationalism found in much work associated with construction management research, especially in relation to the literature on construction planning.

However, whilst there is a surge in the number of academic publications on the subject, the uptake of HRM practices in industry still lags behind (see Dainty *et al.*, 2000). Writers have suggested that the transience of the industry and the widespread use of casualised self-employed labour (Winch, 1998) results in the lack of formal employment of HRM in construction (see Debrah and Ofori, 1997). In fact, Haas *et al.* (2001) found that formalised HRM systems tend to be under-utilised in a sector that devolves HRM practices to line managers (Renwick, 2003) based on the project site.

[1] paul.chan@unn.ac.uk

The construction industry is made up largely of small and medium-sized enterprises (SMEs), which often do not have HRM departments. Indeed, Dainty *et al.* (2000) have suggested that construction companies tend to rely on less formal structures in terms of managing the employment relationship. More recently, Raidén and Dainty (2006) indicated that construction organisations tend to display the traits of a “chaordic” (a balance between the chaotic and the orderly) organisation. Chan and Kaka (2007) also observed that benign paternalistic relationship between site managers and their workers tend to underpin the employment relationship in the construction project environment.

Although the dominant discourse suggests that construction organisations are not very good in engaging with strategic HRM (SHRM) (Raidén and Dainty, 2006), the extant literature remains relatively opaque in terms of explaining how informal HRM actually work in construction. A research opportunity arose to help plug this gap. Access was granted to a medium-sized construction company without a HRM department for the purpose of understanding the informal mechanisms of how human resources are managed. This paper presents and discusses some preliminary but illuminating findings. The next section will outline the salient points raised in the many debates surrounding HRM in construction.

HRM DEBATES IN CONSTRUCTION

The consideration of human resources in construction in the academic literature has only emerged relatively recently. In the existing body of knowledge, there has been much criticism over the industry’s lacklustre approach towards HRM. Dainty *et al.* (2000) suggest that construction companies tend not to place HRM as top priority. Chan and Kaka (2007) also observed that construction managers often put technical planning ahead of workforce issues. This reinforces Green’s (1999) arguments against the industry’s adoption of lean principles. Green (1999) suggested that managers often do not consider the impacts of lean tools and techniques on workers’ autonomy and job satisfaction.

Druker *et al.* (1996) also suggested that the emphasis on construction planning meant that human resources are often treated as another factor of production and implied that construction organisations rarely operationalise the rhetoric of soft HRM (i.e. welfare for workers). Many writers have looked at skills development, for instance, to support the assertion that HRM features less prevalently in construction (see Beckingsdale and Dulaimi, 1997; Forde and MacKenzie, 2004; and Clarke, 2006). Indeed, Dainty *et al.* (2000) promoted the need for sophisticated ways of managing human resources by calling on companies to consider human resources more strategically. Chan and Cooper (2006) indicated that this could be done by reflecting on recruitment, employee deployment and development practices within construction organisations.

Nonetheless, Raidén and Dainty (2006) questioned this dominant discourse by claiming that their case study organisation did consider the development of their human resources, albeit not formally. They explained that due to the transient nature of construction work, construction organisations often had to balance the long-term planning of human resources against short-term economic efficiencies necessary to deliver projects. Raidén and Dainty (2006) suggested that further studies be undertaken to support their claim. As mentioned previously, an opportunity arose that enabled the examination of HRM within a medium-sized contracting firm. Interestingly, this firm did not have a HR department. Therefore, the study sought to:

- Explore the practice of HRM within this firm and examine how the practice of HRM filters down to the project level, and to;
- Investigate the recruitment, deployment and development practices within the firm.

THE STUDY

The study focussed on ConstructCo, a construction company specialising in concrete operations that co-existed with three other subsidiary companies under a parent group, ConstructPLC (see Figure 1 below). Of the companies, ConstructCo was the biggest in size (based on persons employed, turnover and portfolio of activities). Moreover, in terms of employment, ConstructCo had a mix of both directly employed general labourers and subcontract labour (including self-employed, labour-only subcontractors and trade subcontractors). Thus, it was decided that ConstructCo would be most appropriate in providing insights into the dynamics of HRM in construction. At the time of study, ConstructCo undertook a project involving the structural phase of the redevelopment of a large retail unit in the Northwest of England. With no office based in the region – ConstructPLC was based in Hertfordshire – there was an expansion opportunity of creating a regional office near the project. Due to confidentiality reasons, the names of the companies have been anonymised here.

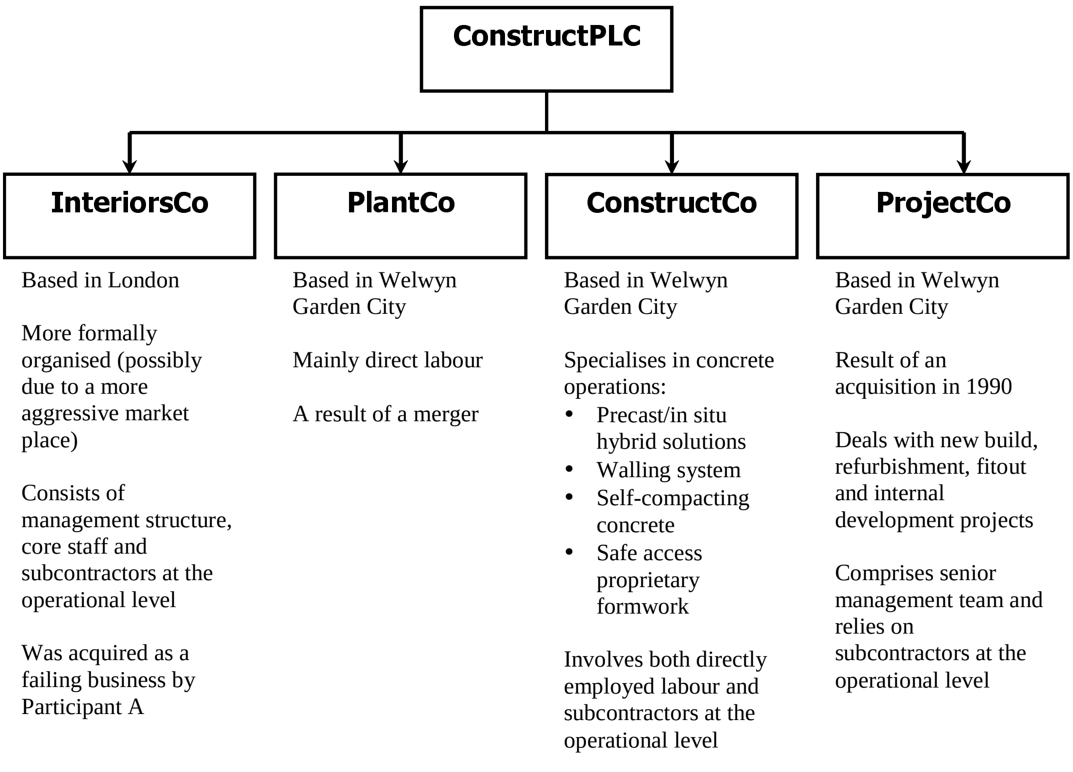

Figure 1: Organisational structure showing the location of ConstructCo

A total of 19 semi-structured interviews were conducted with key participants in ConstructPLC from November 2004 to April 2005. Each semi-structured interview lasted between 1 to 3 hours and was audio-taped for analytic reference. The interview followed an interpretive research framework intended to gather rich descriptions of the recruitment, deployment and development practices that went on in ConstructCo, as well as what went well in the project, what went badly in the project, and what were the perceived improvements in retrospect. To ensure a full understanding of both strategic and operational considerations of HRM, a range of interviewees were selected to cover both managerial staff and workers on site (see Table 1 below for a profile of the interviewees). A summary sheet was completed immediately after each interview. This captured key points made by interviewees whilst the interview remained fresh in the researcher's mind. The summary sheets were then sent back to the interviewees to ensure accuracy of the researchers' understanding of the issues raised (see Figure 2 below).

Table 1: Profile of interviewees.

Interviewee	Organisation / Position	Job Function
A	ConstructPLC – Chairperson	Senior Management
B	Construct PLC – Group Secretary	Senior Management
C	ProjectCo – Managing Director	Management Team
D	PlantCo – Managing Director	Management Team
E	ConstructCo – Chief Estimator	Management Team
F	ConstructCo – Project Manager	Line Manager
G and H	ConstructCo – Joiners	Employee
J and K	ConstructCo – General Operatives	Employee

EMERGENT FINDINGS

This section discusses the emergent findings, which are presented as follows. First, a general overview of HRM in ConstructPLC is explained. An analysis of recruitment, deployment and development practices at the project level (specific to ConstructCo and the large retail project) will then follow.

HRM in ConstructPLC

HRM across ConstructPLC, with the exception of PlantCo, was generally informal. There was no designated department within any of the four companies in ConstructionPLC with the main remit of managing human resources. It was observed that HRM was construed by managerial staff as bearing the same administrative functions of personnel management in the 1980s, i.e. the management of payroll, pensions, sick leave and holiday entitlement. The function of accounting, therefore, played an important role in HRM in ConstructPLC.

Nonetheless, people were seen to be important assets throughout ConstructPLC’s business and the managerial staff all operated an “open-door” policy for all their members of staff. Typical issues include career progression (usually through formal wage reviews and/or the less prominent informal appraisal process) and disputes on e.g. non-performance on health and safety on site. A number of interesting observations were made here.

First, there was a clear distinction between office-based staff and site-based operatives. Although the “open-door” policy applied to everyone within ConstructPLC, it was found that senior managers in ConstructPLC were mainly responsible for office-based staff, devolving the responsibility of managing site-based operatives to site managers. This distinction pervaded throughout recruitment, deployment and development practices, explained below.

Second, it was indicated by the interviewees that the informality of HRM meant that “open-door” policy could work quickly and effectively. That is, problems could be solved at an instant, usually “through a phone call”. There was, however, no concerted effort in tracking down how this “open-door” policy manifested in reality, i.e. it was purely on a case-by-case basis. Still, there was a suggestion made by a number of interviewees that the “open-door” policy was seldom utilised. Within the confines of this study, however, it was unclear whether this was due to a lack of emerging problems, or whether staff and operatives were fairly autonomous and so maintained their discretion not to consult managers, or simply because staff and operatives were not aware of the existence of an “open-door” policy due to dominance of informal HRM. It is likely to be a dynamic interaction between the three reasons put forward here.

Following on from the distinction between office-based staff and site-based operatives, it was noted that despite the informality of HRM in ConstructPLC, there existed a natural hierarchy in the redress of issues. So, operatives naturally consulted their foremen, and if the problem remained unsolvable, then the problem would be referred to the project manager, and then the next higher up (e.g. regional director) and so forth. Similarly, a discontented secretary would first approach her/his line manager, and if the problem persisted, the line manager would refer to the next higher up and so forth.

However, the "open-door" policy also meant that staff and operatives could potentially pass over their line managers and go directly to the next higher up. Again, this was not usually the case as the interviewees believed that the problems tend to be solved fairly quickly and effectively by line managers. Furthermore, interviewees believed there was a culture of respect across the group and that everyone operated in sync within the informal framework. It was discovered that this culture resulted from a somewhat top-down approach, which could be traced back to the Chairman of ConstructPLC (Participant A). In fact, new managers are constantly initiated into the group/company as Participant B claimed that "if a manager does not share this value of respecting the workers, then he will be called in and I will say this is how it is done in [ConstructPLC]". Indeed, ConstructPLC operated like a family business, even though Participant A started out as an employee of the group. Still, he bore the main responsibility for building up the group through business acquisitions, which probably explained the deep entrenchment of his philosophy throughout the four companies in ConstructPLC.

As mentioned previously, PlantCo maintained a more formal framework of HRM. The Managing Director of PlantCo (Participant D) kept a Microsoft Excel spreadsheet of all the employees in the company, detailing their individual pay rates, holidays and more importantly, training needs and deployment. In other words, according to Participant D, he would know where (i.e. which project in which geographic location) a particular employee is located at any given time, and at what point in time should an employee undergo a particular training regime. PlantCo stood out from the rest chiefly because all the employees (mainly plant operators and maintenance staff) were directly employed by the company. Therefore, it made business sense to enforce a more formal framework of managing human resources. However, this was considered to be an exception rather than a rule for the construction industry, since the plant hire sector of the industry tended to employ directly due to the need for staff reliability in operating plant (which are expensive capital investment).

Indeed, the wider macro-level labour market dictated the extent to which HRM was formalised in ConstructPLC, and the construction industry at large. Because of the dependence on sub-contract labour and the encouragement of self-employment (Winch, 1998), it is extremely difficult to shift to direct employment even though companies like ConstructPLC are willing to do so. As a result, HRM remains informal where sub-contract labour and self-employment perpetuates (see Drucker and White, 1996). Moving towards more formal frameworks in sectors where direct employment appeared to be the norm e.g. in plant hire. Let us now turn to the HRM practices in ConstructCo.

Recruitment practices in ConstructCo

The distinction between office-based staff and site-based operatives was extremely pronounced in recruitment practices of ConstructCo. For office-based staff, recruitment was fairly stagnant since the workforce remained relatively stable (there was a major reshuffle/rethink of office-based job roles in the early 1990s by the Group Secretary). Instead, recruitment of office-based staff was performed mainly internally, usually through promotion/developmental opportunities for applicants. Examples were given of helpdesk staff progressing to become a quantity surveyor, or receptionists upgrading to become an administrator. Where external recruitment was concerned, an example was found in the appointment of the regional director (Participant S) of ConstructCo.

In this case, a need to recruit was identified in ConstructCo's intention to expand its presence in the Northwest of England. A recruitment agent was approached and a suitable applicant was selected based on matching up the job and person specifications with the CVs of potential applicants. Further interviews (either face-to-face or over the telephone) with suitable applicants to validate work experience and establish the individual's vision for ConstructCo in the Northwest were conducted by the recruitment agent where appropriate (based on recruitment agent's discretion). According to the Group Secretary, appointment of office-based staff tended to be subjected to a probationary period. This allowed ConstructCo to "test" the employee to see if the representation of CV/interview is accurate. This practice emanated from a negative past experience where an employee's behaviour apparently transformed (for the worse) from the time of interview to the commencement of work.

Where site-based operatives were concerned, the process was less formal. Recruitment was normally done through the grapevine. The need to recruit was usually based on the effective start-date on-site. Calls would be made through known contacts, performed in the main by the general foremen. Such known contacts tended to exist in the foremen's heads (or notepads) and are amassed from the foremen's experience on previous projects. On the other hand, potential employment was elicited in the operatives' social setting, e.g. local builders' pub. Again, news of projects starting up would be spread through the grapevine, either through the foremen's contacts or the operatives' initiative to approach ConstructCo. The recruitment process usually began with the question "are you looking for work?" or "are you looking for workers?"; followed usually by a discussion of pay and start date. Working conditions were rarely raised as these were notionally associated with the reputation of the firm.

In the selection process, greater prominence was placed on the worker's attitudes (Is she/he reliable? Will she/he turn up for work? Will she/he get along well with other workers?); and less emphasis on technical abilities. There was a general belief by the interviewees that technical abilities would be evidenced by (a) references offered by the prospective worker, usually based on previous projects worked on; and/or (b) technical questions asked during the interview, although this is performed in a rather *ad hoc* manner. Furthermore, the flexibility of the workforce through sub-contract labour and self-employment meant that there was an ease of firing incompetent operatives if an operative was found to be a fraud. Again, where new operatives were employed, a probationary period of a week (or sometimes a day) would be in place so that ConstructCo retained the flexibility to fire the "frauds". Indeed, it was observed that the probationary period represented a somewhat experimental, if informal, approach in which ConstructCo managed the recruitment of staff (both office-based and site-based).

In both office-based staff and site-based workers, a disconnection between theory and practice of recruitment was found. Ideally, according to Taylor (2002), a good recruitment and selection process should begin with rigorous and robust job analysis that should give rise to detailed job and person specifications. However, it was found that in reality, this was rarely performed. Instead, there was a reliance on traditionally-defined roles (e.g. a traditional joiner, bricklayer, secretary, receptionist) with a greater emphasis placed on quantitative measures (i.e. how many bodies do we need?) as compared with the quality of skills involved.

Because of the informal framework of ConstructPLC the selection process was also less formalised. Furthermore, this was usually founded on the subjective evaluation of the interviewer (using the interviewer's personal judgement of what is good or bad, which often reflects benchmarking against the interviewer's perception of their own performance). Moreover, safeguards, e.g. probationary period, were put in place to ensure the attainment of the right fit in the recruitment of human resources. Such experimentation suggested that there was some kind of thinking process behind ConstructCo's recruitment, albeit in an informal manner.

Deployment practices in ConstructCo

Deployment was found to be less essential and virtually non-existent at the project level because of the reliance on sub-contract and self-employed labour. The allocation of resources was usually tied up with the recruitment and selection process, often arising rapidly upon the award of a contract. Similar to recruitment practices above, it was believed that traditionally-defined job roles were crucial since this enabled the project manager and general foreman to establish the numbers needed. However, this meant that there was lesser focus on the quality of skills tied to a specific job role. This did pose problems at the project level with the need to re-hire as a result of incompetence, e.g. errors due to site engineers and fraudulent joiners.

Furthermore, deployment of human resources appeared to be a dynamic combination of the planned and emergent. For instance, it was found that there was an inclination towards resource planning where sub-contract labour (particularly in terms of work packages) was concerned. Conversely, where directly-employed labour was involved, deployment tended to be a matter of matching availability with the dynamic needs derived from the project schedule.

Interestingly, it was discovered that general operatives tended to be directly employed whereas more highly skilled labour e.g. joiners and steelfixers tended to be sub-contract and/or self-employed labour. This supports the argument that flexibility is the prevailing criteria for HRM at the project level. In other words, the use of general operatives acted as a buffer for variations in project schedule and workloads that could occur throughout the life of a project; whereas the use of highly skilled labour was task-specific and therefore could be planned according to a given programme.

A limitation of this study needs to be stated. Whilst the discussion on deployment related mainly to site-based operatives, deployment was not mentioned in the discussion of office-based staff.

Development practices in ConstructCo

As mentioned previously, ConstructPLC as a group operated on an informal basis. There was therefore no predetermined career progression path within the group for each of the four companies. Developmental opportunities were largely contingent on the individual employee's discretion and initiative. However, this begged a worrying question as to whether individual employees were best placed to identify and act on their developmental needs. Furthermore, there was the aspect of commercial viability of developing employees. Often, it was difficult to balance employees' developmental needs with the operational pressures of delivering projects (see Beckingsdale and Dulaimi, 1997; Dainty *et al.*, 2000).

It was found that when interviewees were asked what they were good at in terms of their personal skills and experience, all the participants invariably found it difficult to articulate these in a coherent manner. Two possible reasons account for this. First, participants might have found it difficult to frame an answer to such a question because they were not used to describing their abilities. Second, the hesitation could simply be the result of (lack of) personal reflection rather than uncertainty. Even so, all the participants chose to focus on such softer skills as communication and inter-personal skills when discussing their strengths, whilst downplaying their technical abilities. Furthermore, on the question of possible improvements, it was noted that a majority of the interviewees did not actually talk about improving their skills base. Instead, most interviewees chose to highlight external influences, e.g. improving information flow, reducing the rigidity of the personal protection equipment policy by the main contractor; with only a handful of interviewees (mainly managerial) who talked about specific personal skills e.g. motivating people, enhancing lateral thinking.

There was recognition of a dearth of training in the industry. Unsurprisingly, therefore, training for the improvement of technical abilities or even softer skills was not performed in a structured manner and would appear to be on a case basis. Nonetheless, training existed in health and safety where there is mandatory legislation. Furthermore, there was a general perception that informal mentoring and learning-by-watching/doing took place with younger operatives learning from more experienced operatives (within and more likely beyond ConstructCo e.g. operatives from other firms on previous/current projects). However, this learning was not structured and again dependent on personal initiative and aptitude to learn.

Where office-based staff was concerned, there was some evidence of investment in training. However, this appeared to be *ad hoc* and on a case-by-case basis. An example was provided of the helpdesk staff progressing to become a quantity surveyor, through a sponsored degree course (both financial sponsorship and in terms of study time).

CONCLUSIONS

In conclusion, the study revealed that whilst there was no formalised HR department in ConstructPLC, there was consideration of HRM through the examination of recruitment, deployment and development practices of the case study via a delicate balance of the planned and emergent. This corroborates, to a certain extent, with Raidén's and Dainty's (2006) notion of the 'chaordic' organisation. The case findings highlighted a greater tendency for formalisation of HRM procedures for office-based staff and direct employees, with more informalisation for project-based staff. The extant literature criticises such informality, however, such informality has served ConstructPLC well. This is because of the somewhat patriarchial, top-down approach driven by the Chairman (Participant A).

Specifically, recruitment was performed tactically based on the award of a contract. Job analysis was rarely performed; instead, there is reliance on traditionally-defined job roles, placing more emphasis on skills planning from a quantitative perspective. Negative impacts of incompetent employees (i.e. inappropriate skills) were mitigated and flexibility encouraged through probationary periods administered informally during the recruitment of office-based and site-based staff. This, however, could potentially increase the cost (and wastage) of re-hiring, and arguably the potential problem of latent skills shortages (Chan and Cooper, 2006). Deployment of skills was virtually non-existent as recruitment was often used as a means to resource a project. Development opportunities were available to directly-employed labour, although this was contingent on the capacity and capability of the individual labourer. Development opportunities were, however, non-existent for non directly-employed labour, with the exception of mandatory training requirements of health and safety.

EXCHANGE RELATIONSHIPS IN BUILDING SERVICES MAINTENANCE ACTIVITY: A TEST OF TRANSACTION COST ECONOMICS AND THE RESOURCE DEPENDENCY VIEW

Adrian J Bridge[1]

School of Urban Development, Queensland University of Technology, 2 George Street, Brisbane, Queensland, Australia

The firm is faced with a decision concerning the nature of intra-organizational exchange relationships with internal human resources and the nature of inter-organizational exchange relationships with market firms. In both situations, the firm can develop an exchange that ranges from a discrete exchange to a relational exchange. Transaction Cost Economics (TCE) and the Resource Dependency View (RDV) represent alternative efficiency-based and power-based explanations of the nature of the exchange relationship. The aim of the paper is to test these two theories in respect of air conditioning maintenance in retail centres. Multiple sources of information are generated from case studies of Australian retail centres to test these theories in respect of internalized operations management (concerning strategic aspects of air conditioning maintenance) and externalized planned routine air conditioning maintenance. The analysis of the data centres on pattern matching. It is concluded that the data supports TCE – on the basis of a development in TCE's contractual schema. Further research is suggested towards taking a pluralistic stance and developing a combined efficiency and power hypothesis – upon which Williamson has speculated. For practice, the conclusions also offer a timely cautionary note concerning the adoption of one approach in all exchange relationships.

Keywords: human resource management, maintenance, relational contracting, transaction cost economics.

INTRODUCTION

The firm is faced with a decision concerning the nature of intra-organizational exchange relationships with internal human resources and the nature of inter-organizational exchange relationships with market firms. In both situations, the firm can develop an exchange that ranges from a discrete exchange to a relational exchange. Transaction Cost Economics (TCE) and the Resource Dependency View (RDV) represent alternative efficiency-based and power-based explanations of the nature of the exchange relationship. With regard to more mainstream construction activity, progress has been towards empirical testing of TCE on the issue of inter-organizational relationships, including Eccles (1981). Again, in terms of mainstream construction, Cox and his colleagues have focused on developing a power-based approach to inter-organizational relationships (for example, Cox 1999; Cox and Townsend 1998; Lamming and Cox 1999). With respect to building services maintenance, Lai *et al*. (2006: 333) considered the application of TCE on the issue of

[1]a.bridge@qut.edu.au

inter-organizational relationships. However, this empirical contribution does not focus on the specific operationalization of the TCE dimensions. Therefore, despite all of this progress, there remains substantial scope to further develop and test more widely established approaches to operationalizing the TCE and RDV dimensions on the issue of inter-organizational exchange relationship in building maintenance. There also appears to be an absence of work that tests these theories with respect to intra-organizational exchange relationships in building services maintenance. The aim of the paper is to test these two theories in respect of one particular sector of building services maintenance activity – namely, air conditioning maintenance in retail centres. More specifically, the investigation focuses on intra-organizational relationships with Operations Managers (OMs) and inter-organizational relationships with mechanical services contractors (MSCs).

In the next section, TCE and RDV are briefly described in terms of their application, hypotheses and relationship. Details concerning the research design and results then follow. Finally, the conclusions focus on the relative power of TCE and RDV and the prospects for a pluralistic approach.

THEORETICAL PERSPECTIVES ON EXCHANGE

Transaction cost economics

Williamson proposes that a range of exchange relations (from discrete to relational exchange) may be economical in inter-organizational exchange, whilst the richest form of relational exchange is substantially the purview of vertical integration. Hence, Williamson's initial working hypothesis can be refined thus:

- The greater the potential for the appropriation of quasi-rents, or *hold-up*, the more likely the activity will be internalized *with an ensuing relational exchange*.
- The lesser the potential for hold-up, the more likely that the activity will be externalized *with a lesser relational exchange than that associated with internalization.*

Williamson's (1999) constructive critiques concede the possibility that internalization may be selected as the first choice organizational form (in pursuance of improvements in production costs) and not as the last resort. If internalization is chosen for purposes other than to avoid hold-up, then relational exchange may not always occur. Indeed, it seems reasonable to expect as wide a range of exchange relationships within the firm as we find between firms. This would then lead to the possibility of relaxing an implied heuristic within TCE's contractual schema. That is, the requirement that TCE should account simultaneously for the make-or-buy decision *and* the nature of the exchange relationship with respect to internalization. In other words, and with respect to internalization, there are appears to be the opportunity to explore separating these two decisions and treating them as *two – sequential* decisions. By treating the make-or-buy decision and the nature of the exchange relationship as two sequential decisions, and having selected internalization, the focus of the transaction switches from the *activity* (on the issue of the make-or-buy decision) to the *resource* (on the issue of the nature of the exchange relationship decision). In turn, this may effect the operation of all of the TCE variables assumptions – as explained by Bridge (2004). In this study, however, the semi-structured interviews revealed that the conventional approach remained the most effective way to measure each of the TCE dimensions.

That said, one of the significant matters that arises out of this development in TCE's contractual schema is the prospect of some significant level of hold-up without necessarily a high level of uncertainty and frequency. The employment contract is different from other contractual arrangements, in so far as the exact nature of the tasks is deliberately undefined. The employer purchases a capacity to work, such that if the employer can organize to extract a higher level of productivity from the employee then no cheating has occurred (Marginson 1993). In this sense, the influence of exogenous uncertainty is much reduced by virtue of the nature of the adaptability built into the employment contract. Having made non-trivial investments in a human resource, the firm has an interest in this resource delivering a better than perfunctory performance and maintaining their employment with the firm. This may then lead to a *weaker form* of potential hold-up than that conventionally described in TCE. Whilst this weaker form of hold-up may be insufficient to explain the firm's decision to internalize the activity associated with the human resource, it may be sufficient to explain the nature of the exchange relationship with the human resource.

Resource dependency view

Pfeffer and Salancik (1978) develop the notion of power and dependency in their version of RDV and envisage a number of different ways by which a firm may choose to respond to demands made on it from a discernable group that may be internal or external to the firm. In circumstances in which the firm is dealing with an important exchange and is not able to develop substitutes nor diversify, and is unable to undertake a relevant merger or vertically integrate, then the firm is faced with the remaining strategy of attempting to adapt by mediating the exchange through some kind of formal and/or informal social coordinating mechanism – amounting to relational exchange. Pfeffer and Salancik's (1978) hypothesis can be refined thus:

- The greater the degree of bilateral dependence (two-way interdependence and balanced both ways), the greater the likelihood that *the exchange is relational and based on credible commitments (as positive balancing measures*).
- The greater the degree of unilateral dependence (one-way interdependence and unbalanced), the greater the likelihood that *the exchange is discrete with high prices or credible threats as negative balancing measures* (in addition to the tacit threat of using some other exchange partner or use of simple termination clauses).
- The greater the degree of independence (two-way and balanced), the greater the likelihood that *the exchange is discrete with reasonable/low prices and an absence of credible threats* (reliance on tacit threat of using some other exchange partner or simple termination clauses only).

Relationship between TCE and RDV

RDV covers many of the same issues as TCE, in so far as both these approaches incorporate a major concern for the negative effects of opportunism and hold-up in complex situations that cannot be controlled easily by the contract alone (Rindfleisch and Heide 1997: 31). However, TCE treats asset specificity as a situation of resource dependency that independent and voluntary agents deliberately take recourse to, whilst the power approach typically assumes such a situation to be unanticipated and unwanted by the dependent party (Groenewegen and Vromen 1996: 376). This situation is illustrated in Figure 1 and concerns the case of *special purpose investments*.

TCE and RDV both endeavour to explain the existence of relational exchange (as shown in the mid-point of Figure 1) by appealing to the influence of dependency. However, in the case of *special purpose investments*, the point of departure between TCE and RDV concerns the nature of motivation surrounding the relational mid-point in Figure 1. On the one hand, TCE sees the parties to the exchange actively seeking this position in the interests of efficiency, with the dominant party willing to share some of its power. On the other hand, RDV considers that the parties have reached this position reluctantly – for the time being, neither party is able to attain more power in the relationship, so that almost a stalemate develops.

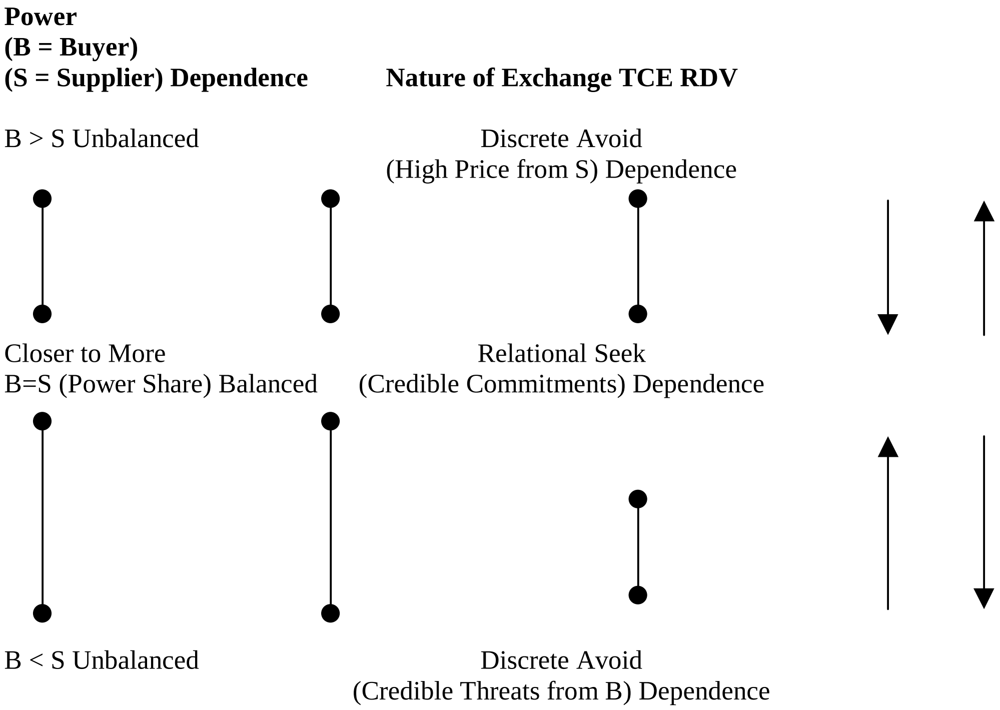

Figure 1: Special purpose investments – seeking dependency in pursuance of efficiency vs. avoiding dependency in pursuance of power

Without a move to the mid-point, inefficient outcomes may materialize. At one end of the scale, when the buyer is more powerful, then this could lead to higher prices (as the supplier prices the risk of the buyer appropriating profits). In contrast, when the supplier is more powerful, this could lead to credible threats (as the buyer may attempt to pre-empt the supplier’s *ex post* bargaining advantage). For TCE, any of these inefficient outcomes are a significant concern. Hence, this theory see actors attempting to mitigate and/or avoid these outcomes by *seeking dependencies* and dependency balancing, which includes developing harmonious relations as a preferred course of action. In contrast, RDV is much less concerned with these outcomes, choosing instead to view these developments as short-term inefficiencies, which are much less important than the longer-term survival of the firm. The survival characteristic that RDV emphasizes is *size*: larger firms are considered to be more resilient than smaller firms in the face of environmental changes.

The fundamental differences in the objectives of the firm in TCE and RDV, as illustrated in Figure 1, can be traced to different assumptions concerning rationality. TCE adopts a semi-strong form of rationality, or bounded rationality, as one of its behavioural assumptions, so that decision makers seek to optimize, within the bounds of their knowledge, the match between the governance structure and attributes of the transaction, in order to minimize transaction costs. Here, the firm is seen as focusing on each transaction in isolation and developing governance structures that deal with *ex post* and temporal dependencies. Thus, the operationalization in TCE centres around the individual transaction. In contrast, the firm in RDV is able to take a more holistic stance, and a less than optimal individual transaction might be an important part of a longer-term strategy to ensure the firm's survival. More specifically, the firm may be facing *ex ante* and ongoing dependencies that require a process of concession and/or avoidance and/or adaptation in order to restore the balance of power in favour of the focal firm. Thus, the operationalization in RDV goes beyond the characteristics of the individual transaction and focuses more on the *entire* exchange and possible multiple transactions between the parties. In summary, the strength of TCE relative to RDV turns largely on the market/competitive conditions surrounding the firm that determine the extent to which maximizing on transactions becomes an economic imperative.

RESEARCH DESIGN AND RESULTS

Explanatory case studies

The design and presentation of the explanatory case studies in this paper draws heavily from Yin (1994). An explanatory case study approach was adopted as means to test the hypotheses for two main reasons. First, the collection of data in respect of the research questions in this paper are not straightforward given the secrecy surrounding this kind of decision making. Here, interviews and other sources of evidence may be used to address some reluctance to provide detailed and open answers. Second, and consistent with the first reason, multiple sources of information are more effectively generated when a respondent has clearly in his/her mind a particular case (in this study, the case is taken to be a retail centre). Four criteria can be used to improve the quality of case studies: external validity; construct validity; internal validity; and reliability. The first three criteria are now used as a structure to present the case study design and results. Reliability refers mainly to issues associated with inconsistency arising out of data collection by multiple researchers. In this study, all data was collected by the author.

External validity

In pursuance of notion of *analytical generalization,* comprising *theoretical and literal replication,* six case studies of retail centres were selected. All of these are in one state's capital city in Australia. The cases shown in Table 1 were chosen to represent theoretical replication – in order to produce contrasting results but for predictable reasons (due to differences in the size of the centres). Whereas, the cases shown in Table 2 were selected on the basis of literal replication – with the expectation that they should provide similar results as for each of the first three cases.

In Table 1, the type and size of each retail centre is classified using the main classifications of retail centre developed by Property Council Australia (2000). Case Study 3 is partially air conditioned in contrast to full air conditioning in Case Study 3A. However, the nature of the air conditioning is these cases are similar – each with an absence of central plant and a Building Management System. Moreover, the extent or scale of air conditioning is comparable, in terms of maintenance time and the value of the contract. Thus, these two cases are expected to provide similar results. Table 1 adopts an economic distinction between internalization and externalization (Lai 2000). Consistent with this approach, wholly owned subsidiaries are described as firms that are internal to some other larger firm. The implication of an internalization or externalization is the creation of intra-organizational relationships and inter-organizational relationships respectively. As mentioned in the introduction, this paper focuses on intra-organizational relationships with OMs and inter-organizational relationships with MSCs. Finally, although there are a few general maintenance staff in Case Studies 1, 1A, 2 and 2A, the OMs indicated that these staff are not able to be used to replace the MSCs even for a very short period of time. Therefore, general maintenance is a distinctly different activity to planned routine mechanical maintenance, does not affect the inter-organizational relationships in this paper and is beyond the scope of this paper.

Table 1: Brief profile of case studies used to show theoretical replication

Retail Centre	**Case Study 1 Super and Major Regional (> 50,000m^2)**	**Case Study 2 Regional (30–50,000m^2)**	**Case Study 3 Sub-Regional and Neighbourhood (< 30,000m^2)**
Type and size	Major Regional	Regional	Sub-Regional
Mechanical Services	Fully Air Conditioned	Fully Air Conditioned	Part Air Conditioned
Centre Management	By Centre Management firm external to Owner	By Centre Management firm internal to Owner	By 1 x Part-Time Centre Manager internal to Owner
Operations Management	By 1 x Full-Time Operations Manager internal to Centre Management firm	By 1 x Full-Time Operations Manager internal to Owner/Centre Management firm)	By 1 x Part-Time Operations Manager internal to Owner
Planned Routine Mechanical Maintenance	By Mechanical Services Contractor (with internal technical staff) external to Centre Management firm	Mechanical Services Contractor (with internal technical staff) external to Owner/Centre Management firm	Mechanical Services Contractor (with internal technical staff) external to Owner

Table 2: Brief profile of case studies used to show literal replication

Retail Centre	Case Study 1A Super and Major Regional (> 50,000m^2)	Case Study 2A Regional (30-50,000m^2)	Case Study 3A Sub-Regional and Neighbourhood (< 30,000m^2)
Type and Size	Super Regional	Regional	Neighbourhood
Mechanical Services	Fully Air Conditioned	Fully Air Conditioned	Fully Air Conditioned
Centre Management	By Centre Management firm internal to Owner	By Centre Management firm internal to Owner	By Centre Management firm external to Owner
Operations Management	By 1 x Full-Time Operations Manager internal to Owner/Centre Management firm	By 1 x Full-Time Operations Manager internal to Owner/Centre Management firm	By 1 x Part-Time Operations Manager internal to Centre Management firm
Planned Routine Mechanical Maintenance	By Mechanical Services Contractor (with internal technical staff) external to Owner/Centre Management firm	Mechanical Services Contractor (with internal technical staff) external to Owner/Centre Management firm	Mechanical Services Contractor (with internal technical staff) external to Centre Management firm

Construct validity
Establishing theoretical propositions prior to the conduct of any data collection is an essential part of explanatory case studies. In particular, extant theory – along with associated empirical work, promote the operational measures of theoretical constructs and help avoid subjectivity in the collection of data. This study employs two tactics to increase construct validly – namely, the use of multiple sources of evidence (to create, through data triangulation, converging lines of inquiry) and the procedure of allowing the informants (decision makers) the opportunity to review and comment on the case study report. The decision maker with respect to the intra-organizational relationship with the OM is the Centre Manager (CM) and the decision maker with regard to the inter-organizational relationship with the MSC is the OM.

The multiple sources of evidence comprised a structured questionnaire completed by each decision maker, an interview with each decision maker and documentation provided by the decision maker and collected by the author in relation to the decision maker's firm and the retail centre. With regard to the structured questionnaire, Table 3 gives a very brief outline of the questions used. Apart from each question being contextualized for each decision maker, in terms of the relationship that this manager is responsible for, the same questionnaire was administered to each decision maker and received by the author in advance of the interview with the decision maker. As a starting point for the design of the questionnaire, previous and well-established empirical studies were used as the basis of the development of the items used to capture the dimensions on the nature of the exchange relationship and the two theories (as mentioned in the comments column in Table 3). In order to translate these previous studies from the context of the originating activity to the activity and relationships under investigation in this paper, semi-structured interviews were then undertaken with a CM and an OM in Brisbane and a final draft of the questionnaire was then piloted with six CMs and eight OMs across Sydney, Melbourne, Adelaide and Perth. As a clearer example of the results of this translation procedure, reproduced below are the full questions – in respect of the Items 1 and 2 concerning Human Asset Specificity (HAS) in the version of the questionnaire contextualized for OMs – that determine the relationship with the MSCs:

- Item 1: How long would it take a recently appointed and competent contractor to become familiar with your centre and to reach their expected level of performance? Please insert months:___Months
- Item 2: How much did your current contractor in your centre need to customize their technology (hardware and software), knowledge, skills, policies, procedures and practices to suit your centre? Please circle on the scale: Minimal adaptations 1 2 3 4 5 6 7 Substantial adaptations

In contrast to the questionnaire, the other questions in the case study interviews were largely unstructured/open-ended. The extent of documents provided by each decision maker comprised mainly company information, internal letters, maintenance schedules, induction handbooks and documents downloaded from websites relating to the specific retail centre and also representing the firms concerned. Finally, and on the conclusion of the final case study interview, decision makers were sent a case study report (with written receipt confirmation obtained) confirming their answers to the questionnaire (including any adjustments the decision maker made to their initial answers during the course of the interview), along with confirmation of any other relevant advise provided by the decision maker.

Internal validity

Internal validity is an important concern for explanatory case studies and when the analytic tactic of pattern matching is advocated – as is the approach in this paper. The application of pattern matching inevitably leads to some interpretation in the analysis of results as part of creating summary empirical patterns of data and then in matching these patterns with theoretically predicted patterns. However, the subjectivity involved in this process is minimized in this study by developing guidelines to translate the quantitative data generated by the questionnaire into summary empirical patterns and then reviewing other sources to establish whether this information corroborates or contradicts the summary empirical patterns.

Table 3: Items in structured questionnaire

Outline of item	Comments
Nature of exchange relationship: Dimensions: *Solidarity* • Item 1: Cooperation • Item 2: Expectation of continuation *Role Integrity* • Item 1: Complexity of all relations • Item 2: Complexity of expectations *Mutuality* • Item 1: Lack of monitoring of performance • Item 2: Imprecise terms and conditions of contract	Each item in each of the three dimensions of this dependent variable is based on Kaufmann and Stern (1988). Kaufmann and Stern's approach is preferred by the author as this approach considers the nature of the exchange to be a continuum from discrete exchange to relational exchange. A 7-point semantic differential response format is used for each item – with the 7/high end labelled in terms of a high incidence of the item and 1/low end of the scale labelled in opposite terms - a low incidence of the item.
TCE: Dimensions: *Human Asset Specificity (HAS)* • Item 1: Time to reach expected performance • Item 2: Specific adaptations required *Uncertainty (Exogenous and Endogenous)* • Item 1: Difficult to predict range of tasks • Item 2: Difficult to predict time to complete each task • Item 3: Difficult to predict frequency of each task • Item 4: Difficult to specify performance requirements • Item 5: Likelihood of changes in core knowledge and skills • Item 6: Difficult to monitor performance • Item 7: Unfairness of objective measures of performance *Frequency* • Item 1: Full-time equivalent staff (FTE)	The three TCE dimensions are attributable to Williamson (1985). As part of the semi-structured interviews used in the development of the questionnaire, HAS was advised by interviewees as the most relevant/dominant type of asset specificity. Items 1 and 2 are based on John and Weitz (1988). The uncertainty items are based on Walker and Weber (1989) and Anderson and Schmittlein (1984). The frequency item is also based on John and Weitz (1988). A 7-point semantic differential response format is used for the items – except for: • HAS Item 1: Measured in full-time equivalent months or days • Frequency Item 1: Measured in discrete numbers Again, with the 7-point semantic differential response format, the 7/high end labelled in terms of a high incidence of the item and 1/low end of the scale labelled in opposite terms - a low incidence of the item.
RDV: Dimensions: *Criticality* • Item 1: Lack of tolerance in correcting unsatisfactory performance • Item 2: Lack of tolerance in correcting unsatisfactory pay/working conditions *Magnitude of Exchange* • Item 1: Proportion of cost • Item 2: Proportion of revenue *Lack of Discretion* • Item 1: Lack of influence on actions • Item 2: Lack of influence on actions *Few Alternatives* • Item 1: Few other sources • Item 2: Few other sources	The items in each of Pfeffer and Salancik's (1978) four RDV dimensions are based on Provan *et al.*'s (1980) and Saidel (1991). A 7-point semantic differential response format is used for each item – with the 7/high end labelled in terms of a high incidence of the item and 1/low end of the scale labelled in opposite terms - a low incidence of the item. Since the exchange relationship is determined by the manager in the firm buying the service and based on this manager's perception of the net dependence in the exchange, both Item 1 and Item 2 are provided by this manger. The semi-structured interviews and the pilot study used in the development of the questionnaire ensured that both Item 1 and Item 2 are able to be readily answered by the buyer.

This data and the summary empirical patterns are shown in Table 4 (see overleaf), along with the guidelines (key to Table 4). The approach used to review other sources of evidence centred on the identification of text and quotations that could be directly connected with the theoretical dimensions (for example, Bresnan 1991). That said, the focus in this paper is on the presentation and analysis of the questionnaire data.

Having summarized the empirical patterns using the guidelines in Table 4, the next step was to select a predicted pattern that corresponds with each of the empirical exchanges. In doing so, each of the inter-organizational relationships are considered efficient, on the basis that all the OMs felt they were paying a reasonable/low price for the service and there was a complete absence of any costly credible threats. This is significant in selecting the RDV predicted patterns, as different patterns would be selected for an inefficient discrete exchange in contrast to an efficient discrete exchange. In order to assess the match between empirical and predicted patterns, Yin (1994) advocates simple “eyeballing” of data to establish substantial matches and mismatches.

With regard to RDV and the net dependency column in Table 4 (overall mean), there is one match between the summary empirical pattern and the predicted pattern on the inter-organizational relationship between the centre management firm (represented by its OM) and the MSC in Case Study 1A. Moreover, if some tolerance is allowed and added to the Table 4 guidelines that specify a balanced dependence when the mean scores are exactly equal, then the empirical patterns concerning the other external relationships could be interpreted as showing some reasonably strong match with predicted patterns. However, the low mean scores representing both the buyer and supplier in terms of the internal relationships create a substantial mismatch between the empirical and predicted patterns. In contrast, TCE’s asset specificity shows empirical patterns that substantially match the predicted patterns - across both internal and external relationships

CONCLUSIONS

As relational exchanges were observed in the absence of bilateral dependency, the results do not support the RDV hypotheses. In contrast, the results provide clear support for TCE. Furthermore, this support for TCE is enhanced by evidence of analytical generalization created by the results. That is, differences are evident – as expected, between cases 1, 2 and 3 and between cases 1A, 2A and 3A in terms of TCE’s asset specificity. Here, larger centres require more time in which to process unique knowledge and information pertaining to the centre and its air conditioning system. At the same time, similarities between each case study and its companion “A” case study are also evident. More specifically, the results support Williamson’s assertion that asset specificity is the “big locomotive” in TCE. This support for TCE is based on the development in TCE’s contractual schema – that separates the make-or-buy decision and the nature of the exchange relationship decision, and then treats these two decisions as *two sequential* decisions. This development sees the resource (and not the activity) as the focus of the transaction when internalization has been selected and gives rise to the prospect of a weaker form of hold-up that can occur in the absence of a high level of uncertainty and frequency. This weaker form of hold-up is unlikely to help explain the make-or-buy decision but the results indicate that it has the potential to enhance TCE’s explanatory power on the issue of the nature of the exchange relationship.

Key

- Results in each cell are entered in the same order as the items are outlined in Table 3
- 7-point scales: E. High = Extremely High with mean closest to 7; V. High = Very High with mean closest to 6; High = mean closest to 5 and Low = mean between 1 and 4
- Extremely Relational = mean closest to 7; Very Relational = mean closest to 6; Relational = mean closest to 5; Neutral = mean closest to 4: Discrete = mean closest to 3; Very Discrete (V.Dis) = mean closest to 2 and Extremely Discrete = mean closest to 1
- HAS: Extremely High = >12 months; Very High = >6 months; High = > 2 months and Low = < 2 months
- Frequency: Extremely High = > 20 FTE staff; Very high = > 10 FTE staff, High = 1 to 9 FTE staff; and Low: <1 FTE staff
- RDV: Net dependency = mean of scores representing Buyer's dependency and Supplier's dependency – both from Buyer's perspective: Where imbalance (B>S or B<S) then low = difference of 3 or less and high = difference of 4 or more: Where balance (B=S) then low = same scores of 4 or less and high = same scores of 5 or more

For the vast majority of retail centres, the market for centre management (that includes operations management) and the market mechanical services can be most closely assigned to either the stereotypical market structure depicted by monopolistic competition (comprising more than a small number of firms) or to perfect competition (with many firms). Hence, the level of price competition in both these markets is at least reasonably strong. Therefore, the results are consistent with the expectation that TCE should be more powerful in more competitive markets that encourage firms to maximize on transactions. Furthermore, the other sources of evidence collected in this study, showed the existence of very settled intra-organizational and inter-organizational relationships. Again, this evidence is consistent with maximizing behaviour and the results in this paper that show TCE outperforming RDV.

In terms of further research, it seems important to explore the anticipated relative strength of RDV in markets in which the transaction is much more complex (perhaps including reciprocal trade and the influence of third parties) and in which there exists only a few buyers and/or few suppliers. Although TCE and RDV can be considered as alternative theories under a particular set of competitive conditions, these explanations can also be considered as complementary when a full range of competitive conditions are viewed. This would illustrate why it is that Williamson (1985: 236–8) feels that the power-based approach may be able to make a contribution and notes that a combined efficiency-power hypothesis is not able to be rejected. This combined hypothesis, perhaps best represented by TCE and RDV, would require the coexistence of different scientific research programmes (SRP), as TCE and RDV could not be part of the same SRP – given their different assumptions concerning rationality. Thus, the complementarity between TCE and RDV requires that a wider view be taken than say the complementarity between TCE and Resource-Based Theory – which may possibly be developed within the same SRP (Bridge and Tisdell 2004).

In terms of practice, and with respect to intra-organizational exchange, the results concerning the exchange between centre management firms and OM staff indicate that whilst these firms may be much more powerful than their OMs, these firms can prosper by sharing some power to create a relational exchange with these staff. This may be of some reassurance to mainstream construction firms seeking to avoid a command and control approach amongst their employees. On the other hand, and in terms of inter-organizational exchange, the results concerning the exchange between the centre management firms (represented by the OMs) and the MSCs show that, even in the presence of a recurring transaction (all six of the OMs interviewed in the case studies confirmed that they would expect the incumbent MSC to succeed at contract renewal), discrete exchange can be an economic and viable approach. Therefore, industry reforms incorporating normative prescriptions for widespread relational contracting lack relevance with respect to exchanges with contractors in this study's supply chain.

REWARDING COST ESTIMATION ACCURACY

Said Boukendour[1]

Department of Administrative Sciences, University of Quebec, PO Box 1250-Hull, Gatineau (QC), J8X3X7, Canada

Some estimate inaccuracies are inherently related to the lack of available information whereas others are related to lack of disciplined behaviour in cost estimation processes. Then the issue is how to induce the appropriate behaviour for improving cost estimating accuracy? An estimator who predicts the cost of a project with a specified range of accuracy is like an investor who expects that a stock price will remain within certain limits during a certain period of time. A butterfly spread strategy, which is used by the investor, can by analogy used as a conceptual and methodological framework for designing an incentive system that would encourage estimate accuracy.

Keywords: accountability, estimating, incentives, options, spread.

INTRODUCTION

Estimate accuracy is of vital importance for effective decision-making and cost control for both owners and contractors. For the owners, underestimating a project creates the risk of cost overruns, which for being resolved will need additional funding or reducing in scope. In contrast, overestimating creates the risk that the project will be deemed unprofitable and wrongly rejected. If it is funded, the over-allocated money will be spent to the detriment of other projects. For the contractors, underestimating bid proposals create the risk of winning contracts that will be transformed into high loss later. Conversely, overestimating bid proposals create the risk of losing opportunities. In all cases, inaccurate estimates translate into loss of money that could jeopardize the profitability and even the survival of a company

There are several sources of estimate inaccuracies. Some are inherently related to the lack of available information due to the project definition and unforeseeable events and conditions such as changes in scope and requirement, technical problems and economic conditions. Others are related to the lack of skilled staff and disciplined behaviour in cost estimation processes (Mackie and Preston 1998; Flyvbjerg *et al*. 2002; GAO 2004)

Many efforts were undertaken to improve methods and tools but, to our knowledge very few have been made, neither in practice nor in the literature, to induce disciplined estimating behaviour through incentives. This article attempts to fill this gap by proposing a rewarding model based on an options spread strategy.

THE BUTTERFLY SPREAD EXPLAINED

In order not to annoy the reader who is unfamiliar with the financial jargon, let us introduce imaginary characters whose names are Peter and Sarah. Peter was a cost

[1] said.boukendour@uqo.ca

estimator prior to his retirement. Impassioned by forecasting, he enjoys speculating on stocks in order to pay the holidays of his dreams. During a ceremony to which Peter was invited, he met Sarah, a young cost estimator who had been recruited a few months before his departure from the company. He spoke to her about his speculating activities especially about his favourite strategy: a butterfly spread.

Recall that a stock option is the right to buy (call) or to sell (put) a stock or any other underlying asset at a certain price (exercise price) for a limited period of time. The buyer of the option is the holder of the option who decides whether to exercise his or her right. The seller of the option (the writer) is obliged to abide by the buyer's decision.

At expiration, the intrinsic value of the option is equal to the difference between the spot price and the exercise price. If this difference is positive, the option is in-the-money. Otherwise, it is out-of-the money and expires worthless. However, before the expiration date, the option's price is always positive. Even if it is very small, while the option is still alive, it remains possible that the stock price will rise beyond the exercise price.

A butterfly strategy is a viable strategy for one who thinks that the stock will not experience much of a net rise or decline at the expiration date. Using only calls, the butterfly spread consists of selling two calls at the middle exercise price and buying two calls: one at the lowest exercise price and the other at the highest exercise price.

The first time that I used this strategy, explained Peter, was to bet on the stock of the company which was at £700. I was betting that the price would not fall below £600 and would not rise above £800 the three next months. I established a butterfly spread by selling two calls of £700 exercise price for £30 each, and buying one call of £600 for £60, and another of £800 for £10. All the options were European options and matured in three months time. Unlike American option, the European options can only be exercised at the expiration date. Finally, my net cash debit was only of £10.

At the expiration date, the stock was at £750. So, I exercised the call of £600 and gained £150 but the two calls of £700 which I sold were exercised against me and I lost £100. Obviously the option of £800 expired worthless since the spot price was of £750. Finally, my net gain was of £50, i.e.: 500%. If with a little more chance the stock remained stable at £700, I would have the maximum profit of £150, i.e.: 1500%.

Figure 1 below depicts the potential profits and losses of Peter according to the quality of his forecast. Note that the shape of the curve looks like a butterfly from which the strategy gets its name.

Figure 1: Payoffs

REWARDING COST ESTIMATION ACCURACY

Peter suddenly asked Sarah: “Why wouldn't you use the butterfly spread for rewarding the cost’s estimators as a function of the quality of their prediction?” Indeed, an estimator who predicts the cost of a project with a specified range of accuracy is like an investor who expect that a stock price will remain within certain limits during a certain period of time. Therefore, the cost estimator can bet on his or her estimate using a butterfly spread.

Sarah replied “Where would you obtain the options to establish the spread”. Do not worry, said Peter, it is not necessary that these options actually exist. Options are contracts, and the essence of a contract is commitment. The company and the cost estimator can establish the spread by an agreement just as many institutions do with options over the counter. Hence, they become reciprocally the buyers and the sellers of all the options involved in the spread. There is also no need for the market to exist since the calls can be priced using an options pricing model.

The long history of options pricing theory began in 1900 when the French mathematician Louis Bachelier used Brownian motion to model the stock prices. But, it is only in 1973 that Black and Scholes developed the first pricing formula for an European call options. They assume that stock prices adjust to prevent arbitrage, change continuously, and follow a log normal distribution. Further, they assumed that the interest rate and the volatility of the stock remain constant over the life of the option. These restrictions are necessary to derive their formula using Brownian motion and differential stochastic calculus:

$$
\begin{aligned}
&c = SN(d_1) - Ke^{-rT}N(d_2) \\
&with: \\
&d_1 = \frac{\ln(S/K) + (r + \frac{1}{2}\sigma^2)T}{\sigma\sqrt{T}} \\
&d_2 = d_1 - \sigma\sqrt{T}
\end{aligned}
$$

Where:

C: call price

S: current stock price

N(.): cumulative standard normal distribution

K: strike price

σ: instantaneous standard deviation

r: risk-free interest rate

T: time to expiration

Since the publication of this seminal article, numerous options pricing models that remove some of these restrictions have been proposed in the literature. Haug (1997) provides a complete guide of option pricing formulas accompanied by their code. Despite its unrealistic assumptions, the Black-Scholes model remains attractive in practice because it is simple and easy to use. For this reason, we shall use it to illustrate how to price the options involved in the spread.

Let us substitute S for the estimated cost, K for the strike (exercise) price, r for the risk-free interest rate, T for the project duration, and σ the project cost volatility. Except for the project cost volatility all the other parameters are given.

Volatility is a very important parameter of the option price, which is not directly observed but only approximated using statistical means. Let us assume that the ratio of actual cost to the estimated cost follows a log-normal distribution. This assumption is consistent with many empirical findings (Garvey 2000).

Thus, the cost volatility can be estimated on the basis of a sample of completed representative projects. The standard deviation can be calculated as the logarithm of the percentages of their under runs and overruns, i.e.: ln [(actual-estimate) /estimate].

$$\sigma = \sqrt{\sum_{i=1}^{n} \ln(\frac{A-E)}{E})^2}$$

Where A_i and E_i are respectively the actual cost and the estimated cost of the project i, i=1,2…n.

A STYLIZED EXAMPLE

Let us consider a project estimated at £6 million whose volatility is estimated at 29% as indicated previously on the basis of a sample of 67 completed projects. Table 1 below describes the potential profits and losses of the cost estimator depending on the level of confidence. If, for instance, the level of confidence is set at ±σ, the cost estimator will establish the butterfly spread by buying one call at £ 4,26 million exercise price for £1,824,911, selling two calls at £6 million exercise price for £691,735, and buying one call at 7.74 million exercise price for £205,263. The cost estimator will invest the net debit of £646,704. If the actual cost is exactly £6 million, the cost estimator will earn the maximum gain of £1.74 million.

Table 1: Payoffs as a function of confidence intervals

Confidence	Calls premiums for the lowest, middle and highest exercise price			Net debit	Maximum gain	Return
	Lowest	Middle	Highest			
±0σ	691735	691735	691735	0	0	
±0.25σ	906316	691735	519931	-42776	435000	1017%
±0.50σ	1167111	691735	385612	-169252	870000	514%
±0.75σ	1474497	691735	282721	-373747	1305000	349%
±σ	1824911	691735	205263	-646704	1740000	269%
±2σ	3480440	691735	53203	-2150172	3480000	162%
±3σ	5220000	691735	12969	-3849499	5220000	136%

When the actual cost deviates from the target of £6 million, the maximum profit drops until reaching the limit of net debit, which is the maximum loss of the estimator. Calculations also show that the net debit and the maximum profit drop when the accuracy increases. For instance, when the accuracy increases from one sigma to half a sigma, the net debit decreases from £646,704 to £169,252 (-74%) whereas the maximum profit decreases only from £1.74 million to £870,000 (-50%). Thus, the maximum profit drops less quickly than the net debit does. This explains the higher returns of the narrowest range of accuracy. In other words, the more accurate is the estimate, the higher the cost estimator's return.

Very interesting, said Sarah but this involves a huge amount of money that no cost estimator can afford. Peter replied: "Was I obliged to buy all the stock of the company when I used the butterfly spread?" Sarah concluded: "I see, the cost estimator can determine how much money he or she wants to bet and will get compensated accordingly."

But, exclaimed Sarah, what is going to happen if the estimator is capable of affecting the final cost of the project? (This question was suggested by one of the anonymous reviewers.) Peter said: “This would look like to the Enron scandal. The model is appropriate for estimators who have neither stake nor a responsibility in the implementation of project.”

SOME THEORETICAL AND PRACTICAL ISSUES

From a theoretical perspective, the compensation of cost estimators can be viewed as a principal-agent problem. The principal-agent problem arises in every situation where one person (the principal) hires another person (the agent) to perform some service on his behalf, and when there are a conflict of interests and asymmetrical information (Jensen and Meckling 1976). The standard agency model of incentives is concerned with the optimal contract that a principal must choose to induce the best effort from the agent. When the outcome depends on extraneous factors, the agent will require a high-risk premium that may render the incentives unprofitable for the principal. An effective way of reducing risk of extraneous factors is to provide the agent with incentives schemes based on a fixed pay plus a contingent compensation (Milgrom and Roberts 1992).

The causes of the estimate inaccuracies are multiple and complex. Some causes are related to the skills and behaviour of the estimators. Others are exogenous and unforeseeable. The butterfly spread strategy provides cost estimators with just enough incentive to induce the adequate behaviour but not enough to make them assume unforeseeable risk. Intuitively, the model seems consistent with the standard agency model of incentives. It remains to be demonstrated mathematically how to design an optimal contract using a butterfly spread**.**

From a practical perspective, many issues must be resolved before implementing the model. One of these issues is whether the team’s members should be rewarded individually or as a group. How the distribution of rewards should be structured to reflect the different level of risk assumed by each individual? Another issue is related to the elapsed time between the estimate date and the project completion. Delaying gratifications until the actual cost is known makes no sense especially for projects that take several years to complete. How does one determine when the distribution of rewards is effective in order to induce the expected behaviour?

NEWLY EQUITIZED CONSTRUCTION SMES IN VIETNAM: PROBLEMS AND SOLUTIONS

Quan T Nguyen,[1,2] Christopher N Preece,[1] Tam V Tran[2] and Steven Male

[1]*School of Civil Engineering, Univerity of Leeds, Leeds, LS2 9JT, UK*
[2]*Faculty of Construction Economics, National University of Civil Engineering, Hanoi, Vietnam*

Hundreds of construction state-owned small and medium sized construction enterprises in Vietnam have been equitized to date. They have faced many post-equitization problems. However, researchers have focused mainly on the equitization process, with limited research having been done on the post equitization period. A survey of 25 newly equitized construction SMEs using a qualitative triangulated research approach has been undertaken to address this gap. Five significant problems have emerged from the survey, which include both internal issues and problems created by external factors. Among the solutions that firms have applied, the enticement of a strategic investor may be considered as an appropriate option to sort out the internal problems. Also, firms should not stay passive and wait for the environment to change in their favour. Firms need to decide which solution(s) to apply as well as get involved in the process of making their business environment clear, clean and fair for their own benefits.

Keywords: construction companies, equitization, SMEs, Vietnam.

INTRODUCTION

"Equitization" is the official word that has been used instead of "privatization" in Vietnam. Aivazian *et al*. (2005) argues that privatization has been considered as a solution to sort out state-owned enterprises (SOEs)'s problem such as having "poor financial performance" (Bai *et al.* 2000) and this was not an exception in Vietnam. Hundreds of SOEs, including construction SOEs, have now been equitized, and most of them are small and medium sized enterprises (SMEs) (Dam 2004). Operating with the new structures, the newly equitized construction SMEs have faced many problems – post-equitization problems. However, literature shows that researchers have focused mainly on the equitization process, not on the post-equitization period. During the survey for this research, respondents (selected from the top managers of newly equitized construction SMEs in Vietnam) strongly explored their concerns about their firm's post-equitization problems. Most of them were very perplexed in finding a good way for their firms to develop strongly after equitization.

This paper focuses on the problems arising after construction SMEs equitized and discusses the possible solutions that firms can consider to sort out these problems.

For this purpose, the research commented by searching answers from theories of the firm and work on SMEs (Hoorn 1979; Hillebrandt and Cannon 1990; Keysey and Watson 1993; Hall 1995), strategic management (Stacey 1993; David 2001; Campbell *et al*. 2002; Burnes 2004) and strategic management in construction (Betts and Ofori 1999; Chinowsky and Meredith 2000; Langford and Male 2001). Then it was decided

[1] cenqnt@leeds.ac.uk

that most of these theories had originated in western capitalist societies and business schools and a more localized model of business/strategic management in SMEs had to be constructed from indigenous sources and fieldwork to reflect an emerging socialist market economy that had only recently moved from a command control structure. However, a review of privatization in other transition economies shows that there have been similar challenges for SMEs in these countries. The similarities are discussed below, together with the findings in newly equitized construction SMEs in Vietnam.

CONSTRUCTION SMES AND EQUITIZATION IN VIETNAM

Construction SMEs in Vietnam: classification

The term “enterprise” in Vietnam refers to “an economic unit that independently keeps business account and acquires its own legal status” (GSO 2005). They can be considered as state-owned enterprises, non-state enterprises or foreign direct invested enterprises. SOEs include enterprises with 100% of state capital or joint-stock companies with domestic capital, of which the Government holds more than 50% shares (GSO 2005). Only firms with 100% of state capital could be “equitized”.

Construction enterprises include enterprises that have registered and operate construction activities as their core business. They are often referred to in Vietnam as “contractors in construction activities” (National-Assembly 2004) or “contractors” for short. They are dispersed under many government management agencies, which include the Ministry of Construction, other ministries with specialized construction projects and local authorities.

Regarding the size of firms, if a firm has either registered capital less than 10 billions Vietnam Dong (approximately £320,000, exchange rate as at January 2007) or less than 300 employees, it can be considered as a small and medium sized enterprise (SME). There is no specific definition for a construction SME in Vietnam but construction SMEs in Vietnam account for over 90% of the whole construction firms if classified by size of labour force (Gso 2005).

This paper only focuses on the small and medium sized state-owned construction companies that have been equitized during the last 10 years.

Definition of equitization

Equitization in Vietnam is defined as “the transformation of SOEs into joint-stock companies and selling part of the shares in the company to private investors” (Truong 2006). This movement aims to (Government 2002):

- Improve the performance and competitiveness of enterprises by ownership diversification, with involvement of workers as shareholders; thus creating a dynamic management mechanism.
- Mobilizing capital from employees and outside domestic and/or foreign investors, for technology improvement and enterprises’ development.
- Balancing interests of the stakeholders in the equitized enterprises.

That is to say, equitization in Vietnam differs from privatization in the usual western sense in that it does not tend to reduce the state shares in the economy as a whole. It aims to sort out the difficulties for capital and mechanisms for state-owned companies. Another difference is that employees and managers of the firms can get a significant portion of shares in the newly equitized firms (Truong 2006).

Methods to equitize SOEs in Vietnam and the equitization process in construction sector

There are four methods to equitize a SOE in Vietnam (Government 2002; Truong 2006; Vu 2006):

- Keeping the state shares intact and issuing additional shares.
- Selling a fraction of the existing state shares.
- Selling of all existing state shares to workers and private shareholders (mostly applied to loss-making SOEs).
- Selling a fraction or all state shares and issuing new shares concurrently.

According to Truong (2006), the equitization process in Vietnam falls into two stages: the pilot stage from 1992–1996 and the expansion stage from 1996 up to now. Vu (2006) detailed the process into four stages: voluntary stage (6/1992–4/1996); expansion of the pilot programme (5/1996–5/1998); acceleration of the equitization programme (6/1998–5/2002); and continuing with the equitization programme (up to now). Nevertheless, in the construction sector, there were no construction firms equitized from 1992 to 1996. Until the period 1997–2001, the Ministry of Construction had to force 16 firms to equitize. However, since 2002, the pace has speeded up. In 2003 and the first 8 months of 2004, 82 construction firms that belong to the Ministry were equitized successfully. Most of them are SMEs. Now the number of equitized firms has reached hundreds. The newly equitized construction firms report that their ratio per registered capital reached 45.2% in comparison to 8.37% before equitization, average dividend is 24.3% (about three times greater than saving interest) (Dam 2004). That is to say, equitization has brought construction SOEs many successes. However, this paper only discusses the problems arising in the period of post-equitization for the newly equitized construction SMEs.

RESEARCH METHODS

The research question and the research approach

The research question driving this study is: “What are the problems of newly equitized construction SMEs in Vietnam and how firms confront with them?” It forms part of a research problem on construction SMEs’ strategic management that is using the same survey. The respondents were selected from top managers of construction state-owned SMEs that have been equitized over the last 10 years. The interviewees include members of the directorial boards (directors/general directors or vice directors/vice general directors depending on how a firm named the positions), other members of the management boards who are section managers and involved in the long-term decision making of the firms.

A qualitative triangulated research approach was used. In addition to undertaking direct interviews by the researcher, questionnaires were sent out through the researcher’s network of contacts who were working in the industry. Also, other available sources of data such as internship reports by student-trainees, annual reports as well as other accessible documents from the selected firms have been used to enrich the data. Other researchers’ works on the similar topic are also referred to when appropriate.

Fieldwork

The survey upon which this study is based covered the newly equitized state-owned construction SMEs in the two economic centres of the country: Hanoi and Ho Chi Minh City. For the broader research, approximately 70 construction SMEs out of a population of about 160 firms being contacted have participated in the survey, including interviews and questionnaires. Among them, 25 firms were newly equitized construction SMEs. The data for this research came from these 25 companies. Table 1 illustrates the structure of the survey sample.

Table 1: Structure of the survey sample

	Local or Central		Region		Respondent type		Data collection type		Total
	Local	Central	North	South	Directorial Board	Section Managers	Int	Ques	
In number	8	17	20	5	12	13	15	10	25
In %	32	68	80	20	48	52	60	40	100

Note: Int, Ques: survey done by interviewing and questionnaire completion respectively.

The survey was conducted using a set of ten major topics as guidelines. These were the basis of ten initial questions, designed to secure open answers and forming the interview questionnaire. The first questionnaire was constructed in English and needed translating into Vietnamese. To avoid using academic terms, the Vietnamese version was piloted with two respondents who worked as section managers in two construction firms (who were not familiar with academic terminologies). More detailed questions have also been asked for in-depth information when the interviewer thought necessary.

A mailed questionnaire was developed from the interview questions, which included the ten initial questions and the detailed questions raised in the context of the first five interviews. Many open-ended questions were added to avoid missing any valuable information.

Among the firms that participated in the survey, there were some firms where the state-owned share accounted for 51%, some where the state-owned share is less than 51% and there was one firm with the state-owned share reduced to 0% (fully privatized). Some respondents refused to mention the state-owned share in their firm, and the percentage of each type could not be fully worked out.

RESULTS AND DISCUSSIONS

According to the survey, the most noteworthy problems that newly equitized construction SMEs in Vietnam have faced fall into five categories:

- Lack of capital capability.
- Ineffectiveness in corporate management.
- Lack of properly competent human resources.
- The asynchrony and incompletion of the legislation system.
- External social issues, such as corruption and discrimination against newly equitized firms.

Among these five categories, the first three have been grouped as internal problems, while the last two could be considered as problems created by external factors.

However, the external environment also impacts on firms and therefore influences the so-called “internal problems”.

One can easily notice that the internal problems mentioned above are not unique to newly equitized construction SOEs in Vietnam. Literature shows that these problems have happened to SMEs in other countries, including SMEs in construction (Hoorn 1979; Birley 1989; Keysey and Watson 1993; Hall 1995; Dansoh 2005).

There are also other problems that have been mentioned in the survey. They include lack of a strong brand name, obsolete technology, clients’ delay in payment for finished projects. A strong brand name might be achieved when the firm is well managed and their management board is aware of developing its long-term value (Huynh 2005). This problem could be categorized into the second category. Due to the fact that most of the construction works or projects that this type of firms are involved in are not very complex, and do not required very modern technologies, many respondents agreed that obsolete technology is not as critical as the five problems listed above. There are several reasons that lead to the delay of clients in payment, such as the complication of payment procedures, distribution mechanism of state budgets etc.

The following paragraphs will discuss these problems and how firms have confronted them.

Lack of capital capability

To carry out their construction projects, firms in Vietnam, including the newly equitized SMEs, need working capital. They have to pay for labour costs, materials, rent of construction equipment if any, etc., before getting payment from their clients. The most important source for this is payments from clients for completed construction works or projects. Traditionally, construction SOEs consider the Government as their biggest client. However, in projects funded by the state budget, the payment process is very slow due to complicated administrative procedures. Sometimes, particularly in provinces, the funds that have been distributed to the local budget within a financial year is insufficient for all of the projects to run, so the management agencies need to select some projects to pay, perhaps randomly, and delay payments to others into another financial year. The delay in payment has sometimes changed a profitable project in to a loss making one. Possessing a small amount of capital, like in other countries (Keysey and Watson 1993), newly equitized construction SMEs found it very difficult to secure enough capital not only to run projects, but also to re-invest to develop. Therefore, firms have had to find other ways to solve this problem.

The solutions that have been applied by participating firms in the survey can be divided into two groups: short-term and long-term. The short-term solutions include mobilization of capital from available sources. However, banks, which might have been considered as the most convenient source of lending in other countries, are not that easy for securing funds in Vietnam. Since being equitized, SOEs have lost their priority in borrowing money from the state commercial banks, credit and financial institutions. They have to follow banks’ stricter rules with smaller lines of credit because they are not supported completely by the Government as before. In other words, the banks’ view on their reliability has been reduced. An alternative, to borrow from private or foreign-investment banks, is not seen as a good solution, because firms find it difficult to present a feasible study/report to persuade the banks due to the characteristics of construction works and the firms’ human resources’ competence.

Firms have to find other short-term solutions such as borrowing from their employees, shareholders and even from relatives and friends of the firms' management boards or project managers. Some project managers had to mortgage their family's assets to get money for their own "project-in-charge". That is to say, these sources are limited, not stable and sometimes very costly.

The considered long-term solutions include listing in the stock market, land development, business diversification and client selection. Twenty-one firms in the survey would not consider the first option until ten years later because they thought the stock market in Vietnam has not been well developed. Only one firm has put it into their five-year plan. Some firms inherited land from the pre-equitized state-owned company and considered the second option to utilize as their advantage by developing investment projects for real estate development. Some of them have turned to the client side and now employ other firms as contractors or do the construction works themselves (thus creating jobs). However, after some years, the real estate market in Vietnam has been slowing down, and many land development investment projects have been delayed.

Business diversification is another option that more than half of the surveyed firms have applied. Some of the firms have developed other businesses within the construction industry, such as providing consultancy or design services. Others bid for other types of projects such as irrigation, traffic and industrial work. Some undertake trading in construction materials and some trade in consumer and industrial products or supply services such as tourism, transportation and export-import. However, they admit that such kinds of diversification have brought with them many other problems and have not been as effective as they expected.

The last option can be considered as a long-term as well as short-term solution. Instead of bidding for every project that a firm can undertake, firms have taken account of the capital capability of the client into their consideration before getting involved into the projects they offer. Some firms, particularly firms from the South have even focused on foreign direct investment projects only, they have said they rarely bid now for state-funded projects. However, FDI projects are not completely safe. The public media have reported some foreign investors or main contractors' delaying payments or refusing payments to their domestic (sub)contractors (MOI 2004).

Ineffectiveness in corporate management

The problem of ineffectiveness in corporate management has been considered the most critical in the newly equitized firms in the survey. Results from the survey shows that this results from three major issues: top managers' lack of managerial skills, mechanisms for decision-making in firms and psychological barriers.

According to Huynh (2005), the managerial skills of a firm depend on two factors: the internal relationships (corporate culture, human resource competences); management techniques and technologies in use. The first factor will decide what kind of management techniques and technologies should be applied into the firm. It is the fact that management techniques and technologies are available from textbooks and business schools. However, most of the top managers of state-owned construction SMEs in Vietnam have been promoted from a technical background. Though some of them have attended several management or economics courses, they often use their own experiences in their new management position. About 60% of the top managers participating in the survey admitted spending much of time on doing professional tasks or checking their staff's work, such as estimations or tender documents due to the fact that they are not at ease with delegating to their staff.

In theory, after equitization, the managerial capability of a firm should be improved due to the involvement of many shareholders. Actually, this is not completely correct. Several reasons have been mentioned by respondents. Most of the shareholders holding small shares are not aware about their rights and therefore never get involved in the decision making process. In addition, the equity in most construction SMEs is highly closed to internal staff. Shares have been concentrated into a group of people that include top managers and their friends and relatives. This situation is similar to the "insider privatization" in Russia, Czech Republic, Hungary and Poland and in Asian countries, including Mongolia and China (summarized by Li and Rozelle 2004). As a result, the people that can have strong effects to the firms' decision remain unchanged. The change in managerial capability, therefore, is very limited. In addition, the internal equity in construction SMEs sometimes leads to the firm's unity being broken. There have been some conflicts/complaints or even lawsuits have happened in newly equitized firms. It has weakened the managerial capability of the firm.

Respondents, mostly from firms with more than 50% state share, claimed the firm's status as one of "new container but same spirit" after equitization. Actually, there is a resources limit in the governmental agencies in charge of the state shares in equitized firms. The people in charge of the state shares in the firms sometimes use their rights to veto important investment and management decisions that most of the shareholders agree with due to the fact that they want to conserve the state capital they are obliged to look after. There is also a risk for them that the administrative command from the line management agency can remove him/her from their current position.

All of the respondents in the survey were aware of their firms' situation and noted that in order to improve their corporate management skills, firms need to change. However, the best change to consider is to replace all of the top managers but the psychological barriers are among the significant obstacles to these changes. Some people in charge of state shares in firms do not want to take risks in order to retain their "chair at the table". This is similar to the situation in privatized Chinese firms. Senior managers do not have motivations to make any improvements because they do not have "cash flow rights" (Chen *et al*. 2006). Respondents claimed that some big shareholders do not want the change because it may threaten their rights and profits. Some are noted as simply lazy and do not want to spend time for new approaches when they think the old ones are still in order. In firms with problems of unity, people are too busy with sorting those issues out and do not have time to even think of change.

Firms facing these problems in the survey are still using many of their own solutions, but they admitted that they need a better way. A suggestion by Huynh (2005) is to secure a strategic investor, which can be an individual or an organization; this may be a good answer. According to him, a strategic investor needs to be able to:

- Recognize the long-term development trend of a firm and can help to develop a long-term strategy.
- Have strong financial capability or ability to mobilize investment capital.
- Have suitable managerial skills.
- Know about technology.

- Have the ability to expand the firm’s market.

In consideration of this long-term solution, top managers and shareholders in the firm need to admit to having to share their rights, interests, profits and obligations with the new shareholder. If a strategic investor is selected carefully, this solution may help sort out the first problem as well. In fact, in 12 newly equitized SMEs that are members of a corporation or holding company, the corporation or mother-company has been selected as the strategic investor. However, firms may still face the same problem of “new container but the same spirit” as mentioned above.

Lack of properly competent human resources

Most of respondents claimed that their human resources do not have rational competencies or their firms do not have enough staff that can do the job well. The most of quoted reason for that is they cannot compete with larger companies in luring competent staff through salaries or other benefits due to their limited resources. However, there are several solutions that firms have applied.

Some firms only pay attention to a few key people, such as the section managers and project managers (or site managers in construction sites). Since they are SMEs, their structure is often very compact (Birley 1989; Ackroyd 2002). They then empower project managers to employ their own engineers and technical/professional people. They apply the “*khoan* mechanism” – one kind of subcontract between the firm and their teams, in which the firm takes a percentage of the contract value and lets the team(s) manage the remaining. The team can take all the profit within the certain amount of money that they receive from a “khoan” contract. By that mechanism, project managers may have more funds to provide more benefits for their own staff and can secure competent staff. Others apply a training-on-site programme for staff, especially newly employed engineers and workers. They claim that by this programme, they have a reserve of competent staff for the next part of a project or new projects. Some firms apply both solutions. Nevertheless, firms still claim that they are lacking in competent human resources. To solve this problem completely, they may need to develop and/or need a long-term strategy/policy. A strategic investor’s involvement may be a good solution to this.

The asynchrony and incompletion of the legislation system

This issue, in one aspect, can reflect the economic mechanisms of the country. This is an external factor that firms cannot impact on directly. They have to cope with the fact that regulations change very fast and often overlap one another, and different regulations can be issued by different governmental organizations. Some respondents claim that a decision or an ordinance has just been issued; and firms have not been able to learn about it quite before another issuance is released to replace the old one. Some regulations issued by local governmental agencies conflict with those issued by the central governmental bodies. Some laws or decrees had been issued for a long time, but the supporting regulations and instructions remain in draft form. Firms have no way but to adapt to this. The most efficient way may be that firms set up a team to deal with this issue, as their second job, in order to update as soon as possible knowledge on new regulations and hence release this heavy burden from the top managers. However, the situation is improving. World Trade Organization membership has required that the country amends its legislative system to suit to the legitimate requirements from this organization. Respondents are expecting a clearer and more effective legislative system in the near future.

Impacts from external social issues

Discrimination of newly equitized firms, including construction SMEs still exists. The case of borrowing money from banks and financial institutions is a good example. Newly equitized construction SMEs find themselves suffering disadvantages in comparison to other state-owned companies. The state-owned companies get favourable conditions in land use rights, lower interest on borrowing money from the state commercial banks and financial institutions. They can borrow from the bank without mortgaging their assets, but use their prestige as a state-owned company only. Their debt is easily delayed or cleared when they have trouble in payment. After equitization, firms lost most of these favourable conditions. For instance, they have to mortgage their land to get money from the bank. Nevertheless, some firms do not have the rights to use the land for that purpose because they have not been transferred from the local government agencies (number of respondents admitted=3). Respondents claim that their firms face also discrimination in dealing with the administrative procedures when they have to work with governmental organizations. However, the environment has been improving. Discrimination has been made more aware publicly and has been cleared out on a step-by-step basis by new regulations and laws. This problem is related to the previous problem.

Corruption is a major problem, especially in the construction sector where the majority of invested capital comes from the state budget. This is a problem not only for the newly equitized SMEs, but also all the firms that operate in the sector. In some state-funded projects, particularly projects at the local level, the Government representatives in charge of issuing the decision for construction contracts always give their favour to the firm that may give them back the highest commission. The public newspapers have reported many cases in the period from 2004 to 2006. Respondents admitted that this type of “lubricant cost” is a problem for their firms. This makes the competition unfair, and firms have to find mechanism to make this expense official under other expenses. Another negative consequence is firms have to reduce the quality level on projects, and cutting expense to recover the cost. Vietnamese society in general is more aware of this and things would appear to be changing. The completion of the legislative system can help reduce this. In addition, the emergence of new markets for firms to compete in such as the foreign investment and the private sector gives them more options to avoid being involved in corrupt practices. Last but not least, construction firms now are aware of building up their brand name; therefore they pay more attention to quality and avoid risks of involvement in problems such as corruption.

CONCLUSIONS

Since the period 1997–2001, when 16 construction enterprises were equitized, the number of equitized construction SOEs, including SMEs has increased significantly. Besides the many advantages that equitization has brought, this paper has presented research that has highlighted newly equitized SMEs in construction in Vietnam have also faced many problems. The most significant problems include lack of capital capability; ineffectiveness in corporate management; lack of properly competent human resources; the asynchrony and incompletion of the legislative system; and external social issues, such as corruption and discrimination against newly equitized firms. These five problems have been classified as internal problems (the first three) and problems created by the external environment (the last two).

The firms that have participated in the research have applied several solutions, both short-term and long-term to help solve these problems. However, one solution has emerged that may be considered to help sort out all the internal problems: the enticement of a strategic investor into the firms. Though respondents agree about the importance of a strategic investor, they remain afraid of this type of involvement in their firms' operation and also what kind of strategic investor they should choose. More detailed research should be carried out to establish the answer to these questions.

To cope with the problems regarding the legislative system and the economic mechanisms of the country, firms have no option but to adjust themselves to it. A suggestion that may be useful is that firms need to update themselves very quickly with these changes in the improvement to the legislation system, need to remain aware of them, and avoid involving themselves in corrupt practices. Also, firms need to become involved in the process of making their business environment clear, clean and fair for their own benefits. To conclude, the firms themselves need to decide which solution(s) they should choose to solve their post-equitization problems.

FLEXIBILITY MANAGEMENT IN THE CHANGING COMPETITIVE ENVIRONMENT

Benson Lim,[1] Florence Ling and George Ofori

Department of Building, National University of Singapore, 4 Architecture Drive, 117566 Singapore

The ability to anticipate and respond to opportunities or pressure for changes, both internally and externally, is important to ensure competitiveness and sustainability of an organization. Flexibility management (termed as 'manufacturing flexibility in manufacturing research) is emerging as a key competitive strategy in response to the constantly changing competitive environment. Authors have attempted to relate the value of flexibility to crisis management, real option approach and human resource management in construction business. It appears, however, flexibility management is widely recognized as a multi-dimensional concept that is not being well-understood. The objectives of this paper are to: (1) review the fundamental principles of flexibility management; (2) consider its application in the construction industry; and (3) develop a conceptual model for delivering flexibility in the construction industry. The review shows that the major variables of manufacturing flexibility include business strategy, organizational attribute, supply chain relationship and technology. This research project is based on the premise that flexibility concept is applicable to the construction industry given that these key variables are comparable to those forming the competitive environment of the construction industry.

Keywords: competitiveness, management of change, management of firm.

INTRODUCTION

The cyclical nature of the construction industry coupled with the increasing level of foreign competition and changing expectations of customers have placed much stress on managerial personnel to find ways in surviving the changing competitive environment (Lansley 1983, 1987). Organizations cannot afford to wait until consequence of these changes become apparent but need to move from reactive tactics to anticipatory strategic planning to ensure its competitiveness and sustainability (McGregor 2000).

Flexibility management is emerging as a key competitive strategy in response to the constantly changing competitive environment (Oke 2005; Olsson 2006). Although the concept of flexibility management is well documented in the manufacturing literature (termed as manufacturing flexibility), little is known of its appropriateness within the context of construction industry in response to its competitive environment. Recognizing this gap, this research project will be conducted in five phases: (1) problem identification in the changing environment; (2) literature review of flexibility management in manufacturing and construction industry; (3) model design; (4) model testing; and (5) model validation. With respect to the first three phases of this research project, the objectives of this paper are to: (1) review the fundamental principles of

[1] g0500825@nus.edu.sg

flexibility management; (2) consider its application to the construction industry; and (3) develop a conceptual model for delivering flexibility in the construction industry.

WHAT IS ‘FLEXIBILITY’?

Gupta and Goyal (1989) defined ‘flexibility’ as the ability to cope quickly with changing circumstances and environmental uncertainty. Bucki and Pesqueux (2000) shared the view that being flexible allows organization to vary and adapt according to the environmental changes or organization’s needs and thus defined it as “the ability to adapt, in a reversible manner, to an existing situation, as opposed to evolution, which is irreversible” (2000: 62). However, some authors take the view that the term ‘flexibility’ should be orientated toward either a more operational or economic approach. From an operational perspective, Nagarur (1992) defined it as the ability of a system to quickly adjust or adapt to any changes in relevant factors like product, process, loads and machine failure. Das and Patel defined it as “the ability of a system or facility to adjust to changes in its internal or external environment” (2002: 266). Upton, however, perceived ‘flexibility’ in a more economic way, and defined it as “the ability to change or react with little penalty in time, effort, cost or performance” (1995: 207). Zhang *et al*. extended this definition and described ‘flexibility’ as “the organization’s ability to meet an increasing variety of customer expectation without excessive costs, time, organization disruptions or performance losses” (2003: 173).

Besides defining ‘flexibility’, authors (Evans 1991; Swafford *et al*. 2006) attempted to relate ‘flexibility’ to other resembling concepts; somewhat the notion of ‘agility’ is often used synonymously to ‘flexibility’. They described it as an ability to be nimble in moving into an advantageous position. Goldman *et al*. (1994) listed nine elements of organizational agility such as: (i) continuous improvement, (ii) changes and (ii) flexible. This assertion placed flexibility as a component to agility. Thus, it is recognized that organization needs to be flexible before attaining agility. There seems to be a common theme in all these definitions and concepts. The term ‘flexibility’ is defined in the research as the ability to respond or readapt, in a reversible, timely and appropriate manner to the changing competitive environment.

FLEXIBILITY MANAGEMENT IN MANUFACTURING AND ITS KEY ENABLERS

Flexibility management has been widely studied in the manufacturing literature (termed as manufacturing flexibility) over the past decades. Flexibility in manufacturing is seen as an integrative multi-dimensional concept rather an independent variable that can be defined and measured in isolation (Slack 1987; Beach *et al*. 2000). Many studies (e.g. Koste and Malhotra 1999; Koste *et al*. 2004) have attempted to identify various types of flexibility dimension such as: (i) volume; (ii) expansion; (iii) logistic; (iv) operation; (v) market; (vi) procurement; (vii) spanning; (viii) labour; (ix) process; (x) modification; (xi) program; (xii) financial; (xiii) material; (xiv) machine; and (xv) product. Despite these efforts in identifying various types of flexibility dimension, Oke (2005) observed that there is no general consensus of how flexibility should be determined. Also, he found that some reported empirical studies and analytical models of flexibility have the tendency to treat flexibility as a uni-dimensional concept. Slack (1983) suggested that an organization may exhibit its flexibility in many different ways. Some authors suggested that flexibility should be determined exclusively by the flexibility of an organization’s resources and processes (e.g. Slack 1987; Carlsson 1989) as well as its operating polices and management practices (Gupta and Buzacott 1989). Besides identifying and developing generic taxonomy of flexibility dimension, studies were conducted to investigate the relationship between different flexibility types and the influence of exogenous variables in the implementation of flexibility management in manufacturing (e.g. Pagell and Krause 2004).

Despite many works done on manufacturing flexibility concept, Beach *et al*. (2000) pointed out that little or no attention has been given to the method of acquiring those flexibility dimensions. Thus, they highlighted the need to investigate key enablers contributing the attainment of flexibility. They postulated that flexibility is a product of several enablers such as corporate culture, management structure, facility layout, information technology, process technology and human resource. Vokurka and O'Leary-Kelly (2000) hypothesized that the understanding of environmental factor with the integration of key enablers such as organizational attributes, business strategy and technology will lead to attainment of required flexibility. Kara and Kayis (2004) reinforced that labour, information technology, process technology and organization structure can be seen as the method for delivering flexibility.

Supporting some of the above propositions, some studies found that there is a negative relationship between firm's size and flexibility (Fiegenbaum and Karnani 1991; Das *et al*. 1993). Likewise, many studies have shown that business strategy is one of the key enablers in flexibility management (Gupta and Somers 1996; Vokurka and O'Leary-Kelly 2000). Different business strategies (e.g. low cost vs. differentiation strategy, defensive vs. offensive strategy, reactive vs. proactive) will call for different level of flexibility. Beach *et al*. (2000) suggested that future studies should consider the influence of corporate culture on the choice of strategy adopted toward the implementation of flexibility. Upton's (1995, 1997) studies showed that the extent of emphasis placed by managerial has positive impact on flexibility development.

Suarez *et al*. (1996) studied the effects of several managerial based policies (i.e. lean management, supply chain management) on three flexibility dimensions (i.e. volume, production, new design). They found that supplier involvement has a positive relationship on the three flexibility dimensions. Their finding was further substantiated by Chang *et al*.'s (2005) study that found that supplier involvement plays an important role in the development of a firm's flexibility and its performance. The implication of these two studies is that supply chain relationship has a major impact on the acquisition of flexibility. Also, Carlsson (1989) recognized that organization structure and people are the key determinants in flexibility management. In an open and flat organization, the chances of dealing successfully with adversities and uncertainties seem to be considerably greater than in a closed and rigid organization. Englehardt and Simmons (2002) found that a prevailing organizational challenge is to provide both structure and flexibility that suit this constantly changing environment. They recommended decentralization and flattening, matrix organizations and network organizations to enhance flexibility.

In addition to the above key enablers, Karuppan (2004) highlighted that human resource is the foundation in developing flexibility. She suggested that an organization should invest in balancing its employees' flexibility via training opportunities. Also, Crocitto and Youssef (2003) suggested that an appropriate (i.e. user friendly and compatible) information technology is also an essential component of flexibility. It facilitates the establishment of an effective communicating network among employers, employees, supply chain parties and customers. Likewise Correa (1994) discussed two different streams of process technology in improving flexibility i.e.: (i) flexible automation approach to modify process to changes and (ii) methodology based approach concentrates on the interaction of organization, human resources and conventional. Yadav *et al*. (2000) highlighted that process technology cannot itself contribute to flexibility. It should be accompanied by human resources, supplier relationships, market skills and training, and information technology to enhance its flexibility capabilities in response to a changing business environment. Sharing this view, Garcia and Turner (2006) highlighted that organizations need to be innovative in improving and creating their processes, and constantly appraise themselves against process improvement paradigm(s). Some examples of process improvement paradigm include: (i) Capability Maturity Model Integration (CMMI®) by Carnegie Mellon University and (ii) Organizational Project Management Maturity Model (OPM3) by Project Management Institute.

FLEXIBLITY MANAGEMENT IN CONSTRUCTION

The notion of learning from manufacturing industry is not new. Some successful examples of such learning are the application of various management concepts such as six sigma, just in time, lean production, supply chain and total quality management. Turning to flexibility management in construction, some researchers in the field of construction management have recognized the need for flexibility in order to survive the turbulent business condition (e.g. Lansley 1983, 1987). Lansley (1983) highlighted that the need for flexibility (an ability to realign existing resources to meet new demands) is accepted by most organizations, although the means for achieving flexibility remains elusive. Other studies (i.e. Lansley *et al*. 1974, 1975) on the development of conceptual models based on organization structure, management style and problem solving skill have been successful in describing the determinants of flexibility to practising manager. Based on these models, Lansley (1983) proposed a practical approach to auditing organization flexibility via identification and analysis of constraints. Following this, Lansley (1987) attempted to establish a link between the environment of the construction industry and the contractors' strategies by considering the differences in the nature of demand on construction organization over three decades of different business environments. He found that these environments required construction organizations to structure their operations in different ways where managerial staffs have to adopt different problem solving skills.

Other researchers have attempted to use flexibility as one of their measures on the prediction of organization effectiveness. Handa and Adas (1996) used the dimension of flexibility in two aspects: (i) structural context and (ii) rule and regulation. The former contains variables such as level of joint venturing, subcontracting and information flow. The latter consists of variables such as attitude towards change and level of process control. Dikman *et al*. (2005) used flexibility as an independent variable to measure effectiveness of construction organizations.

Besides organizational settings, flexibility concept has also been used in element-specific and project-oriented research in construction. For examples, Ofori and Debrah (1998) explored flexibility management of workers in Singapore. Their study provided a review of labour market flexibility and employment structure as well as a critique of flexibility model. They revealed that product-related organizations tend to reduce the number of their core employees and vary the number of their peripheral workers such as part-timers and temporary workers in response to production demand.

Gil *et al*. (2005) developed a framework on product and process flexibility to cope with challenging project deliveries.

There is a need for greater flexibility in presenting project information due to the diversity of people, organization and activities involved in the construction process (Betts 1991). Betts's study revealed that the use of relational database technology and integrate database design methodology improve the flexibility of information retrieval. Ekstrom and Bjornsson (2005) used the concept of real options to assess the value of flexibility in information technology investment. They found that it is possible to quantify the value of flexibility for information technology investment but the selection of measurement instrument is directly related to the nature of individual project. Ford *et al*. (2002) have also used the real options approach to ascertain strategic flexibility during project evaluation process. Their study revealed that the existing usage of flexibility in project management is not structured adequately to provide useful strategy design and valuation tool. They found that the use of real option approach in project evaluation would potentially increase project value by: (i) explicitly designing definite uses of managerial flexibility during projects and (ii) valuing the flexibility in pre-project planning.

Along the project flexibility domain, Walker and Shen (2002) explored the link between planning and flexibility towards good construction time performance through a framework of project understanding and knowledge transfer. They found that organization, team competence and commitment to exploring alternative options are the keys to good construction time performance. In order to respond to unanticipated challenges during the course of a project and succeed, the development of a learning culture that fosters flexibility within a systematic problem solving approach is necessary (Walker and Loosemore 2003). Their study revealed that this flexible approach could be achieved using a crisis management model. Interestingly, Olsson's (2006) study revealed that all the projects investigated by him had been actively involved in flexibility management across the project lifecycle.

CONCEPTUAL FRAMEWORK FOR DELIVERING FLEXIBILITY

Based on the above review, the importance of being flexible is well recognized within the context of both the manufacturing and construction industries. It appears, however, that the concept of flexibility in construction is fairly fragmented and not well-understood. Some researchers tend to perceive flexibility as a uni-dimensional construct rather than an integrative multi-dimensional concept. Also they tend to look specifically at individual elements such as information technology and human resource in attaining flexibility. Beside this, construction-related studies on flexibility tend to use project(s) as subject matter, but not considering a construction organization as unit of analysis. It is maintained that the emphasis should be placed on construction organization itself since the ability of being flexible involves the interdependency of various key enablers of an organization. For example, labour flexibility is dependent on flexibility of the organizational structure in which this flexibility capability will in turn influence the construction project delivery.

To achieve a better understanding of flexibility management for construction business in a changing competitive environment, a conceptual framework for delivering flexibility is developed (see Figure 1). It is hypothesized that flexibility management comprises eight key enablers: (i) supply chain relationship; (ii) organizational culture;

(iii) human resource; (iv) business strategy; (v) information technology; (vi) process technology; (vii) firm size; and (viii) organizational structure. Likewise, flexibility is operationalized into 15 dimensions: (i) volume; (ii) expansion; (iii) logistic; (iv) operation; (v) market; (vi) procurement; (vii) spanning; (viii) labour; (ix) process; (x) modification; (xi) program; (xii) financial; (xiii) material; (xiv) machine; and (xv) product.

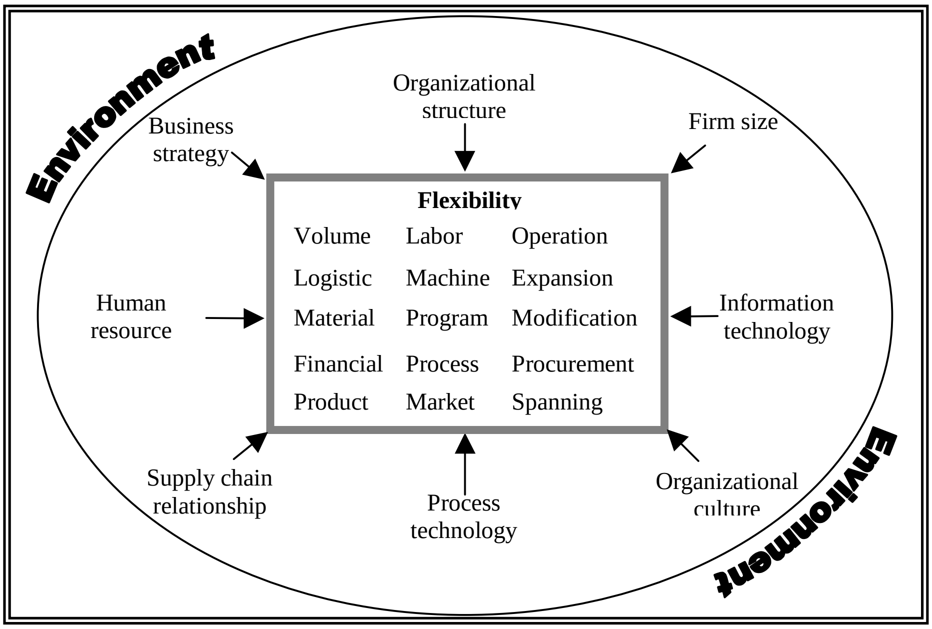

Figure 1: Conceptual model for delivering flexibility in a construction organization

THEORETICAL FOUNDATION ON FLEXIBILITY MANAGEMENT

Within the context of a construction organization, both complexity theory and resource based theory (RBT) corresponding to “how organization behaves” and “how organization competes” in response to a changing environment form the theoretical foundation of this research. Complexity theory presumes organization as an adaptive system that comprises a complex linkage of elements that behaves in line with its environment and ultimately emerges into a higher performance entity (Tetenbaum 1998). Likewise, RBT presumes an organization as a collection of unique resources and capabilities that provides the basis for its strategy and the primary source of its return (Grant 1991).

It is recognized that a construction organization should be analyzed as a single entity that is heavily linked with many interactive elements (nodes), which is determined to a great extent by an organization’s resource and capabilities. In this case, the nodes will represent the key enablers in delivering flexibility (Figure 2a). Figure 2b illustrates the exertion of an external force (e.g. changes, chaotic event happened) on the organization system. This external force will reshape the structure of those elements (e.g. human resource, organization structure and technologies) within the organization system with the resultant system that reacts adaptively in dynamic way as illustrated in Figure 2c. In the face of any event, the linkages between the nodes (i.e. resource and capabilities) denote the level of flexibility within an organization.

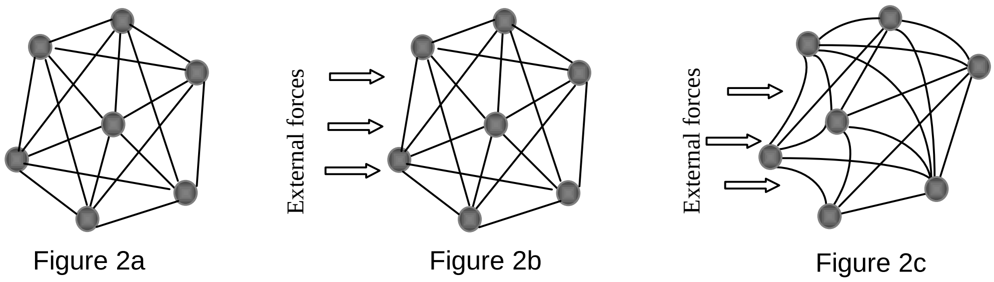

Figure 2: Organization as an adaptive system to the changing environment

FUTURE DATA COLLECTION EFFORT

The conceptual model (Figure 1) would be subjected to testing and validation. A two-phase data collection process is proposed. Phase I involves conducting semi-structured interviews with three experts from the industry. The purpose is to uncover the languages and terms associated with the flexible concept. Phase II involves the investigation of contractors' flexibility management by conducting an industry-wide survey. Survey questionnaire is formulated based on results of semi-structured interviews and literature review. The aims of survey are twofold: (i) to ascertain the importance of key enablers in the proposed conceptual model; and (ii) to confirm enablers lead to flexibility and thus achieve better organization's performance. Prior to the actual run, a pilot test shall be conducted to test clarify of survey questionnaire.

Given that the size of firm is a key enabler in flexible management, the target group of large and medium sized general building contractors (Group A1, A2, B1 and B2) will be selected from the contractors' registry of the Singapore Building Construction Authority (BCA). These four targeted groups are categorized in accordance to their financial grade under the BCA contractors' registry (see http://www.bca.gov.sg). To enhance the validity of this study, we attempt to refine the sampling frame by comparing the list of registered contractors between the year 1999 (a year after Asian Financial Crisis) and 2007 where those contractors who still appear in the list as of 2007 will be contacted. This is based on the belief that these contractors have executed some flexibility measures in riding the wave of changes over the periods of recession in the local construction industry. In the analysis stage, a structural equation modelling technique could be used to analyse the interrelationship of each key enablers towards the attainment of flexibility.

CONCLUSION

In undertaking the initial stage of this research, flexibility management is seen as a necessity in the constantly changing competitive environment. Judging from the manufacturing literature, construction industry is still far from attaining a full understanding and adoption of flexibility management. From the review of literature, it was found that key enablers to flexibility are: (i) supply chain relationship; (ii) organizational culture; (iii) human resource; (iv) business strategy; (v) information technology; (vi) process technology; (vii) firm size; and (viii) organizational structure. These key enablers form the conceptual framework that may be used by organizations to achieve flexibility. Likewise flexibility is operationalized into 15 dimensions: (i) volume; (ii) expansion; (iii) logistic; (iv) operation; (v) market; (vi) procurement; (vii) spanning; (viii) labour; (ix) process; (x) modification; (xi) program; (xii) financial; (xiii) material; (xiv) machine; and (xv) product.

FROM SITUATION ANALYSIS TO DECISION OPTIONS: AN IMPROVED SWOT APPROACH

Weisheng Lu,[1] Roger Flanagan, Koray Pekericli and Carol Jewell

School of Construction Management and Engineering, University of Reading, PO Box 219, Reading, RG6 6AW, UK

Decision making theory suggests that a typical process for making decision comprises sequential steps such as setting objectives, understanding decision situation, generating decision alternatives, evaluating and selecting an optimal option, and so on. This research focuses on the process of generating decision options from a situation analysis. In practice, this process still heavily depends on decision maker's creativity despite the Strengths, Weaknesses, Opportunities, and Threats (SWOT) approach has greatly facilitated it. This research aims to aid the generation of decision options by considering artificial intelligence (AI) as a possible solution. It starts with a critical review of the SWOT as a powerful and popular tool for conducting situation analysis. A weighted matrix is introduced to improve the current SWOT approach. By manipulating the matrix, a heuristic rule is derived. The heuristic rule can be fed into future AI software to generate various decision options.

Keywords: decision making, decision support, situation analysis, SWOT, decision options, artificial intelligence.

INTRODUCTION

Past decades have seen the flourish of different schools of theories about people making decisions. The "rational-analytic" school (e.g. Newell and Simon 1972; Simon 1982) suggested that any decision involves a choice selected from a number of alternatives. The task of rational decision making is to select the alternative that results in the more preferred set of all the possible consequences. The "naturalistic" school (e.g. Klein 1998) emphasizes how people use intuition, action, and adaptation to deal successfully with situations that involve uncertainty and risk. Phillips (1984) proposed a Requisite Model to distinguish itself from any other kind of decision-making model. Compared to different intellectual debates on above theories, A RAND Project AIR FORCE (PAF) survey argues that the frontier of research is seeking to synthesize these different viewpoints and to produce practical suggestions to support decision making that is both analytical and intuitive Having understood various streams of decision making theories, this research has no intention to join their debates.

This research is more about the "rational-analytic" school which assumes that a typical process for making decision comprises sequential steps including setting objectives, understanding decision situation, generating decision options, evaluating and selecting a best/optimal option, and so on (Cooke and Slack 1991). The research focuses on the process from understanding decision situation to the generation of decision options. Understanding decision situation, also called environment analysis,

[1] w.lu@reading.ac.uk

environment scanning, situation analysis, situation assessment or situation audit, is to understand the internal and external environment before any decision is to be made. The philosophy can even be found in Sun Tzu's (BC600) idea : 'Know your enemy, know yourself, and you can fight a hundred battles with no danger of defeat'. Various tools, i.e. five forces model (Porter 1980), resource-based approach (e.g. Wernerfelt 1984; Barney 1991) have been devised to conduct situation analysis. Amongst these tools, the SWOT approach is probably the most powerful and popular one. However, there is not much exciting research advising people how to generate decision options based on a SWOT analysis. Decision options, also called decision alternatives or decision choices, are generated from the situation analysis, from which decision makers can make their choice. Simon (1982) suggested that if there are more choices available for a decision-making problem, the rationality of decision-making will be increased. In actual exercises, the generation of decision options relies heavily on people's creativity; if someone is more creative, he is more capable of generating decision options. It would be helpful if there were a tool that could facilitate this process by simulating human beings. Proctor (1992) expressed a similar interest and made an attempt by developing a computer-aided creativity tool. However, his computer package is very basic, as IT was in its early development at that stage.

The aim of this study is to develop a method for generating decision options based on a SWOT analysis by considering the computer as a possible tool. The study starts from a critical review of the SWOT approach. A weighted matrix is introduced to improve the current SWOT method. By manipulating the matrix, one or more heuristic rules will be derived. The heuristic rules can be interpreted by some AI software packages, and so compiled as a list of decision options. The research enriches the knowledge of the SWOT analysis by envisaging the gap between situation analysis and the generation of decision alternatives. More importantly, it opens a new window by introducing the AI to the decision support exercises.

A CRITICAL REVIEW OF THE SWOT APPROACH

SWOT is an acronym for Strengths, Weaknesses, Opportunities and Threats. It is a commonly used tool for analysing internal and external environments in order to attain a systematic approach and support for a decision situation (e.g. Kotler 1988; Wheelen and Hunger 1995). It has its origins in the 1960s (Learned *et al*. 1965), and reached its zenith through Weihrich's (1982) milestone work. The principle for using the SWOT analysis is that any decision made should match the environmental threats and opportunities with the organization's weaknesses and especially its strengths. Weihrich (1982) propose a seven-step framework whose core part can be shown in Figure 1. To use the tool, users need to identify and evaluate the opportunities and threats facing an organization, and its strengths and weaknesses. Then users need to develop decision options based on the SWOT analysis. There are four generic decision options, as shown in Figure 1. The S/O options maximize strengths and opportunities; The T/S options maximize strengths and minimize the threats; The S/W options maximize opportunities and minimize weaknesses; The T/W options minimize the weaknesses and threats. Weihrich's (1982) TOWS matrix provides a systematic fashion to connect internal and external factors to stimulate new decision options. Since that, the TOWS matrix has become one of the most powerful and popular tools for supporting decision making.

	Strengths	Weaknesses
Opportunities	S/O Maxi-Maxi	S/W Maxi-Mini
Threats	T/S Mini-Maxi	T/W Mini-Mini

Figure 1: The TOWS Matrix Source (adapted from Weihrich 1982)

Despite the belief that it is somewhat outdated, the SWOT analysis is still one of the most powerful and popular tools for conducting situation analysis. Different from other tools that are doomed to be outdated quickly with the fast development of the fickle management science, the SWOT analysis is still popular because of its inclusivity. It does not exclude other theories that emerged afterwards. As Glaister and Falshaw (1999) suggested, a SWOT analysis may itself encompass a number of different forms of analysis, for example, Porter's five forces model, and resource-based approach, etc. Several other factors have contributed to its popularity: its simplicity; the model can be used without the need for extensive information system; it provides decision makers with a systematic structure for conducting analyses (Piercy 1991).It can be observed that a large number of applications regarding the SWOT approach were reported. Steward (2002) utilized it to determine the implementation of IT/IS projects in construction. Dyson (2004) applied it to the development of strategies for the University of Warwick.

A number of recently reported studies tried to enhance the value of the SWOT approach. Some tried to provide guidelines for where analysts can identify factors of strengths, weaknesses, opportunities and threats. Panagiotou (2003), for example by noticing that "planners are left without indication as to where to search for such (S, W, O, T) variables", suggested a TELESCOPE OBSERVATIONS framework where each letter stands for an aspect for identifying SWOT factors, e.g. T standing for Technological Advancements. The idea itself is not much more novel than the PEST (Political, Economical, Social, and Technical factors framework as suggested earlier by Weihrich (1982). Some other research tried to quantify the SWOT factors by utilizing different quantifying approaches. Notably, there is a hybrid method called A'WOT (Kurttila *et al.* 2000). In this method, the factors by a SWOT analysis are evaluated by using multi-criteria decision support method – AHP (Saaty 1980) in this case. The idea of utilizing the AHP technique within the SWOT framework is to systematically evaluate the SWOT factors and make them commensurable with regard to their intensities (Kurttila *et al.* 2000). In fact, it lacks legitimacy to use the AHP method to compare factors falling in different groups (strengths, weaknesses, opportunities, and weaknesses). Nonetheless, the idea of quantifying SWOT factors is interesting.

There is a limitation of the SWOT analysis that has not been mentioned by previous works. Readers are often excited to see that the identification of SWOT factors is well guided, and the SWOT analysis is well structured. Consequently, a matrix as shown in Figure 2 is derived. However, when it comes to the following step – generating decision options – most writers are "wise after the event" or arbitrary. There are few logical links between the SWOT analysis and the decision options. The only advice readers can get is "to be creative"; users should be creative to generate decision options. Indeed, this process is highly creative (Cooke and Slack 1991), and it seems there is little writers can do with people's creativity. While it is likely that some people are inherently more creative than others (Ribeaux and Poppleton 1978), modern thinking has shifted away from the idea that the situation is one of all-or-nothing, that we are either creative or not, towards the notion that the creative process can be stimulated and improved in the majority of people (Cooke and Slack 1991). It will be very helpful if there is a tool that could stimulate people's creativity and generate more decision options.

	Strengths (S_1, S_2, S_3, …, S_i)	Weaknesses (W_1, W_2, W_3, …, W_j)
Opportunities (O_1, O_2, O_3, …, O_m)	S/O decision options Maxi-Maxi	S/W decision options Maxi-Mini
Threats (T_1, T_2, T_3, …, T_n)	T/S decision options Mini-Maxi	T/W decision options Mini-Mini

Figure 2: A SWOT matrix with factors of strengths, weaknesses, opportunities and threats

AN IMPROVED TOWS MATRIX

Assuming that after a SWOT analysis all the factors are agreed and their relative importance is determined, a weighted TOWS matrix can be derived as shown in Figure 3. The SWOT factors could be identified by brainstorming, or by using the various guidelines such as the PEST, the TELESCOPE FRAMEWORK, or whatever. The relative weightings of the SWOT factors could be derived by engaging the AHP method (Saaty 1980) or the Likert-Scale, and so on.

			Strengths S_1, S_2, S_3, …, S_i	Weaknesses W_1, W_2, W_3, …, W_j
			ω_{s1}, ω_{s2}, ω_{s3},…, ω_{si} (Σ=1)	ω_{w1}, ω_{w2}, ω_{w3},…, ω_{wj} (Σ=1)
Opportunities	O_1, O_2, O_3 … O_m	ω_{o1}, ω_{o2}, ω_{o3}, …, ω_{om} (Σ=1)	S/O decision options Maxi-Maxi	S/W decision options Maxi-Mini
Threats	T_1, T_2, T_3, … T_n	ω_{t1}, ω_{t2}, ω_{t3}, …, ω_{tn} (Σ=1)	T/S decision options Mini-Maxi	T/W decision options Mini-Mini

Figure 3: A weighted TOWS matrix

As the principle of the SWOT approach, any decision option should make use of the opportunities and strengths, or use the opportunities and avoid threats, etc. In reality, not all SWOT factors are matched. Possibly, there may be no relationship between an opportunity and a strength. Weihrich (1982) suggested the use of a '+' to indicate a match between two factors in different category, and an '0' to indicate a weak or non-existent relationship. Consequently, an interaction matrix can be developed. This research will slightly change this mechanism and use a coefficient 'r' to indicate a match, where r=1 means a match and r=0 means a weak or non-existent relationship. Weihrich (1982) also warned that different relationships may have different weights in terms of their potential, so each should be carefully evaluated. In this research, a mechanism has been introduced to indicate different weights of SWOT factors, as shown in Figure 3. By combining these, a weighted interaction matrix can be derived. Use the Opportunity-Strength (O/S) matrix as an example and a weighted interaction matrix can be derived as shown in Figure 4. A similar matrix can be used for analysing the other three generic decision options, e.g. W/O, S/T, and W/T.

			Strengths $S_1, S_2, S_3, \ldots, S_i$					
			ω_{s1}	ω_{s2}	ω_{s3}	…	ω_{si}	(Σ=1)
Opportunities	O_1	ω_{o1}	r_{11}	r_{12}	r_{13}	…	r_{1i}	
	O_2	ω_{o2}	r_{21}	r_{22}	r_{23}	…	r_{2i}	
	O_3	ω_{o3}	r_{31}	r_{32}	r_{33}	…	r_{3i}	
	…	…	…	…	…	…	…	
	O_m	ω_{om} (Σ=1)	r_{m1}	r_{m2}	r_{m3}	…	r_{mi}	

r=0 or 1

Figure 4: A weighted interaction matrix (O/S) between opportunity and strength factors

The weighted O/S interaction matrix can be further expressed as Equation (1).

$$\text{O/S matrix} = \begin{bmatrix} \omega_{o1} * r_{11} * \omega_{s1} & \omega_{o1} * r_{12} * \omega_{s2} & \omega_{o1} * r_{13} * \omega_{s3} & \cdots & \omega_{o1} * r_{1i} * \omega_{si} \\ \omega_{o2} * r_{21} * \omega_{s1} & \omega_{o2} * r_{22} * \omega_{s2} & \omega_{o2} * r_{23} * \omega_{s3} & \cdots & \omega_{o2} * r_{2i} * \omega_{si} \\ \omega_{o3} * r_{31} * \omega_{s1} & \omega_{o3} * r_{32} * \omega_{s2} & \omega_{o3} * r_{33} * \omega_{s3} & \cdots & \omega_{o3} * r_{3i} * \omega_{si} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ \omega_{Om} * r_{m1} * \omega_{s1} & \omega_{om} * r_{m2} * \omega_{s2} & \omega_{om} * r_{m3} * \omega_{s3} & \cdots & \omega_{om} * r_{mi} * \omega_{si} \end{bmatrix}_{m \times i} \tag{1}$$

Using a hypothesis case as an example, there are five opportunity and eight strength factors identified. Their weights and match coefficients are all determined. An O/S matrix can be derived as shown in Equation (2).

$$\text{O/S matrix} = \begin{array}{cc} & \\ & \\ O1 & 0.1 \\ O2 & 0.2 \\ O3 & 0.2 \\ O4 & 0.3 \\ O5 & 0.2 \end{array} \begin{array}{c} \begin{array}{cccccccc} S1 & S2 & S3 & S4 & S5 & S6 & S7 & S8 \\ 0.125 & 0.0625 & 0.250 & 0.0625 & 0.125 & 0.250 & 0.0625 & 0.0625 \end{array} \\ \begin{bmatrix} 1 & 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 1 & 1 & 1 & 0 \end{bmatrix} \end{array}$$

$$= \begin{array}{c} \\ O1 \\ O2 \\ O3 \\ O4 \\ O5 \end{array} \begin{array}{c} \begin{array}{cccccccc} S1 & S2 & S3 & S4 & S5 & S6 & S7 & S8 \end{array} \\ \begin{bmatrix} 0.0125 & 0 & 0.0250 & 0.00625 & 0 & 0 & 0 & 0 \\ 0.0250 & 0.01265 & 0 & 0.01250 & 0.0250 & 0.0500 & 0.01250 & 0.01250 \\ 0.0250 & 0.01265 & 0.0500 & 0.01250 & 0.0250 & 0.0500 & 0.01250 & 0.01250 \\ 0 & 0.01875 & 0.0750 & 0.01875 & 0.0375 & 0 & 0 & 0 \\ 0.0250 & 0 & 0.0500 & 0 & 0.0250 & 0.0500 & 0.01250 & 0 \end{bmatrix} \end{array}$$

$$= \begin{array}{c} \\ O1 \\ O2 \\ O3 \\ O4 \\ O5 \end{array} \begin{array}{c} \begin{array}{cccccccc} S1 & S2 & S3 & S4 & S5 & S6 & S7 & S8 \end{array} \\ \begin{bmatrix} 1.25 & 0 & 2.50 & 0.625 & 0 & 0 & 0 & 0 \\ 2.50 & 1.265 & 0 & 1.250 & 2.50 & 5.00 & 1.250 & 1.250 \\ 2.50 & 1.265 & 5.00 & 1.250 & 2.50 & 5.00 & 1.250 & 1.250 \\ 0 & 1.875 & 7.50 & 1.875 & 3.75 & 0 & 0 & 0 \\ 2.50 & 0 & 5.00 & 0 & 2.50 & 5.00 & 1.250 & 0 \end{bmatrix} \end{array} / 100 \tag{2}$$

When creating decision options, one may expect that an option can maximize the use of opportunities and strengths. This accords with the principle of the SWOT analysis as discussed previously. Using the above O/S matrix as an example, as shown in Figure 5, if a decision option can cover {O3, S1, S2, S3, S4, S5, S6, S7, S8}, it makes use of the opportunities and strengths to the largest extent. Here the {O3, S1, S2, S3, S4, S5, S6, S7, S8} is called the heuristic rule, as shown in Equation (3).

$$HR_1 = \{O3, S1, S2, S3, S4, S5, S6, S7, S8\} \tag{3}$$

It can be used for stimulating people to generate decision options that cover all these opportunity and strengths.

$$\begin{array}{cc}
 & \begin{array}{cccccccc} S1 & S2 & S3 & S4 & S5 & S6 & S7 & S8 \end{array} \\
\begin{array}{c} O1 \\ O2 \\ O3 \\ O4 \\ O5 \end{array} & \begin{bmatrix}
1.25 & 0 & 2.50 & 0.625 & 0 & 0 & 0 & 0 \\
2.50 & 1.265 & 0 & 1.250 & 2.50 & 5.00 & 1.250 & 1.250 \\
2.50 & 1.265 & 5.00 & 1.250 & 2.50 & 5.00 & 1.250 & 1.250 \\
0 & 1.875 & 7.50 & 1.875 & 3.75 & 0 & 0 & 0 \\
2.50 & 0 & 5.00 & 0 & 2.50 & 5.00 & 1.250 & 0
\end{bmatrix}
\end{array}$$

Figure 5: Heuristic rule for generating decision options

CAN THE COMPUTER HELP?

The previous section introduced an improved TOWS matrix, based on which decision options can be generated to make best use of opportunities and strengths. Human beings can do this but sometimes it is difficult for them to deal with large amounts of information, and to be creative enough. Can a computer help in this case?

Proctor's (1992) work provides a similar insight into this problem. His computer-based approach randomly picked up a keyword from a database, which is carefully developed "to make for interesting ideas". The keyword could indicate a strength, weakness, opportunity, or threat factor that is purely judged by a decision maker. The mechanism will be utilized again to determine the potential options from the SWOT analysis. This study is respected more because of its idea than the success of the IT approach itself.

There are many other exciting AI research findings which could be possibly utilized in this research to generate decision options creatively. Boden (1995) suggested that this kind of creativity could be scientifically understood and facilitated by using AI if the "conceptual space" can be successfully defined. Some computer-based musical composition programs have been developed, i.e. Johnson-Laird's (1989) "Jazz Improvisation". Some AI programs are able to tell stories (e.g. Turner 1992). Although these AI programs are far from mature, one could be optimistic that a program for generating options in this research is possible since the context is relatively simple. As an advantage, the heuristic rule narrowed the "conceptual space". The approaches such as neural network, system dynamics, genetic algorithms, all may provide a basis for this program.

CONCLUSION

It is a logical sequence in a rational decision making process to understand a decision situation firstly, then to generate decision options, and consequently to select a best or optimal option from them. The SWOT analysis is a powerful and popular approach for conducting situation analysis, but there is not much exciting research advising people how to generate decision options based on a SWOT analysis. It is a process of creativity and it is highly desired that there is a tool to aid this creativity process. This study introduced a weighted interaction SWOT matrix to improve the current SWOT approach. This new approach has incorporated the latest advances in SWOT analyses. By calculating the matrix, a heuristic rule for stimulating the formulation of decision options is derived.

The heuristic rule can ideally be interpreted by some AI software packages, and compiled to a list of decision options. Although this research has not developed such an AI package, it seems feasible to develop it after reviewing the related development in creativity AI. Future studies will be conducted to develop such an IT package and validate it in different scenarios.
