SCENARIO PLANNING FOR CONSTRUCTION COMPANIES

Robby Soetanto,[1] Chris I. Goodier, Simon A. Austin, Andrew R.J. Dainty and Andrew D.F. Price

Department of Civil and Building Engineering, Loughborough University, Leicestershire LE11 3TU, UK

The ability to understand the future holds the key to sustained competitive advantage. The key question is how to embed this ability into the strategic management skill-sets of companies using appropriate tools, techniques and processes, and involving the appropriate stakeholders. Futures methodology literature suggests that scenario planning is a powerful technique for looking at the future that is rarely used in construction. An implementation framework for company scenario planning is proposed derived from relevant parts of the literature and evolved through a series of interactions with industry. The framework emphasizes that the awareness of external factors and industry scenarios, and the extent of stakeholder engagement throughout the process will determine the overall efficacy of scenario planning. Benefits will accrue from having a common understanding of alternative futures by explicitly capturing perceived future events, drivers and pathways in scenario mapping exercises. This should place companies in a better position to navigate their future and deal with potential threats and opportunities.

Keywords: corporate planning, future studies, negotiation, organizational learning, research methods.

INTRODUCTION

The impact of the construction industry on the UK economy is substantial. Construction firms work within a tradition of competitive tendering and small profit margins, but have to be able to respond to fluctuating market demand in order to survive. Construction work often has to be performed in inhospitable or ‘difficult’ environments and the industry has a poor health and safety record (Egan 1998). Construction has been found to be ineffective at planning for the long-term future and lacks forward thinking. A number of reports scrutinizing the performance of the sector (e.g. Egan 1998) have called for the industry to look beyond their next project and prepare themselves better for potential future events and trends.

Strategic planning is a critical management function which could ensure the long-term survival of construction organizations (e.g. Betts and Ofori 1992). Here, ‘strategic planning’ is taken to mean a management function for developing a longer-term plan (beyond the next project), which will shape company characteristics and determine the market in which it is going to operate. Many reasons have been put forward for construction organizations’ lack of effort in strategic planning (Brightman *et al.* 1999), most being inadequate resource capacities, instability of employment and the unpredictability of the construction market. Strategic planning is often the

[1] r.soetanto@lboro.ac.uk

responsibility of senior managers; however, the time they can dedicate to the task is limited as they also have day-to-day operational responsibilities (Burt and van der Heijden 2003). This problem is increased by the prevalence of small construction companies in the sector. Fierce competition and the transient nature of construction employment often results in smaller companies struggling to survive, let alone plan for the long term. Hence, their focus is often just on their current project, as well as winning the next one. If they do plan ahead, then this may have to be aborted because of an emerging need to respond to emerging market demands, hence rendering the whole process of long-term planning less beneficial. In most cases, there is little evidence of a formal process in the formulation of long-term strategies (Edum-Fotwe 1995; Brightman *et al.* 1999). There is thus little capacity for strategic planning in companies in the construction sector and little emphasis on the need for long-term planning as its benefits have not been fully and immediately realized.

Rapid social, economic and technological developments have provided many threats and opportunities for construction companies. The existing modus operandi is perhaps no longer sustainable if they wish to sustain their competitiveness at local, national or global levels. Hence, the need to plan more strategically and better foresee future possibilities is more important than ever before. Enhancing their capacity to foresee futures and plan for them is critical if companies are to prepare and adapt to emerging trends and eventualities that may lie ahead. Scenario planning has recently been heralded as a promising tool to generate possible, probable and preferred longer-term futures (i.e. 20–25 years) for organizations (Hiemstra 2006). This paper reports on a review of literature which provides the basis for developing a process framework for enhancing a construction company's capacity for strategic planning using scenario planning. First, recent evidence of strategic planning practice derived from a survey of senior construction professionals is presented. The role of scenarios in strategic planning is subsequently explained. Causal mapping techniques to capture individual and organizational cognition about the future are described also. A proposed scenario planning activity (the framework) within a firm is then presented. The paper concludes with a discussion regarding the barriers of implementing scenario planning, recommendations for approaches to overcome them, future research activities and potential contribution to knowledge in this area.

STRATEGIC PLANNING IN CONSTRUCTION COMPANIES

Understanding current strategic planning practices within companies is a prerequisite to improving it. Several studies have outlined the generic approaches of strategic planning practices in construction organizations (Brightman *et al.* 1999; Price 2003). A questionnaire survey of senior construction managers in the UK was recently undertaken by the authors to provide information regarding strategic planning practices. Here, the aim is not to provide definitive facts based upon a representative sample, but to provoke further thought and discussion and to enhance the knowledge of current practices in strategic planning.

The first two questions asked the respondent's position within their organization and their experience (i.e. number of years) within the construction industry. The respondents were then asked whether they had been involved in long-term strategic planning and decision making, and if so, how far ahead their strategic planning looked (in terms of number of years). They were asked to identify events that had had an adverse effect on their corporate strategic planning and the extent to which they can possibly avoid or minimize these given the right tools/techniques. The subsequent questions asked about the tools and techniques that the respondents usually use as part of their planning. Here, multiple choices of common tools/techniques were provided, including SWOT (strengths, weaknesses, opportunities and threats) analysis, gap analysis, PESTEL (political, economical, social, technological, environmental and legal) analysis, competitor analysis (i.e. analysing the behaviour and development of similar competitors), as well as no specific technique. Spaces for 'other' answers were also provided.

The final question enquired as to the data and information that the respondents thought most useful for strategic planning, and their effectiveness (in terms of ability to help make the right decisions) in a Likert scale of 1 to 4 where 1 indicates 'poor' and 4 'excellent'. Multiple choices of information were provided, including 'forecasts from internal/external sources', 'statistics (past data)', 'newspapers and magazines', 'personal contacts' and 'intuition and experience'. Again, spaces for 'other' answers were provided. At the end of the questionnaire, the respondents were invited to write additional comments and their contact details, should they wish to get further involved in the research. The questionnaires were distributed during a construction professional institution's annual conference in autumn 2006. Considering the practicality of their distribution, the questionnaires were designed to be fairly simple and took about 15 minutes to complete. Two of the authors attended the conference and personally distributed the questionnaires, as well as leading the delegates through a facilitated process for completing the questionnaires. Forty questionnaires were completed and consequently analysed.

The majority of the respondents were experienced construction professionals who had been in the industry for a significant amount of time (an average of 24 years). Most (85%) declared their involvement in the formulation of long-term strategic planning and decision making. The length of the future plans that they had been involved in varied, but almost half (56%) had a corporate plan for the next five years. Only 18% and 12% indicated that their plans were for 10 and 3 years respectively. Much smaller percentages of them planned for 1, 2 and 20 years. This concurs with Brightman *et al.*'s (1999) assertion that planning horizons are generally limited to between 3 and 5 years. Longer-term plans are often sensitive to changes caused by social, political, economic and technological developments. The majority (70%) indicated that they have personally experienced events that have had an adverse effect on their corporate planning. Most reasons cited were events over which they have no or little control, such as market slumps/recession and change in government policies (political decisions). Current issues such as skills shortage, energy prices and climate change, were also cited, indicating their awareness of the possible impacts that these might have now and in the future.

Most respondents used a combination of several techniques for planning, rather than a single technique. The response showed that 68% used SWOT analysis and 58% used competitor analysis. Gap and PESTEL analyses were used by 32% and 20% respectively. Interestingly, 15% of respondents who were involved in strategic planning activities did not use any techniques at all. A small number of 'other' tools were indicated including 'mind-mapping', 'what-if scenarios' and 'blue-sky thinking/brainstorming'. Anecdotal evidence collected from key construction stakeholders during previous workshops and interviews suggests that 'what-if scenario' techniques and brainstorming sessions are often conducted informally among key decision makers during discussions in company meetings, for example, when they considered alternative options.

Regarding information for developing their strategic planning and its effectiveness, the average responses for ‘forecasts from internal/external sources’, ‘statistics (of past data)’, ‘newspapers and magazines’, ‘personal contacts’, ‘intuition and experience’ were 2.6, 2.5, 2.1, 2.6 and 2.7 respectively. The results highlighted the heavy reliance on intuition and experience in the formulation of strategic plans. It is interesting to note the perceived higher effectiveness of intuition and experience compared with ‘harder’ information such as forecasts and statistics. These findings show a higher degree of subjectivity during the formulation of corporate strategic planning with little participation from lower ranks within the organizational hierarchy. A more formal strategic planning technique which is able to elicit and unify aspirations from staff at various levels might help organizational competitiveness through helping to capture the relatively untapped potential of its workforce.

THE ROLE OF SCENARIOS IN STRATEGIC PLANNING

Thinking about and planning for the future is an integral part of human life. An example of its simplest form is the plans that most people make in the early morning, when they think about their activities for the day, whereas the most complex future planning attempts to look into the long-distance future (e.g. 20–50 years’ time). In everyday life, people naturally construct sequences of future events in their minds when they consider the possible implications of their decisions and actions. In other words, people are unconsciously familiar with building scenarios. So what are scenarios in general, and what do we mean by corporate scenario planning? What are the advantages of using scenarios in comparison to other ‘harder’ futures studies techniques such as forecasting?

A scenario can be simply described as a storyline comprising a range of interconnected and uncertain future events and their possible consequences. Scenarios are often employed for decision-making activities in which some parameters are uncertain or poorly defined, hence scenario-planning techniques’ ability to deal with ‘wicked’ (as opposed to ‘tame’) problems (Rittel and Webber 1973; cf. Rosenhead and Mingers 2001: 5). Earlier futures studies techniques (e.g. based on the extrapolation of current trends) have failed to live up to their expectation as a predictive tool. Instead, scenarios are tools for presenting people perceptions of the alternative environments in which decisions and actions might be played out (Brightman *et al.* 1999). It is not about predicting events or determining the most likely scenario, but is about developing several plausible stories that describe how the environment in which an entity (e.g. an individual or organization) lives or operates, may develop, given certain future events, trends and developments and then exploring possible ‘discontinuities’ and ‘surprises’ (i.e. wild cards) (Hiemstra 2006).

Scenarios provide a framework to develop and evaluate corporate strategies. The utility of scenarios is often analogous to ‘wind-tunnel’ or ‘test-bed’ for corporate strategic decisions. Hiemstra (2006) found that taking a long-range view of about 20 to 25 years is best for corporate planning because this permits people to imagine that things will be different, to make fundamental changes in their organizations, and to seize opportunities that are not given by shorter views (of, for example, three to five years). Some may argue that planning for 20 years is almost impossible, so strategic plans will most likely remain three to five years, which is practical given the speed at which the world is changing today. Thus, scenario planning aims to extend people’s views of the future through thinking of various possibilities, which provides a ‘test-bed’ for strategic plans, allowing them to navigate their future and choose an appropriate direction. This will enhance the organizational capacity for strategic planning and managers' decision-making capabilities (Schwartz 1991; cf. Chermack 2004). However, little is known regarding the conceptual linkage between the decision-making process and scenario planning, in terms of how scenario planning enhances the process and its outcome.

Recently, Chermack (2004) explored the core problems that present themselves in the dynamic decision-making process and outlined the use of scenarios in potentially decreasing the incidence of unexpected decision failure. He identified four main contributors to decision failure, namely: (1) bounded rationality; (2) an emphasis on exogenous variables; (3) 'stickiness' and friction of information and knowledge; and (4) mental models and cognitive maps with their corresponding decision premises or rules. He also explained how the scenario-planning process can reduce the impact of these to improve the effectiveness of the decisions made. Scenario planning makes explicit the mental models of managers for the purposes of analysing, sharing, reconstructing and altering them. Effective decisions should be based upon shared mental models, resulting from the joint decision-making process by key stakeholders (van der Heijden 1996). The main benefit of scenario planning is derived from the process which facilitates organizational learning for the purpose of continuous improvement. The ultimate outcome is not in the scenarios themselves, but within the process as experienced by the participants. Thus, scenario planning is a process of creating an agile, adaptable and prepared organization by 'softening' (and possibly changing) organizational culture to be more receptive towards new thinking (Korte and Chermack 2007). The next step to comprehend this process is understanding what the mental models are and their representations, and how they can be shared, negotiated and altered. This is described in the following section.

MAPPING INDIVIDUAL AND ORGANIZATIONAL COGNITION ABOUT THE FUTURE

Mental models provide a frame of reference for the interpretation of events or phenomena in life (Eden and Ackermann 1998). Mental models govern people's thinking about the future, whether as an individual or as a member of an organization. As noted previously, people are constantly thinking about future events and their interdependencies. Hence, these events and interconnections reside within people's minds and are constructed and interpreted based upon the frame of reference, i.e. mental models. These mental models ultimately govern individuals' behaviours and actions. Changing behaviour requires changing or modifying these mental models.

These mental models become more important when people are working in groups, such as teams, organizations or companies, where coherent and concerted behaviours and actions are essential if a group's objectives are to be achieved. Mental models are the basis for the reasoning of behaviours and actions of individuals within a group. People need to communicate and negotiate intentions and plans, which in turn will be moderated by the other members of the group. This interaction within organizations for developing longer-term plans is called 'strategic conversation' (van der Heijden 1996). To permit this strategic conversation, we need a media of representation, which makes explicit these mental models. Cognitive maps have been advocated by many scholars to objectively exhibit mental models. In general, a cognitive map is simply a graphical representation of a person's thinking, which locates the person in relation to their informational environment (Fiol and Huff 1992; Eden and Ackermann 2001). A number of terms, such as 'mind map', 'brain map' and 'concept map' have sometimes been confused to mean the same thing. Also, the term ‘cognitive map’ was initially meant rather differently and used to represent mental models of the relative locations and attributes of phenomena in spatial environments (Billinghurst and Weghorst 1995; Kitchin and Freundschuh 2000). In this research, we use the term ‘causal map’ which means a map that exhibits people’s perception of a causal network of relationships in a form of nodes and paths (Eden and Ackermann 1998). Nodes contain future events whereas paths (arrows) describe causal relationships between these events, that is, a relationship to show that the occurrence of Event A will lead to the occurrence of Event B or certain actions will lead to particular outcomes. Eden and Ackermann (1998) proposed a way of structuring the map according to a tear-drop/pyramid shape, with the goal/desired outcome at the top, the strategies/key issues, and assertions, supporting facts and options at a lower level. Figure 1 demonstrates an example of a section of a causal map generated from an interview with the regional manager of a civil engineering professional institution as part of data collection exercise to build industry scenarios in specific areas. In this example, the events are arranged not up and down, but left to right so as to allow a sense of time sequence. It addresses the predicted shortage of chartered civil engineers in 2017 due to retirement and decreasing membership. The map was constructed using Decision Explorer™ software, which has been considered the most advanced computer support for cognitive mapping (Tegarden and Sheetz 2003).

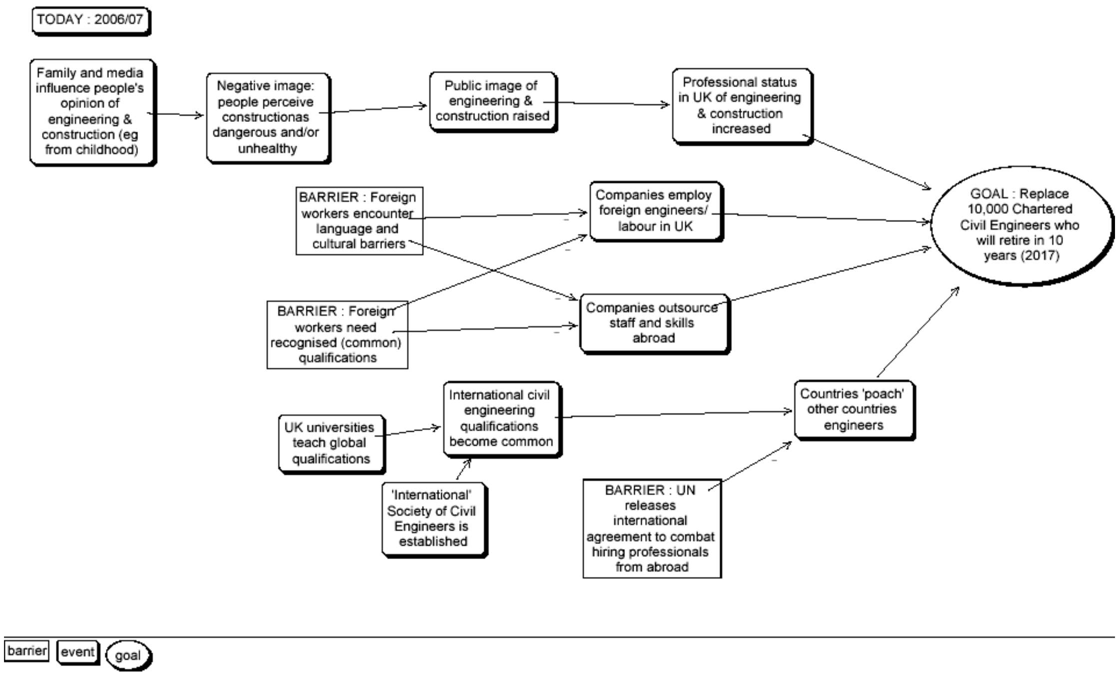

Figure 1: An example of a causal map

The functions of a cognitive map in organizational decision making include: issue structuring (which focuses attention and triggers memory); issue closure (which reveals gaps); and creative problem solving (which highlights key factors and supplies missing information) (Fiol and Huff 1992). Fiol and Huff (1992) identified three components of the cognitive map, namely: identity (to identify key actors, events and processes); categorization (to provide information about the interrelationships of the actors, events and processes); and causal and argument (to provide information about potential interconnections among entities of the importance to the organization through time, i.e. the ‘route’). The identity and categorization components provide the inputs for the causal and argument components. Fiol and Huff (1992) highlighted the significance of managing these interactive components and balancing multiple and often conflicting components and maps of individuals. Individual maps are unlikely to be identical but they may partially overlap.

Corporate strategic decisions are often made through a process of negotiation among stakeholders, in which their idiosyncratic views, interpersonal relationships and politics all come into play. Causal maps can be used for negotiation by reconciliation of goals, the merging of concepts/events and the verification of pathways to the future. Integration of individual maps should maintain a balance between unity and diversity. Lack of unity leads to a dysfunctional map, whereas lack of diversity negates creative production of alternative views of the future, and may also stifle innovation (Fiol and Huff 1992).

Eden and Ackermann (1998, 2001) suggested a way of exposing an individual's causal map to others through a process of 'negotiating' and/or 'merging'. 'Negotiation' occurs when two or more causal maps are going to be integrated by (e.g. organizational or company) stakeholders during a decision-making process. Here, multiple perspectives of an issue facing an organization are invited. 'Negotiation' often involves 'merging', where two concepts are amalgamated into one in the presence of informants and/or interviewers. Theoretically, two or more events can only be merged if they mean exactly the same thing intrinsically. In practice, this is often difficult as even the same word can mean two different things. Merging events would normally involve ascertaining their meanings to the members of a group in a meeting or workshop session. This may lead to three possible outcomes: the events mean exactly the same thing; the events can be merged but need rewording; or the events cannot be merged as the team cannot reach a consensus. The merged maps are referred to as a collective causal map. A number of studies have shown that this process is often problematic mainly because of disagreement on language and its meanings, indicating a lack of shared experiences relevant to a particular domain (Langfield-Smith 1992; Tegarden and Sheetz 2003).

Figure 2 shows how two small parts of two different causal maps can be merged. The maps were produced from two interviews addressing the problem of labour shortage in the construction industry. The goals are slightly different; the first concerns the shortage of engineering professionals, while the second is about labour shortage in general, but focuses more on operatives.

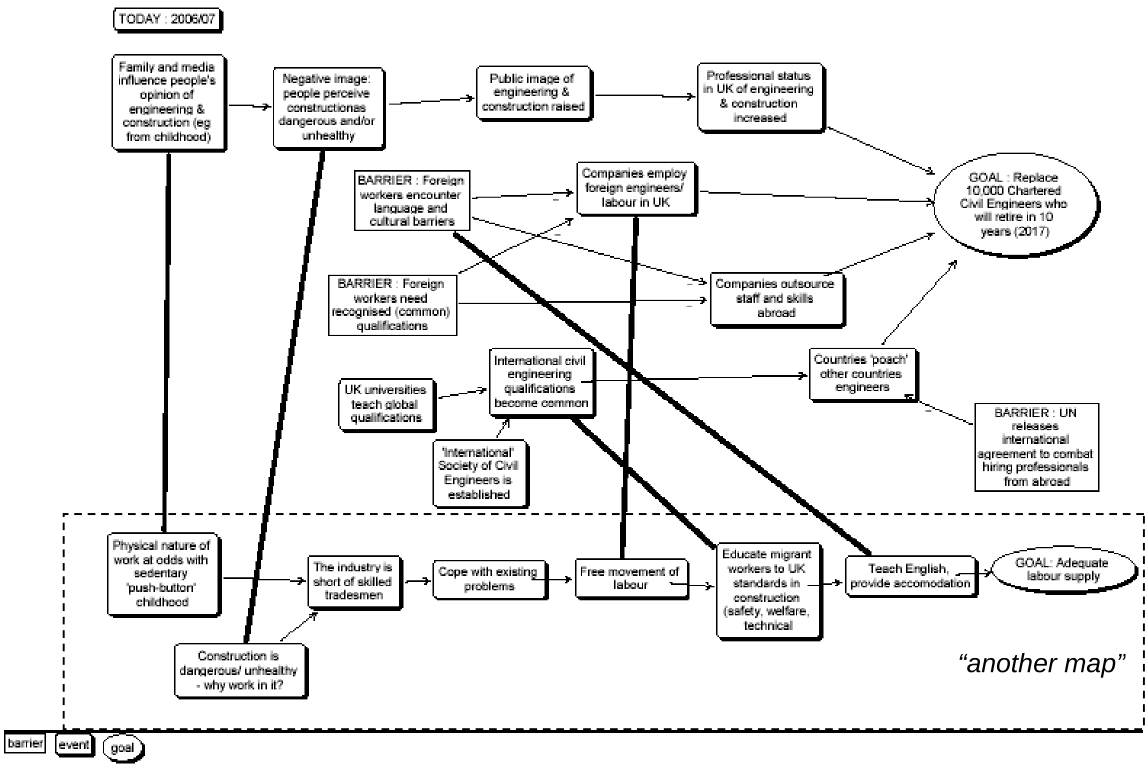
SCENARIO-PLANNING ACTIVITIES: A PROPOSED PROCESS FRAMEWORK

There are as many planning frameworks as there are scenario planners. The process framework presented here is not meant to be prescriptive, but to give generic guidance on how the key principles of scenario planning are implemented in this research. Brightman *et al.* (1999) provided an example of developing scenarios in a construction firm, which is different from this framework, mainly in terms of how employee participation is incorporated in the process and the approach in building the causal maps. The scenario planning is not a 'one-off' but a continuous exercise, linking the development of scenarios and the evaluation of strategic decisions against the scenarios and the implementation of the consequent decisions. This process permits opportunities for reflection and re-perception, as examining possible alternative futures from different angles can clarify key issues and help stakeholders to prepare and develop strategies for achieving their preferred futures (List 2006).

Step 1: Appoint a mapping facilitator and selecting representatives

The first step is to appoint a mapping facilitator, which could be an external consultant or a member of the internal staff (van der Heijden 1996). The person should be a broad thinker with an ability to understand dissimilar issues of importance to different divisions and levels of organizational hierarchy. He/she should possess excellent interpersonal skills to enable them to interact with people from a range of levels. A reasonable knowledge of the organization, in terms of, for example, both ‘hard’ daily business, operation and organizational structure, and ‘softer’ interpersonal relations and organizational politics would also help the facilitator to appreciate issues and concerns as well as the underlying message and implied reasoning. Nevertheless, he/she should be sufficiently detached to maintain an objective view and impartial judgement. This is the balance required between an external consultant and an internal member of staff. An external consultant would bring a new perspective as a view from an ‘outsider’. Nevertheless, internal staff with the above skills may be more advantageous to the business or organization concerned in the long term.

The process begins with selecting representatives from a range of divisions or levels, ensuring those at lower levels are adequately represented. Such representatives would bring benefits in terms of capturing untapped perspectives from different levels, realizing the potential benefits of employee participation and empowerment in solving organization problems. Apart from exploring different views and identifying problems and potential solutions from an operational level, this approach will develop a sense of ownership and commitment to ensure wholehearted support from employees. These representatives will form a ‘scenario team’.



Note: Bold lines indicate linkage between identical events from two different maps

Figure 2: Example of a combined causal map

Step 2: Construct individual causal maps using interviews and brainstorming exercises

A combination of brainstorming and interviews is used to construct individual causal maps via a *Post-it Note* exercise. The aim is to get the most benefit from both techniques while compensating for their different weaknesses. Individual rather than group exercises are preferred in order to capture the individual's pure idiosyncratic views in the first instance – group exercises tend to be influenced by the strong personalities and often result in unproductive disagreements (Scavarda *et al.* 2006). Group exercises can also work against staff at lower levels who feel unable to express their view freely within the presence of their superiors. Facilitator bias in the *Post-it Note* exercise is also much less than that in the interview. Nevertheless, a recorded interview during the session is useful for the benefits of the later analytical stages in the process, particularly for clarifying any issues when merging and negotiating the individual maps.

The individual causal map is constructed on an A1 paper, where a representative can write events on the *Post-it Note* and stick on the paper. *Post-it Notes* ensure flexibility in that they should permit events to be moved freely within the space provided. Cause-and-effect relationships (i.e. arrows) between events can then be drawn – using pencil initially and colour-marker later on. Generally, the map is constructed on a timeline over the next 10–20 years, which does not have to be exact, but is more indicative of the timescale. First, representatives are to identify organizational goal(s), and possibly divisional goal(s), and how both are interlinked (i.e. to build a system of goals (Ackermann *et al.* 2005)). These should be placed on the right-hand side of the A1 paper (i.e. in the future). Then, they write down on the *Post-its* the state of the current situation, together with past events which are relevant predecessors to the present situation, and these are placed on the left-hand side of the paper (i.e. today). The space in between the envisioned 'goal' and the current situation then provides room for external and internal events to take place within that timescale. External events are those related to the changing landscape of political, economical, social, environmental and technological developments, which are outside the influence of the organization. Internal events are possible events happening within the firm, such as changing managing directors or entering new markets, and also possible interventions, such as the recruitment of older workers due to a lack of younger staff (here, to respond to 'ageing population'). The internal events are, to a large extent, controllable by members of the organization. Awareness of industry trends in a broader sense is relevant to this process. Representatives also need to think critically about possible discontinuities and 'wild cards' that may change the 'terrain' on which the firm has to operate. This ensures that the scenarios will embrace as many future uncertainties as possible.

Step 3: Analyse the individual causal maps

This step includes a number of activities, including desk-work, consultation with representatives and other stakeholders, and preparation for the company workshops. The desk-work converts the *Post-it Note* maps into a form suitable for communication, further analysis and manipulation, usually in a computer graphical format with user-friendly software, such as Decision Explorer™. This also involves listing the goals, the current situations, future events, interventions and identifying possible common events to merge. It is also possible at this stage to have a brief consultation with the representatives and stakeholders, to clarify any issues arising, discrepancies or confusing aspects, and develop an awareness of the political and social interaction within the firm. The facilitator(s) should be aware of any possible problems arising from these 'intangible but influential' aspects of the firm. The facilitator should then prepare the outline of activities for the group work (i.e. workshop).

Step 4: Discuss causal maps in a company workshop

An 'organization' is a negotiated and social order, which recognizes that resolution between members to create a new negotiated order requires a social process that explores different perspectives and negotiates an acceptable way forward (Strauss and Schatzman 1963; cf. Eden and Ackermann 2001). Hence, it is imperative that this negotiation process is conducted on an open and cooperative basis, where top level management are receptive towards ideas from those at lower levels in order to obtain social and psychological commitment. Once a sufficient number of individual representatives' causal maps on the same, or similar, theme(s) have been constructed on a one-to-one basis with the facilitator and the analysis completed, a group company workshop can then be held.

The group discussion opens by the presentation of all the individual causal maps. The collective map(s) developed by the facilitator are then presented. The goals and the current situations are reviewed and the representatives interrogated for possible differences and similarities, and they may then be organized within a hierarchy. The next step is to explore possible pathways to achieve the goals, by scrutinizing external events (including discontinuities and wild cards) and the internal interventions necessary to achieve those goals. The merging of events is used to extend the thinking of the participants to alternative ways to achieve a particular outcome. By this time, possible future scenarios for the firm can be identified. It is recommended to identify between two and four (at most six) scenarios to reflect the uncertainties and to ease communication (Brightman *et al.* 2002). These scenarios should contain an interplay of a range of external events that portray possible future environments in which the firm has to operate. The scenarios are also linked with the final goals and the state of the current situation. Any future decisions for the firms should be trialled using the scenarios. In this sense, the resulting outcome is envisaged to resemble the characteristics of both strategic explorative and normative scenarios, which focus not only on internal and external factors, but also on certain objectives and how these could be realized (Börjeson *et al.* 2006).

The outcome of the workshop should be communicated to all staff within the company, whether they were engaged in the process or not, to allow them to reflect on the scenarios and possibly to raise their concern(s). An event inviting them to air their views would provide useful feedback for the scenario team. It is best to consider the scenarios as 'life documents' which are subjected to continual review, update and challenge by organization members. Regular meetings among the scenario team will help this process. The scenario team is analogous to an 'engine of change' for the organization. The whole process will create an awareness of decision-making 'context' for the firm, and improve organizational agility by continuous learning through an established organizational memory.

CONCLUSIONS

The literature review and recent survey revealed little awareness of participating in long-term planning techniques in the UK construction industry. Scenario planning has the potential to enhance the capacity and capability of construction companies to deal with the dynamic and uncertain nature of the sector. Scenario planning will facilitate the creation of adaptive and agile organizations which are better prepared for the future by capturing the creative thinking of its members. Scenario planning is beneficial not only for large organizations, but also for small and medium-sized construction companies, which may have the embedded flexibility that can be honed by the use of scenario planning. The formal application of the technique will improve the company's capacity to learn from past experiences through an established organizational memory. Overall benefits should outweigh the investment made as scenario planning can draw on true potential and commitment through the enhanced empowerment and involvement of the company's staff as well as senior members.

Hence, utilizing scenario planning in construction companies could be viewed as the implementation of innovation in organizations. Scenario planning is also about the changing of organizational culture for the purpose of establishing a 'learning' organization. It is reasonable to expect that some may also resist, or disagree with these proposed changes or their outcomes. Convincing people to embrace these techniques would require the communication of the specific benefits for the company and improving (or convincing) the management's thinking regarding engaging with the future (Burt and van der Heijden 2003). Involving a variety of stakeholders in the process would help to alleviate this obstacle. Importantly, trust between those involved (including the facilitator, scenario team and other stakeholders) has to be nurtured throughout the process. Scenario planning exercises are only deemed successful if they change the minds of people engaged in the process (Wack 1985). These approaches will help to improve the success of scenario planning in construction companies.

FUTURE RESEARCH AND POTENTIAL CONTRIBUTION OF THE WORK

Future work will implement the scenario-planning framework described through a longitudinal study in a number of UK construction companies and consultants. The research will also develop a framework for assessing the efficacy of the approach in terms of the organizational learning experienced and the effectiveness of the process. This will provide a sound basis for the promotion of scenario-planning techniques in the construction industry. Overall, the research endeavours to contribute valuable and much-needed knowledge to this under-developed area in the construction sector.

A CRITICAL ASSESSMENT OF THE VIABILITY OF COST BENEFIT ANALYSIS IN THE MANAGEMENT OF CONSTRUCTION HEALTH AND SAFETY

Elias Ikpe[1], Keith Potts, David Proverbs and David Oloke

School of Engineering and the Built Environment, University of Wolverhampton, PO Box 219, Wolverhampton, WV1 1SB, UK

Health and safety issues are major concerns in the UK construction industry. Evidence suggests that research studies on construction health and safety management issues have yet to lead to a significant reduction in the number of accidents. To tackle the causes of days lost through accidents and to improve production in the construction industry, the industry needs to understand the cost–benefit analysis (CBA) of effective health and safety management. The introduction of CBA will decrease work-related injuries and help to achieve a higher rate of productivity. A review of the viability of cost–benefit analysis and its relevance for health and safety management in the construction industry is presented. This is part of a wider study to improve the management of health and safety and to propose a way forward for safer and healthier construction sites. The willingness to pay (WTP) approach is identified as the most suitable approach as it is more consistent, computationally easier and is not based on assumption. This method also has the potential to contribute to a reduction in costs, deaths and injuries in the construction industry. The results of this investigation will form part of an ongoing study of cost–benefit analysis for construction health and safety management.

Keywords: construction health and safety management, cost–benefit analysis, viability.

INTRODUCTION

According to the Health and Safety Executive (HSE 2006) each year in the UK there are over 1 million injuries at work and 2.3 million cases of ill health experienced by workers. In addition around 40 million working days are lost to business and over 25 000 individuals are forced to give up work because of injury or ill health. These cost British employers an estimated £3.3–£6.5 billion each year of which £910–£3710 million results from accidental damage to property and equipment. Unfortunately, most organizations do not know what accidents and ill health really cost them in time and money.

Accidents in the construction industry continue to occur at a high rate despite different measures adopted by HSE to reduce the rate of accidents. There is, however, little research work that deals with the cost–benefit relationship of health and measures on construction sites. This high rate of accidents in the construction industry indicates a potential benefit from the introduction of a cost–benefit analysis (CBA) approach prior to initiating the construction project. A literature review of

[1] elias.ikpe@wlv.ac.uk

CBA and its potential for helping improve health and safety management in the construction industry is presented. The industry needs a guide such as CBA for effective accident reduction because the existing regulations set by the UK government on health and safety issues have not yet reduced accidents in the construction industry to an acceptable level.

The aim of the paper is to critically assess the viability of the use of CBA and how its use will lead to improvement in the management of health and safety in the UK construction industry. The objective is to identify an appropriate method of measuring benefits of health and safety management in the construction industry. The process described in this paper would be appropriate to guide contractors and decision makers on how costs and benefits of health and safety could be estimated and measured and also to encourage them to invest in health and safety.

BACKGROUND

Carcoba (2004) defines cost–benefit analysis (CBA) as a technique designed to determine the feasibility of a project by quantifying its costs and benefits. CBA is a practical way of assessing the desirability of projects where it is important to take a long view and a wide view (Barker and Button 1995). CBA helps policy and decision makers better understand the role they can play in helping them fulfil their decision-making responsibilities (Lagas 1999). It provides a means of comparing complex projects, even when benefits and costs occur during different time periods. CBA also provides a means for systematically comparing the value of outcomes with the value of resources achieving the outcomes required (Watkins 2006). It could be regarded as a systematic means to enumerate all benefits and all costs (Marsh and Flanang 2000).

CBA aids the decision-making process by giving monetary values to the costs and benefits so that a comparison can be made to choose the best option. It involves estimating the equivalent money value of the benefits and costs to the community of projects to establish whether they are worthwhile (Watkins 2006). Thus cost–benefit analysis could be of value to help improve health and safety management in the construction industry.

INTERNATIONAL PRACTICE OF CBA

The practice of CBA differs between countries and even between sectors within countries. Some of the differences may include the types of impacts that are included as costs and benefits within the appraisals, the extent to which impacts are expressed in discounting rates in monetary terms and different discounting rates between countries (Arrow *et al*. 1996). CBA has been widely used in Japan, Sweden and the USA to improve their decision making and the performance of organizations. A brief review of these international experiences now follows.

USA

The motivating force behind CBA in the USA was a desire to allay conflict and reach an agreement. Most of the early development work on CBA as a discipline was the result of problems faced by the US Army Corps of Engineers in deciding how and where to build bridges in supporting combat operations. Before the creation of the corps, evaluations of public investments were almost completely ad hoc (Arrow *et al*. 1996). The prestige of the corps along with its increasing quantification of project cost and benefit was used by Congress to simplify its decision making and avoid the wildly uneconomic projects produced by logrolling (Bjornstad 2006). CBA is often referred to in the USA as benefit–cost analysis (BCA). BCA is now a well-known established discipline in the USA. It is a technique used for assessing the desirability of government projects and policies. It considers alternative policies and identifies the one that yields the greatest gain to society. It provides much useful information to the political process. It has been widely used in the design of environmental policies and to help resolve disputes under the US legal system.

According to Arrow *et al*. (1996) in the USA, the use of CBA is based on at least three alternatives for consideration and the choice of alternative is based on the most effective cost within the context of budgetary and political considerations. In choosing the alternative, the analyst considers at least three alternative means of achieving programme objectives. This will provide them a comparative baseline. The analyses of CBA are two types (Arrow *et al*. 1996):

- BCA which is defined as a systematic quantitative method of assessing costs and benefits of competing alternative approaches.
- A cost effective analysis (CEA) is a simplified BCA which can be done when either the benefits or the costs are the same for all the alternatives.

The best alternative is either the one with benefits or the one with lowest costs.

CBA is believed to be very helpful in government rule making and other regulatory efforts. As part of the 1998 Budget Message to Congress and in fulfilment of the Government Performance and Results Acts, the report demonstrated the challenges to be overcome if government is to inform decision making using CBA (Bjornstad 2006). In 1994, President Clinton issued an executive order confirming the government's commitment to CBA and highlighting the bipartisan support for CBA in federal regulatory decision making. At the highest levels, the US government maintains that CBA is indeed helpful to identify the potentially good versus the potentially bad of 'significant regulatory action' (Ackerman 2004 as cited in Bjornstad 2006). It is regarded as a cost effective and improved method. It helps in making difficult decisions and also in making the best choice of the alternatives.

According to Lagas (1999), the US last four presidents, divided equally by party, have required that CBA of regulatory rule making be conducted in their Office of Management and Budget (OMB). The Clinton administration from 1992 until 2001 extended the role of CBA through its support of the Government Performance and Results Act and through its interpretation of its role under this Act; the Clinton administration placed greater emphasis on the quantitative measurement of costs and benefits as part of the regulatory process. In addition, CBA has been used effectively to preserve environment or health in the USA through the Environmental Protection Agency. The Environmental Protection Agencies have committed to develop agency-wide guidance for CBA that parallels its highly successful risk management guidance (Bjornstad 2006). Furthermore, the Flood Control Act of 1936 provided what could be interpreted as the first legislative mandate to use CBA in the USA by declaring that the Federal Government should improve or participate in the improvement of navigable waters or their tributaries, including watersheds thereof, if the benefits to whomsoever they may accrue are in excess of estimated costs.

Sweden

In Sweden, there has been significant interest in the subject for over 20 years (Johanson and Mabon 1998 as cited in Johanson and Johren 2006). Significantly, the subject of cost–benefit analysis (CBA) has consistently worked itself up the occupational safety and health (OSH) agenda in the last few decades.

As an example, a Swedish forestry contractor experienced high levels of work-related injuries over a period of a decade and in 2004 carried out a CBA on investments to try and decrease these injury levels (Johanson and Johren 2006). This was introduced to decrease work-related injuries and to achieve a higher rate of productivity. The successful outcome has led to CBA now playing an important part in the contractor's decision-making processes at work.

In Sweden, the costs of sick leave are less than 1% of personnel costs (Johanson and Johren 2006). This was achieved because of the introduction of the use of CBA. It was revealed that organizations that invest more in training have lower costs for sick leave. Furthermore, the costs of safety have decreased in recent years; this could be seen as the basic argument for the use of CBA in health and safety management. The costs of injuries include the loss of productivity and disruption caused (Joyce 2001). The use of CBA will improve production in the construction industry and also benefits workers, employers and society.

Japan

The business environment surrounding Japanese industries has been very strict for the past few years because of long stagnation forcing executives to adopt effective management to make the most of limited resources (Japan Industrial Safety and Health Association 2000). This prompted the government of Japan to introduce CBA especially in developing new safety measures. The costs were grouped into two as costs related to safety (expenses invested to prevent accidents) and costs caused by accidents. When these costs occur, the government shoulders part of the responsibilities by offering some compensation under the Labour Law but sometimes the organization bears the cost when the company has violated its obligation to ensure safety.

The implementation of health and safety management in Japan led to an improvement of production and productivity, improvement of work motivation and personal relationships in the worksite, and improvement of the corporate image of the organization. The introduction of CBA in Japanese industrial safety has reduced the rate of accidents. If the UK construction industry were to adopt such Japanese and Swedish practices by introducing CBA procedures, accident rates might begin to fall to an acceptable level.

THE USE OF CBA

CBA could be used to examine or investigate the social and economic viability of health and safety management in the construction industry at the planning and operational stages (Ikpe *et al*. 2006). The decision makers can obtain useful information on the positive and negative effects to know if the benefits exceed the costs. The construction industry faces numerous constraints, which could hamper the effective management of health and safety. The main source of constraint to implement health and safety management is cost (Kheni *et al*. 2005). This constraint has a negative impact on the management of health and safety which can result in poor health and safety of construction sites and may also manifest in the form of a poor quality of service. The need for effective health and safety management must be addressed to deliver safe and good projects (Carpenter 2006). The improvement of construction health and safety management will reduce accident costs and contribute significantly to the well being of workers, employers and society (Shutt 1995).

Accidents have negative effects on the construction industry and give the industry a bad reputation (Ikpe *et al*. 2007). According to the HSE (2006) losing skilled workers even for a few days can have a bigger effect than direct financial costs might suggest. Evidence from a literature review suggests that improving health and safety management at the worksite can generate significant savings. One of the most obvious costs as identified by HSE is in respect of a person taking time away from work. Mishan (1982) identified benefits to be gained to include the time saved and the benefits of increased comfort and convenience. A well-managed CBA approach to health and safety management might lead to significant cost savings and improvements in safety performance (Ikpe *et al*. 2006).

CBA is a key input for the investment review that should take place before a new project proceeds to the acquisition or development phase (Snell 1997). Most studies concerned with the effects of health promotion programmes have tended to ignore the economic consequences. Conrad (1987 as cited in Johanson and Johren 2006) proposes that one reason for this may be that the effects of health programmes are mostly subjective, individual results. Although this is certainly true, such factors as changes in sickness rates and productivity, among others, could be measurable in monetary terms. However, the main economic effects of health and safety are probably changes in productivity. The direct benefits from improved safety in construction are the reduction of accidents and financial losses due to accidents and ill health. Such cost reduction therefore benefits society as a whole and not merely the workers and employers. According to Gary (1969) accident reduction is clearly an economic benefit.

CBA MEASUREMENT

In order to measure economic benefits and costs of accidents, they must be expressed in monetary terms. Where all benefits and costs can be expressed in monetary units, CBA provides decision makers with a clear indication of the most efficient alternative, that is, the alternative that generates the largest net benefits to society (Georgi 1993). CBA focuses on the future, so decisions have to be based on the expected costs and benefits of proposed alternatives (Seeley 1996). While past experience may be relevant in helping to estimate the value of the future benefits and costs, CBA should be explicit about the underlying assumptions used to arrive at estimates of future benefits (Lagas 1999).

For the purpose of estimating, the cost of injuries is more difficult to measure as is the cost of medical treatment for the injured person. In the case of measuring a fatality, problems may arise of putting a value on human life. However, it can be expressed in monetary terms. The measurement of costs and benefits helps to solve the most important question of economic practice, which also determines the effectiveness of social labour. The effectiveness of labour is usually evaluated in terms of productivity (Novozhilov 1997).

Methods used in CBA measurement

According to Lagas (1996) the use of incorrect methods of CBA orients economic activity towards excessive expenditures and the pursuit of imaginary results, and gives rise to contradictions between economic accountability and the plan. Some methodologies used in CBA include the following.

The *net present value* (NPV) method considers all future cost–benefit flows (Bjornstad 2006). This method yields one value that is easily interpreted. If the value is positive, the project yields benefits that exceed its costs. If the value is negative, costs exceed benefits. The present value is calculated using the following formula by (Bjornstad 2006) as:

$$PV = FV\left(\frac{1}{1+r}\right)t$$

where *PV* = present value, *FV* = future value and r = discounting rate t discounting periods.

Another method is the *willingness to pay* (WTP). The WTP for improved health is a function of the productivity improvement (Morris and Willcocks 1996) and is expressed as

$$\text{WTP} = \text{price paid} + \text{consumer surplus}$$

The WTP reflects the amount that someone who does not have a good would be willing to pay to buy it. It represents the maximum amount of money that individual is willing to pay in exchange for an improvement in circumstances or consumer surplus brought about by a policy (Layard and Glaister 1994). It is based on the assumption that it is reasonable for people to be willing to pay to avoid accidents and to obtain improved conditions (Kopp *et al*. 1997). It is the maximum amount of money one would give up to buy some good or service, or would pay to avoid harm (Pearce 1983). In order to tackle the causes of days lost through accidents and to improve production in the construction industry, the willingness to pay approach could be used to acquire the benefits or to avoid the costs. The worth or value of a thing to a person is determined simply by what a person is willing to pay for it (Mishan 1982).

The *internal rate of return* (IRR) is another method for determining value that does not depend on the determination of a discount rate and that expresses value in terms of a percentage. IRR is based on the assumption that the cost–benefit flows are reinvested at the internal rate of return. If projects like construction health and safety are to be examined, IRR may yield results that are inconsistent with a ranking based on the NPV method. The method requires the compounding of all positive cost–benefit flows to the last period of the project life period, at a given rate. The formula for compounding values forward is expressed as:

$$\text{FV} = \text{PV}(1+r)T - t$$

where *t* is the compounding periods and *T* is the final period.

The *discounting rate* method is the rate by which benefits that accrue in some future time period must be adjusted so that they can be compared with values in the present. In principle, this rate is the rate that equilibrates the demand for savings by investors and the supply of savings from savers who refrain from spending all their income on current consumption (Brent 2003). This method is not as consistent as net present value or willingness to pay as it is based on assumptions.

The choice facing the decision maker is which of these many methods to apply in cost–benefit analysis for health and safety management. If the discounted present value method is adopted, the question for the appropriate rate of discount arises. In such exceptional cases there would then seem to be no more justification for discounting such future benefits to be enjoyed by workers in the construction industry.

Although NPV represents an effective method to be adopted as it is both consistent and acceptable, CBA focuses only on either the mean or mode of the NPV or IRR and it can be argued that this on its own does not provide enough information for a valid decision where projects may be uncertain (Barker and Button 1995). However, the WTP approach is identified as the most suitable approach as it is more consistent, computationally easier and is not based on assumptions. This method also has the potential to contribute to a reduction in costs, deaths and injuries in the construction industry and may be more appropriate to compute the benefits of health and safety on the basis of individual willingness to pay. Thus in applying to health and safety management policy, it will seek to obtain the amount that contractors will be willing to pay to improve health and safety management in the construction industry.

WTP has not been used as a measure of benefits in economic valuations of health and safety in the construction industry as in other fields. It can be used to find out benefits to any individual of non-marketed benefits such as clean air, peace and quiet (Pearce 1983). Pearce (1983) gave an example of this as the willingness to agree to work in a hazardous environment where there is great risk of death and risk means cost. Another advantage of WTP is that it can be used to provide individuals with an incentive to realize their maximum benefits. WTP as measure of benefits can estimate the benefits in monetary terms as individual willingness to pay. The disadvantage of WTP is that it cannot be used to measure CBA if the outcome is uncertain. Another disadvantage is that the WTP estimate is usually based on hypothetical questions and the correlation with actual behaviour is generally unknown. It can increase the impact on decision makers. The justification for adopting these methods of measurement (WTP) is that they correspond with the psychological sense of gains and losses because benefit and cost are measured in terms of gains and losses.

CONCLUSION

The potential of using CBA for improving the management of construction health and safety in the construction industry has been presented. If undertaken in the construction industry, it will allow decision makers to identify potential improvements on health and safety management. Cost–benefit analysis has not been as widely practised in the construction industry as in others. The introduction of CBA will decrease work-related injuries and help to achieve a higher rate of productivity. CBA is capable of being used effectively for improving health and safety management in the construction industry. If the risk of death or injury could be significantly reduced in the construction industry by applying cost–benefit analysis then there would little to doubt why it should not be implemented.

The proper method of measuring benefits is willingness to pay (WTP). The WTP approach is more consistent, computationally easier, is not based on assumptions and has the potential to measure benefits of improving health and safety management. This method also has the potential to contribute to a reduction in costs, deaths and injuries in the construction industry. A well-managed CBA approach to health and safety management might lead to significant cost savings and improvements in safety performance. This information could be a useful guide for contractors and decision makers to address health and safety issues on construction sites.

FUZZY SETS METHOD APPROACH FOR VENDOR SELECTION IN GREECE

Odysseus G. Manoliadis[1] and Ioannis Tsolas[2]

[1]*School of Technological Application, Technological Education Institute of Kozani, Kozani, Greece*
[2]*School of Applied Mathematics and Physics, National Technical University of Athens, 9 Iroon Polytechniou Str, Zografou Campus, Athens, Greece*

In Greece, as in many other countries, the current system of the most advantageous tender selection still causes concerns in terms of its potential crises, such as the problematic quality inappropriate evaluating methods, insufficient reviews on the contract fulfilment result and feedback. This paper presents a systematic procedure based on fuzzy sets theory aiming to evaluate the capability of grouped vendor suppliers to deliver the project as per the owner's requirements. The theory of fuzzy sets is applied to the above problem in order to estimate criteria weights for this case. The criteria examined were economical criteria, technological criteria, item delivery criteria and service criteria. In order to face problems concerning the applicability of the problem in practical cases deriving from the Greek Legislative Law, a methodology is tailored to face categorized cases after clustering historical data. A case study from a procurement case in Greece is following. The results strengthen the opinion that the fuzzy sets method is a powerful and appropriate technique for deriving objective solutions in categorization of procurement cases and is a rather subjective area such as the procurement system for vendor selection. Conclusively, the proposed methodology can be used as a tool to adopt the quantitative methods properly combining the different opinions of the evaluation committee members in order to represent the overall evaluation.

Keywords: contractor selection, decision analysis, fuzzy logic, tendering.

INTRODUCTION

Selecting the tender is an important step during government procurement processes. It directly determines whether an entity is capable of attaining high-quality products within fixed budget and time allotment. Lately, increasing importance of tender selection decisions is forcing organizations to rethink their evaluation strategies and hence the selection of suppliers has received considerable attention in the literature (Nydick and Hill 1992; Verma and Pullman 1998; De Boer 1998; Handfield *et al*. 2002).

Vendor selection in Greece was first done based on tender price alone. Greek government procurement had predominantly awarded the contract to the lowest tender. This was quite risky and sometimes led to the failure of the project in terms of time delay and poor quality standards. It was profound the necessity to inspect and improve on the current system of most advantageous tendering selection. Ten years ago the valuation of vendors was changed based upon EU guidelines (i.e. 72/62/EC, 93/36/EC and 80/67/EC) and is merely a multiple criteria decision making (MCMD) procedure. The criteria used were economic and technical and the procedure was

[1] omano@tee.gr

becoming more popular. The first attempts to evaluate these criteria were to sum up their values though lately ranges of weights were proposed by Legislative Law (i.e. 394/1996). However, the current system of the most advantageous tender still causes concerns in terms of its potential crises, such as the problematic quality inappropriate evaluating methods, insufficient reviews on the contract fulfilment result and feedback.

Therefore, how to adopt the quantitative methods properly combining the different opinions of the evaluation committee members in order to represent the overall evaluation of the committee as well as to improve the major concern of the most advantageous tender system is worthy of research attention.

The objective of this paper is to present a systematic procedure based on fuzzy sets theory to evaluate the capability of grouped vendor suppliers to deliver the project as per the owner's requirements. The theory of fuzzy sets is applied to the above problem in order to estimate criteria weights for this case and is compared to the existing procedure in terms of a multi criteria decision making technique.

In the following paragraphs, first there is a briefing on determining the tender that ranks first as regulated by the existing law in Greece is discussed. The literature review on evaluating the selection methods of the most advantageous tender follows. Then, the theory of fuzzy sets aiming to improve the evaluation procedure in categorized case studies is proposed. Finally, a case study is utilized to validate the advantages of the recommended procedure improvement.

TENDERING AS REGULATED BY THE GREEK LEGISLATION

The most advantageous tender committee is composed of experts for evaluation and selection (Legislative Law 370/1995), while taking technology, quality, function, price etc into evaluation items. In recent Legislative Law 394/1996, the committee identifies weighting criteria for each case and for cases of the same kind in each organization the same committee is used and sometimes the same weights. It is a kind of group decision making policy during evaluations. Therefore, how to adopt the quantitative methods properly combining the different opinions in weights is the major concern of the most advantageous tender system.

Laws and regulation for the existing ranking method

In accordance with the Greek Legislative Law concerning Regulations for Evaluation of the Most Advantageous Tender (Legislative Law 2286/1995), the criteria weights that refer to the ranks or scores given to the tenders by the evaluation committee are published in the Legislative Journal documentation. By adoption the ranking method, the most advantageous tender is determined mostly according to the importance or weights of evaluation items by the head of the procuring entity or the concurrence of the majority of the evaluation committee. After compiling the evaluation of all criteria for all tenders from all committee members, the one with the best ranking is the known as the ranking first tender. Moreover, in order to ensure certain credibility of the evaluation a table with the calculation of scores is presented to the tenders. This procedure is recorded in this study and compared with the proposed method.

Reviews on the existing laws and regulations

The aforementioned discussion reveals that the related regulations of the current ranking methods are mainly about selecting and evaluating the criteria in terms of weights. However, this method is merely arbitrary and obviously has the following drawbacks:

1. It has being easily subjected to the influences of biased weights evaluations of a small number of committee members: If a few of the committee members give a particular criterion the best or the worst weight, however, it is very likely to result in biased evaluations.
2. There are still no laws to follow in actual executions. Some agencies have not tested the consistency of evaluation result among committee members. As a result, regulations remain a routine paperwork with no actual functions.

LITERATURE REVIEW ON EXISTING METHODS

In this section, we present the results of an extensive literature search on criteria weights in decision support for grouped case supplier selection. In the literature, extensive work is noticed on research based on historical data and the buyer's experience current or familiar suppliers are evaluated on a set of criteria (Zenz 1981; Timmerman 1986). The evaluations actually consist of categorizing the supplier's performance on a criterion as either 'positive', 'neutral' or 'negative'. After a supplier has been rated on all criteria, the buyer gives an overall rating, again through ticking one of the three options. In this way, suppliers are sorted into three categories. The so-called linear weighting models weights are given to the criteria, the biggest weight indicating the highest importance. Ratings on the criteria are multiplied by their weights and summed in order to obtain a single figure for each supplier. The supplier with the highest overall rating can then be selected. This basic linear weighting model is described mostly in purchasing textbooks. De Boer *et al*. (1998) use the outranking approach. This approach, among other things, allows the buyer to specify in advance limits to the compensation for bad scores on one or more criteria. In a rating model Nydick and Hill (1992), Barbarosoglu and Yazgaç (1997), Narasimhan (1983) and Narsimhan and Stoyno (1986) propose the use of the analytic hierarchy process (AHP), a method of MCDM, to deal with imprecision in supplier choice. AHP circumvents the difficulty of having to provide point estimates for criteria weights as well as performance scores in the basic linear weighting model. Sarkis and Talluri (2000) propose the use of the analytical network process (ANP), a more sophisticated version of AHP, for supplier selection. Willis *et al*. (1993) use such pair-wise comparisons among suppliers, measuring each criterion in terms of its specific unit of analysis. Another group of authors has suggested various statistical techniques to deal with imprecision when using linear weighting models. Williams (1984) proposes the use of conjoint-analysis in deriving criteria weights. Min (1994) and Petroni and Braglia (2000), apply the so-called 'indifference trade-off' method and principal component analysis for essentially the same purpose. The vast majority of the publications found on criteria weights seem to have been written in the context of selecting a supplier for the purchase of a product to be used. The existing articles on methods for supplier selection do not sufficiently address this contextual issue. Often they assume, explicitly or implicitly, that their method is applicable in all purchasing contexts. At most, a reference is made to a particular industry in which a method has been empirically tested or the need to change the criteria considered when applying the method to another type of product.

PROPOSED METHOD

Our framework addresses a practical approach of fuzzy sets theory in order to be applicable in categorized purchasing contexts. In doing so, characteristics like the type of procurement, the product and the phasing and organization of the whole supplier selection process are clustered by using historic information. Similar approaches, such as Cluster Analysis (CA, Hinkle *et al*. 1969; Holt 1998), consist of a basic method from statistics that uses a classification algorithm to group a number of items that are described by a set of numerical attribute scores into a number of clusters so that the differences between items within a cluster are minimal and the differences between items from different clusters are maximal. Also artificial intelligence approaches and specifically case-based-reasoning (CBR) are software-driven database systems that provide a decision-maker with useful information and experiences from similar, previous decision situations. A CBR is still very new and only few systems have been developed for purchasing decision-making. Between these pioneer studies, Ng and Skitmore (1995) developed a CBR system for the pre-qualification of suppliers.

The applications of knowledge management vendor selection, which may be generated from or adapted to fuzzy sets theory and fuzzy logic, are wide-ranging. Fuzzy logic is a new approach to the analysis of problems too complex to be susceptible to analysis by conventional methods. It is an entirely non-numeric approach that allows user to make verbal judgments through natural language expressions like ‘very good’, ‘somewhat poor’, etc.

Such fuzzy judgments are then quantified using the extension principle applied to fuzzy set theory (Zadeh 1975). Mathematical theory of fuzzy sets forms a promising approach to bridge this gap between technically necessary precision and the empirically more appropriate, but imprecise description of the problem (Zadeh 1975). Based on the aforementioned drawbacks for the problem considered in our study, Kumar and Shankar (2004) propose an improved ranking procedure to choose the supplier as the most advantageous tender. Also another characteristic paper from Noorul and Kannan (2005) aims to demonstrate how the fuzzy model can help in solving such decisions in practice. Similarly fuzzy goal programming approach is applied in the paper of Michailov (2004) for solving the vendor selection problem with multiple objectives, in which some of the parameters are fuzzy in nature.

In the following paragraphs, a methodological framework based on fuzzy sets theory for vendor selection is selected since the existing data are unreliable and unavailable in the Greek databases. It is divided into two sections. First, the methodology to estimate the criteria weights is presented then the comparison of results of the method used to incorporate these criteria weights and those of the existing multiple criteria decision making procedure follows.

Estimation of criteria weights

Fuzzy sets theory is a useful tool for dealing with vendor selection, taking into account uncertainty in the interpretation of alternatives, particularly when there is a group of similar procurement cases. These and other problems of integration of fuzzy set methods to vendor selection are discussed in many top-ranking international journals. Using this theory in the procurement process, we take into account technical, ecological and economic factors. In this case, the knowledge management fuzzy model is based on a multi-criteria theory of multiple vendors and choice of alternatives.

Definition 1. Let X be a set (universe). D is called a fuzzy subset of X if D is a set of ordered pairs: $D = [(x, \mu_D(x)), x \in X]$, where $\mu_D(x)$ is the grade of membership of X in D. $\mu_D(x)$ takes its values in the closed interval [0,1]. The closer $\mu_D(x)$ is to 1, the more x belongs to D; the closer it is to 0 the less it belongs to D. If [0,1] is replaced by the two element set {0,1}, then D can be regarded as a subset of X.

Definition 2. The α level set of fuzzy subset D is the set of those elements that have at least a membership: $D(\alpha) = [x: \mu_D(x) \geq \alpha]$. A fuzzy subset n^* is called normal if there is at least one z such that $z_{n^*}(z) = 1$.

In particular, consider that there is a set of m vendors as described in equation (1):

$$A=\{a_1, a_2, \ldots a_m\} \tag{1}$$

and a fuzzy set of criteria described in equation (2):

$$C=\{\mu_c(a_1)/a_1, \mu_c(a_2)/a_2, \ldots, \mu_c(a_m)/a_m\} \tag{2}$$

where the membership function $\mu_c(a_i)$ expresses the experts knowledge about grade vendors satisfaction to criteria C.

If there are several criteria $C_1, C_2, ..., C_n$ and the coefficients of relative significance of these criteria are $\alpha_1, \alpha_2, \ldots \alpha_n$, the rule for selection of the best vendor selection taking into account α_i will be written as intersection of C_i

$$D = \left(C_1^* \cap C_2^* \cap \ldots C_n^*\right) \tag{3}$$

where

$$C_1^* = \left(C_1^{\alpha_i}, a_i \geq 0\right) i=1,\cdots,n, \frac{1}{n}\sum_{i=1}^{n} a_i = 1 \tag{4}$$

The coefficients of relative significance α_i are found by comparison of pairs of criteria. Assume now a ixj matrix B each of the elements b_{ij} of this matrix corresponds to the relative importance of criterion i to criterion j. These elements must satisfy the condition: $b_{ij} = 1/b_{ji}$ .The value of elements b_{ij} of matrix B has a scale from 0 to 9 and is defined in Table 1. For example, the element $b_{ij} = 1$ if the scale of evaluation of relative importance of criteria C_i and C_j is that of equilibrium; the element $b_{ij} = 9$ if the scale of evaluation of relative importance of criteria C_i and C_j is that of great importance.

Table 1: Scale of evaluation of relative importance of criteria

Relative importance of criteria C_i and C_j	**Element b_{ij}**
Equilibrium	1
Very of little importance	3
Of little importance	5
Importance	7
Great importance	9
Intermediate values	2,4,6,8

Next, the self-vector of the matrix B is determined from the solution of equation (5):

$$Bw = \lambda_{max} w \tag{5}$$

where λ_{max} is maximum of self-number of the matrix. The solution sought is given by $\alpha_i = n\, w_i$, where n is a predefined number of i criterion and w is the corresponding weight.

The mathematical operation of intersection of fuzzy sets is in agreement with operation of the search for minimum of the membership functions of these fuzzy sets.

In this specific problem, preference is given to vendors that are characterized by the greatest value of the membership function.

Multiple assessment in this example was carried out by four criteria:

- Economical criteria (EC).
- Technological criteria (TC).
- Item delivery criteria (IDC).
- Service criteria (SC).

As an example of the above criteria, consider the procurement of an excavation equipment. The economical efficiency of vendors may be the price and purchases done during the past three years. The technical criteria might be the capacity of the excavation equipment, emissions, noise when working and when idling etc. consumption The delivery time, ability to deliver on time belong to the item delivery criteria while service criteria SC might be warranty, after sales service etc.

Since we deal with parameters that are not always measured in monetary units a normalization procedure *R(x)* is used to convert the non-monetary units to a 0 to 1 scale. The normalized value *R(x)* – key link between non-monetary units and an 0 to 1 relationship – is given by the equation:

$$R(x) = \left| \frac{R(i) - Rj}{R(i) - R(w)} \right| \tag{6}$$

where *R(i)* is the ideal value, *R(w)* is the worst value and R_j is the value of j criterion where j corresponds to the 1 to 4 i.e. the EC, TC, IDC, and SC value of the alternative.

Specifically:

With the EC, we evaluate the economical efficiency of vendor characteristics. EC =1, if the characteristics are economically efficient; EC = 0, if they are not.

With the TC, we try to evaluate vendor characteristics and the feasibility of these TC =1, if the characteristics are fully suitable; TC = 0, if they are not.

With the IDC, we evaluate the additional negative effects of the proposed alternative. IDC =1, if the negative effect is absent, ECC = 0, if it is not.

SC provides an estimate of the service factors. SC =1, if the response is positive; SC = 0, if the response is negative.

Incorporation of criteria weights into the multi criteria decision making

The procedure that is following is used to incorporate the above criteria to the vendor selection as well as to compare the results with the existing evaluation. This can be achieved by adopting a MCDM technique (i.e. AHP). MCDM is widely used in urban and regional planning and is a useful methodology in arranging available information concerning choice possibilities (Nijkamp *et al*. 1990). MCDM is a technique designed to value two or more criteria. It is particularly useful for evaluation criteria that cannot be easily quantified in normal market transactions. It uses the approach of applying weights to these impacts to determine a preferred outcome. MCDM involves measuring criteria values such as, delivery time, service time etc., in normalized units that are then turned into comparative value functions. Therefore, due to the fact that some of the above cannot be assessed in economic terms, the MCDM techniques of weighting and ranking are applied to value services, which are often in non-monetary terms. The total scores using a comprehensive application of AHP for a real-world case is presented along with the analysis to choose the best supplier in order to rank project alternatives and arrive at a decision accordingly. Emphasis, therefore, is placed on the identification of criteria, namely the economical criteria (EC), technological criteria (TC), item delivery criteria (IDC), service criteria (SC) and the measurement and incorporation of these criteria in the project evaluation process. The model is formulated as follows:

$$MCDM(i)=I_{EC}* W_{EC} +I_{TC}* W_{TC} +I_{IDC}* W_{ITC} +I_{SC}* W_{SC} \tag{7}$$

where

i is the alternative number I_{EC}, I_{TC}, I_{IDC}, and I_{SC} denote respectively the contribution of economical criteria (EC), technological criteria (TC), item delivery criteria (IDC), service criteria (SC) indices to the overall index MCDM(i) and

W_{EC}, W_{TC}, W_{ITC}, W_{EC} are the criteria weights

and

$$I_{EC}, I_{TC}, I_{IDC}, I_{SC} \in (0,1)$$

$$W_{EC}, +W_{TC}, +W_{ITC}, +W_{EC} =1 \tag{8}$$

CASE STUDY

A case study is described where there is need for vendor selection as grouped for excavation equipment and is a real case. There were four vendors differing in terms of the of the committee economic criteria, (EC) technical criteria (TC), item delivery criteria (IDC) and service criteria (SC) indices. The figures presented in the next of the study are normalized.

Application of the proposed model

The pair wise values of the economic criteria (EC), technical criteria (TC), item delivery criteria (IDC) and service criteria (SC) are presented in Table 2.

Table 2: Values of the four criteria assigned by an expert panel

VENDOR	Criteria			
	EC	TC	IDC	SC
1	1	1	1	1
2	0.5	2	0.5	2
3	0.8	3	0.8	3
4	0.7	0.6	1	0.6

The coefficients of relative significance α_i are found by comparison of pair of criteria. To start this assessment, the coefficients of relative importance are initially entered into matrix B. Elements bij of matrix B are tabulated in equation 9.

$$B = \begin{bmatrix} 1 & 5 & 6 & 7 \\ 1/5 & 1 & 4 & 6 \\ 1/6 & 1/4 & 1 & 4 \\ 1/7 & 1/6 & 1/4 & 1 \end{bmatrix} \tag{9}$$

The criteria weights as components of self-vector of the matrix with λ_{max} = 4.390 are as follows: W_{EC} = 0.619, W_{TC}= 0.235, W_{ITC} = 0.101, W_{EC} = 0.045.

Incorporation of criteria weights into the multi criteria decision making

Table 3. Results of the proposed model

VENDOR	EC* W_{EC}	TC* W_{TC}	IDC* W_{ITC}	SC* W_{EC}	Overall Index
1	0.619	0.211	0.081	0.036	0.947
2	0.309	0.094	0.101	0.0315	0.536
3	0.495	0.211	0.101	0.045	0.852
4	0.433	0.141	0.101	0.027	0.702

Application of the existing method
The values were taken from the committee members' estimation according to the Greek Legislative Law.

The corresponding weights to the above according to the experts' opinions are as follows: WEC = 0.60, WTC = 0.20, W_{ITC} = 0.10, W_{EC} = 0.10.

Table 4: Results of the existing procedure

VENDOR	EC* W_{EC}	TC* W_{TC}	IDC* W_{ITC}	SC* W_{EC}	Overall Index
1	0.6	0.18	0.08	0.08	0.94
2	0.3	0.08	0.1	0.07	0.55
3	0.48	0.18	0.1	0.1	0.86
4	0.42	0.12	0.1	0.06	0.7

Comparison of the proposed model and the existing procedure and discussion
For the case study considered, the first vendor scores high in both the proposed model (with a score of 0.9473) and the existing procedure (with a score of 0.94) and is more advantageous according to the criteria rating and weights developed. This is due to the similarity of the weights of economic criteria, technical criteria and item delivery criteria (0.619 to 0.60; 0.235 to 0.20; and 0.101 to 0.10, respectively) though there is a difference in service criteria (0.045 to 0.10) that derived somehow similar to the solution when the Legislative Law Indicative weights are followed. As can be seen, the correct calculation of the weights is the key element of the procedures discussed. The arbitrary determination of the weights in the existing procedure may lead to bias of the method.

CONCLUSIONS

This research proposes an improved evaluation procedure based on the utilization of fuzzy sets that can be used in real procurement cases. These cases are categorized to certain groups so that the methodology can be applied to a number of similar cases. It is also a practical approach because with analysis of a particular procurement case, the result can be utilized in a number of similar cases in terms of criteria weights of the methodology and not on arbitrary identification. This improved procedure not only possesses theoretical foundations, but also it enables the testing on the consistency in group evaluation results and complies with the Greek Legislative Law and the EU directives. It can also evaluate differences among individual and committee members, as the results take into account the experts' opinions and can be used as a tool to adopt the quantitative methods properly combining the different opinions of the evaluation committee members in order to represent the overall evaluation. Using different weight criteria for each case, the improved procedure is able to lower the impacts of deviated evaluation of individual committee members as well as reduce such biased evaluation to some particular suppliers. Therefore, this improved procedure may enhance the quality in determining the most advantageous tender. The further development of this approach could create a methodological framework for vendor selection processes.

TOTAL QUALITY MANAGEMENT IN CONSTRUCTION: A CASE OF JORDAN

Ayman H. Al-Momani[1]

Civil Engineering Department, Mu'tah University, Mu'tah PO Box 7, Karak, Jordan

This paper proposes to investigate the status of construction industry in Jordan, report an overview of TQM initiatives in Jordan and attempt to develop assessment model of performance for local contractors to respond to market pressures caused by the size and complexity of new construction projects. The developed model has the potential to enable contractors to build on existing quality management systems and provide useful practical guidance that compels the organization to seek a new level of excellence. Potential to achieving the required organizational environment is explored, and the criteria mentioned in the model are taking place. TQM is a desired culture of an organization committed to customer satisfaction. The more conscious the contractors are about the requirements mentioned in the model, the better the chances are for their the project's success. Such initiatives are necessary to meet customer requirements and to help construction companies to survive and face increasing competition.

Keywords: award for excellence, construction industry, Jordan, performance assessment, TQM.

INTRODUCTION

Quality is a major concern for all sectors of the national economy, including construction. The concepts have changed over the decades. Having focused on the concept of quality control in the 1950s and 1960s, and on the concept of quality assurance from the mid 1960s until the beginning of the 1980s, it is the concept of total quality management (TQM) which is now on the agenda.

The construction industry has many problems because of its complicated nature of operation. This industry is comprised of a multitude of occupations, professions and organizations (Kanj and Wong 1998; Milakovich 1995; Sommerville 1994). Projects require the involvement of larger number of specialists in design, fabrication, construction, and operation and maintenance, each contributing necessary pieces to the product development process (Gil *et al*. 1999). This involvement prevails in different phases, which include: feasibility, development, construction and start-up (Schultzel and Unruh 1996). Goals tend to conflict as different parties have different priorities (Wong and Fung 1999). Similarly, Himes (1995) emphasized that the construction industry has a reputation of conflict, mistrust, claims and litigation.

The key element needed for organizational success is the ability to identify what is changing in the environment and to respond proactively through continuous improvement efforts (Brown and Eisenhardt 2000). One form of operations management practices is total quality management (TQM), which has received a growing amount of attention in the last two decades (Jung and Wang 2006). The

[1] ahmomani@mutah.edu.jo

primary aim of a quality system is to prevent non-conformity at all stages of a project and, as a result, the control of non-conformances, waste and quality loss reduction should become a focal point in any organization's quality improvement efforts. Non-conformities can include any kind of deviation from the ‘specified requirements’, and may be in the form of failure, waste, defect, error and any other loss that might prevent a product or service from meeting its ‘fitness for purpose or use’ and ‘customer satisfaction’ (Smith *et al*. 1999)

Partnering, supply chain management (SCM) and total quality management (TQM) are all concepts or approaches that can be applied as initiatives to solve problems in the construction industry and meet the needs of customers (Kanji and Wong 1998). TQM is also a philosophy that helps to improve all aspects of an organization and is aimed at exceeding customer expectations (McIntyre and Kirschenman 2000). Despite this unwillingness, Lahndt (1999) stated that the construction sector had begun to realize the importance of TQM and that quality had become a main construction goal. Cheetham (1993) has indicated that quality systems in the construction industry perform two valuable functions. The first is, by their very existence, raising the level of quality awareness throughout the company. This, in turn, can favourably influence attitudes towards quality on the part of the employees. The second function is to enable certification: a certified system being a tool that enables a company to compete in an increasingly quality conscious market.

The importance of TQM in construction firms is widely acknowledged today (Saha and Hardie 2005; Jaffari 1996; Love *et al*. 2000; Walker and Keniger 2002). Analysed within the multiple stakeholder perspective, TQM has a significant impact on the organization itself, its survival and profitability, the customers, the suppliers, the social context, and the employees (Henry 2000; Serpell *et al*. 2002; Jahren and Federle 1999). As pointed out by Xiao and Proverbs (2002), adapting TQM creates a culture of trust, participation, teamwork, quality-mindedness, eagerness for continuous improvement, continuous learning and, ultimately, a working culture that contributes towards a firm’s success and existence.

Total quality has long been practiced in the developed countries such as Japan, USA and UK. Construction quality in Japan has improved greatly since the introduction of TQM in the 1970s (Bennet *et al*. 1987). More and more construction companies are adopting TQM to improve their performance (Kanji and Wong 1998; Fung and Wong 1995; Jido 1996; Sommerville 1994). Much evidence is now emerging to show that TQM does deliver improved performance when implemented effectively (Hendricks and Singhal 2001; Easton and Jarrel 1998). A longitudinal study of TQM implementation by Taylor and Wright (2003) highlighted some necessary antecedents for TQM success. In particular, mangers need to understand the nature and purpose of TQM, and the potential benefits that can accrue from its implementation (Taylor and Wright 2003).

THE CONTROVERSY ABOUT THE VALUE OF TQM

TQM has recently been getting a bad rap in the popular business press regarding its ability to improve financial performance. Mixed results on outcomes have been reported in literature: the adoption of the TQM marginally affects actual improvement of organizational performance (Broetzmann *et al*. 1995) and the relationship of TQM practice is positively associated with operational performance measures (Chi and Eboch 1998). The launch of the Malcolm Baldrige National Quality Award

(MBNQA) framework in 1995 narrowed the number of disputes on what elements TQM practices. Many researchers have based their work on MBNQA criteria (Jung and Wang 2006).

REASONS FOR PURSUING TQM

Jordan is still in the developing stages of TQM and the concepts are being slowly adopted. The construction sector generally has lagged behind other industries in practising and implementing TQM. In many cases, creating drawings with a minimum number of errors, fulfilling the requirements of a contract and defining technical specifications do not guarantee the quality required by owner. Therefore, quality initiatives in Jordan and the launching of the award for excellence provide an opportunity for contractors and designers to renovate their practices and information on quality management.

The construction industry will not last long in its present state of isolation, where it is completely out of touch with initiatives centred on quality. Therefore, fundamental changes in current practices of construction are required. These changes go to both operational and national levels. Leaders and top management should create an environment that fosters participation of construction contractors and designers to incorporate the factors affecting quality practices.

RESEARCH OBJECTIVES

Leonard and McAdam (2002) observed that most of the existing models are operational level focused. There is a need for models to be used at the strategic level in terms of planning and longitudinal planning. However, TQM is a new concept introduced in Jordan. The present study comprised one of the early stages of major construction investigation that was undertaken to improve overall quality of construction. The objective of this research is to focus on the status of the construction industry in Jordan, report an overview of TQM initiatives in Jordan and attempt to develop a performance assessment model for local contractors to respond to market pressures caused by the size and complexity of projects.

Such initiatives will be necessary to meet customer requirements, and to help construction companies to survive and thrive in the face of ever-increasing competition.

CONSTRUCTION INDUSTRY IN JORDAN

The construction industry is unique because of differences in management practices and construction methods both between countries and within the industry itself. Both design and construction team members are different for each project (Low and Tan 1996). Continuously changing customers’ needs adds to the peculiarity of construction projects. In 2005, the Jordanian economy successfully achieved a high growth rate in the real Gross Domestic Product (GDP), exceeding the population growth, reaching 7.2% as compared to 7.7% in 2004. The construction industry in Jordan and the associated income arising from it witnessed a boom during the past six years due largely to the significant infrastructure and real estate investments made, especially in housing development and tourism projects. This sector is the sixth largest employer in the country, employing more than 7% of the total labour force with an annual turnover accounting for approximately 8% of GDP (Export & Finance Bank 2003).

The favourable sentiment in the sector was reflected by the 55.3% rise in new firms. A total of 73 new construction-related companies were established in year 2005 compared to 47 new firms in 2004, while the aggregate capital of new firms increased by 19% to JD 3.1 million year-on-year. Reflecting construction activity and in line with government expansionary credit policy, bank credits extended to construction during the first half of 2005 surged by 143.3% to JD 115 million, driven by a 225% jump in the second quarter of the year relative to the same period last year (Audi Bank 2005).

Public spending on construction projects is the most important factor behind the growth in the construction sector in Jordan, followed closely by private construction investment. The Ministry of Planning is responsible for allocation of the majority of construction projects throughout the Kingdom and therefore receives the largest share of allocated funds. The Ministry of Public Works is the main conduit for government spending on infrastructure projects. A number of public institutions connected to the Ministry share the role of regulating the sector in Jordan such as: Tenders Department; Contractors Associations; Engineering Association; and Housing and Urban Development Corporation.

The country has gone through massive structural and large-scale projects. These projects were mainly in the fields of transportation, tourism, education and health, i.e. highways, airports, the Port of Aqaba, hotels, schools, and hospitals, as well as water projects. A number of large real estate projects have been launched, the largest of which are the US$ 1.0 billion Royal Metropolis, the US$ 620 million Saraya Aqaba developments and the US$ 340 million Abdali Investment and Development Project. These projects involve the construction of hotels, commercial, residential, retail and entertainment facilities. Jordanian contractors and consultants have had minimal involvement in such large-scale projects, while foreign contractors were profoundly involved. This might have been because foreign contractors are considerably more experienced and skilled than local contractors are.

The construction sector faces many performance problems such as delays; numerous design changes; increased quantities; payment delays; improper planning; escalating costs; shortages of materials; poor contract management; and inadequate contractor experience (Al-Momani 2000). The volume of work carried out by the construction sector shows sharp fluctuations over the years. This may be attributed to many factors such as: limited available funds, lack of sound institutional and legal frameworks; administrative and allocation inefficiencies; management and financial inadequacies; and the political uncertainty that has overshadowed the region. In this context, poor construction quality damages the competitiveness of the nation's industries.

Pressure to improve quality

In the light of the difficulties facing construction contractors in their performance, they have encountered much pressure to improve quality that is explained below:

- *First:* construction increasingly is a complex process, with a plea for participation of specialized professionals, contractors, sub-contractors and suppliers to deliver a project. Therefore, the client will come into contact with many agents to ensure best performance. This calls for collaborative management efforts and coordination on their part. Structured relationship will facilitate the achievement of TQM requirements.

- *Second*: the media responds and enhances the growing interest in the demand for quality construction, as well as publicizing the newsworthy examples of quality.
- *Third*, rising standards of living increases consumerism and choices, and change is evident in clients' expectations. Clients increasingly expect the same service from construction industry.
- *Fourth*, tremendous growth in the use of quality methods in other sectors have led to quality thrusts nationally and internationally.

Higher customer satisfaction, better quality products and higher market share are obtained if the construction companies adopt TQM in their operation (Kanji and Wang 1998). These concerns shed lights on importance of TQM in construction in this research.

Improving construction quality

As a result of different pressures, there have been a number of initiatives in Jordan to ensure and improve construction quality. The Kingdom of Jordan joined the quality race in 2000. Below is a list of these initiatives:

- Professional initiatives, such as standard setting, training, and audit methods.
- Governmental regulations such as licensing and inspection.
- Establishing a department of specification and standards, and a quality control units promoted by professional and some governmental units.
- National quality and performance strategies.
- Quality prizes and awards
- Patent information, participation and rights.
- ISO 9000 Registration.
- Total quality management (TQM).

In addition, the government is well placed to understand what constitutes best practice and extend the learning throughout the industry.

STRUCTURE OF KING ABDULLAH II AWARD FOR EXCELLENCE

Award background and objectives

Adebanjo (2001) asserts that business excellence and quality complement each other and should co-exist. For the purpose of this paper, the King Abdullah II Award for Excellence (KAAE) is used. The King Abdullah II Award for Excellence (KAAE) is the highest level of quality recognition in Jordan. The award was developed by the Industrial Development Directorate (IDD) at the Ministry of Industry and Trade, and the Jordan-United States Business Partnership (JUSBP) administered by the International Executive Services Corporation (IESC), and funded by the US Agency for International Development (USAID). The award is granted once every two years and divides participating firms into five main categories:

- Large manufacturing companies.

- Small- to medium-size manufacturing companies (less or equal to 50 employees).
- Large service organizations.
- Small- to medium-service firms (less or equal to 100 employees).
- Newly added agriculture and agricultural marketing organizations category.

The criteria are divided into enablers and results. The award is characterized by a concept that consists of five distinctive areas, each representing a different aspect of the organization. The enablers cover leadership, strategic planning, processes management, resources management and results. The "results" are separated into business results, products and costumer satisfaction**.** These five areas are divided into sub-areas concerned with the achieved results and areas concerned with how these results have been achieved (enablers). As a whole, an enterprise can achieve a total of 1,000 points whereby the different areas are weighed according to their relative importance (Table 1). The model consists of an integrated cycle of continuous improvement. The cycle starts with self-assessment of results and, on the basis of the findings, an organization can decide what actions can be taken to strengthen enablers to improve the results. The company that wins the competition is entitled to use the quality label of the King Abdullah II Award for Excellence in advertisements and publications.

Table 1: The evaluation criteria of the King Abdullah II Award for Excellence (KAAE)

Leadership	150
Strategic Planning	150
Resource Management	250
Process Management	200
Results	250
TOTAL POINTS	1000

The award aims to create qualitative transformation and to develop the performance of government and institutions in serving Jordanian citizens and investors, as well as to enhance positive competitiveness among government departments and institutions through promoting awareness of the concepts of distinguished performance, innovation and quality, and establishing the culture of excellence that is founded for best practice. The award strives to assist organizations to achieve overall competitiveness; good governance; satisfied customers, suppliers and partners; committed employee involvement; community approval; and significant gains in business results and productivity. The award has gained broad acceptance among both profit and non-profit organizations.

STRUCTURE OF PERFORMANCE ASSESSMENT MODEL FOR LOCAL CONTRACTORS

As outlined by Dale (1999), business excellence in its pure undiluted form is based on TQM and, as such, should incorporate all its facets and this should be recognized. Stading and Vokurka (2003) stated that the international community is generally evolving toward a common set of beliefs about the TQM process. This becomes a source of competitive advantage for individual firms competing in the global marketplace if content is considered and appropriately weighted.

The conceptual model for this study is graphically depicted in Figure 1. The ‘fundamental concepts’ underpinning the Excellence Model reflect its total quality origin. The model has five core precepts: leadership, strategic planning, process management, resources management and results.

The award criteria are built on common beliefs of a TQM strategy process. The nature of these precepts shows the quality issues in construction industry from both project and industry levels. Using the model, a multidisciplinary team is formulated. Their objective is the development of a TQM environment. The project quality management environment is established in stage 1, and a path foreword TQM deployment plan is determined in stage 2 (knowledge-skill development and product-process development). In stage 2, the owner, designer and the contractor begin the alignment process by reviewing the project's technical requirements. A multidisciplinary team is empowered to make the necessary improvements to the project, identify problems, allocate risk and become involved in process change. This stage could require training requirements. Once the mutual understanding is achieved, the team must align the TQM requirements and involvement of all members.

Managers use cross-functional work teams to break down long-standing barriers, improve effectiveness and meet goals. They will have to participate in activities such as promoting innovation, encouraging team activities, close working relationships, and meeting with owner, contractor and suppliers. Key quality management elements of stage 2 are again performed during stage 3. In this stage, two main issues include aligning the project vision and mission with the customer needs and expectations. The project team must integrate the TQM concepts to the project from its inception to its completion. In stage 4, the team applies the concepts of continuous improvement to the project. Incorporating the principles of continuous improvement via the PDCA cycle into the plan is indispensable for TQM principles to flourish.

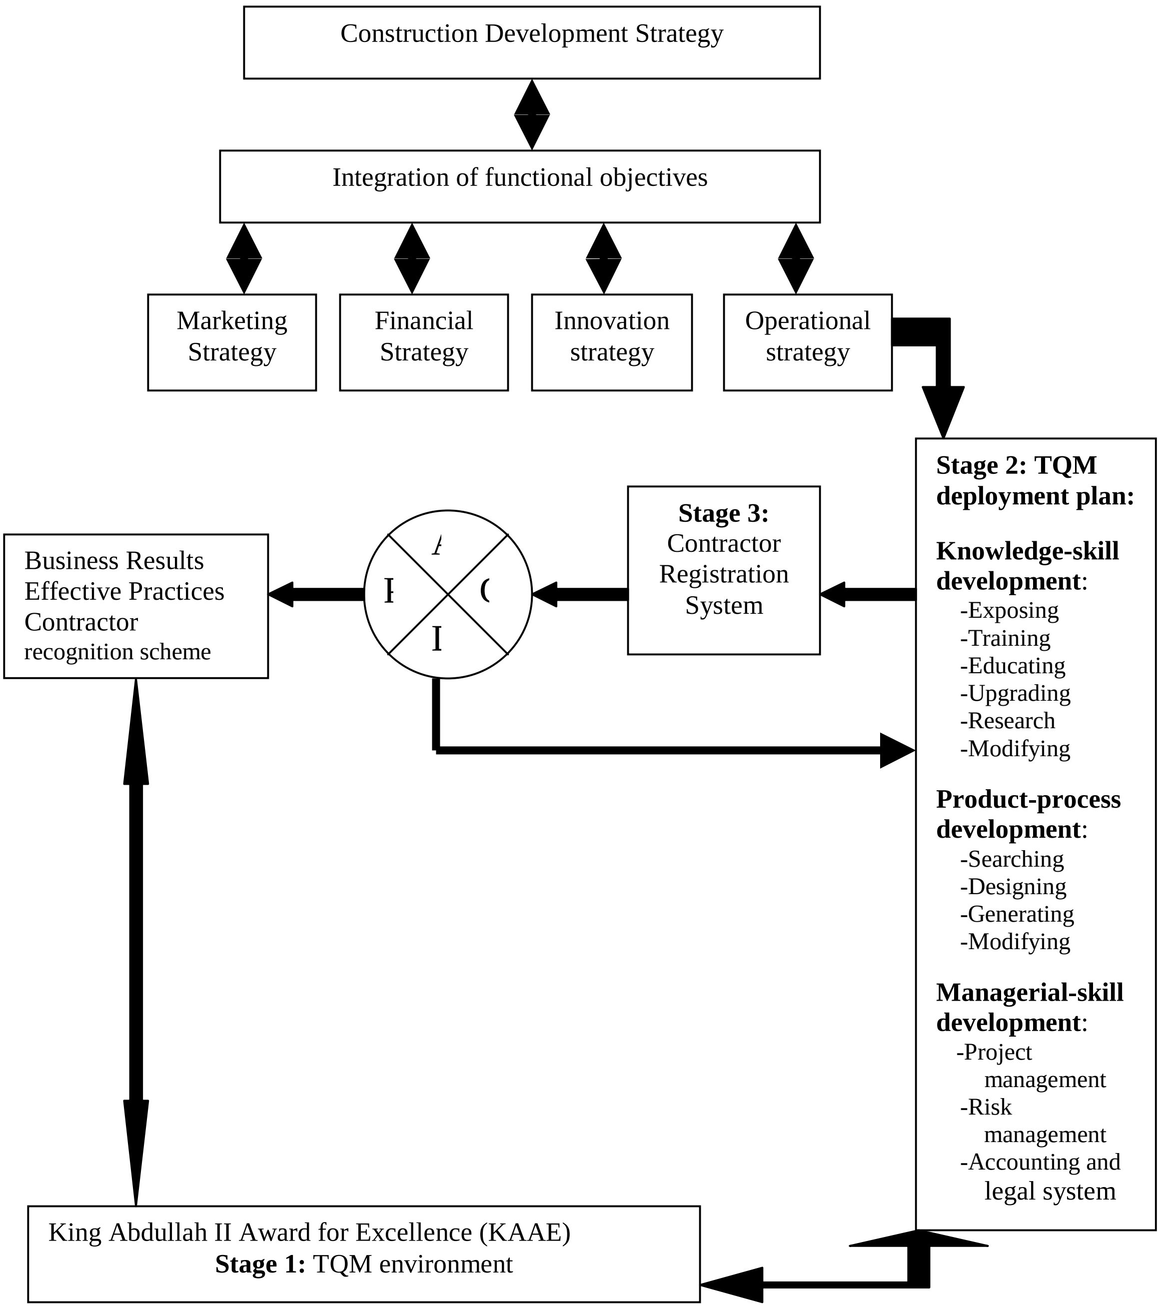

Figure 1: The structure of performance assessment model for local contractors

Once the plan is deployed, the team must periodically assess and review the results of applying TQM. Based on periodic reviews, the management team must adjust the TQM plan to encourage improvement. This enables managers to take remedial action before tolerance limits are exceeded and begin to impact on construction delivery. This stage examines the organization's performance and improvement in key business areas, customer satisfaction, financial performance, human resource results, supplier and partner results, and operational performance. Compensation, recognition, and rewards are provided for results, such as submitting improvement ideas for reductions in cycle time and at less-than-projected cost. The model will help to develop an ethos where managers, project team member and contractors perform together which means they are able jointly to look at the way the process is carried out and take improvement action if necessary.

The implementation of the model would gain a line of its own within the construction sector. The model has the potential to enable contractors to build on existing quality management systems for ways to achieve excellence in the construction and assessment process. In the light of the above, specific potential benefits that are offered by the model may be summarised as follows:

- *First*, the King Abdullah II Award for Excellence (KAAE) can be implemented in harmony with the contractor's assessment process, although they each have a unique role in determining different types of performance.
- *Second*, the compatibility of KAAE and the contractor's assessment process can be adopted to build contractors competence and capabilities; this is in line with findings reported in other studies.
- *Third*, the integration between contractor's assessment process and (KAAE) is and innovative tool in promoting best construction practices.
- *Fourth*, integration produces a greater explanatory power than TQM alone in terms of contractors' advancement, and enhances their capacity and performance.

It is posited here that the award dimensions will have different effects on the strategy of development in the construction sector. The King Abdullah II Award for Excellence and the contractor's assessment process encourage the construction industry to continually maintain a good quality management system.

According to findings from several studies, quality management is likely to remain an important corporate strategy in the future (Liu and Kleiner 2001). A corporate culture aimed at TQM and continuous improvement is considered as an important factor that enhances the companies’ capabilities, especially for innovation (Zwetsloot 2001). The model was viewed as being a permissive framework that provided a structured approach to continuous improvement and quality initiatives. As highlighted above, this study has produced interesting findings in promoting best construction quality practices.

CONCLUSION

The model is formulated on the premise that total quality management is the sole technique utilized in construction, and provides a generic framework that can be equally applied to any construction firm regardless of size, sector and structure. The proposed model is drawn to represent an analytical approach that could enable top managers to understand and plan the total quality programs needed in their companies.

The proposed model offers knowledge and skills to local contractors in the disciplines of total quality management. The managers will learn to design effective training that meets the identified gaps in key skill areas and industry sectors. Construction contractors will undoubtedly have to shoulder a major burden of leadership for two reasons: one ideological and the other very practical. Companies will therefore be equipped with the required tools to survive, to face increasing competition and to expand when the time is right. TQM is a desired culture of an organization committed to customer satisfaction. In all cases, however, the criteria mentioned in the model are taking place. The more conscious the contractors are about the requirements mentioned in the model, the better the chances are for their success and the projects. The Ministry of Public Work and Housing has a role in maintaining the quality of construction industry. It must be prepared to cope with the industry's specialized needs and must acquire these capabilities with the aid of educational programmes that take cognizance in TQM.

The results of this research have many implications. The implementation of TQM in construction was expected to promote leadership rather than supervision; intensify the beneficial interaction efforts to participate in work-related decisions; provide a common language in which to operate a comprehensive performance management system that is readily acceptable to technical and managerial staff alike; inspire commitment from the entire organization; to attempt to refine and extend team work; inspire people to seek continuous improvement; and provide a framework for sharing effective practices of construction in its widest sense. This, in turn, can be expected to favourably impact the structures of the construction industry.

It is hoped that this research will provide a foundation and a stimulus for such follow-on efforts. The study should be of value to policy makers, construction managers and construction organizations. Investigating the complete system (as shown in Figure 1) is far too complex an undertaking for one study. Research into the sub-system should be conducted individually and should take into consideration how each sub-system interacts with others. Further research is currently underway, in which it is intended to build up a new approach to assess quality programmes in the construction sector. The proposed system will form the basis of a new model that is specific to construction industry rather than the general models currently used. The King Abdullah II Award for Excellence (KAAE) and the assessment model will create much needed awareness among government and industry leaders about the significance of quality for economic survival and success in today's highly competitive world. The framework results in this study can be very useful as a guide to assessment, planning, and improvements at both the organizational and sectoral level.

A STUDY ON QUALITY MANAGEMENT DURING THE PRE-CONSTRUCTION STAGE OF DESIGN-AND-BUILD PROJECTS

Hamzah Abdul-Rahman,[1] Faizul Azli Mohd Rahim, Mohd Suhaimi Mohd Danuri and Low Wai Wah

Center of Project and Facilities Management (PFM), Faculty of Built Environment, University of Malaya, 50603 Kuala Lumpur, Malaysia

In the demand for improved procurement methods, the design-and-build approach has become prevalent in the construction industry. However, quality issues in public design-and-build projects raise the alarm for attention. A study was conducted to determine the main inherent quality-related factors, to identify the potential benefits of quality management implementation and to suggest principal quality management methods that can be applied during the pre-construction stage. Data were collected via a questionnaire survey and semi-structured interviews with selected contractors. The interviews served to supplement data received from the questionnaire surveys. The level of management quality among the sample of contractors operating public design-and-build projects was found unsatisfactory. The critical quality-related factors that have contributed to this problem include budget constraints, time constraints, client's complexity, poor communication and design variations. Research findings revealed that the management of time and cost was the most important method in reducing quality-related problems.

Keywords: construction project, design-and-build, procurement, quality management.

INTRODUCTION

The use of the design-and-build procurement method has increased worldwide (Xu and Greenwood 2006). In Malaysia, project delivery methods have changed in the past few decades (Wong 2002a) and design-and-build has become prevalent in the construction industry (Reeves 2002; Kwan 2004). In design-and-build, a contractor takes full responsibility for the whole design and construction process from initial briefing to completion (Chappell *et al*. 2001). Design-and-build is a significant procurement in terms of sustainability (Alnaser and Flanagan 2007; Ugwu and Haupt 2007) and a dominant delivery method (Al-Reshaid and Kartam 2005) in future.

Additionally, quality remains a critical issue in the construction sector (Karim *et al.* 2006). From the contractors' point of view, quality is the cornerstone of competitive strategies to widen and secure clients (Low and Sze 2005). Quality concerns are about the satisfaction of customers' needs, suitability for intended use and performance according to specification (Raj 1988). A quality project can then be defined as a product that meets client requirements specified in the specification.

Quality management is considered as a priority and a potential solution in respect of quality problems. It is defined as the organization structure, responsibilities, activities,

[1] arhamzah@um.edu.my

resources and events appertaining to a firm that together provide organized procedures and methods of implementation to meet quality requirements (BS 5750 1987). Quality management helps to mitigate further consequent quality problems. With effective quality management, quality-related problems can be eliminated and prevented at the early stages (Battikha 2002).

SOME POOR QUALITY SCENES IN CONSTRUCTION

Although the construction industry in Malaysia carries with it many success stories, it is worth noting some areas that often have become challenges and issues to the industry in pursuit of rapid development. According to the Federal Audit Reports 1999–2005 from the National Audit Department of Malaysia, the industry has for many years suffered from quality issues. In the Federal Audit Report 1999, the quality of 23 cases of construction works in seven hospitals did not fulfil the contract specification. The quality of the housing projects, Territorial Army Regiment and Transit Camp, and five Matriculation Colleges suffered serious defects and damages in the Federal Audit Reports 2000–02.

In the Federal Audit Reports of 2003 and 2004 several completed projects were reported to be of unsatisfactory quality. In the Federal Audit Report 2005, the Freshwater Fish Research Centre and the development of new hospital projects did not comply with the specifications and some works sustained serious defects. Among the reported cases, some were constructed based on the design-and-build concept and apparently poor quality in design-and-build projects is not isolated to the Malaysian construction industry.

A BRIEF OVERVIEW OF PREVIOUS RESEARCH SCOPE

Design-and-build studies have varied in scope and focused on different areas. Some (Low and Lim 2000; Chan *et al*. 2001; Ling and Min 2004) looked at the success performance and some (Knight *et al*. 2002; Low and Lim 1999) focused on the failure factors. Work by Ling and Lee (2005) investigated 34 attributes affecting project service quality on design-and-build. The study by Ling (2005) examined the extent of quality achievement and the significance level of 60 quality factors between design-bid-build and design-build. Dulaimi *et al*. (1998) looked at the inherent problems which can influence effective design management. Chan and Yu (2005) stressed contract strategy for design management. Research by Cornick and Barre (1991) studied the quality management aspects and highlighted that design-and-build supports the successful application of quality management to a building.

Such studies highlighted several aspects of academic knowledge gaps. First, there is scarcity of research focused on the quality aspect of design-and-build. Second, there is little academic research on the quality management in design-and-build. Third, there is a need to focus on the pre-construction stage of project development owing to the early involvement of different and multidisciplinary professionals working as a team.

DEBATABLE TIME, COST AND QUALITY ISSUES

Some consider design-and-build projects a success (Akintoye 1994); others consider design-and-build is no better than the traditional procurement system (Retherford 1998; Smith and Wilkins 1996). Studies in Hong Kong indicated that the use of design-and-build provides the benefits of shorter construction time (Tam, 2000) and reduction of cost overruns (Dissanayaka and Kumaraswamy 1999). However, Wong

(2002b) revealed that employers in Malaysia often encounter project cost overruns and delays.

One study found that there is no significant quality advantage with the adoption of the design-and-build method (Akintoye 1994). The negative views of design-and-build included lower quality material and equipment (Abi-Karam 2005), poor design quality (Anumba and Evbuomwan 1997) and failure to fulfil owners' expectations (Yates 1995; Rowlinson 1987). However, some studies reviewed contrasting results and views on quality aspects. Some studies argued that design-and-build projects are able to produce equal or sometimes more desirable quality of work (Lam 1998; Konchar and Sanvido 1998). In fact, a quantitative study uncovered that there is no significant difference in quality between design-bid-build and design-and-build projects (Ling 2005).

QUALITY-RELATED FACTORS

Table 1 presents 18 potential quality-related factors extracted from the literature (Dulaimi *et al*. 1998; Faisol and Adnan 2001; Wong 2002a; Wong 2002b; Knight *et al*. 2002; Ling 2005) and a preliminary survey with a few construction professionals.

Table 1: Quality-related categories

Quality-related categories	Quality-related factors
1. Project-related participants	Client (client's complexity and client's involvement), contractor, design consultants and project manager
2. Project work atmosphere	Effect of traditional procurement, lack of communication, poor relationship and design variation
3. Project characteristic	Novation, time constraint, fast tracking pressure, budget constraints and project complexity
4. Project's information and documentation	Inadequate design, scope and planning, insufficient detail of contractor's tender price and lack of information and documentation management
5. Project management	Poor project management

QUALITY MANAGEMENT IN CONSTRUCTION PROJECTS

Much of the literature confirms that quality management implementation provides tangible benefits to the project parties and the organizations. The identified benefits are:

1. achieving good communication with numerous professionals from entirely different backgrounds in the construction industry (Duncan *et al*. 1990);
2. providing well-documented processes that reduce errors, and provide readily accessible information for employees to acquire knowledge (Bauer *et al*. 2002);
3. improvement of quality awareness (Casadesus and Karapetrovic 2005);
4. improvement of efficiency and effectiveness of plans;
5. improvement of employee morale and exceeding customer requirements (Gitlow 2001).

Several common quality management methods were extracted from the literature (Ashford 1989; Ashworth and Hogg 2002; Chung 1999; Dulaimi *et al*. 1998; Bubshait *et al.* 1999; Gray and Hughes 2001; Law 2004). These included project management contract, contract review, documentation and data control, design management, design control, design review, management review, start-up meetings, constructability planning, time and cost management, build up an effective team and culture change.

RESEARCH AIMS AND OBJECTIVES

The research aims to find out the critical quality-related factors inherent during the pre-construction stage and to recommend appropriate means of managing quality before the start of construction works. The objectives of the study are:

1. to determine the main quality-related factors in public design-and-build projects;
2. to identify the potential benefits through the implementation of an appropriate quality management technique in design-and-build projects; and
3. to examine the principal quality management methods of curtailing quality-related problems in design-and-build contracts.

RESEARCH METHODOLOGY

By reference to the work of Chan and Yu (2005), qualitative and quantitative methods were conducted in the study. The research was limited to government-funded projects.

Quantitative research approach

For the purpose of generalization, a quantitative questionnaire was adopted because of its wide geographic coverage (Naoum 1998). A total sample size of 500 was posted to the contractor firms as sample sizes larger than 30 and less than 500 are appropriate for most research (Roscoe 1975). The names and the addresses of 24 contractors were obtained directly from the Public Works Department (PWD), while the remainder 476 contractors were selected based on random sampling method from the Malaysian Construction Industry Development Board (CIDB) Directory 2005/06 and website.

Contractors were used for the sample as they are responsible for design and construction tasks and carry the most risks. In Malaysia, as the majority of the design-and-build projects were undertaken by higher tender capacity organizations, contractor Grade 7 serves as a better representative population. The focus of the survey was in the state of Selangor and the Federal Territory as they have the highest construction activities and more than 50% of the total contractors' population are found here.

Each respondent was provided with a set of questionnaires and an official letter that contained the research problem statement and research objectives. Questionnaire forms were sent out in mid-December 2005. A one-month period was allowed for the participants to complete the questionnaire. Data were computed in the form of frequency distribution in percentage and mean. A pilot survey was conducted with five professionals having between five and 20 or more years of experience prior to the major fieldwork. The pilot survey aims to test the clarity of the questions by ensuring the questions provide the necessary data to meet the research objectives. Based on the weaknesses specified by the respondents, some questions are either restructured or provided additional explanation (Appendix 1).

Qualitative research approach

To supplement the findings of the structured questionnaire, semi-structured interviews were conducted in February 2006. The study was successfully made up with 10 multidisciplinary professionals, namely project managers, project directors, contract managers, quantity surveyors and engineers. During the interview, interviewees were briefed on the research problem and the research objectives. Interviewees were requested to fill in the questionnaire and to provide additional comments on the issues raised in the questionnaire.

QUESTIONNAIRE FINDINGS

Out of the total 500 sets distributed, 44 usable questionnaires were returned and analysed (8.8% response rate). Respondents comprised six (13.6%) directorate personnel, 28 (63.3%) managerial personnel, six (13.6%) technical personnel and three (4.5%) administrative personnel. The results of the survey were obtained mainly from the managerial personnel with more than 10 years of experience, representing 52.3% (23) of the total respondents.

The use of design-and-build to mitigate time or cost overruns problems

More than half of the respondents provide a positive perception of the use of design-and-build project to mitigate the problems of time or cost overruns where nine (20.5%) respondents strongly agreed and 27 (61.4%) respondents agreed. Six (13.6%) respondents were neutral on this statement and two (4.5%) respondents disagreed that the use of design-and-build projects is able to mitigate the problems of time or cost overruns.

Quality problem between design-and-build and traditional procurements

More than one-third of the total respondents reacted negatively on the use of design-and-build procurement where two (4.5%) respondents strongly agreed and 16 (36.4%) respondents agreed. Another 27.3% (12) of respondents were neutral, 13 (29.5%) respondents disagreed and one (2.3%) respondent strongly disagreed that quality-related problems in design-and-build appear to be more serious than in traditional contracts.

Inherent quality-related factors during the pre-construction stage

Based on the analysis in Figure 1, the five most crucial factors impairing project quality during the pre-construction stage were budget constraints with 86.4% (38), time constraints with 79.5% (35), client's complexity with 72.7% (32), poor communication with 70.5% (31) and design variation with 68.2% (30). In contrast, novation and effect of traditional contract were rated as the least affected quality-related factors with 13.6% (6) and 25.0% (11), respectively.

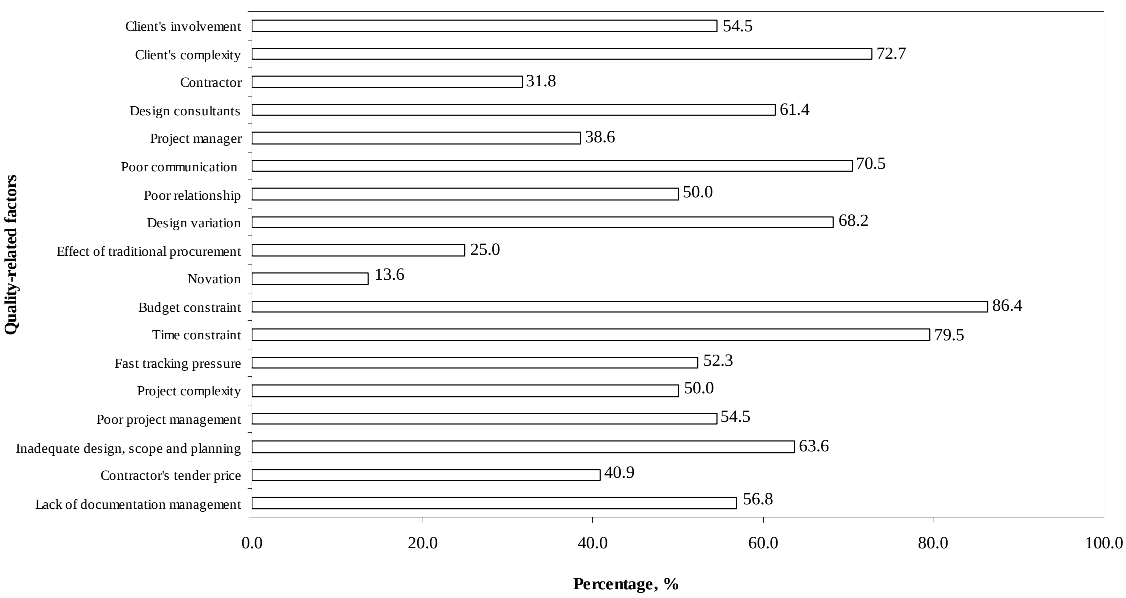

Figure 1: Result data of quality-related factors

Benefits of quality management during the pre-construction stage
Figure 2 shows that all the six benefits achieved responses of more than 50%. The three most significant benefits that would be increased via the implementation of quality management during the pre-construction stage were documentation with 86.4% (38) of total responses, quality awareness with 84.1% (37) of respondents, and achievement of client's requirements and efficiency and effectiveness of plan with 81.8% (36) of total respondents.

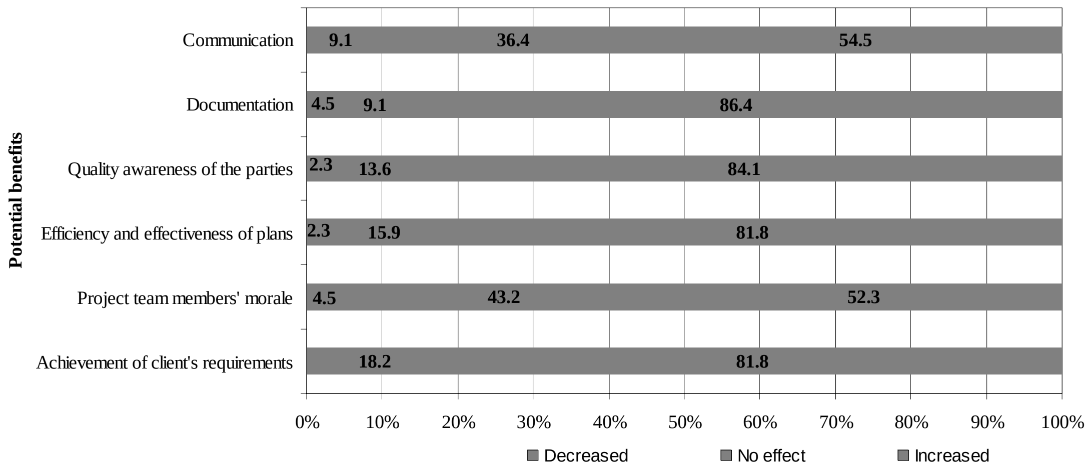

Figure 2: Potential benefits through quality management practice

Quality management methods during the pre-construction stage
Based on the survey results in Figure 3, five critical quality management methods during the pre-construction stage in preventing quality-related problems were time and cost management (4.6), constructability planning and design control (4.4), building an effective team (4.3) and design management (4.2). The least important quality management methods were cultural changes (3.3) and contract review (3.4).

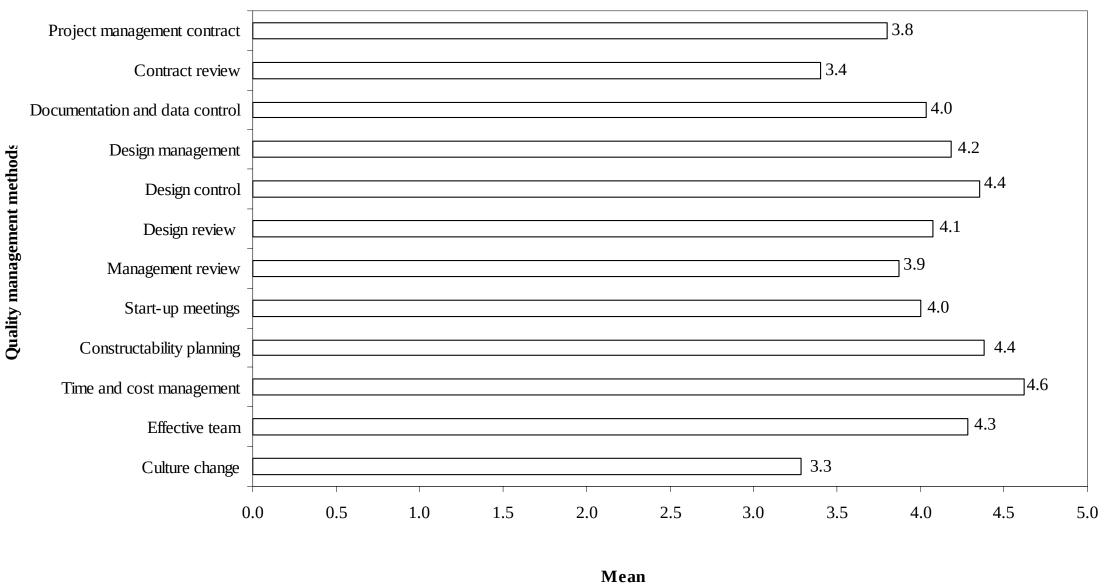

Figure 3: Importance of quality management methods based on mean

SUMMARY OF INTERVIEWS FINDINGS

The use of design-and-build to mitigate time or cost overruns problems

Seven interviewees agreed that involvement of the contractor at the early stage of the project can improve the performance of time and cost aspects. This is because of the improved project constructability and the reduction of design problems during construction. Three interviewees indicated a neutral viewpoint as time and cost aspects depend highly on human factors rather than the type of procurement.

Inherent quality-related factors during the pre-construction stage

Among the inherent quality-related factors during the pre-construction stage were consultants, contractors, project complexity, time constraints and cost constraints. The reasons provided by the interviewees were: (1) contractors have total control over design and construction works; (2) project complexity imposes a higher challenge of foreseeing potential problems at the early stage of the project; (3) the increase of overtime to meet the tight project schedule will influence quality of productivity; and (4) in respect of cost constraints, contractors generally tend to maintain the profit margin rather than quality of the materials. All interviewees disagreed that novation contributes any inherent quality-related problems during the pre-construction stage as novation is seldom practised in this context.

Benefits of quality management during the pre-construction stage

The majority of the interviewees agreed that implementation of quality management at the pre-construction stage provides considerable benefits to the project parties and the final product. Some argued that the benefits of quality management implementation during the pre-construction stage can be fully gained provided project parties strictly implement it throughout the project period.

Quality management methods during the pre-construction stage

The most important quality management methods during the pre-construction stage are design management, design review, start-up meeting, constructability planning, time and cost performance. Nevertheless, causes such as human factors can affect project time and cost performance.

Quality problems in design-and-build and traditional procurements

From the contractors' point of view, quality-related problems appear to be more serious in design-and-build projects than in conventional projects in spite of the fact that the use of design-and-build bridges the gaps between design and construction. The result is supported by Rowlinson (1987) and Akintoye (1994) but is in contrast to Lam (1998). It might be explained that: (1) quality problems mean different things to different people; (2) this may accord with conclusions drawn by Ling (2005): quality problems in design-and-build are not completely due to the procurement system but are also because of other quality-related factors; or (3) construction professionals are more willing or able to commit to time and cost performance rather than quality performance.

Inherent quality-related factors during the pre-construction stage

Budget constraint was the most critical quality-related factor inherent during the pre-construction stage as contractors generally select cheaper designs or hire less experienced labourers to maintain the profit margin. Time constraints pose pressure on the project participants to produce a viable design which can increase the likelihood of design problems during the construction stage and supervision of critical design information. The client's complexity may affect the productivity of the design consultants. More time is required when clients are unsure of the project's needs.

The fourth critical quality factor, lack of proper communication among design and construction project parties tend to break down the integration of project information, skill and knowledge among the project parties. This may lead to the situation where the client's requirements cannot be clearly and fully captured and defined during the pre-construction stage. Design variation is considered as the fifth crucial factor as a change in design will affect the quality of design output and the situation becomes worse if the project schedule is tight and communication between project parties is poor. Findings of the survey discovered that novation is not widely practised in public design-and-build projects, and contractors in practice are flexible to the change in design-and-build projects which pose less impact on project quality.

Benefits of quality management during the pre-construction stage

Findings of the survey evince that implementation of quality management during the pre-construction stage encourages the project parties to fulfil the client's requirements owing to increase in awareness by project parties of the importance of maintaining quality in the project, proper project documentation, and efficiency and effectiveness of plans. The findings are supported by Love *et al*. (2004) as the study found that there was an increase in awareness and focus by all employees and improved staff morale through the initiating of a quality management programme.

Quality management methods during the pre-construction stage

Based on the findings of inherent quality-related factors, the survey findings reflected that time and cost management were the principle means of curtailing quality-related problems during the pre-construction stage. This is because proper managing of time and cost aspects ensures better task coordination, within tasks and across projects which could affect the project quality. Furthermore, proper time and cost management may lead to the proper control of project parties' performance.

Design control is important as it involves controlling of the project design within the client's requirements and ensuring a constructability design is produced before the start of the construction stage. As constructability planning involves the integration of construction and planning knowledge, effective constructability planning helps to identify project barriers and problems before the start of the project. In design-and-build, building up an effective team is an important consideration during the pre-construction stage to ensure that design and construction teams from various disciplines are able to work together and to integrate and accept each other's knowledge.

Research findings showed that design management is closely connected with quality issues. According to Dulaimi *et al*. (1998), effective design management is essential to reduce the perceived problems that can affect the design quality. Thus, practical and comprehensive management is essential during the pre-construction stage.

CONCLUSIONS AND RECOMMENDATIONS

Three major concluding implications are: (1) budget and schedule factors often prevail in public design-and-build projects, which has led to a compromise in quality (this is the area of practice that requires improvement and attention by construction participants); (2) results of quality-related factors and quality management methods form a causes–solutions mirror of pattern which drops a hint to suit the remedy to the crucial quality-related factors; and (3) comprehensive management, teamwork and communication are important elements during the pre-construction stage.

Based on the research findings, several recommendations to the industry include: (1) changes in management attitude, improving the working culture, commitments from clients, contractors and design consultants, are of paramount importance to enhance the value of project quality; (2) government should increase the standard level of quality requirements in project specification; (3) leadership learning and knowledge sharing should be integrated at the early stage of the project; and (4) clients should provide incentives to contractors who able to balance quality, time and cost.

The study is limited in several aspects. The most significant limitation is that the survey findings are based only on the contractors' viewpoints. The response rate of the survey is considered small and unreliable for generalization. Further research can be directed to the private sector to explore quality factors and alternative mechanisms in mitigating quality issues. The research could focus on the construction stage to examine the correlation and the significance of quality factors between the pre-construction and construction stages. Finally, it would be interesting if multiple case studies were used to generate more research data.

ACKNOWLEDGEMENTS

The authors would like to extend thanks to all construction professionals who have participated in this study. A deep sense of gratitude is also extended to those who have in one way or another provided valuable comments to improve the paper.

APPENDIX 1: DEFINITION OF TERMS

Inherent quality-related factors during the pre-construction stage

Terms	Definitions
1. Client's involvement	Client involved actively in the project
2. Client's complexity	Many parties represent the clients or clients always unsure of needs
3. Contractor	Inexperienced and irresponsible contractors
4. Design consultants	Inexperienced and irresponsible consultants
5. Project manager	Inexperienced and irresponsible project managers
6. Poor communication	Poor communication between contractors, consultants and clients
7. Poor relationship	Adversarial relationship among project parties due to differences in disciplines and hierarchy authority
8. Design variation	Change of design and drawing
9. Effect of traditional method	So used to traditional procurement
10. Novation	Client's consultants' appointments are transferred to the contractor
11. Budget constraint	Client is too concerned about keeping within the budget
12. Time constraint	Tight project schedule
13. Fast tracking pressure	A project delivery method whereby some portions of construction can begin before the design of other portions is completed
14. Project complexity	Complex in terms of design, size and building components
15. Poor project management	Poor in planning, organizing, leading and controlling
16. Inadequate design, scope and	Insufficient detail design, scope of works and planning

ANALYSING COSTS OF MATERIAL ACQUISITION FOR CONSTRUCTION PROJECTS

Yuan Fang and S. Thomas Ng[1]

Department of Civil Engineering, The University of Hong Kong, Pokfulam Road, Hong Kong.

Materials are important in every construction project as they attribute to a significant proportion of total costs. Because of this, planners and managers should carefully plan and control the ordering, distribution and storage of materials, i.e. the logistic process. Among various available project data, the cost of material acquisition can serve as an indicator to show the efficiency of logistic process. The research devises a material management tool by reference to the acquisition cost. In the proposed model, the delivery of materials is linked to the construction schedule to establish the determinant variables affecting the material acquisition costs *viz*. the delivery cost, storage cost and direct cost of material. Working start time and distribution times are selected as the determinant variables. With GAs (genetic algorithms) tools as simulation method, it is found that just in time delivery and a suitable construction schedule can lead to lower material acquisition costs.

Keywords: construction material, material logistics, acquisition cost, genetic algorithms.

INTRODUCTION

Much attention in construction management research is directed into improving productivity. This is crucial to contractors that strive to maximize their profit and business opportunity. Amongst various factors that could affect construction productivity, resource management is a critical but rather neglected issue. As stated in the European Construction Institute Total Productivity Management Report (ECI 1994), materials delivered to the site are a productivity-related aspect that calls for the introduction of well developed systems to monitor and control their flow. Early and accurate scheduling of materials based on the project schedule and keyed to the master plan for the storage of materials is highly desirable (Enshassi 1996).

Previous studies pointed out that the cost of materials in a typical construction project could be up to 70% of the total cost. Apart from the direct cost, the costs of materials also embrace the logistic cost. In the absence of much room to significantly reduce the direct cost, managers would try to minimize the costs for transporting and storage of resources. The importance of logistic cost has been highlighted in many studies. For instance, an empirical study in Finland (Wegelius 2001) has shown that the total logistic costs for the supply of plasterboard accounted for 27% of its purchase price. Sobotka and Czarnigowska (2005) postulated that any actions towards the rationalization of size, structure and organization of material consumption, along with proper planning of delivery and storage could increase project efficiency.

[1] tstng@hkucc.hku.hk

Despite this, the management of construction materials has seldom been taken seriously by contractors. Approaches for managing and handling materials are rarely examined thoroughly by planners, managers, purchasing teams and estimators at the preliminary project planning stage. Many managers still rely on maintaining excessive buffer stock on site without considering the costs of multi-handling, storage, disruption, damage, wastage, and so on. Besides, the responsibility of various participants and the time in which resource management planning is to be carried out remain vague in many construction projects. Good resource planning should, therefore, focuses on best satisfying the daily resource consumption of a project and cutting down on the unnecessary costs.

In this paper, a material acquisition model is proposed. The model examines the material costs with reference to the project schedule and storage/delivery method so as to support decision-makers in making material planning decisions. Genetic algorithms (GAs) are used for model development due to its simplicity, robustness and ability to handle various functional representation problems, such as those with very complex inter-functional and intra-functional relationship (Lam *et al*. 2001). The paper begins with a brief introduction of the material management practice. The mechanism of the proposed material acquisition model is highlighted. Finally, a case example is used to illustrate the concept of the proposed model.

MATERIAL MANAGEMENT PRACTICE

To avoid workers and plant staying idle, most construction projects tend to keep a certain amount of stock on site. This may inevitably increase delivery and inventory costs due to multiple handling and storage. As the storage space on site is limited, sometimes an intermediate warehouse may be set up by the contractor nearby for the temporary storage of larger construction components. This may further lengthen the communication channel and delivery process. For these reasons, it may be desirable to apply a Just-In-Time (JIT) concept. Using JIT means materials are delivered directly from supplier’s warehouse to the site JIT to the request. Akintoye (1995) suggested that the JIT philosophy could be applied for logistics management on worksites to raise the productivity levels. A study in Denmark reported a 10% rise in productivity in housing projects when JIT was adopted (Bertelsen 1995).

A modified system consists of both on-site storage and external supply components as shown in Figure 1 is proposed. While less bulky materials are stored on site, larger construction components shall be kept at suppliers’ warehouse. In Figure 1, the construction process consists of activities *w*1, *w*2 and *w*3 with a different start dates, and each activity will necessitate certain resources to complete. Assuming that three resources (i.e. C1, C2 and C3) are needed for the project, the manager shall refer to the sequence of activities and their start dates before initiating an order.

Upon receiving the request, the purchasing team would review the amount of stock on site before the order is placed such that the storage, transportation and purchasing cost can be minimized. For bulky items, the manager will review the progress of work and liaise with the supplier to determine the exact date and time for material delivery. Therefore, the manager must maintain good communication with the purchase team and suppliers to keep them updated on the progress and resource needed.

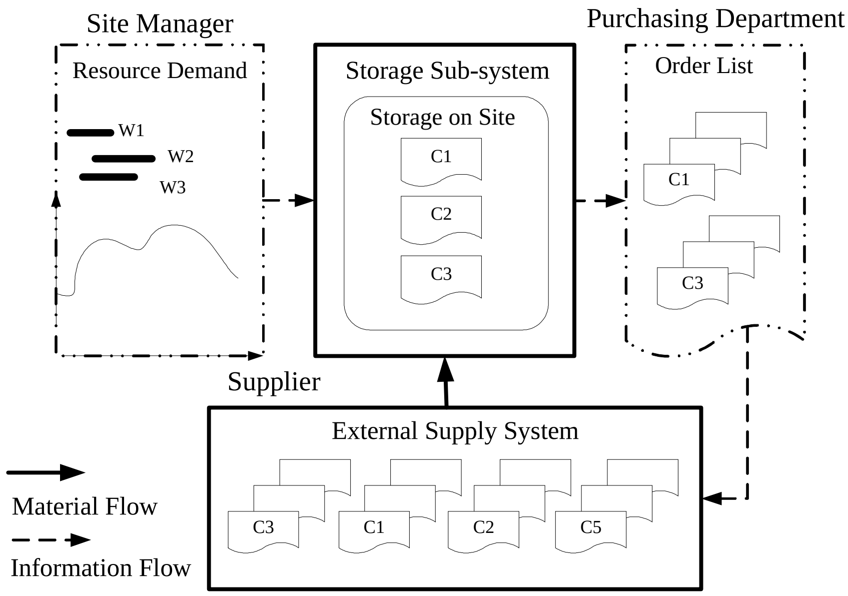

Figure 1: Material acquisition model

MATERIAL ACQUISITION COST FUNCTIONS

Based on the modified system, the following assumptions are derived for subsequent model simulation.

1. The total quantities of resource consumption can be determined when an order is placed. The purchasing team can place an order approximate to the total quantities of materials needed.
2. As the supply contract should have been signed and the terms agreed, it is not necessary to consider the discount rate at this stage.
3. The cost for ordering is considered minimal and is therefore ignored.
4. The quantity of distribution quantity is the same each time, while the frequency of delivery is determined by $q_1 = q_2 = ... = q_i = ... + q_n = \frac{\sum_{j=1}^{D} R}{n}$, in which R is the daily resource consumption.
5. The delivery interval is separated by the delivery times equally.

The most basic form of the material acquisition function is represented by Equation 1:

$$K = K_L + K_D \quad (1)$$

where K represents the total material acquisition costs; K_L and K_D are the logistic costs and direct costs respectively.

The direct cost (K_D) is computed by:

$$K_D = c_j \cdot \sum_{i=1}^{n} q_i \quad (2)$$

where c_j is the unit price of material j; q_i is the quantity of delivery i; and n signifies the total number of delivery.

The logistic costs (K_L) include the cost of transportation from the supplier's warehouse to site (K_T); cost of capital being frozen as a result of the inventory (K_C); cost of penalty on material shortage (K_P); and cost of storage on site (K_S).

$$K_L = K_T + K_C + K_P + K_S \tag{3}$$

$$K_T = k_{et} \cdot n \tag{4}$$

where k_{et} represents the cost of external transport per delivery.

$$K_C = c_j \cdot p \cdot \sum_{i=1}^{D} s_s \tag{5}$$

where p denotes the cost of capital being frozen for the inventory per number per day; D is the number of days; and s_s is the volume of inventory on the building site per day.

$$K_P = \sum_{i=1}^{D} p_d \cdot S_i \tag{6}$$

where p_d is the penalty for each item of material in shortage; and S_i is the number of material shortages on i day.

$$K_S = C_s \sum_{i=1}^{D} s_s \tag{7}$$

where C_s is the inventory cost in building site per day.

The above equations describe the optimization problem on the basis of a period of time. The optimization of logistic processes, however, is a dynamic succession of daily optimization problems, which will be treated independently, even though they are not. The one-day problem solution sets the initial conditions of the problem for the next day. Therefore, different solutions for the same daily problem originate a different scheduling problem for the coming day. Here, the performance of the system is analysed by considering a longer time units, such as weeks, months or the whole project period.

IMPACTING VARIABLES

The cost functions capture the relationship between the costs of material acquisition and certain variables. In the cost functions, some parameters – like the cost of external transportation per delivery and the cost of maintaining an inventory, and so on – may remain unchanged. However, some could vary and any changes of such variables will affect the total cost.

Material consumption variable (x_1)

One of the variables affecting material consumption is the start time of an activity (T_{is}) as it must satisfy the following:

$$T_{iES} \le T_{is} \le T_{iLS} \tag{8}$$

$$\max\{T_{js} + t_j\} \le T_{is} \tag{9}$$

where T_{iES} is the activity's earliest start time; T_{iLS} is the activity's latest start time; T_{js} represents all the start times preceding an activity; and t_j is the activity duration.

Although this variable does not appear in the cost functions, different activity start times will lead to different resource demands and, hence, different order schedules. The change of x_1 will result in different K. As Equations 8 and 9 require the activity to begin before the latest start time but after the earliest start time, an activity cannot begin until all the preceding activities are accomplished. The difference between T_{iLS} and T_{iES} is the flexible time FT. The activity can begin at anytime during this period. A suitable activity start time will give a perfect resource consumption curve, which will result in the lowest cost.

Distribution variables (x_2)

The distribution variable concerns the number of distribution (n) from suppliers' warehouses to the site, i.e. $0 < n \leq D$.

This variable decides how many distributions will be made by the suppliers. The purchasing team must decide the best timing to supply the materials to site in order to avoid overstock or materials shortage from occurring. Any material bottlenecks will lead to construction delays and induce extra costs. Yet, an overstock will in turn increase the storage fee and frozen capital and both will affect the profit.

GENETIC ALGORITHMS

Genetic algorithm (GA) technique is used for model development. GAs originate from computer simulation research in biology systems. Through the inspiration of biological simulation techniques, Professor Holland and his students in Michigan University developed a self-adaptation optimization technology based on genetic and evolution concepts (Holland 1975; Goldberg 1989). GAs perform the three genetic operations –selection, crossover and mutation – on a population of individuals (i.e. genes). A solution to a given problem is represented in the form of a string called a 'chromosome', which consists of a set of genes holding a set of values for the optimization variables (Gloderg 1989). The fittest individuals in the environment (optimization problem) will have a higher chance to survive for mating (crossover). The new population will replace the ones that did not survive. Therefore, the new generation ought to be fitter than its parents are and with less chance of dying. This process continues until a sufficient fitness is achieved (Silva *et al*. 2005)

For GA programming, there are three main aspects to be considered. The first is the coding method, and a suitable representation of the solutions in form of a chromosome should be established. For the material acquisition cost simulation, the variables of x_1, x_2 can be defined as the chromosomes. The initial populations of these variables are generated randomly. The second issue to be considered is the fitness function. This function determines how well an individual is fitted to the environment. In this paper, the material cost functions are used as fitness function. The last aspect is the operations. Each of the three operations (i.e. selection, crossover and mutation) can be performed in various ways; this has been the subject of extensive studies in the last decade, as the way in which the operations are executed can influence the efficiency of the algorithm significantly. Therefore, many parameters such as the size of the population, crossover and mutation rate, etc., have to be determined.

RESULTS AND DISCUSSIONS

Using a project schedule with eight construction activities (Sun 2004) as shown in Table 1, the unit price of material c_j is 2.55; the cost of frozen capital for inventory p is 0.24; the penalty for each item of material shortage p_d is 10; the cost of external transportation per delivery is 250; and the daily cost of site storage C_s is 5 per item (Sobotka and Czarnigowska 2005).

Table 1: Working schedule

Work	Duration	Work Earliest Start Time (T_{iES})	Work Latest Start Time (T_{iLS})	Flexible Time (*FT*)	Resource Consumption Per Day (*R*/*D*)
A	8	0	0	0	600
B	10	0	8	8	300
C	10	8	8	0	500
D	11	8	23	15	400
E	17	8	17	9	300
F	16	18	18	0	700
G	9	19	34	16	600
H	9	34	34	0	400

According to Table 1, $\sum_{i=1}^{n} q_i = \sum_{d=1}^{43} R = 42{,}500$. The variables in this model are activity start time (x_1) and number of times for delivery (x_2). The activity start times of activities B, D, E and G are considered as variables because they have flexible time. Here, x_1 is an integer matrix, where $T_{iES} \leq x_{1i} \leq T_{iLS}$; and $x_{12} \in (0{,}8]$, $x_{14} \in (8{,}23]$, $x_{15} \in (8{,}17]$, $x_{17} \in (19{,}34]$. Besides, x_2 is an integer, where $0 < x_2 \leq D$; $x_2 \in (0{,}43]$.

Here, 40 individuals and 30 generations were set for the simulation. The individuals get closer to an optimal result as the generations evolve. The simulation results of the minimal cost and population average cost for each generation are shown in Table 2.

Table 2: Minimal cost and population average cost of each generation

Generation	*1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*
Minimal Cost (1.0e+006)	0.4422	0.4706	0.4385	0.4043	0.2813	0.2813	0.2813	0.2464
Average cost (1.0e+006)	1.3123	1.3244	0.7976	0.9779	0.9492	0.7671	1.0451	0.7120
Generation	*9*	*10*	*11*	*12*	*13*	*14*	*15*	*16*
Minimal Cost (1.0e+006)	0.2464	0.2464	0.2632	0.2632	0.2632	0.2424	0.2464	0.2464
Average cost (1.0e+006)	0.7306	0.6618	0.7792	0.7889	0.6076	0.6902	0.6686	0.5401
Generation	*17*	*18*	*19*	*20*	*21*	*22*	*23*	*24*
Minimal Cost (1.0e+006)	0.2173	0.2173	0.2173	0.2173	0.2173	0.2173	0.2173	0.2173
Average cost (1.0e+006)	0.5356	0.5814	0.6934	0.5071	0.4777	0.4922	0.6172	0.5717
Generation	*25*	*26*	*27*	*28*	*29*	*30*		
Minimal Cost (1.0e+006)	0.2173	0.2173	0.2173	0.2173	0.2173	0.2173		
Average cost (1.0e+006)	0.5340	0.4018	0.4305	0.3550	0.5260	0.4780		

According to Table 2, the minimal cost decreases as the generation times increase. At the 17th generation, the minimal cost becomes stabilized. The population average cost for each generation is also in a decreasing trend, although there are still mutations occasionally. The minimal material acquisition cost is \$21,730 and the variables for this result is (x_{12},x_{14},x_{15},x_{17},x_2) = (1,9,13,32,41). This implies that when activities B, D, E and G begin onthe 1st, 9th 13th and 32nd days respectively, and the material distribution is based on the daily delivery until the 41st day, the material acquisition cost will be the least. The material to be delivered to site is 1,037 items per day.

Figure 2: Resource consumption and storage

Figure 2 shows the daily resource consumption and daily storage when $(x_{12},x_{14},x_{15},x_{17},x_2) = (1,9,13,32,41)$. As shown, there are still some shortages from dates 19-27, 34 and 35. This is due to an excessive requirement of materials during these periods, notwithstanding the adjustment of the start date for the activities. In other words, such a high material requirement cannot be avoided by simply adjusting the activity start date. Since the optimal delivery quantity and interval is based on the minimal material acquisition cost, the purchasing team can increase the size of delivery size during those periods that are likely to have material shortage.

CONCLUSIONS

In the construction industry, careful planning of construction materials plays an important part in increasing productivity. As the materials costs contribute to a large proportion of the total construction costs, good resource planning can benefit a project having time and cost constraints. In this paper, a material acquisition model is set up and the related cost functions are highlighted. The model aims to optimize the material acquisition cost. The simulation is carried out in Gas to help identify the relationships amongst the cost, delivery method and project schedule.

This study can be seen as an initial step towards an integrated construction logistic modelling and simulation. The resource acquisition model in the paper is based on the JIT concept where no off-site warehouse is used. The outcomes of this paper form a basis for further research. Further research will focus on resource planning of systems with an intermediate warehouse, systems with more than one construction project, etc. The assumptions in this study can also be modified according to the modelling situation.

Lean and agile supply chain strategies for high volume manufacturing with standardized products and a repetitive environment have been well explored. In contrast, there is a lack of research into low volume engineer-to-order (ETO) products in contexts such as construction. The purpose of this paper is to examine characteristics of the lean and agile paradigms and explore their relative importance to ETO construction projects. It helps to overcome the confusion regarding 'is lean appropriate for a construction supply chain?'. This is a conceptual study developing definitions and models for ETO supply chains by synthesizing of available literature. Characteristics of lean and agile paradigms are reviewed and mapped against the ETO structure. The classification developed makes the case that construction-related ETO supply chains have far more in common with the agile characteristics.

Keywords: agile construction, lean construction, supply chain management.

INTRODUCTION

Two paradigms that have received a significant amount of attention in supply chain management are lean thinking and agile manufacturing. The term 'lean construction' has been coined to describe applications of lean thinking in construction and has received a lot of attention from both academics (Howell 1999; Koskela 1992) and UK government initiatives (Egan 1998). Agility has also been proposed as a possible strategy in construction, but it has received much less attention (Barlow 1998; Naim and Barlow 2003).

Some of the recent literature questions the extent to which lean thinking is a universal strategy that can be applied in all contexts (Christopher and Towill 2002; Cooney 2002; James-Moore and Gibbons 1997; Naylor *et al*. 1999). Similarly, the applicability of lean thinking in a construction environment is being questioned (Barlow 1998; Thomas *et al*. 2002). This paper aims, first, to define the context of construction projects relative to other supply chain structures and, secondly, it sets out the possible lean and agile strategic choices for such construction projects. A fundamental question answered in this paper is 'are lean and agile strategies appropriate for engineer-to-order construction projects?'.

This paper is conceptual, based on a synthesis of academic literature on lean and agile operations and supply chain structures. In the next section the construction

[1] goslingj@cardiff.ac.uk

environment is characterized as an engineer-to-order supply chain and is compared with other supply chain structures. Then, the key differences highlighted in the lean thinking and agile manufacturing literature are described. Finally, the ETO classification is mapped against the characteristics of lean and agile strategies to examine possible applications.

THE ENGINEER-TO-ORDER SUPPLY CHAIN STRUCTURE

A range of supply chain structures have been proposed to illustrate the diverse range of supply chain operations. Based on Hoekstra and Romme (1992), Naylor *et al*. (1999), Yang and Burns (2003), Olhagar (2003) and Lampel and Mintzberg (1996) six different supply chain structures can be defined: engineer-to-order (ETO), buy-to-order (BTO), make-to-order (MTO), assemble-to-order (ATO), make-to-stock (MTS) and ship-to-stock (STS). Based on the aforementioned authors, Figure 1 shows the level of standardization and customization that takes place before a customer order is received in each of the different supply chain structures. The line that runs through the different structures shows the point at which the customer order enters the supply chain. The customer, in this case, is taken to be the next direct receiver of the material in the supply chain as opposed to the ultimate end user.

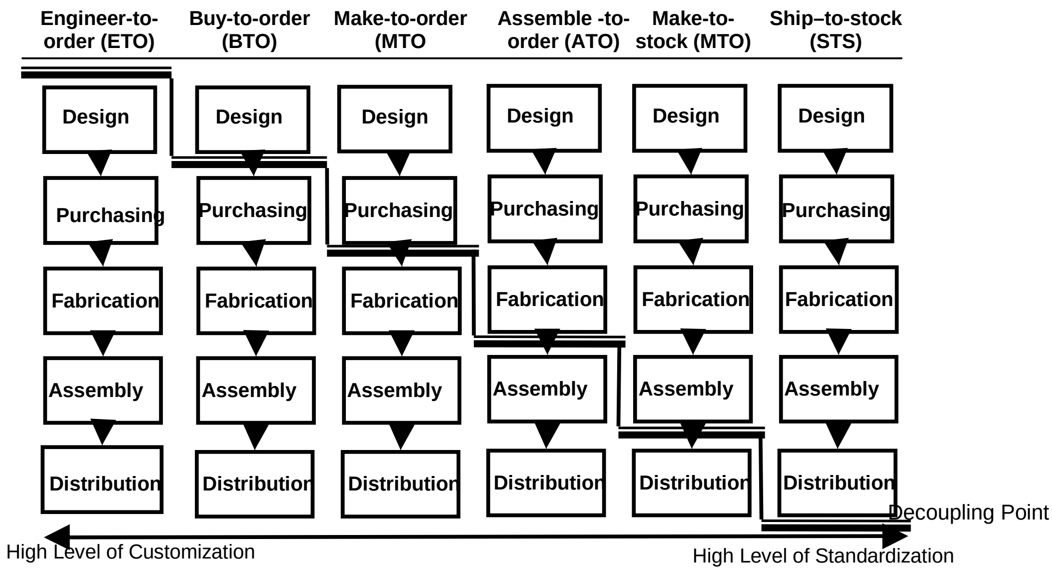

Figure 1: The six different supply chain structures (synthesis from various sources)

In order to add clarity to the ETO supply chain structure, a literature review was conducted on ETO products and supply chain structures. Differences between supply chain structures were identified through this literature review and were subsequently synthesized into a number of dimensions that can be used to differentiate between different structures. Table 1 summarizes the main differences between the supply chain structures. These have been categorized as inputs and outputs, with inputs illustrating the strategic enablers and outputs showing the outcomes visible to the customer. The following descriptions highlight some of the key characteristics by reference to the extremes of the spectrum and to intermediate structures as appropriate.

Core competences

Each of the supply chains described has a core competence. The ETO structure has a core competence of delivering highly customized products to meet an individual customer order. A BTO structure is able to deliver customized products that have diverse raw materials and components and the MTO excels at delivering customized products that have common raw materials and components. An ATO supply chain structure has a core competence in delivering cost effective mass customization. MTS and STS environments, on the other hand, excel at managing standardized, high volume products to either a pre-defined central outlet or local outlets while offering low cost and instant availability (Amaro *et al*. 1999; Naylor *et al*. 1999).

Table 1: Attributes of different supply chain structures (synthesis from various sources)

Attributes	**Engineer-to-order (ETO)**	**Buy-to-order (BTO)**	**Make-to-order (MTO)**	**Assemble-to-order (ATO)**	**Make-to-stock (MTS)**	**Ship-to-stock (STS)**
Outputs						
Customization	Extremely high	Very high	High	Moderate	Low	Very low
Time to market	Extremely high	Very high	High	Moderate	Low	Very low
Volume	Extremely low	Very low	Low	Moderate	High	Very high
Complexity	Extremely high	Very high	High	Moderate	Low	Very low
Inputs						
Decoupling point	Design	Purchasing	Fabrication	Assembly	Distribution – central	Distribution – local
Purchasing	Identify sources of supply	Schedule product deliveries from suppliers	Hold raw materials/ components	Fabricate or buy modules	Hold finished goods centrally	Hold finished goods locally
Stocks	No stock	No stock	Raw materials	Pre-assembled modules	Finished goods	Finished goods
Design	Produce new design	Modify existing design	Pick from wide range of options	Pick from limited range of design options	Take design as is	Take design as is
Method	Project/job shop	Job shop	Batch	Batch/Flow	Flow	Flow
Forecasting	Extremely low	Very low	Low	Moderate	High	Very high

Level of customization

Offering customization to the market is increasingly becoming recognized as a source of strategic advantage (Lampel and Mintzberg 1996; Pine 1993; Salvador *et al.* 2001). This recognition of the strategic importance of satisfying true customer demand has been reflected in the supply chain literature, where market-driven supply chains have received much attention (Childerhouse 2002). The ability to fully customize according to the needs of an individual customer is a central feature of the ETO supply chain (Amaro *et al.* 1999). In other supply chain structures the levels of customization offered to the customer are lower. In the ATO structure customization is delivered through mass customization. Choice for the customer would be offered in the form of standardized options and would be configured to order from stock of 'modules' (Naylor *et al.* 1999). In a MTS or STS supply chain the customer has little scope for customization and would have to take a standard product 'off the shelf'.

Time to market

The time to market for a product has also been used to categorize supply chains and manufacturing operations (Fisher 1997; Olhager 2003). The production to delivery time ratio (P/D ratio) is often quoted as a method to make decisions about time to market. If the production lead time is greater than the desired maximum customer delivery time that is acceptable to the customer (P/D ratio is greater than 1) then a produce to stock, that is, either MTS or STS structure is more appropriate. If the production lead time is lower than the desired maximum customer delivery time that is acceptable to the customer (P/D ratio is lower than 1) then a supply chain does not necessarily need to produce to stock (Olhager 2003).

In an ETO structure, a customer is often exposed to the total supply chain, which can include design, procurement, manufacture, assembly, testing and commissioning of a product, so the time to market can be extremely high. However, it is likely that the customer will be prepared to wait longer for a fully customized product and may agree to a due date at a negotiated cost at the design stage (Amaro *et al.* 1999). The more a supply chain resembles a STS structure the quicker a customer can be satisfied.

Production volume

Product mix and volume have long been key classifications for production and supply chain operations (Olhager 2003; Salavador 2002). High and low volume supply chains pose different challenges to operations. When compared with high volume supply chains, low volumes often pose problems in terms of power regimes and uncertainty in the volumes of components required (Hicks 2000). ETO products are generally characterized as high variety and extremely low volume, possibly ‘one-off’ builds, whereas MTS products are often produced in large volumes (Cameron *et al.* 2004). The more a supply chain resembles a STS structure the higher the production volume will tend to be.

Product complexity

The complexity of a product will have a bearing on the supply chain structure that is employed (Hicks *et al.* 2000). Product complexity refers to the depth of the product structure, the amount of sub-assemblies and the amount of components that form the product. An ETO product will often have a deep product structure, complex sub-assemblies and many components. Consequently, the supply networks for complex products tend to be broad upstream, whereas less complex products tend to be dominated by fewer players (Cameron *et al.* 2004; Hicks *et al.* 2001). In contrast, a STS structure is likely to be suitable for a product with a shallow product structure. The ATO and MTO structures are likely to have moderate depth of product structure with careful thought given to modularity, product architecture and management of product variety (Salvador *et al.* 2002; Boothroyd *et al.* 1994; Pine 1994).

The decoupling point

The customer order decoupling point (CODP) is a stock holding point that separates the part of the supply chain that responds directly to the customer from the part of the supply chain that uses forecast planning. The decoupling point can act as a strategic buffer against the variability in demand and an efficient way of scheduling standardized parts. Upstream from the CODP all products are produced to forecast; downstream from the CODP all products are pulled by the end user (Hoekstra and Romme 1992; Naylor *et al.* 1999; Christopher 2000; Olhager 2003; Mason-Jones *et al.* 2000). Figure 1 shows the decoupling point for the six different supply chain structures. As an example of its application let us consider three of the strategies. The decoupling point in the ETO supply chain lies at the design stage. The customer order asserts a high level of customization for all activities in the supply chain. Distribution, assembly, fabrication, purchasing and design are all customized according to customer order. The decoupling point in the STS supply chain is the local distribution channel; here there is no customization whatsoever.

Purchasing and stocks

The position of the decoupling point, described above, has a significant impact on the purchasing and strategic stockholding. Suppliers in an ETO structure are identified and mobilized in response to a specific customer order and would, typically, service a particular project. An ETO product may put every order out to competitive tender to a group of potential suppliers with the correct capabilities (Amaro *et al.* 1999; Hicks *et al.* 2000). Stock will then be purchased according to the needs of a specific project. In a BTO structure the supply chain is established but no stocks are purchased. Product deliveries are scheduled from established suppliers after an order has been received. At the other end of the spectrum, the STS structure holds finished goods from established suppliers at a local distribution channel in order to satisfy forecasted demand very quickly.

Design

The level of influence that a customer has in the design process has significant implications for the supply chain. For example, design for production and assembly techniques, such as modularity, simplified product architecture, carefully revised product commonalities and interfaces, have been promoted as methods of reducing costs and supporting mass customization (Boothroyd *et al.* 1994). Based on Amaro *et al.* (1999), the degree of design customization can be categorized along five different classifications: produce new design; modify an existing design; pick from a wide range of design options; pick from a limited range of design options; and take existing design as is. An ETO project will require a new design with a large amount of customer input, whereas a MTS or STS supply chain, for example, designs for a general market based on recommendations by marketing departments (Rahman *et al.* 2003). Designs will show increasing levels of standardization and reduced direct customer input the further a supply chain moves away from the ETO structure. In a BTO supply chain similar existing designs are modified to new customer requirements whereas the MTO and ATO mass customization strategies are used to offer degrees of standardized options.

Production method

The production method refers to the technique used to manufacture or assemble a product. Four popular assembly methods are job shops, batching, flow and project. The technique used will vary depending on the complexity and volume of the product (Hicks *et al.* 2000; Ballard 1998; Porter *et al.* 1999). The production method for an ETO supply chain will incline towards a project or job shop assembly method. Project production offers a unique product, requiring large-scale inputs to be coordinated so as to achieve customers' requirements. Various projects may be 'live' at any one time, resulting in a multi-project environment (Porter *et al.* 1999). A STS structure is more likely to involve flow production. Flow production is characterized by the large volume production of a small range of standard products (Porter *et al.* 1999). An ATO structure may involve a mixture of batch and flow production, with flow being utilized upstream from the CODP and batch utilized downstream from the decoupling point.

Level of forecasting

The ease with which demand for a product can be forecasted has also been widely used to classify different supply chains (Fisher 1997; Naylor *et al.* 1999; Olhager 2003). The level of forecasting is closely related to demand volatility and the level of customization. In supply chains where demand volatility and customization is high the potential for forecast error usually increases. Supply chains that have more stable demand characteristics and standardized products can usually forecast demand more accurately.

The level of forecasting possible in an ETO supply chain structure is extremely low in relation to other structures. The high degree of customization and low volumes involved result in high levels of uncertainty and lumpy demand patterns. Any stock runs the risk of becoming obsolete and incorrect to specification. When products are more standardized and volumes are higher, such as in the MTS and STS structures, the level of forecasting possible increases, as it is possible to forecast aggregate demand more accurately. ETO companies often have to forecast skills, capacities and industry trends, whereas MTS companies are required to forecast the type of product, quantity and location (Rahman *et al.* 2003).

DIFFERENTIATING LEAN AND AGILE SUPPLY CHAIN STRATEGIES

Since the advent of agility (Iacocca Institute 1991) an academic debate has taken place to distinguish lean and agile philosophies and their applicability (Naylor *et al.* 1999; Christopher and Towill 2000; Hines *et al.* 2004; Van Hoek 2000; Vonderembse *et al.* 2006). Some have stated that lean is a prerequisite for agile supply (Goldman *et al.* 1995; Narasimhan *et al.* 2006); others have argued that lean is an overall umbrella of which agility is part (Papadopoulou *et al.* 2005). The aim here is to identify the principal strategic differences between the lean and agile paradigms at the supply chain level. An extensive literature review was conducted to highlight the strategic differences. Table 2 summarizes the key differentiators of lean and agile strategies. Naylor *et al.* (1999) offer useful definitions to summarize the differences between these paradigms, which have been widely adopted by, among others, Christopher and Towill (2002) and Narasimhan *et al.* (2006). Leanness means developing a value stream to eliminate all waste, including time, and to ensure a level schedule. Agility means using market knowledge and a virtual corporation to exploit profitable opportunities in a volatile market place.

Table 2: Differentiating lean and agile strategies (synthesis from various sources)

Differentiator	Lean	Agile
Outputs		
Market winner	Cost	Service level
Performance characteristics	Cost efficiency	Delivery and flexibility
Product variety	Suitable for low variety	Suitable for high variety
Variability	Suitable for low variability	Suitable for high variability
Inputs		
Responding to the market	Confirmed orders/smooth demand/level scheduling	Respond quickly to market changes
Forecasting method	Algorithmic	Consultative
Supply chain relationships	Close relationship with a small number of suppliers	Virtual/extended enterprise
Sourcing decisions	Cost and quality	Speed, flexibility and quality
Approach to waste	Reduce the 7 wastes	Focus on service level, not eliminating waste
Capacity	Smooth capacity	Hold spare capacity
Time compression	Remove NVA and shorten as long as it does not increase cost	Invest aggressively to reduce lead times

Market winner

Classifications have been developed to highlight that lean and agile strategies differ in their suitability for different markets. The application of market winners and qualifiers has been used widely to distinguish markets for lean and agile strategies. If service level is the market winner with cost, quality and lead time as the market qualifiers, then agility is more appropriate. If cost is the market winner and quality, service level and lead time are the market qualifiers, then leanness is more suitable (Mason-Jones *et al.* 2000; Naylor *et al.* 1999).

Performance characteristics

Empirical studies have attempted to highlight the performance characteristics of lean and agile supply chains (Narasimhan *et al.* 2006; Power *et al.* 2001; Sharp *et al.* 1999). Cost efficiency is a primary performance outcome associated with lean thinking whereas agile supply chains demonstrate superior abilities in terms of delivery and flexibility (Narasimhan *et al.* 2006). More agile companies have been found to be more customer focused than less agile companies (Power *et al.* 2001) and agile supply chains have also been found to have developed abilities to continuously change (Sharp *et al.* 1999).

Product variety and variability

Product variety and volume are frequently alluded to in the lean and agile literature. Variety and variability have both been offered as a basis for selecting lean or agile strategies. High variety and high variability is commonly associated with the application of agility and low variety and low variability with the application of leanness (Christopher 2000). Much of the literature suggests that a feature of the agile supply chain is flexibility with regard to product lines and variants. An agile supply chain responds accurately to markets through customization (Christopher 2000; Yusuf *et al.* 1999). The agile supply chain also excels at shifting capacity to meet sporadic changes in demand, which is particularly desirable in volatile markets (Yusuf *et al.* 2003).

A focal point of the criticism of lean supply chains has been their inability to cope with variability. In order to add value to the customer the lean approach seeks to find ways to manage variability by flattening or controlling demand (Naylor *et al.* 1999; Hines *et al.* 2004). It has been noted that in high value, low volume industries the implementations of leanness are scarce. This is due to the high degree of customization, inherent complexity of the process routings, diverse processing times and high product mix. It is also difficult to map the flow and level production in such environments (Papadopoulou *et al.* 2004). Agility excels in fast moving volatile markets that place a premium on shifting quickly in terms of product lines and product volume; leanness excels in markets with stable demand and standardized product lines (Christopher 2000; Mason-Jones *et al.* 2000; Naylor *et al.* 1999).

Responding to the market

A key differentiator between lean and agile approaches is the response to the market and uncertainty. Should a supply chain focus its energies on stabilizing uncertainty or becoming flexible in order to take advantage of market changes? A lean agenda seeks to drive out fluctuations by smoothing demand and achieving a level schedule. The lean enterprise seeks to deliver value through careful consideration of the cost–value proposition (Hines *et al.* 2004; Naylor *et al.* 1999; Papadopoulou *et al.* 2005). A key attribute underpinning agility is a capability to reconfigure in a way that responds quickly to the variations and disturbances in the marketplace (Christopher 2000; Naylor *et al.* 1999; Sharp *et al.* 1999; Yusuf *et al.* 1999). To be truly agile a supply chain must be market sensitive, with capabilities in reading and responding to real time demand and routine and painless adaptation (Yusuf *et al.* 1999).

Forecasting method

The forecasting method used for lean and agile supply chains can also be distinguished. Demand in an agile supply chain may be met by 'intelligent' consultation and through developing abilities in becoming market sensitive (Christopher 2000; Mason-Jones *et al.* 2000). This consultation approach places an increased significance on the need to distribute real time data throughout the supply chain (Christopher 2000; Power *et al.* 2001; Yusuf *et al.* 1999). Demand in a lean supply chain is much more likely to be met by forecasting (Mason-Jones *et al.* 2000).

Supply chain relationships

There are differences in the lean and agile literature on how supply chain relationships should be treated and managed. Lean thinking reinforces the need for close supplier relations, a reduced supply base organized under a tier system. Supplier associations, systems integrators and exchange of personnel are documented as examples of lean commitment to relationship building. At the centre of this type of collaboration is transparency, jointly defined value, joint analysis of waste and working together to allow a smooth flow of material through the supply chain. It emphasizes joint commitment to reducing waste and continuous improvement (Hines 1994; Womack and Jones 1996).

The literature on agility suggests the virtual or extended enterprise as a key part of the agile supply chain (Christopher 2000; Yusuf *et al.* 1999; Goldman *et al.* 1994; Gunasekaran 1999; Sharp *et al.* 1999). A critical mass of organizations with diverse core capabilities that can be combined to satisfy different customers is necessary. The virtual supply chain aims to pull together resources and skills that can quickly respond to individual needs and have been described as 'fluid clusters' of suppliers or project teams that come together to meet a particular need or opportunity (Mason-Jones *et al.* 2000). Virtual enterprises are temporary and represent a fundamental source of flexibility for the agile supply chain (Gunasekaran 1999). Competencies and resources are held in the form of a virtual or extended enterprise in order to reconfigure and respond quickly in terms of expertise, skills, materials and extra capacity (Yusuf *et al.* 2003). The approach to choosing suppliers may also reflect a lean or agile agenda. In a lean supply chain, suppliers with competencies in low cost and high quality will be required, whereas agility calls for suppliers who can demonstrate speed, flexibility and quality (Vonderembse *et al.* 2006).

Approach to waste and capacity

Leanness calls for the elimination of all waste. In particular, the seven wastes of over-production, waiting, transportation, inappropriate processing, unnecessary inventory, unnecessary movement, defects have been widely quoted (Womack *et al.*. 1990). In a 'pure' lean supply chain there would be no slack. In an agile supply chain, where there is a focus on service level, spare capacity may be reserved and stock needs to be carefully considered to meet rapid changes in end user requirements (Naylor *et al.* 1999; Christopher and Towill 2000; Yusuf *et al.* 1999). A lean supply chain advocates standardized flows of material according to just-in-time principles and close integration of supply chain partners. Internal production flows can be stabilized by Kanban systems and continuous improvement initiatives incrementally drive out forms of waste. An agile supply chain also seeks to drive out waste but not at the expense of speed and flexibility. Strategic stock points (or decoupling points) may be used to reduce the time of finished goods to the marketplace and spare capacity may be held to deal with fluctuations in demand.

Time compression

Time compression plays a crucial role in both lean and agile philosophies. The importance of time compression for agility has been well documented (Mason-Jones *et al.* 1999; Towill 2003; Yusuf 1999). Lean thinking also promotes the reduction and elimination of non-value-adding time and classifies it as a waste (Womack and Jones 1996). The difference in the approach to time compression is that lean thinking aims to shorten lead time as long as it does not increase costs; an agile supply chain may seek to aggressively invest in ways to reduce lead times even if it incurs a cost but maximizes service to the customer (Vonderembse *et al.* 2006).

MATCHING LEAN AND AGILE CHARACTERISTICS TO ENGINEER-TO-ORDER PROJECTS

An important assertion in this paper is that the majority of construction projects have much in common with the ETO supply chain. The scope of construction is diverse, but many projects will reflect the majority of the ETO supply chain structure attributes set out in Table 1. Previous classifications have argued that increasing levels of leanness are appropriate in the STS structure and increasing levels of agility are appropriate moving through the supply chain structures towards the BTO (Mason-Jones *et al.* 2000; Naylor *et al.* 1999). Using the classifications outlined in the previous sections of this paper, Table 3 shows the proposed relationships between the attributes of the ETO structure and the characteristics of agility, which have not previously been researched. Some key themes that emerge from matching characteristics of leanness and agility into the ETO project environment are now discussed.

Responding quickly to market changes

Owing to the strategic outputs of an ETO supply chain (see Table 3), responding to the market becomes a premium. This supports the application of an agile strategy. A supply chain can either attempt to become more responsive or can manage the demand flow. Developing flexibility and market sensitivity, in the case of the ETO supply chain, appears to be of greater importance than developing stability and efficiency. The responsiveness of an ETO supply chain will depend, largely, on the network of collaborative firms and suppliers based on core competencies to meet the market demand in good time. Sourcing decisions in an ETO should be biased towards speed, flexibility and quality rather than purely cost considerations. The agile ETO supply chain responds to customization requirements and sudden demand swings by holding extra capacity in the form of the virtual/extended enterprise and by placing the decoupling point at the design stage.

Managing customization, variety and variability

Ability to manage product variety and variability is crucial for construction enterprises. A possible strategy to manage the diverse product variety in construction is to ‘forward shift’ through supply chain structures via modularity. A firm can seek to forward or backward shift through supply chain structures for strategic benefit. A forward shift may help to reduce the delivery lead time to customers and increase manufacturing efficiency while a backwards shift may help to increase the knowledge of customer orders at the time of production (Olhager 2003). In the house-building and commercial sector there have been moves to forward shift through the supply chain structures by adopting modular design and greater standardization of supply chain activities (Barlow *et al.* 2003; Voordijk *et al.* 2006). This kind of modularity moves construction away from the ETO structure towards the assemble-to-order structure and helps to combine aspects of leanness and agility. In the manufacturing literature this combination has been termed 'leagility' (Naylor *et al.* 1999).

Invest aggressively to reduce time to market

The time to market in the ETO construction projects is often extremely high. Previous research highlights the importance of lead time reduction in the ETO environment. Late changes in design and competitive bidding have been suggested as major contributors to long lead times in ETO projects (Elfving *et al.* 2005). Concurrent engineering techniques, performance measures and business process re-engineering have been suggested as strategies to compress time (Gunasekaran 1999; Towill 2003).

Table 3: Relationships between the ETO supply chain structure and agile characteristics

Attributes of engineer-to-order supply chains structure	Proposed relationships to agile characteristics
Outputs	
Highly customized products to meet an individual customer order	• Responding quickly to the market (input) • Focus on service level, not eliminating waste (input)
Extremely high level of customization	• High variety (output) • High variability (output) • Hold spare capacity (input)
Extremely high time to market	• Invest aggressively to reduce lead times (input) • Respond quickly to the market (input)
Extremely low production volume	• High variability (output)
Extremely high product complexity	• High variety (output)
Inputs	
Decoupling point at the design stage	• Product variety (output) • Responding to the market (input)
Identify sources of supply to order	• Virtual/extended enterprise (input) • Sourcing decisions based on speed, flexibility and quality (input) • Hold spare capacity (input)
No stock	• Delivery and flexibility as desired performance characteristics (output)
Produce new design for each order	• Product variety (output) • Responding to the market (input)
Project/job shop method	• High variety (output) • Hold spare capacity (input)
Extremely low level of forecasting	• Consultative forecasting method (input)

CONCLUSIONS

This is, primarily, a conceptual study developing definitions and models for ETO supply chains. This paper provides models and constructs as a basis to think about agility in the ETO sector. The literature on supply chain structures has been reviewed and the attributes of six supply chain structures have been described. This paper has shown that construction has much in common with the ETO supply chain structure. Literature on lean and agile strategies has also been synthesized to develop a table of differentiators to distinguish lean and agile strategies. Strategic characteristics of agility have been mapped against attributes of ETO supply chains to develop frameworks and definitions for the agile ETO supply chain. The research question addressed in this paper was 'are lean and agile strategies appropriate for engineer-to-order construction projects?'.

This paper highlights that there is much overlap between the attributes of the ETO structure and the characteristics of agility. Our observations are that the supply chain structure classification is a superior framework for considering strategies, as the relationships and concepts surrounding leanness, agility and other best practice models are difficult to disentangle. The classifications in this paper allow construction enterprises to assess the most appropriate strategies for their projects and the implications are that organizations working in the ETO sector need the strategic characteristics of agility. Further research is required to determine the application of these classifications; this will to be undertaken via detailed case studies.

TOWARDS BRIDGING THE 'FINANCING GAP' IN CONSTRUCTION FIRMS IN GHANA WITH SPECIAL REFERENCE TO CAPITAL EQUIPMENT ACQUISITION FINANCE

M.D. Owusu,[1] E. Badu,[1] D.J. Edwards[2] and T. Adjei-Kumi[1]

This empirical research conducted in Ghana validates and demonstrates the existence of a financing gap between financial institutions and contractors in relation to capital equipment acquisition. The results show that the demand for finance from contractors is far in excess of the supply from lending banks. Several interrelated factors account for this gap. The survey found that there was a strong desire to establish a contractors' specialized lending bank to feed the local construction industry. The factor analysis performed placed significant emphasis on the establishment of a conducive legal framework and formulation of effective lending policies within which lenders and borrowers can operate. There would be the need for further research to explore the possibilities of exploiting the credit bureau system in Ghana since information asymmetry was crucial in the financing gap.

Keywords: factor analysis, financing gap, lending system, loanable fund.

INTRODUCTION

The financing gap has rigorously been challenged in literature in the context of cross-country, cross-economic sectors and cross-organizational domain as a measure of financing requirements for the 'necessary' investment in the short and long run and provides the basis for the determination of financing shortfalls (Ray and Hutchinson 1983; Taylor 1994). Galizia and Steinberger (2001) identified the financing gap as the difference between the capital formation and the savings of the corporate sector. Easterly (1999) confirmed the earlier proposition of Taylor by concluding that the financing gap is a temporal gap between investment ability and savings ability of classical organizations in which this gap is in a form of aid when viewed from cross-country perspectives.

In generic terms, the financing gap defines the difference between the demand and supply of external finance by corporations over a given period and measures the need for external funds. An explanation was advanced for this measure, thus: for a given level of capital formation, whatever funds the corporate sector cannot generate from internal sources (retained earnings or cash flow), these have to be advanced from other sources

[1] degraft2000@yahoo.com

(thus, through the banking sector, non-banking financial sector, trade credit, etc.). These funds come typically in a form of credit facilities from statutory financial institutions, coupled with high demands from construction corporations with acute shortage in supply (Galizia 2003). Available literature and empirical data confirmed that the aggregate demand of finance exceeds the aggregate supply. Easterly (1999) attested that there exists a financing gap in the lending systems of financial institutions regarding provision of finance to firms of varying degrees of capitalization within and across different sectors of the economy. This observation was consistent with the findings from the Macmillan Committee of Inquiry into Finance and Industry of the UK (Macmillan Report 1931); the Federal Reserve System of the USA (1958); and the Radcliff Committee of the UK (1959). Later, Bates (1960) and Stole and Curley (1970) challenged the previous findings by stating that firms' financing gap does not exist in the United States and the United Kingdom in the sense that short- and long-term finance and equity capital are available to those who prove their creditworthiness.

While some researchers identified financing gaps, others were of the view that there are no such gaps. The conflicting evidence and analogous mismatches are attributed to the approach and criteria adopted by various researchers to define or measure the financing gap. Unfortunately, it is hard to find research work in developing countries, like Ghana, to support the above discourse.

The primary goal of the paper is to advance knowledge and validate whether there is a financing gap in the lending system of Ghana regarding construction funding with special emphasis on capital-equipment acquisition finance; and identify potential strategies to bridge those gaps if any.

THE STRUCTURE OF GHANAIAN CONSTRUCTION INDUSTRY: THE PAST AND THE PRESENT

The government of Ghana, as in many countries, is the major underwriter of the construction industry and exercises its control through two construction ministries (Eyiah and Cook 2003). The Ministry of Water Resources, Works and Housing (MWrWH) formerly Ministry of Works and Housing (MWH) is responsible for housing infrastructure while the Ministry of Transportation (MT) formerly Ministry of Road and Transport (MRT) is responsible for roads and civil-related infrastructures (Ghana Highway Authority 2004).

Agencies supporting these ministries include the Ghana Highway Authority (GHA) responsible for trunk roads connecting 13 400km of the national capital to the regional capitals, from regional capitals to district capitals and towns within the regions (inter-regions and districts), the Department of Feeder Roads (DFR) responsible for feeder roads connecting 32 000km of the rural communities to the trunk road network, production centres and markets with the Department of Urban Roads (DUR) that also connects 3700km roads within the seven (7) metropolitan and municipal areas (Ghana Highway Authority 2002).

In addition to the requirement by law for companies operating in Ghana to register with the registrar general, construction firms that wish to undertake public projects are required to register with the appropriate construction ministry. After registration, contractors are classified into various categories depending on the type of work they wish to undertake. The MWrWH classifies contractors into categories D and K, while the MRT classifies contractors into categories A, B, C and S (Eyiah and Cook 2003). Contractors in each category are further grouped into financial classes 1, 2, 3 and 4 based on their technical and managerial expertise, financial standing, previous performance, and equipment and plant holding. The minimum requirement for qualification into each class and category is provided in guidelines by the ministries. Contractors can register with any of the ministries, and then be grouped into one or more of the categories and their respective classes. For example, a contractor can be classified as A1–A4, B1–B4 and D1–D4 and K1–K4. An attempt to state the number of contractors in the country and in each category would be misleading in that both ministries do not have an up-to-date list of contractors operating within their sectors. The difficulty in doing so emanates from the easy entry and exit to the industry.

Fortunately, the Association of Building and Civil Contractors Ghana (ABCCG) has a comprehensive list of paid-up members of those in the financial class 1 category. While many individuals consider the industry to be a lucrative sector, others leave, without notification, due to the inherent problems. The contractors association has existed in Ghana since pre-independence. The Ghana Contractors Association, as it was called, was renamed the Civil Engineering and Building Contractors Association of Ghana (CEBCAG) in 1985. Membership of the association is open to any company registered as civil engineering or building contractors with the MRT and MWrWH. Conflicts of interest resulted in the spilt of the association into the Association of Road Contractors and the Building Contractors Association. Consultancy services in Ghana are provided by several agencies and organizations including the Building and Road Research Institute (BRRI), Architectural and Engineering Services Limited (AESL), and several private sector consulting firms with professional institutional memberships. The main professional bodies controlling professional conduct in the industry are Ghana Institution of Surveyors (GhIS), Ghana Institution of Engineers (GhIE) and Ghana Institution of Architects (GIA).

SOURCES OF EXTERNAL FINANCE FOR THE CONSTRUCTION SECTOR IN GHANA

The formal capital market, mainly banks, leasing firms and other financial intermediaries, is the main possible source of obtaining external funds for contractors in Ghana (Bank of Ghana 2000). Unfortunately, the informal capital market in Ghana operates in almost total obscurity. Very little is known about its size, scope and the types of individuals that provide it. Studies of the informal capital market are virtually non-existent in Ghana and it is safe to say that policy makers and academics know almost nothing about the characteristics of this market, except that it is likely to be a large and important market for private firms to raise equity capital (Aryeetey *et al*. 1994). Of course, there are good reasons for this obscurity, thus the informal capital market involves transactions in private equity securities not subject to the rigorous disclosure requirements for public equities, and there is almost no institutional infrastructure supporting the market. In addition, the market appears to be highly localized and segmented. Currently, the formal capital market of Ghana where contractors raise debt finance consists of the Bank of

Ghana as the central bank controlling and supervising the activities of 18 different clearing banks (deposit banks) categorized as: (1) commercial banks; (2) development banks; (3) investment banks; and (4) merchant banks holding universal licence with minimum equity base of ¢70 billion – equivalent to US$7.6million (Bank of Ghana 2006). There is also an apex institution known as ARB Apex bank licensed by the Bank of Ghana to oversee the operations of 117 rural banks licensed as unit banks in the country.

Other financial institutions such as money market financial institutions (i.e. discount houses) complement the operations of the banks. Similarly, there are also non-bank financial institutions comprising (1) building societies; (2) savings and loans companies; (3) finance houses; (4) leasing and hire-purchase companies; and (5) venture capital funding brokerage firms (Bank of Ghana 2006). In addition, there is a stock exchange, which provides the platform for secondary dealings in equities of listed companies with no construction firm listed on the stock market. The other group of institutions operating within the financial system is the insurance companies, which are licensed and regulated by the National Insurance Commission (NIC).

EQUIPMENT ACQUISITION FINANCE STRATEGY: THEORETICAL AND EMPIRICAL EVIDENCE FROM GHANAIAN CONTRACTORS' PERSPECTIVES

The following sections are based on the actual questionnaire responses from contractors and the outcome of the in-depth interviews with senior executives of leading leasing firms and financial institutions in Ghana. A construction contractor wishing to acquire capital equipment for the execution of a particular project or possible business expansion in Ghana is presented with a wide range of choices by which the financing of the acquisition can be accommodated (Edwards *et al*. 1998). Despite the apparent flexibility of the profiles, the choice will essentially come down to one form of financing; thus loan or credit facility to offset the purchase, hire purchase, rentals and/or leasing arrangement, etc. (Viswanath 1999).

According to Edwards *et al*. (1998) the financial benefits alone may show there is little to choose between the competing forms of finance when tax benefits available to both the financier and the customer are taken into account. However, the legal distinctions between these financing arrangements are essential, affecting the issues of ownership, security, title, balance sheet reporting, etc. (Viswanath 1999). In most developed countries such as the UK, USA and Germany, favourable tax and accounting rules have had a significant influence on the development of the capital equipment financing industry (Edwards *et al.* 1998). The empirical results consistent with theoretical arguments suggest that construction firms in Ghana mainly utilized unallocated profit or equity capital, debt finance (via short-term borrowing) and instalment debt (via leasing and hire purchase arrangements). Many studies suggested that equipment acquisition finance via instalment debt or term financing plan (leasing) has become an important financing alternative the world over. Over the years, this form of capital asset finance has played a significant role in the economic development of most developed countries through the provision of much needed capital assets for productive businesses. The high incidence rate of equity capital compared to other forms of long-term leverage for equipment acquisition revealed by studies in Ghana is an indication of the underdeveloped state of long-term leveraging in the industry. But this is still too problematic for most companies having low annual profits to purchase major production means considering the relatively high capital intensiveness involved in equipment acquisition. Bank credit is hardly achievable for many construction companies because of the shortage of long-term credit, that is, credit for a period of over one year. Leasing arrangements provide for a fixed interest rate on the credit. Very few or no banks in Ghana possess financial resources to be offered credit on fixed interest rates for a period over one year (Bank of Ghana 2006). The banking sector suffers a shortage of capital and the funds from depositors are not large in amount or in terms of periods. Many banks manage to survive only because of transfer payments and cash operations. Getting credit from banks can also be complicated psychologically, as banks prefer to give credit to credible customers and enterprises they have been working together with for several years (CAL Bank 2005). Besides, the conditions of equipment finance on credit, payments and guarantees are softer and less aggressive in comparison with bank demands. There is a specific factor to the Ghanaian market that may in the short to medium term increase the attractiveness of equipment acquisition finance via leasing: the formulation of appropriate legal regimes that will facilitate repossession of assets in the event of default.

EQUIPMENT ACQUISITION FINANCE PROGRAMME: EXPERIENCES FROM THE DEFUNCT BANK FOR HOUSING AND CONSTRUCTION (BHC)

The Bank for Housing and Construction (BHC) of Ghana was a government-owned bank originally created as Development Finance Institutions (DFIs) to provide support for targeted construction activities in Ghana (Eyiah and Cook 2003). It was established to provide credit for private housing schemes, equipment financing schemes for contractors, expansion and modernization of immovable property, estates and industrial construction. At the time of its inception, the problems contractors faced in securing finance from established bank sources were imminent. Literature on the equipment finance programme for contractors by the BHC is limited. However, discussions were held with practitioners, academics and government officials to generate information for detailed coverage of the experiences of the contractor finance programme by the defunct BHC. The study by Eyiah and Cook (2003) was also consulted.

A considerable level of success was achieved at the initial stages of the equipment finance programme, until the emergence of several interrelated problems. Paramount of these was persistent delayed payments due to contractors by the government for works completed. Coupled with this, many of the beneficiaries lacked the managerial and technical capability to make a profit on projects in which they were engaged, or to secure more lucrative ones (Eyiah and Cook 2003). Efforts to address this latter problem had their own setbacks. While the assistant team, sponsored by the World Bank, was based in the regional capital (Accra), contractors who were to be supported came from all over the country with projects in different locations. The scope of assistance required and the number that needed support rendered services inadequate. These factors contributed to repayment default, although others defaulted deliberately. Inevitably, they were to provide collateral, hence abolishing a major objective of the programme. Notwithstanding, default payments became unbearable, prompting the bank to treat contractors with no preference. The next involvement of the BHC was the ‘Highway Projects’ and the Programme of Action to Mitigate the Social Cost of Adjustment (PAMSCAD) programme. The first concerned the government’s effort to rehabilitate and maintain the national road network. The second was part of government’s attempt to alleviate social tensions resulting from the adoption of the structural adjustment programme.

The BHC was involved in both programmes on a commercial basis. Funds received from donors were loaned to the bank. It then imported equipment and plant and supplied, on hire purchase, to the targeted group of contractors to enable the successful completion of specific projects. The problems encountered were no different from the previous experience. Highly notable was the acknowledgement by programme sponsors of the need for contractors to compete if they were to grow. Contracts were awarded on the basis of competitive tendering. While some contractors recognized this as an opportunity to engage in more lucrative projects, others saw it as a misfortune as they were not technically equipped to tender for contracts. Consequently, they could not service their equipment loans. There was also the problem of lack of spare parts to maintain equipment, and the generally poor managerial background of contractors meant many could not fully manage the equipment to effect maximum benefit. Furthermore, the contract agreement stipulated that payments for equipment supplied be made in the US dollar equivalent. The disparity between the Ghanaian currency (Cedi) and the US dollar overburdened contractors, resulting in default on repayments (Eyiah and Cook 2003). This resulted in erosion of capital base of the bank.

The involvement of the Social Security Bank (SSB) of Ghana in a similar programme was rather short-lived, after encountering similar problems. Its programmes could also be said to have been a pilot scheme, in that personnel contacted for discussion had no idea that the programme ever existed. Opinions on the practical and academic fronts in Ghana on ways to improve the effectiveness of financing programmes are diverse. There is, however, a consensus that contractors should establish a bank, which would be responsible for all their problems including the provision of finance. Two decades after BHC’s eventual liquidation, notable banks such as Amalgamated Bank and National Investment Bank (NIB) seem to be re-engineering equipment finance schemes in Ghana. Attempts made to produce detailed coverage of this re-engineering process proved futile since most often senior bank executives in charge were not available for discussion. Many are of the view that the sole responsibility of the government in programmes for contractors should be discouraged.

RESEARCH METHODS

The paper employed a combination of primary data (i.e. survey questionnaires) supplemented by secondary data (literature review) to present informative evidence of whether there is a financing gap between the construction sector and lending institutions in Ghana. In designing the questionnaire, efforts were made to ask questions, considering the background of respondents so as to generate understanding and interest. Where appropriate, therefore, we adopted questions of similar studies from Fawthrop (1969). In order to achieve strong theoretical underpinnings of the study, a number of factors had to be considered. First, demand and supply related factors leading to the perceived lending gap were established from literature. Second, questionnaires were formulated in line with the study objectives to solicit empirical data from two main sources: the demand side, consisting of a stratified sample size of 40 construction firms in Ghana; and the supply side, comprising 19 deposit-lending institutions. The respondent firms were selected based on set criteria, such as annual turnover, previous experience in sourcing for external finance for equipment purchases and equipment holding. Construction firms with annual turnover ranging between ¢1 and 10 billion Ghanaian Cedis were considered to have adequate funds to make equipment purchases from equity or retained profits without facing financing crunches in the future.

Previous applications to secure external finance were used as a criterion to collect relevant data to quantitatively appraise the magnitude of deficits in the supply of finance (financing gap) by lenders to contractors in Ghana. Equipment holdings of each firm were used as a criterion to validate the research findings as it provided an indication of the firm's involvement in equipment acquisition. The draft questionnaires were discussed with researchers in Ghana. The updated questionnaires were pre-tested with three contractors and three bankers who had previously been involved in research programmes. The final versions of the questionnaires were packaged into a booklet format as recommended by Dillman (1978). It was imperative to ensure that the right questions were asked, well understood and asked in the right way and the right respondents handled it (Fadhley 1991; Wahab 1996). The questionnaires were administered to the contractors by using the registered list of Association of Building and Civil Contractors of Ghana (ABCCG). A follow-up visit to the respondents to remind them of the agenda concerning the completion of the questionnaires was made via telephone calls, emails and personal visits. The data were gathered and processed into a suitable form for the analysis (thus, sorting, editing, coding, etc.). Descriptive statistics, data reduction (factor analysis) and linear regression were employed to analyse the data.

PRESENTATION OF THE ANALYSIS

Forty questionnaires were dispatched to targeted construction firms; 22 were returned completed. Also, 10 out of 19 of those despatched to the lending institutions were received completed. Response rates of 55% and 52.6% from contractors and banks respectively were used in performing the analysis. The apparently high response rates, compared to those registered in the studies by Easterly (1999), Galizia and Steinberger (2001) and Eyiah and Cook (2003) which had respective response rates of 37%, 49% and 61%, can be attributed to the technique employed in distributing the questionnaires. The analytical procedures employed were aimed at establishing whether there is a gap in the lending system regarding funding capital equipment acquisition. Weights were assigned to levels of agreement attached to variables on a five-point scale. The mean ratings of the variables were obtained using the sum total of points obtained and the number of responses for that particular variable (Everritt and Dunn 1991; Lynn *et al*. 2001). The data from the survey were mostly categorical data with groupings of variables; therefore, factor analysis was used to determine the predominant factors causing the effects. While linear regression analysis was used to model the relationships between demand and supply factors, the t-test was used to test the significance of some variables on the effects.

Table 1 shows that a significant majority of the respondents representing 87.5% agreed that a financing gap existed.

Table 1: Descriptive statistics showing valid percentage of existence of financing gap (Researcher's field survey 2006)

		Frequency	Percent	Valid percent	Cumulative percent
Valid		1	3.1	3.1	3.1
	No	3	9.4	9.4	12.5
	Yes	28	87.5	87.5	100
	Total	32	100	100	

A further analysis using regression was performed to test whether there is a significant relationship between demand and supply of funds which was an interest of the investigation. As indicated in Tables 2 and 3 below, the high regression coefficient value (R) of 0.73 is an indication of a strong linear relation between demand and supply.

Table 2: Regression coefficients (A) (Researcher's field survey 2006)

Model		Unstandardized coefficients		Standardized coefficients	t
		B	Std. error	Beta	
1	Constant	528.707	95.274		5.549
	Supply	0.868	0.145	0.738	5.986

Note: Dependent variable: demand.

Table 3: Model summary (B) (Researcher's field survey 2006)

Model	R	R-Square	Adjusted R-Square	Std. error of the estimate
1	0.738(a)	0.544	0.529	299.108

Note: Predictors: (constant), supply; dependent variable: demand.

The apparent huge difference in the mean difference and lower and upper limits difference at 95% confidence interval as demonstrated by t-values in Table 4 below has confirmed the existence of a financing gap in the Ghanaian construction industry.

Table 4: One-sample t-test (Researcher's field survey 2006)

	Test value = 0					
	t	df	Sig. (2-tailed)	Mean difference	95% Confidence interval of the difference	
					Lower	Upper
Supply	8.346	31	0.000	546.875	413.23	680.52
Demand	13.019	31	0.000	1003.125	845.97	1160.28

This gap took the form of inadequacy or unavailability of institutional short-, medium- and long-term finance to the construction sector. Apparently, both demand side (construction firms) and supply side (financial institutions and central bank of Ghana) contribute to the obvious financing gap. Several factors were attributed to the evident financing gap. On the supply side the following factors were identified as contributing factors: lack of adequate credit policies or special programmes for construction; failure to establish a legal framework within which the banks can effectively operate; inability of the banks to mobilize long-term deposits. Other factors included stringent lending conditions and high lending costs as most often, borrowers are frustrated by the bureaucratic lending procedures and associated lending costs surcharged as processing fee on the facility. The factor analysis performed on these variables to identify the predominant factors causing the effect revealed two possible chief factors, namely the lending policy measures of the financial institutions and the financial strength of the lending banks.

DISCUSSION

Financing channels of the construction sector in Ghana: bank lending as the principal source

When respondent contractors were asked to indicate and specify the principal sources of finance that they relied on for equipment acquisition, the majority indicated bank financing, mostly commercial banks as their principal source. The descriptive statistical test showed quite a significant contribution by merchant and development banks, while leasing and insurance companies, though seen as promising equipment financing alternatives, revealed a marginal contribution so far. Other financing channels such as building societies, finance houses, trust houses, discount houses and mortgage institutions traded poorly. Empirical evidence from representative field results shows that while the majority of the banks are drifting from construction funding, a significant number of the contractors considered bank financing. The interpretation of this analogue is simple: lending institutions may receive several applications for credit facilities from various contractors with varying degrees of capitalization and perhaps grant a few. From our investigation, the supply of credit finance decreases monotonically while demand increases with interest rates.

However, excess demand for credit is common, as applications for credit are frequently not satisfied and this is very consistent with the experiences from developing countries. As a result, the demand for credit finance exceeds the supply at the market interest rate at any given time. This apparent evidence is an indication that demand from contractors far exceeds supply. There is also the possibility of a drop in credit supply to the construction sector as most lenders are retreating from construction finance because of the perceived high risk associated with construction finance. Similarly, the drop in both corporate and bank balance sheets may reduce the latter's willingness to lend, and potentially lead to a flight to quality and credit rationing. The empirical findings of the research confirm the initial research questions and basic hypothesis of the investigation. When the respondents were asked to indicate whether or not a financing gap exists, the overwhelming number represented by 87.5% (Table 1) indicated that there is a financing gap in the lending system of Ghana regarding construction funding (capital equipment funding). Similarly, it was identified from the empirical results that the following 'demand' factors contribute to the apparent financing gap: deficiencies in financial and managerial skills (as this was measured by the lack of experience in the field of activity, inadequate educational background, discrepancies in financial reporting systems, absence of feasibility studies or business plan, etc.); lack of adequate accounting or financial control systems; absence of forward planning; inability of construction firms to provide acceptable limits of collateral and inability to repay loan funds on time.

Collective stakeholder involvement and the way forward towards bridging the financing gap

Various measures have to be constituted to meet both the short-term and long-term financing needs of construction firms, especially capital equipment finance in Ghana. The factor analysis performed on the possible measures to close the perceived gap showed strong coefficient values of more than 0.5 indicating that, if those measures are observed, it will help close the gap. The majority of the respondents were of the view that a specialized ‘contractor bank’ be established solely dedicated to the construction sector as it used to be during the last three decades where Ghana had such a bank. The experiences of the defunct Bank of Housing and Construction (BHC) raised another issue that merits another study. Putting in place a specialized contractor bank has the added advantage of the proposed bank enjoying some protection in times of credit roaring. Similarly, there is the possibility of enjoyment of favourable operating conditions and benefits by both borrowers and lenders alike.

The factor analyses presented placed significant emphasis on the establishment of appropriate and adequate legal frameworks and lending policies within which lenders and borrowers can effectively operate. Observation from the analysis is consistent with the earlier claim by Aryeetey *et al*. (1997) that countries with operational legal systems have more developed financial markets and competitive access to external finance. This would suggest that there is an additional, indirect, channel through which sound laws, legal framework and judicial efficiency affect firms’ access to bank finance. Audretsch and Elston (1995) and Aryeetey (1993) however, found that financial market development affects both the growth in the average size of existing establishments and the growth in the number of new establishments as most industry is dependent on external finance. Thus, the theoretical effect of the development of financial markets on the average size of firms is ambiguous. On the one hand, more firms will be born, reducing the average size of firms. On the other hand, existing firms will be able to grow faster, increasing the average size of firms. Subsidizing interest rates, provision of re-discounting facilities and sharing risks with the government through special arrangements were among highly ranked measures towards bridging the perceived financing gap.

CONCLUSION, RECOMMENDATIONS AND AGENDA FOR FUTURE RESEARCH

The research has investigated the existence of a financing gap in the lending system of Ghana regarding capital equipment finance with empirical data. As such, this paper has demonstrated the existence of such a gap and several interrelated factors accounted for this lapse. Notwithstanding the crucial role of the construction sector towards Ghana’s strategic goal of attaining middle-income status by the year 2020, it is surprising that efforts to enhance the industry’s continuous contribution, with respect to the provision of finance, have achieved little consideration by stakeholders involved. The paper confirmed the assertion of Eyiah and Cook that construction contractors in developing countries have witnessed a massive financial recess, acute growth and eventual liquidation. This has been rigorously challenged and attributed to the lack of collective involvement of stakeholders towards construction financing in Ghana. This has arguably led to the existence of the so-called lending gap regarding construction financing, as most often lenders are reluctant to extend credit to contractors in Ghana.

The study recorded that a high number of the respondents representing 87.5% considered that a financing gap does exist in the lending system of Ghana, and would want immediate stakeholder intervention. A further manifestation of the desperate need for external finance was high among the firms examined. So far, little has been achieved regarding financing of contractors' equipment acquisition financing by both lenders and government. The paper observed that commercial lending or bank financing is the principal source of contractors' funding in Ghana. Unfortunately, most lenders are not interested in the construction sector as their core business line. The paper identified that a few lenders considered contractor financing but with an average sectoral allocation of 5% of their annual proceeds to contractors, which is marginal in relative terms.

Empirically, the research has confirmed and validated the existence of a financing gap in the Ghanaian lending system with field evidence. The idea of establishing specialized bank designated to feed the construction industry in Ghana was weighted very high among the respondents. Since establishing a specialized bank would require investment in time, expertise, systems and methodologies, organizational structures, research would have to be undertaken to identify stakeholders that would want to participate, the role they could play and holistically develop strategies for overall national involvement. Alongside a specialized contractor bank, the paper recommends further research to explore the possibilities of establishing a credit bureau in Ghana since the apparent financing gap was attributed to the asymmetry in information provided by contractors.

QUANTIFYING IMPACT FACTORS OF CORPORATE FINANCING: ENGINEERING CONSULTING FIRMS

Jieh-Haur Chen[1]

Institute of Construction Engineering and Management, College of Engineering, National Central University, 300 Jhungda Rd, Jhungli, Taoyuan 32001, Taiwan

The objective of this research is to identify and quantify the factors that influence corporate financing for engineering consulting companies in Taiwan. The quantification, thus derived based on statistical analyses, expresses the features of the engineering consulting market that fit the company's criteria for considerations of corporate financing. An initial survey of 118 professionals serving in both the financial and engineering consulting markets was conducted from which 36 points that influence the approval of corporate financing were summarized. The significance and quantification of the financing factors was determined from a comprehensive survey, via questionnaire, and factor analysis of two populations, comprising a total of 1124 firms and institutions. The conclusions give us 14 significant factors that can be classified into four component groups: for repayment-explained financing purposes, the corporate perspective, project features and public relations, and financing protection with corresponding weights being 0.328, 0.270, 0.214 and 0.188, respectively. In comparison with the most commonly accepted principle of financing, 5 principles (5P), accepted by financial institutions for years, these four weighted components provide a better basis for conducting corporate financing, and a quantification measurement method for corporate financing for both practice and research.

Keywords: construction industry, construction management, corporate governance, factor analysis, finance.

INTRODUCTION

The financing of engineering consulting firms by using corporate financing is not restricted by the status of their shareholders, executive officers or any particular individuals. Financial institutions for years have used the five principles (5P) of: person, purpose, payment, protection and perspective proposed by Paul H. Hunn as the basis for their financing decisions. Business types and features usually influence corporate financing; nonetheless, the process of financing approval is confidential and inconsistent regardless of the financial institution. It is often puzzling as to which weights of factors influence financing approval towards corporate financing for engineering consulting firms. This problem is an impediment as to how well firms in the engineering consulting market face competition or even develop. The objective of this research is to identify and quantify the factors that influence corporate financing so as to raise financing practicability.

CORPORATE FINANCING

The use of credit rating as a basis to evaluate companies has been accepted by the financial market for years. The 5P system has been commonly utilized to establish credit rating, and as the basis of loan approval. Some studies have emphasized that approval of financing is dependent upon an enterprise's features, credit record and market characteristics. The credit scoring system acts as a basis for analysing the financing parameters, and also for approving loans. The use of the debit–asset ratio, working capital and sales forecasting to establish the credit rating model has assisted banks in assessing the feasibility of loans. Studies also analyse other concepts for loaning issues. From the social viewpoint, loans create opportunities for small and medium scale enterprises as well as for workers. This is connected to loan guarantees. Researchers also suggest that the non-performing loan ratio may stay within a certain range for most financial institutions (Riding and Hanies 2001). Explicating the relationship between the borrower, the bank and the financing process directly affects the cost of the loan, risk management and information. One of the major findings concludes that banks with less capital ask for higher interest rates for loans than do those with better financial strength (Hubbard *et al*. 2002). Additionally, there are three benefits derived for enterprises with long relationships to financial institutions: relatively low credit costs, low limitations of collateral, and more alternatives for requesting loans when facing financial difficulties (Bodenhorn 2003).

For engineering consulting firms, the cost of capital determines the probability of obtaining bank loans (Besley and Brigham 2000). Nonetheless, 66.28% of the total capital used for construction projects is supplied by financial institutions (Price and Shawa 1997). For both manufacturing-oriented projects such as residential construction projects, and service-oriented projects such as professional construction management (PCM) projects, funding gaps depend on project activity arrangements. There has been no research in the finance-related literature, for either the construction industry or the engineering consulting market, undertaken to quantify impact factors for corporate financing.

RESEARCH METHODOLOGY

The modified Delphi method was used in this paper to explore the impact factors considered for corporate financing. The modified Delphi method is based on amendment through open discussion with the intent to obtain expertise during the beginning stage. Researchers suggest that expert interviews can be integrated with open discussion to develop a questionnaire. It is particularly feasible to apply this strategy to an area that has a limited number of studies and sources (Murry and Hammons 1995). Owing to limitations in the literature regarding the corporate finance of engineering consulting firms, expertise from industrial professionals, scholars and government officials, from both the financial and engineering consulting markets, was considered during the first step: 35 experts comprising 15 engineering consulting professionals, whose average working experience was around 20 years, and 20 banking professionals, whose average working experience was approximately 15 years, were interviewed. These 35 professionals were among the top managers from both markets and were recommended based on the top company list. Another randomly selected 83 professionals, whose average working experience reached 10 years, participated in two workshops and three conferences conducted to discover the impact factors. In total 118 professionals serving in 102 different firms or institutions, or affiliated with 45 different associations were selected. These firms and institutions comprise 60 engineering consulting firms and 42 financial institutions, and belong to 36 engineering-related and nine finance-related associations. Additionally, nine high-ranking government officials and five finance and engineering professors attended all the conferences and workshops. The process of impact identification, provision of expertise and suggestions for possible enhancement, for either this research or society, lasted approximately eight months. A total of 36 initial impact points were concluded, as shown in Figure 1, and 13 corresponding document formats were also collected. These points were collected from the brainstorming of experts' experience in the first conference. Based on each point's similarity and characteristics, expertise suggested that all initial points could be collected into 15 factors to be examined during the rest of the conferences and workshops.

Nationwide survey

An industrial survey was conducted by questionnaire to gather information for further analysis of these 15 factors. The questionnaire was aimed at both the engineering consulting and financial markets and involved two sections: one to gather basic information about the interviewee from the investigated company and the other one comprising 16 stems with a corresponding scale which allowed people to express their agreement with the corresponding statement. The first 15 stems follow the order of the 15 factors listed in the right-hand column of Figure 1 and the last stem is designed to catch any possible additional factors that the interviewee may consider to have an influence on corporate financing. Since professionals in these markets have totally different backgrounds, the utilization of a simple form of questionnaire is desired. The widely accepted Likert-type scale for the assessing of attitudes is used. The five choices are 'extremely high impact', 'high impact', 'medium impact', 'low impact' and 'little or no impact'. These 16 stems are listed in Table 1. The nationwide survey targeted all 691 professional engineering consulting firms and all 433 financial institutions registered in 2005; 1124 questionnaires were distributed to their headquarters. Within a month, 245 questionnaire responses were returned. Of these 245 questionnaires, 12 were invalid. The response rate was only 20% owing to the volunteer-oriented basis.

Factor analysis

Conducting factor analysis for the returned questionnaires requires fulfilment of two statistical assumptions: a sample size greater than 200, or greater than the number of stems multiplied by 5. It can be seen that the survey satisfies both minimum sample size requirements. Table 2 shows the mean, standard deviation, mean variance, kurtosis and skewness for each stem. Among all 233 respondents, only nine respondents answered Stem No. 16, representing less than 5% of the total. From the statistical viewpoint, this is insignificant and can be ignored. There was a major difference in the response to Stem No. 9, 10 and 13. In comparison with financial firms the professional engineering consulting firms considered the degree of impact for each factor to be less. This means that even though professional engineering consulting firms understand basic concepts of financing, they underestimate the importance of each factor, which leads to difficulty or even failure to meet the explanation or description of factors considered important by financial institutions.

For market feature analysis, the Bartlett's sphericity test and Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy are used to examine the appropriateness of factor analysis adopted to achieve the research objective. By matching the following factor analysis assumptions: (1) reducing a large number of variables to a smaller number of factors for modelling purposes; and (2) creating a set of factors to be treated as uncorrelated variables, we get the results in Table 3, which demonstrate the Bartlett's test and KMO measure results. The value of KMO overall varies from 0 to 1 but it should be equal to 0.6 or higher to proceed with factor analysis. A higher KMO overall expresses greater appropriateness for the conducting of factor analysis on the database. The sum of the KMO overall in this research database is 0.832 which is of course greater than 0.6. The significance level for the sphericity test ranges from 0 to 1, and represents appropriateness for the carrying out of factor analysis. The default value of the significance level is typically equal to 0.05. Accordingly, the significance level of the database at 2.04×10^{-198} (extremely close to 0) which means that there is a high correlation and that it is appropriate to adopt factor analysis to the database.

Table 1: Stems of questionnaire

Stem No.	Factor descriptions and stems
1.	Do descriptions of funds needed influence the financing mechanism between a financial institution and an engineering consulting firm?
2.	Do descriptions of financial status influence the financing mechanism between a financial institution and an engineering consulting firm?
3.	Does profitability influence the financing mechanism between a financial institution and an engineering consulting firm?
4.	Does goodwill influence the financing mechanism between a financial institution and an engineering consulting firm?
5.	Do corporate credit records influence the financing mechanism between a financial institution and an engineering consulting firm?
6.	Does any project contract influence the financing mechanism between a financial institution and an engineering consulting firm?
7.	Do any project size and duration influence the financing mechanism between a financial institution and an engineering consulting firm?
8.	Do financing amount and its length of period influence the financing mechanism between a financial institution and an engineering consulting firm?
9.	Do descriptions of cash flows influence the financing mechanism between a financial institution and an engineering consulting firm?
10.	Do descriptions of a repayment plan influence the financing mechanism between a financial institution and an engineering consulting firm?
11.	Does availability of collaterals influence the financing mechanism between a financial institution and an engineering consulting firm?
12.	Do types of collaterals influence the financing mechanism between a financial institution and an engineering consulting firm?
13.	Does the use of separate project account influence the financing mechanism between a financial institution and an engineering consulting firm?
14.	Does promotion by the government influence the financing mechanism between a financial institution and an engineering consulting firm?
15.	Do public relations of the corresponding persons influence the financing mechanism between a financial institution and an engineering consulting firm?
16.	Is there any factor needed to list? Please name it and provide the ranking of impact.

Factor analysis included five main tests applicable to the purpose of this study; see Table 2. These five tests are missing value analysis, descriptive statistics, independent samples t-test, homogeneity test and consistency test. Missing data can seriously affect the results. Using missing value analysis to uncover missing data patterns helps to estimate summary statistics and impute missing values. Missing value analysis is done to diagnose whether the database has a serious missing data imputation problem, and to replace missing values with estimates. Here the default threshold is set to 0.05.

Description of fund needed Business interests Source of project Positioning Marketing strategy	→ Purpose of funds needed
Financial strength Firm size Sales Shareholder structure	→ Description of financial status
Successful project Operating performance Profitability record Corporate profitability	→ Profitability
Enterprise image Reputation Goodwill Owner's credit Perspective	→ Goodwill
Corporate credit record	→ Corporate credit record
Firm expertise Contract features of project	→ Project contract
Project size and duration Work activities of project	→ Project size and duration
Financing amount and length of period	→ Financing amount and length of period
Description of cash flows Firm capacity	→ Description of cash flows
Description of repayment plan Guarantor status	→ Description of repayment plan
Collateral availability	→ Collateral availability
Collateral type	→ Collateral type
Use of separate project account	→ Use of separate project account
Promotion by the government	→ Promotion by the government
Human resource Public relations Interpersonal relationship Attitude of the corresponding persons	→ Public relations of the corresponding persons

Figure 1: Induction of corporate financing impact factors

Descriptive statistics are numbers that are used to summarize and describe data. Any other number chosen for the computation also counts as a descriptive statistic for the data from which the statistic is computed. Several descriptive statistics are often used at one time to give a full picture of the data. In this study, a mean value greater than 3 is recommended, representing a greater degree of impact than the average. Accordingly, it is recommended that the thresholds for standard deviation and skewness be set to 0.8 and 0.5 respectively. The independent sample t-test allows for a comparison of the mean scores of two groups for a given variable. When the p-value is less than 0.05, the two groups have significantly different means. The homogeneity test can be thought of as a test of the conformity of the difference between two means. In a homogeneity test, the principal component analysis, scree test and factor loading test are adopted to select factors appropriately. Here, the suggested factor loading, correlation coefficient and KMO thresholds are 0.3, 0.3 and 0.7, respectively. A consistency test is conducted to evaluate the reliability of the questionnaire. Cronbach's alpha is used to assist in carrying out the consistency test and suggests that each alpha value of the tested factors should be greater than 0.7, standing for high reliability (Hair *et al*. 1998; Chiu 2004; Wang 2004). Table 4 demonstrates the results of these five tests. A comparison of the 15 Cronbach's alpha values to the suggested thresholds confirms the reliability of the questionnaire. Factor No. 14, promotion by the government, has three testing results below the thresholds so it is suggested that this be removed. Factors No. 5, 6, 7, 8, 11, 12 and 15 have either one or two testing results below the thresholds, so it is suggested that the five main tests be conducted for the remaining 14 factors after deleting No. 14.

Factor extraction is conducted to divide the group of 14 factors into a few sets before being compared to the current 5P basis. The scree test shown in Figure 2 implies that the 14 factors can be classified into four groups based on eigenvalue > 1. According to the literature it is suggested that there are six common methods for factor extraction.

Trial and error is used. It can be concluded that principle component analysis combined with orthogonal rotation and Kaiser-normalized varimax methods best fit the research goal. To determine the weight of each factor, one finds the common variance of all 14 factors; the results are shown in Table 5. Each factor has a corresponding extraction value as well as corresponding weight. Table 6 illustrates the results of grouping the four components obtained using an after-transformation component matrix. The four components determined based on transformation convergence (with seven iterations), are the: (1) repayment-explained financing purpose; (2) corporate perspective; (3) financing protection; and (4) project feature and public relations, according to each component's characteristics. Each component's weight is calculated using the sum of the corresponding factor weights listed in Table 5.

FINDINGS AND DISCUSSION

The most common principle of financing, 5P, used by financial institutions is compared to the four weighted components that direct reconstruction of corporate financing. This study has suggested that there are both similarities and dissimilarities between 5P and the four weighted components, which are discussed below. Component 1 is named the repayment-explained financing purpose and involves five factors, all associated with financing purpose and repayment. The total weight of Component 1 is 32.766%. It matches the two Ps of 'purpose' and 'payment', and is the most important consideration. This finding suggests that the project contract is an important factor that needs to be taken into account by financial institutions. In Taiwan, financing procedures are equal or extremely similar for all industries. Most engineering consulting firms operate based on engineering projects which have the features of being highly customer-oriented transactions, long transaction procedures, involving a costly bidding process, and having a long-term plus wide-ranging impact on downstream products. Completing projects to fulfil contracts is where revenue comes from. These features affect contract performance deeply. The weight is 15.821% (= 5.184% ÷ 32.766%). This factor is considered in terms of the two Ps, 'purpose' and 'payment', and relatively redirects consideration for financial institutions. The finding for Component 1 indicates that the viewpoint of engineering consulting firms matches that of bankers. Financial institutions desire to clearly understand the reasons that they should support loan approval, and desire to secure repayment ability. The documents listed in Table 7 facilitate this understanding. Additionally, the use of separate project accounts limits the flexibility of working capital for engineering consulting firms. For financial institutions however, it lowers risks caused from uncertain and unidentified use of capital by the borrowers. A commitment to the use of separate project accounts has a weight of 20.656% (= 6.768% ÷ 32.766%) for consideration in two Ps. Component 2 stands for the corporate perspective, and includes four factors describing financial status, profitability, goodwill and corporation credit record. All these are related to corporation development and match the 'perspective' of 5P. The component's weight of 26.949% indicates that profitability and goodwill are significant. In other words companies that perform well earn trust for financing.

The next similarity lies in the fact that financial protection has been highly valued for years. Component 3 is related to the need of financial institutions to have protection for the approval of loans. This corresponds to the 'protection' of 5P. In Taiwan, the most preferred form of protection or collateral requested by bankers is plant assets. It is however unlikely that most engineering consulting firms would own many fixed assets such as construction equipment, land, or buildings. The weight of this component, 18.841%, suggests that most engineering consulting firms undergo some degree of difficulty in acquiring corporate financing. This finding reflects the current financing situation, and concludes no officially supporting document due to diversification of collateral. Component 4, public relations by corresponding persons, reveals a dissimilarity and partial similarity between the 5P and the weighted four components. The factor of public relations by corresponding persons is weighted as 7.167% to the total, and is partially related to the 'people' of 5P. People and project features are both involved in determining the proportion of the weighting of this factor. However, based on the nature of project performance, No. 7 and 8 factors are related to project features. A comprehensive understanding of the features of an engineering consulting project is not easily reachable for most financial professionals.

Table 7: Four components and their corresponding documents

Component No.	Component name	Weight	Factor	Corresponding document
1	Repayment-explained financing purpose	2.958 (32.766%)	■ Purpose of funds needed (No.1), ■ Project contract (No.6), ■ Description of cash flow (No.9), ■ Description of repayment plan (No.10), and ■ Use of separate project account (No.13)	■ Corporation basic information, ■ License, ■ Balance sheet, ■ Income statement, ■ Statement of cash flows, ■ Use of internal capital, and ■ Contracts
2	Corporate perspective	2.433 (26.949%)	■ Description of financial status (No.2), ■ Profitability (No.3), ■ Goodwill (No.4), and ■ Corporate credit record (No.5)	■ Financial statements, ■ Credit report, ■ CPA's financial report, ■ Operating performance records, and ■ Related enterprises' financial reports.
3	Financing protection	1.701 (18.841%)	■ Collateral availability (No.11)and ■ Collateral type (No.12)	No particular documents
4	Project feature and public relations	1.936 (21.444%)	■ Project size and duration (No.7), ■ Financing amount and length of period (No.8), and ■ Public relations of the corresponding persons (No.15)	■ Project schedule, ■ Schedule of on-going projects, contracts, and ■ Operating plans.

These two factors do not exist in 5P, but are weighted in our results as 14.278% of the total.

The findings indicate that there exists a margin at 14.278% or higher to adjust the consideration of corporate financing for engineering consulting firms. When conducting corporate financing, this margin represents the differential created by the market's characteristics. Although it is highly possible that the margin would vary with other markets or industries, the methodology and concepts used in this study can be used to adjust feasible corporate financing in practice. Likewise, the documents collected and their corresponding factors listed in Table 7 may help to unify and simplify the procedures of corporate financing. A common basis for corporate financing in the financial market is achievable.

CONCLUSION

The special characteristics of engineering consulting projects need to be considered during corporate financing as suggested through the interviews, conference and workshop discussions, and statistical analyses. The quantification discussed in this paper identifies 14 factors classified into four components that have an impact on corporate financing for engineering consulting firms in Taiwan. One of our goals is to help these firms understand which of these factors are more influential by looking at their corresponding weights. The attestation of the quantification is suggested through the use of expert interviews, a questionnaire survey and factor analysis. Comparison of the four components to the financial institutions' 5P model illustrates differential due to the special features of the engineering consulting market. Suggestions and findings provided by this study have an impact on both practice and research and state that a certain margin of adjustment should be considered for approving loans.

THE LAW RELATING TO DEFECTS: URGENT NEED FOR REVIEW

Philip Chan[1]

Department of Building, National University of Singapore, Singapore 117566

Two interesting developments have changed the legal positions of developers and subsequent purchasers in respect of building defects. Until recently, it appeared that developers were bound by the rule that if they do not suffer any loss as a result of defects they would only be entitled to nominal damages. Developers have always had the right to contractual remedies in respect of building. The recent cases have held that a developer is entitled to substantial damages even if the developer did not suffer any loss. In the law of negligence, the courts have held that a subsequent purchaser may not recover from the builder and/or designer. The Singapore courts departed from the English cases and held that the management corporation which is in charge of the maintenance of the common property of a development have a right to claim from both the developer and the architect pure economic loss in the form of the cost of repair of the building defects found in the common property. Accordingly, the law relating to defects appears to be unsatisfactory. This paper advocates a change in the law.

Keywords: contract, defects, developers, negligence, subsequent purchasers, substantial damages.

INTRODUCTION

In the realm of real estate, a builder who builds a structure with defects should be made liable for the cost of the repair of the defects or the loss in value of the structure. However, the real issue is to whom should a builder be liable. In the Commonwealth, where the common law system applies, it would appear that under the current English and Singapore law of contract, it is possible for a developer who has sold all the units in the development without suffering a loss to claim substantial damages from the builder. Further, in the English law of tort which Singapore usually applies with little or no modification, subsequent purchasers who have no contract with the builder are not able to recover from the builder, damages in respect of defects found in their property.

It would appear that the subsequent purchaser who is saddled with the defects has no recourse against the builder because of the principle of indeterminate number of plaintiffs claiming against the builder. On the other hand, the developer is entitled to recover substantial damages from the builder although he may not have suffered any loss when the development was completely sold without any loss because of the fear that no other person is entitled to recover from the builder; this has been referred to as the legal black hole.

[1] bdgccf@nus.edu.sg

Thus, the real issue is not whether a contract breaker like the builder should be made liable for defective works but whether a person like a subsequent purchaser who ends up paying for the cost of rectification of the defects or accepts a diminution in value of a structure with defects should be the proper party to be entitled to claim substantial damages instead of allowing a developer to claim substantial damages because it is riding on the slogan that encourages all to avoid the legal black hole like a plague.

This paper analyses the situation through two Singapore case studies to determine whether there is a legal solution to the current position that apparently boggles the minds of most people and puts humanity into a legal framework that works rigidly within the constraints of binding judicial precedent that has a tendency to increase incrementally regardless of the need of an urgent change. This paper examines the two cases within the law of contract framework and the law of professional negligence.

REVIEW OF CASES

The first part of this section reviews the cases on the contract law point on a substantial damages claim where no loss is suffered while the second part examines the cases on the pure economic loss point in professional negligence.

Substantial damages claim cases

The landmark case that is responsible for the opening up of discussion in this paper is the case of *Dunlop* v. *Lambert* (1839) 6 Cl & Fin 600; 7 ER 824. This case has been known as being the exception to the general rule that 'only the person who has suffered the loss would be entitled to have it made good by compensation'.[1] The court in *Dunlop* v. *Lambert* held that the party that shipped goods could recover substantial damages from the carrier as the goods were lost due to a general average sacrifice although by the time the action was taken, the goods were not the party's property or at its risk. However, the said party would be accountable to the true owner for the proceeds of the judgment.

Subsequently, the Bills of Lading Act 1855 (c. 111) which provided for the automatic assignment of the rights of action for breach reduced the importance of the said landmark case. In more recent times in *The Albazero* [1977] AC 774, the House of Lords were of the view that the exception created by *Dunlop* v. *Lambert* should not be unnecessarily extended. Bearing in mind that the rule in *Dunlop* v. *Lambert* was created to get around the undesirable consequences of the privity of contract rule, there would be no such undesirable consequences if it is within contemplation that the carrier will also enter into separate contracts of carriage with whoever may become the owner of goods carried pursuant to the original contract.[2]

While the above-mentioned principles evolved, the subject matter remained that of goods. By 1994, the subject matter extended to immoveable property. The *Dunlop* v. *Lambert* exception was used in a building contract case named *St Martins Property Corporation Ltd* v. *Sir Robert McAlpine Ltd* [1994] 1 AC 85. In this case, there was a concern that because it could be foreseen that the development was going to be occupied and possibly purchased by third parties, any damage caused by a breach of contract on the part of the builder in the form of defects in the development would cause loss to a later owner and not merely to the original contracting party. Indeed, it was an express provision that prohibited the assignment of rights without consent.

The court held that it was proper 'to treat the parties as having entered into the contract on the footing that the [developer] would be entitled to enforce contractual rights for the benefit of those who suffered from defective performance but who, under the terms of the contract, could not acquire any right to hold [the builder] liable for breach'. The basis relied on is known as the narrow ground. This ground also likens the situation to a legal black hole where any possible claims against the builder are sucked into the legal black hole with no one in a position to sue the builder.

To allay the fears of builders who have given warranties to subsequent purchasers, the court held that the *Dunlop* v. *Lambert* exception would not apply to those cases. Another interesting point arose in this case which differentiated from the goods cases.

The court also held that there is further reason why the developer should be allowed to claim substantial damages. It was explained that the developer should be allowed to recover substantial damages as the developer suffered a loss of its 'performance interest'. The basis relied on is known as the broad ground.

Like the earlier goods cases, the legal brakes were applied to the evolution of the *Dunlop* v. *Lambert* exception in immoveable property cases. In *Alfred McAlpine Construction Ltd* v. *Panatown Ltd* [2001] 1 AC 518, it was held that the developer was not entitled to claim substantial damages from the builder for breach of contract because the builder also entered into a duty of care deed with the owner of the site. This was viewed as giving the site owner a direct remedy against the builder in respect of any failure by the builder to exercise reasonable skill, care and attention in carrying out its obligations under the main contract.[3] However, the minority view in this case advocated that the existence of a right of the site owner to claim against the builder should not deprive the developer from recovering for breach of the building contract.

Indeed Lord Millett noted that, 'The problem, in my view, is not one of double recovery, but of ensuring that the damages are paid to the right party.'

Pure economic loss cases

Until more recently, legal damages were categorized as arising from death, personal injury and damage to property. The earliest mention of the relationship between a builder and a subsequent purchaser appears to be an obiter statement of Lord Wilberforce in *Anns & Ors* v. *London Borough Council of Merton* [1978] AC 728. He held (at 758–9) that a builder of defective premises would be liable in negligence to a person who subsequently acquired the house and who sustained injury. In particular, the Law Lord explained (at 759) that, 'the relevant damage is in my opinion material, physical damage, and what is recoverable is the amount of expenditure necessary to restore the dwelling to a condition in which it is no longer a danger to the health or safety of persons occupying and possibly (depending on the circumstances) expenses arising from necessary displacement.'

This case was followed by *Junior Books Ltd* v. *Veitchi Co Ltd* [1983] 1 AC 520. It was an appeal to the House of Lords from the Court of Sessions in Scotland. It was held that the nominated subcontractor was liable to the owner in respect of the cost of replacing the floor as the subcontractor had negligently laid the floor which was defective. The Law Lords had applied the *Anns* two-stage test. Essentially, in respect of the first stage, it was held that the nominated subcontractor must have known that if they did the work negligently the resulting defects would at some time require remedying by the owner expending money upon the remedial measures as a consequence of which the owner would suffer financial or economic loss. In respect of the second stage, Lord Roskill held that there should be no reason why the type of damage recoverable under negligence should not be extended to pure economic loss.

> But in the present case the only suggested reason for limiting the damage (ex hypothesi economic or financial only) recoverable for the breach of the duty of care just enunciated is that hitherto the law has not allowed such recovery and therefore ought not in the future to do so. My Lords, with all respect to those who find this a sufficient answer I do not. I think this is the next logical step forward in the development of this branch of the law. I see no reason why what was called during the argument 'damage to the pocket' simpliciter should be disallowed when 'damage to the pocket' coupled with physical damage has hitherto always been allowed. I do not think that this development, if development it be, will lead to untoward consequences.

Some years later, the House of Lords in *D & F Estates Ltd & Ors* v. *Church Commissioners for England & Ors* [1989] AC 177 appeared to have gone into a reverse gear. It was held that the liability of a builder of a permanent structure which was dangerous effectively arose only if the defects remained and caused personal injury or damage to property other than the structure itself. Further, if the defects were discovered before any such injury or damage was caused, the loss of the owner of the structure in repairing or rectifying defects would be purely economic and was not recoverable. However, it should be noted that the case of *Junior Books* has not really been expressly overruled in *D & F Estates* or in subsequent cases.

Then came *Murphy* v. *Brentwood District Council* [1990] 2 All ER 908. Lord Harwich said (at 926):

> If a builder erects a structure containing a latent defect which renders it dangerous to persons or property, he will be liable in tort for injury to persons or damage to property resulting from that dangerous defect. But if the defect becomes apparent before any injury or damage has been caused, the loss sustained by the building owner is purely economic. If the defect can be repaired at economic cost, that is the measure of the loss. If the building cannot be repaired, it may have to be abandoned as unfit for occupation and therefore valueless. These economic losses are recoverable if they flow from breach of a relevant contractual duty, but, here again, in the absence of a special relationship of proximity they are not recoverable in tort.

It should be noted that in one form or other, pure economic loss cases have been influenced by the observations of the great American judge, Cardozo CJ, in *Ultramares Corporation* v. *Touche* 174 NE 441 (1931) where he expounded on the oft-quoted of 'liability in an indeterminate amount for an indeterminate time to an indeterminate class' (at 444) which ought to be avoided. This has been the guiding light for many if not all pure economic loss cases.

OBSERVATIONS ON CASES REVIEWED

Substantial damages claim cases

The *Dunlop* case represents an exception to the general rule that a person can claim substantial damages only if the person suffers a loss. Its main purpose is to overcome the problem created by the doctrine of privity of contract where the actual sufferers cannot make a claim against the person who created the suffering because the two do not have a contract with each other. It is also important to note that the exception applies such that the person who suffers no loss but is entitled to recover substantial damages is able to do so because this person remains accountable to the actual sufferer. Further, the *Dunlop* case applied where the subject matter of the loss concerns goods that are shipped. Subsequently, the *Dunlop* exception is seldom invoked because subsequent legislation addressed the issue of the lack of privity of contract.

Having set out the salient features of the *Dunlop* case, it can be established that under the current laws, the application of the principle to loss suffered in respect of immoveable property may not be appropriate. Addressing the privity of contract point, it can be seen that unless parties have excluded the application of the Contract (Rights of Third Parties) Act 1999, a purchaser who purchased from the developer ought to be able to sue the builder pursuant to the Act unless the application of the Act has been excluded. Perhaps one solution is to remove the right to exclude the application of the Act in respect of building contracts.

In addition, there may not be an issue of the purchaser suffering a loss if the purchaser buys an existing immoveable property that has patent defects since the principle of caveat emptor applies though this may not apply in England in its common law form as a result of statutory intervention. At least in theory parties who buy and sell immoveable property would in all likelihood include the existence of defects as part of the factors for consideration in agreeing to a sale and purchase price. However, the issue of latent defects remains un-addressed. This opportunity to negotiate a price to take into account loss suffered as a result of patent defects would have addressed the situation in *Dunlop* where it is not possible to reduce the price for the buyer of the goods at the time when the property and the risk transfer to the buyer of the goods in respect of any damage caused by the shipper.

Pure economic loss cases

While the development of the law of negligence in England and Wales appears to concentrate on controlling the front end by imposing the need to establish the existence of a special relationship of proximity, the American approach looks towards avoiding a result that produces ‘liability in an indeterminate amount for an indeterminate time to an indeterminate class’. The other jurisdictions are then compelled to consider both forms of control in seeking an answer.

Such is the richness of the tradition of judge-made law, it would probably take decades for the learned judges to be freed from the shackles of the precedents so as to figure out a commercially practicable solution in respect of a person who suffers because of defects in a building but is not able to obtain damages from the builder who is responsible for the defects for what the courts term pure economic loss. This must, of course, be done without upsetting the established principles of the need to show ‘special relationship of proximity’ between the plaintiff and the defendant and the need to show that the damages awarded are not considered too remote.

In the past, the Parliament in the UK had to intervene in consumer contracts where the doctrine of freedom of contract was held sacred by the judges who were apparently bound by precedents and/or oblivious to the reality of the parties' vast differences in their respective bargaining power to negotiate contracts based on 'pure consensus'. Perhaps it is time again for Parliament to rise to the occasion to intervene in the law of negligence.

SIGAPORE CASE STUDIES

Two Singapore cases are examined for the purpose of this paper. The first case is *Chia Kok Leong and another* v. *Prosperland Pte Ltd* [2005] 2 SLR 484 where the Singapore Court of Appeal was asked to decide whether a developer can claim against the architect substantial damages even though the developer has suffered no loss and the management corporation of the development has a direct legal remedy in tort against the architect.

The second case is *RSP Architects Planners & Engineers* v. *Ocean Front Pte Ltd and another appeal* [1996] 1 SLR 113 where the Singapore Court of Appeal was asked to decide whether a management corporation has a claim against the developers, whether in contract or in tort, for pure economic loss in the form of cost of repair or making good those defects complained of.

The *Prosperland* case

This case involved the construction of a condominium which was completed in August 1993. The respondent developer had engaged the appellant architect for the project. The developer had also engaged a contractor who was the first defendant in the case below but who did not appeal. In this type of development, the formation of a statutory management corporation (MC) is prescribed by the Singapore Land Titles (Strata) Act (Cap 158, 1988 Rev Ed) (now replaced by the Building Maintenance Strata Management Act). The MC becomes the proprietor of the common property of the condominium.

On 2 May 2002, the developer commenced an action against the builder for defective works comprising the de-bonding of tiles that formed the external façade of the building and damage to the glass blocks installed at the lobbies and stairways. In addition, the developer sued the architect for breach of contract in failing to exercise due care in the design and supervision of the project which resulted in the defective works.

At the time of the institution of the action, the developer was no longer the owner of the condominium. The individual units in the condominium were transferred to third parties. The common areas of the condominium became vested in the MC. The developer had not spent any money on repairs. The developer was also not sued by the MC in respect of the defects. The developer was placed under voluntary liquidation in December 2002.

In any event, the developer obtained a 10-year warranty from the builder and the supplier of the adhesives that were used in the external wall tile façade. There is evidence that the MC intended to carry out the repairs and it was also looking towards the developer for relief. The MC also expected the developer to carry out rectifications. Moreover, there is evidence that the developer intended to use the damages recovered for that purpose. The developers and the present owners are related (para. 58).

The Court of Appeal decided (at para. 45) that the present case fell within the narrow ground of the exception expounded in the *St Martins* case. This is because the legal black hole was not removed completely since the management corporation had a limited right to claim in tort against the builder and the architect. There was a deed of care given by the builder to the purchasers. Thus this cannot justify taking away of the contractual rights of the building employer under *The Albazero* exception.

The Court of Appeal decided (at para. 59) that the developer was, in principle, entitled to claim for substantial damages pursuant to the broad ground. It was held that, 'the basis on which a plaintiff is entitled to claim for substantial damages under the broad ground is that he did not receive what he bargained and paid for. It has nothing to do with ownership of the thing or property.'[4]

> Neither should the claim be dependent upon whether a third party can sue the party in default in tort. Why should the existence of such a right in a third party to claim in tort affect the contractual rights of the plaintiff? The only thing which the court should guard against is to ensure that the builder is not required to compensate twice over for the same damage.

The court added that the broad ground is probably more consistent with principle:

> 52 There is no reason why the employer's right to sue for his loss should be dependent on whether he is owner of the property or otherwise. The only problem that could arise, which is more apparent than real, is that the builder could be exposed to double liability. …The court ought not to deprive a party of his just contractual relief on account of perceived difficulty which could be easily surmounted.

It is to be noted that the broad ground does not require that repairs have already been carried out by the developer nor does it require an intention to do so before he is entitled to claim substantial damages (para. 57).

The *Ocean Front* case

This case also involved the construction of a condominium. In this case, the management corporation (MC), a creature of statute, was the plaintiff. It was constituted after the completion of the condominium. Before the constitution of the MC, the developer was given the statutory task of maintaining the common property of the condominium. Accordingly, the MC took over the management and administration of the condominium from the developers from 15 November 1987.

In May 1989, complaints were made by the MC to the developer in respect of the spalling of concrete in the ceilings of the car parks of the various blocks. Repairs were carried out by the developer but these did not resolve the problem. There was also insufficient drainage of some common areas because of a lack of sufficient gradient. This led to a collection of water at several lift lobbies on the buildings.

On 28 June 1991, the MC sued the developer claiming damages in respect of the alleged faulty construction of certain areas of the common property. The parties agreed to obtain the court's answer to the claim as a preliminary issue. The High Court decided in favour of the MC and the developer appealed.

At the Court of Appeal, the issue framed by the court was:

> Whether the management corporation has a claim against the developers, whether in contract or in tort, for pure economic loss in the form of cost of repair or making good those defects complained of.

The Court of Appeal decided to review all relevant cases from the whole of the Commonwealth and concluded:

> 63 From our examination of all these authorities, it seems to us that there is no single rule or set of rules for determining, first, whether a duty of care arise in a particular circumstance and, second, the scope of that duty. In *Governors of the Peabody Donation Fund* v. *Sir Lindsay Parkinson & Co Ltd* [1985] AC 210, at p.240, Lord Keith of Kinkel said:
>
> 'The true question in each case is whether the particular defendant owed to the particular plaintiff a duty of care having the scope which is contended for, and whether he was in breach of that duty with consequent loss to the plaintiff. A relationship of proximity in Lord Atkin's sense must exist before any duty of care can arise, but the scope of the duty must depend on all the circumstances of the case. … So in determining whether or not a duty of care of particular scope was incumbent upon a defendant it is material to take into consideration whether it was just and reasonable that it should be so.'

Having accepted that the answer lies in the circumstances of the case, the Court of Appeal proceeded to isolate the facts that formed the circumstances. The Court of Appeal then applied the principles set out in the *Junior Books* case to the facts identified above.

> 74 … we regard the following facts of crucial importance in determining that there is sufficient proximity between the developers and the management corporation which gives rise to the duty of care: (i) the management corporation was an entity conceived and created by the developers; (ii) the developers were the party who built and developed the condominium including the common property and undertook the obligations to construct it in a good and workmanlike manner and were alone responsible for such construction; (iii) after completion of the condominium the developers were the party solely responsible for the maintenance and upkeep of the common property; (iv) the management corporation as the successor of the developers took over the control, management and administration of the common property and has the obligations of upkeeping and maintaining the common property; (v) the performance of these obligations is very much dependent on the developers having exercised reasonable care in the construction of the common property; (vi) the developers obviously knew or ought to have known that if they were negligent in their construction of the common property the resulting defects would have to be made good by the management corporation. The relationship between the developers and management corporation is as close it could be short of actual privity of contract. …

Further, the Court of Appeal then applied the second stage of the *Anns* test by asking whether there is any reason to reject the duty of care established in the first stage of the *Anns* test.

> 75 We now turn to consider whether there is any policy consideration in negativing such duty of care. First, there is the question whether this would result in imposing liability 'in an indeterminate amount for an indeterminate time to an indeterminate class'. The amount recoverable is the cost of repair and making good the defects in the common property and in no way can it be said to be indeterminate. The class of persons is finite and definable. As for the duration, the time span is also not indeterminate, as the maximum period of time in which the developers can possibly be exposed to liability is limited by the Limitation Act (Cap 163): see s 24B. Secondly, there is also a related objection that recovery for economic loss would result in an indefinitely transmissible warranty. The common property has been and will continue to remain in the control and under the management of the management corporation. There is no question of any transmissible warranty to any other party.

Accordingly, the Court of Appeal allowed, in principle, the MC's claim against the developer in respect of pure economic loss as represented by the cost of repairs of defects found in the common property of the condominium.

OBSERVATION AND ANALYSIS

The *Prosperland* case

Since the principle relied upon in the *Prosperland* case is part of an exception to the general rule, its application should be strictly controlled and used sparingly. It is submitted that the immoveable property cases should be distinguished from the sale of goods cases and that the use of the exception be disallowed.

An important difference between *Prosperland* and *Dunlop* is that while the cause of the damage of the goods is traced back to the shipper and not the seller or manufacturer, there is no party who transports the immoveable property and more importantly, the party who is responsible for the damage is the developer under the sale and purchase contract of the immoveable property while the party who caused the damage is the 'manufacturer' or designer and builder in the case of immoveable property.

Another important difference arising from the first point would be that there is no issue regarding the lack of privity of contract to sue. Again, in comparison, whereas the buyer in *Dunlop* cannot sue the seller since the risk in the goods has passed from the seller to the buyer and further the buyer cannot sue the party who caused the damage, i.e. the shipper, since it is the seller who contracts with the shipper and not the buyer, the buyer in *Prosperland* has a contract with the party who is responsible for the inherent building defects since when the risk in the immoveable property transfers from developer to the buyer on the date of completion of the sale and purchase contract, the defects were already in existence in the immoveable property. In other words, the buyer in *Prosperland* did not suffer the problem of the lack of privity of contract as in the *Dunlop* case since the buyer's recourse would be against the developer.

Accordingly, it is open to the buyer in *Prosperland* to sue the developer claiming damages in respect of the defects in the building. The developer, in turn, would recover from the party that caused the defects, i.e. the builder and/or the designer(s). However, the usual practice in Singapore is for each developer to have a company incorporated for a project. Not long after the completion of the project, the said company would dissolve itself voluntarily thereby transferring the profits of that company to the holding company. This ensures that the said company is not available in the long run for any suits by the buyers.

Thus, the *Dunlop* exception should not be applied in *Prosperland,* indeed in all immoveable property cases since, as explained above, there is no issue of the lack of privity of contract to overcome. However, the buyer may not, for practical purposes, be able to recover compensation from the developer if it no longer exists.

The *Ocean Front* case

It can be seen from the evolution of the law of negligence, the courts are struggling to understand the nature of defects in a building in relation to the issue of remoteness of damage because of its classification as pure economic loss.

Unlike where there is a contractual relationship, a buyer cannot recover from a developer loss suffered in respect of building defects because of the defence of independent contractor that the developer is entitled to use when he points the accusing finger at the builder and/or designers for being legally responsible for the said defects. In the case of subsequent buyers, there is no contractual relationship with the developer. Consequently, such parties can only hope to recover compensation under the law of negligence.

The journey towards being successful in a pure economic loss claim requires the plaintiff to prove that there exists a special relationship of proximity. To this end, only the MC has met with limited success in Singapore. Thus far, the MC has been successful as against the developer and the architect in respect of defects in the common property. However, the position of the subsidiary proprietor in respect of building defects within the unit that belongs to the subsidiary proprietor as against the developer, builder and/or designers, whether as the first or subsequent buyer, has yet to be determined by a Singapore court.

RECOMMENDATION

It is with greatest respect to the Singapore Court of Appeal that it is submitted that the *Dunlop* exception should not be applied to an immoveable property case for the reasons given above. In any event, the position of the buyers in *Prosperland* remains uncertain since there is no mention that the developer remains accountable to them. It is also submitted that the position of the buyer in *Ocean Front* remains uncertain as the case applies to the MC and not to the buyer.

Therefore it is recommended that Parliament regulate the matter through the existing legal framework. According to the Housing Developers (Project Accounts) Rules, a developer may collect money from buyers as the construction of the works progresses and deposit the moneys collected in a designated project account in a bank. Such moneys may be withdrawn progressively for making payments as prescribed by the Rules as certified by the Architect. Upon the completion of the works, the balance of the moneys in the project account may be withdrawn by the developer, presumably as its profits.

It is recommended that instead of allowing a complete withdrawal of the moneys in the project account, a significant percentage of the moneys left in the project account can only be withdrawn upon the expiry of the limitation period relevant to latent defects, i.e. a period of 15 years after the completion of the project. The provision for the 15-year period was adopted from the UK Latent Damage Act 1986. The moneys in the project account may be used to meet the claims by both the MC and the subsidiary proprietors in respect of defects in the building. Perhaps the money could be used to extend the performance bond given by the builder with the amount payable enhanced. Any such claim must be supported by a building surveyor's report. However, to preserve the right to claim, the MC and each subsidiary proprietor must conduct an annual building survey that must be filed with the developer. This ensures that there is no double claiming of the same defect.

Alternatively, parties may not wish to submit the annual building surveyor's report and would then be excluded from any right to claim from the project account. Incidental to this scheme would be the benefit of knowing whether the property is free from serious structural defects if annual building surveys are carried out.

CONCLUSION

The law is not perfect. It has allowed an exception to a rule in the law of contract to gain unnecessary importance. More importantly, it has allowed a cross-application of the exception principle relating to the recovery of damages from sale of goods cases that requires transport to sale of immoveable property that requires no transport without a clear and proper analysis of the contractual relationships of all the parties involved. However, it has been often said that bad law is nevertheless the law until it is overruled.

In the law of negligence, nothing is more disconcerting than seeing the great legal minds struggle with the formulation of a legal principle that requires an understanding of a non-legal concept, that is, how to deal with pure economic loss associated with building defects.

The real issue is perhaps what Lord Millet said in *Panatown*, that of ensuring that the damages are paid to the right party. This objective is just as applicable in a contractual dispute in *Panatown* as it would be in any tortious dispute. The question would be, as always, how much longer must the parties wait for the courts to give a commercially acceptable solution.

As Parliament has reshaped the law of contract in consumer contracts involving goods, Parliament can once again reshape the law relating to building defects to ensure that damages are paid to the right party. This route would always be faster than that taken by the courts but only if both started at the same time. However, Parliament must have the necessary political will and motivation and perhaps even simple awareness that the problem exists.

JAPANESE BIDDING PATTERNS: A STATISTICAL APPROACH

Jun Iwamatsu,[1] Kazuyoshi Endo[2] and Tetsukazu Akiyama[3]

[1]*Research Institute on Building Cost (RIBC), 3-25-33 Nishi-Shinbashi, Minato-ku ,Tokyo, 105-0003, Japan*

[3]*Department of Architecture, Toyo University, Saitama 350-8585, Japan*

In the Japanese construction sector where the bidding system has been recently reformed, the data of the tender results in areas of public construction works and/or consultancy services are now being made open, enabling objective analysis of such data from various viewpoints. In this research, such open data of a nationwide coverage in the last two years or so has been collected comprehensively for academic analysis using some statistical methods. The main point of this research is to gain a rough grasp of the tendering activities in the Japanese construction contractors and/or consultants. There are two methods used in the analysis: (1) analysis by focusing on each individual tendering action and (2) analysis by focusing on each individual enterprise of the three selected sectors. In addition, public investments are seen to be decreasing sharply and the jurisdictional control to bid-rigging practices is being strengthened. The analysis of these data clarifies the tendency that severe competition among the bidders taking place and bidders resorting to price-dumping practices, which is becoming remarkable among the concerned part of the industry.

Keywords: competitiveness, bidding, statistical analysis, construction company, consultant.

INTRODUCTION

Background of research

The construction industry of Japan has been confronting a structural recession, which had never been experienced in the past. Construction investment has fallen to a level of some 50 trillion yen now from about 80 trillion yen in the 1990s.

Under the current Japanese government finance crisis, it is evident that the minus situation of public works expenditures will continue (Figure 1). Although the number of construction licence registrations on the part of contractors is decreasing slightly from a peak level, there still are 500,000 contractors in the shrinking market. That is, construction industry is being thrown into a state of excessive competition. Furthermore, it is in a situation where severe compliance is called for, by the enforcement of the Act for Promoting Proper Tendering and Contracting for Public Works (enforced in April 2001), and the revised enforcement of Antimonopoly Law (January 2006). So-called "bid rigging", widely practiced in the public-works sector, is becoming more severely controlled.

[1] iwamatsu@ribc.or.jp

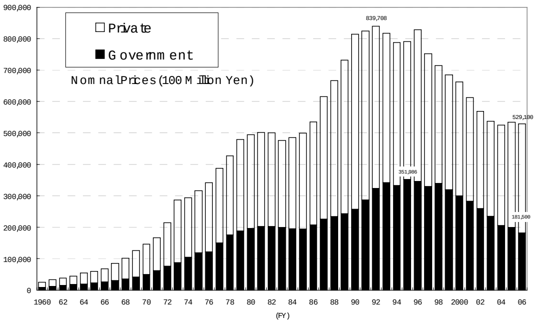

Figure 1: Trend of the amount of construction investments in Japan (nominal value) (Source: *Construction Investment Prospect,* MLIT)

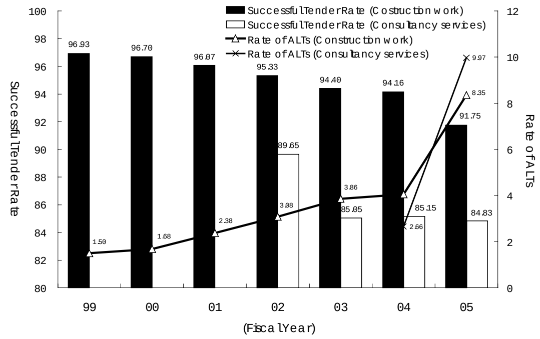

Figure 2: Transition of average successful tender rate of construction and consultancy at MLIT (Source: *Data of Construction Contracts*, MLIT (including pre-MLIT period, i.e. Ministry of Construction). Construction of seaports and airports is excluded)

Under such a situation, a price-dumping tendency is becoming rampant in the competitive tendering or bidding. Figure 2 shows transition of the successful tender rate of construction orders and related consultancy services at MLIT (Ministry of Land, Infrastructure and Transport, Government of Japan) as this ministry performs much of the public construction investment in Japan. A successful tender rate is defined as the rate of the successful tender price compared to the ceiling price (a "ceiling price" is the pre-set amount of cost-of-construction as reasonably predicted by owner-side engineers on basis of the provisions of the Public Account (Financial) Law (enacted by the Japanese government early in 1889). Unlike in other countries, there is a provision where such a pre-estimated amount should stay under a certain ceiling, leading to a rule that the successful tender price should not exceed the ceiling price). The successful tender rate of the construction, which was about 97% on the average in the 1999 fiscal year, fell to a little less than 92% in the 2005 fiscal year. Moreover, the percentage of low-priced tenders is growing and such low-priced tendering was found in a little less than 10% of all tenders in the 2005 fiscal year on both construction works and consultancy services. This is regarded as a questionable tendency from such viewpoints of ensuring construction quality, sound growth of the construction industry, etc., and is being brought up as a political issue. (As for abnormally low tenders, related laws and provisions are now defined under the Public Account Law. That is, officials specializing in related contracts are to decide "the investigation-based prices" to stay between 66.6% (2/3) through 80.0% of the ceiling prices as widely accepted in Japan. In the case of abnormally low tenders, there exists an established procedure to conduct contractor hearings as such. But, in the past, even such low tenders were almost freely processed in the absence of any criteria to discretely determine dumping prices as such with which abnormally low tenders could have been duly rejected. The enforcement in December 2006 of an "applied criterion", however, has led to the powerful action to exclude such price dumping.)

Enforcement of APPTCPW and official announcement of tender results

The Act for Promoting Proper Tendering and Contracting for Public Works (APPTCPW) was enacted as of 27th November 2000 in Japan. The purposes of this Act are to secure the general public's trust toward public works and to promote the sound development of the construction industry that contracts public works commissioned by the Central Government, quasi-governmental agencies and local governments through the (1) establishment of requirements that form the foundation of proper tendering and contracting, (2) public announcement of relevant information, and so on.

Due to the Act, the Regional Construction Bureau of MLIT and several other agencies have recently provided the information about tender results to the public. The tender results are classified into two categories: construction works and consultancy concerning public works. In this research, the authors were able to obtain about 170 thousands tendering information of FY 2005-2006 in each category. The data seems to cover almost all the major tenders in each of those bureaus and agencies. The authors statistically analysed the data.

About the data for analysis

In this research, tender result information was obtained through the Internet (the source of the analytical data was: the website (http://ogb/go.jp/choutatu/htm) for each of the entities listed thereon or that (http://www.ppi.go.jp) of the PPI (Public Works Procurement Information Service) as an antenna window of JACIC (the Japan Construction Information Center). In the last two years, such data has been collectively announced in MS Excel format on MLIT's website (www.mlit.go.jp/chotatsu/kekka/kekka.html). All data, thus collected in this study, has been analysed and rearranged solely by the staff of the Endo Lab. of the Kogakuin University, where the data was mostly converted into SPSS for Windows). It was in autumn of 2006 when we obtained all the tender result data of 10 order organizations throughout the country, as shown in Figure 3 (the Okinawa entity is under direct administration of the Cabinet Office of the Japanese government, while nine other entities are under MLIT administration). Tender results information is roughly divided into two: construction works and consultancy services. Excepting the local Okinawa data, it encompasses the period of about 18 months covering the contracts from April 2005 through August 2006. The data was obtained under the situation of the excessive competition widely seen in the construction industry, as mentioned at the start of this paper. Specific figures of the data are shown in Table 1.

Table 1: Outline of the analysed data

By ordering offices	Construction works		Consultancy services	
	No. of cases of construction	**No. of tenders**	**No. of cases of consultancy**	**No. of tenders**
01 Hokkaido Regional Development Bureau	3,871	33,005	4,427	44,998
02 Tohoku Regional Development Bureau	1,971	20,885	1,538	16,316
03 Kanto Regional Development Bureau	2,674	27,647	2,194	25,919
04 Chubu Regional Development Bureau	1,623	14,070	1,208	13,533
05 Hokuriku Regional Development Bureau	1,235	10,807	969	10,869
06 Kinki Regional Development Bureau	1,724	15,284	1,628	16,455
07 Chugoku Regional Development Bureau	1,460	12,719	1,347	14,263
08 Shikoku Regional Development Bureau	844	7,671	736	7,869
09 Kyushu Regional Development Bureau	2,552	26,713	1,993	20,485
10 Okinawa General Bureau	312	3,188	434	2,469
Grand total	18,266	171,989	16,474	173,176

The period of data collection was April 2005 through August 2006, except "10. Okinawa General Bureau," to include: construction – March 2004 through August 2006, and consultancy – January 2004 through August 2006, only.

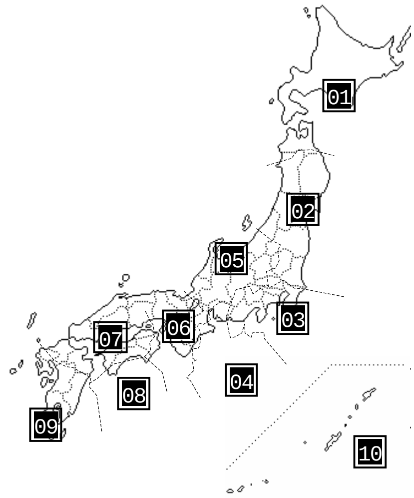

Figure 3: Jurisdictional area (outline)

The specific items of information in the table are: tendering project names, ordering departments in the ministry, specific types of construction projects or consultancy services, the number of tendering times of each bidder (up to three times), ceiling prices, tenderers' names, tendered prices, names of successful tenderers, final tender prices, overall evaluation (given or not given), overall evaluation scores, etc.

As for the construction work data, its coverage was 68.5% of the total monetary value, as derived from the result of our calculation of its ratios against the total value of monthly order prices (which was acquired from the Current Survey on Orders Received). The remainder is presumed to represent private tenders (excepted for analysis reasons) without competition, and orders from other ministries and government offices (i.e. Ministry of Agriculture, Forestry, and Fishery etc.). Since it is a high coverage of data, it should be able to command a whole view of the situation of the whole, which has occurred by order construction work of from a nationwide perspective, and is useful for generalization of an analysis result. (As for the construction work data, the data for the 10 "tendered" cases were analysed in this study, but the remaining 696 "private contract" cases without tender entries were excluded from the analysis. The latter group represents small-scale construction works, with their average contract amount being approximately 112 million yen. Incidentally, the grand total price happens to be some 76,786 million yen or and the overall data coverage can be calculated at 71.4%.)

The direction of analysis

The main point of this research is to enable a rough grasp of the tendering activities in the Japanese construction contractors and/or consultants, while there are two methods used in this analysis: (1) analysis by focusing on each individual tendering action and 2) analysis by focusing on each individual contractor and/or consultant. Through (1), the situation of competitions, according to the types of work and ordering organization, would be expected to be understood based on the number of bidders (tenderers), successful tendering percentage and tendering price distribution. Through (2), it is possible to analyse the pattern of tendering behaviours by defining each contractor's and/or consultant's competitive capacities.

ANALYSIS OF INDIVIDUAL TENDERS

First, analysis is focused on each case of tendering behaviours. Specifically, we analyse the data using such indices as the number of participants to tendering, variation of tendering prices, and successful tender rates. Further, we see the actual situation of the "Performance-based Evaluation Contract with Technical Proposal".

The number of bidders (tenderers)
In Japan, the designated competitive bidding has been popular ever since the overall revision of the Public Account Law in 1900. It is up to the intention of an order organization to determine the maximum number of tendering participants in the designated competitive bidding system.

A notification by the Ministry of Construction once defined the number of tendering persons to be ten in the designated competitive bidding system. Despite the later abolition of that regulation, the system of competition by ten persons has become customary in many cases. In Figure 4, the histogram respectively shows the result of the total number of participants in the first tendering. Figure 4 shows the distribution for the construction works, somewhat spreading on both sides, with the highest participation by ten persons. On the other hand, the distribution for the consultancy services is inclined only toward ten persons.

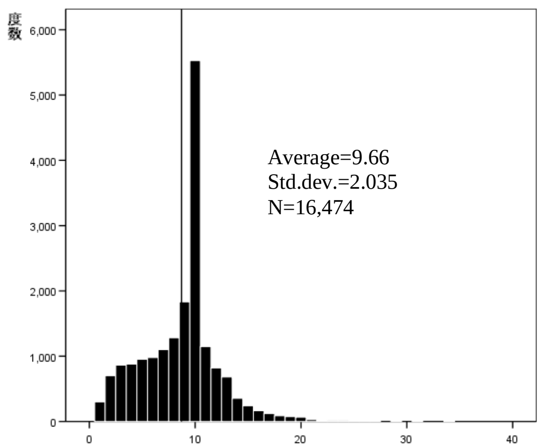

Figure 4a: Histogram of the number of tender participants (construction works)

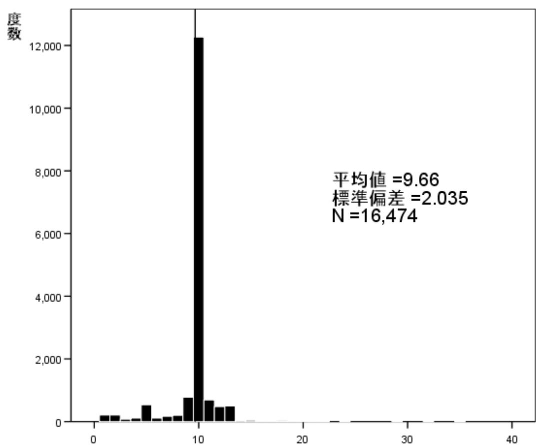

Figure 4b: Histogram of the number of tender participants (consultancy services)

Coefficient of variation of a bidding value
As mentioned above, tendering is performed by more than two competitors. In order to statistically find differences among those competitors, an index is created showing the grade of the variation of bid prices in a tender. The general index in that case is a coefficient of variation of such bidding values. A coefficient of variation is calculated by dividing the standard deviation of the bid value in each tender by the average value as the denominator. The smaller the numerical value is, the less the variation in the tender price.

Table 2 shows the statistical value of tender situation according to the type of works and tender systems. The average value of coefficients of variation of tender value of all construction work is 5.80, and that of consultancy services is 9.30, so it is clear that the latter somewhat varies. The ceiling price of consultancy services will be hardly presumed. Such difficulty can probably be related to the smallness of the successful bid rate, which is described below. In past research by the authors using the construction work data of the same MLIT (MLIT in 2002 used to be called "Ministry of Construction") for 1998 to 1999 (Akiyama *et al*. 2002), the average value was 2.9. In addition, Skitmore (1988) who rearranged many tender-related research papers, the values were spreading from 5.0 to 8.4. In the past, the bidding prices for public works in Japan had small coefficients of variation, showing close coherence. Nowadays, however, variations are showing up in the same range as the research findings in foreign countries. The reason for this rather rapid change would be because the competitive environment in the Japanese sector of tendering is becoming severer. This phenomenon is also reflected in the declining pace of successful bid rates as shown below. It can be assumed from such a change that the Japanese public construction market is changing to a new environment where not only bid-rigging practices are being suppressed but also the genuine mode of price competition is being encouraged.

The changing situation as mentioned above can be verified through calculation of the coefficients of variation of data according to specific types of construction work. In Table 2, the values of various indicators about tender situation are statistically summarized. Having reviewed the data a bit more finely according to the types of construction works, we can see differences in the derived value of the coefficients of variation in related tender values. The reasons considered are that (1) the competitive situation is not equal among the types of work; and (2) the differences arise from the gap of accuracy of the construction cost prediction among them, depending on various technological reasons, and so forth.

Table 2a: Statistical value of tender situation according to the type of works and tender systems (construction work)

		No. of valid data	1st tender				Average successful tender (1000 yen)	Average successful tender rate (%)
			No. of tenders	Average ratio to estimated price	Average no. of tender participants	Coef. of variation of tender value		
Tender Systems	1.Designated comp. bidding	14,339	131,511	102.06	9.16	5.65	69,568	92.24
	2.Open and comp. bidding	2,339	17,894	97.56	7.07	6.07	173,976	90.25
	3.Limited tendering	1	30	100.61	1.90	3.69	42,722	95.26

	6.Others and unknown	231	2,335	104.14	5.57	**15.31**	18,444	89.01
	Ground total	16,266	159,486	103.30	9.66	9.30	11,407	86.73

(Note) "No. of valid data" is taken from successful bid prices. That is, it should be noted that the valid numbers of each indicator in this table differ respectively. Data for tender decliners was not included in "No. of tenders". The numbers with bold-faced type in the table represent unique values.

Successful bid rates

A successful bid rate is a ratio of the contract price to owner's ceiling price. This index is commonly used in Japan as the indicator showing the competitiveness of concerned tenders. However, although this indicator is partial and of a single dimension, there is an injurious effect of its having been the over-emphasized topic of discussions. For example, the Japan Citizen's Ombudsman Association (JCOA) has created a criterion to judge existence of bid rigging in one client if the average successful bid rate exceeds 95% (this council names their criteria as "Doubt-degrees of bid-rigging scandal", releasing the ranking data according to the specific dimensions about the construction work-orders which all local and municipal issue every year). However, there is no logical basis in this judgment position. But, such ceiling prices are not necessarily fair and non-vulnerable, in that a ceiling price with an upper limit restraint is created by the engineer of a client, and that it is set up based on the prediction quantity from the construction document based on their estimation criteria, and also on the ceiling prices of materials, special construction expenses and so on, as published by some price research institutes. Here, in light of such situation, the authors would hereby describe the actual Japanese tender behaviours as can be observed from the indicator of successful bid rates revealing a meaningful indicator.

As shown in Table 2, the average successful bid rate of construction works is 91.74% and that of consultancy services 86.73%. Moreover, as seen from the overall shape of the distribution, consultancy services have a little more spreading distribution.

The specific data of successful bid rates according to type of construction works is also shown in Table 2 above. From the data of construction work, it is clear that the successful bid rates of road paving work, such as "09 Cement/concrete paving" and "02 Asphalt paving", are slightly high, and "03 Steel bridge-top construction" is the lowest. "01 General civil engineering" and "05 Building construction" being performed under many orders show in-between values. The histogram of successful bid rates is illustrated according to these notable construction work types (as shown on the right side of Figure 5. And, the histogram of the ratios resulting from division of the first-time tender value by ceiling prices is also shown on the left side of Figure 5.

Since the clients are to determine ceiling prices, each as an upper limit price, the rates shown here should serve as the ratio to clarify the relative position of each tender value. As these graphs share the same x-axis scale, so the comparison of distribution value. As these graphs share the same x-axis scale, so the comparison of distribution among the construction work types is enabled. (The ratios here are also used officially as data describing MLIT's tender business situation at http://www.mlit.go.jp/chotatsu/contractsystem/getuji.html in Japanese only.)

Examining these two shapes of distribution should clarify the specific features of the data for every type of construction works. In the distribution of tender values, "01 General civil engineering" and "02 Asphalt paving" are represented in a beautiful normal distribution near the 100% threshold (that is, showing the same amount as the ceiling price). And the successful bid rates are densely crowded around the comparatively high portion. Also in "03 Steel bridge-top structure construction", the distribution of tender values appear as inclined toward the low portion, and so are many values of successful bid rates. This will clarify the fact that in "03 Steel bridge-top construction", the market competition by abnormally low tenders (ALTs) is intense. And in "05 Building construction", the average percentage of tender value ratios is 110.2 with the distribution rather distorted by pulling down a little to the right side. Meanwhile, there also exists a portion of comparatively low rates of successful bids. This means that this is a severe area of competition on the part of the bidders of this type of construction work in correctly setting the bid prices. One of the reasons for this could be that the system of estimation is comparatively complicated and, so, it is difficult to estimate correctly in building construction works.

ANALYSIS OF THE CORPORATE BEHAVIORS BY CONSTRUCTION SECTORS

Extraction of the related sectors

We will particularly analyse the tender behaviours of construction enterprises participating en masse in competitive bids. Rather than the consultancy service data, construction work data has been chosen, for convenience' sake, to be analysed. In this research, three peculiar sectors (industry) were extracted by the following three sectors, with data to be analysed in such terms as the aggregation by the type of construction work, data searching by particular names of enterprise, etc. The data has been further selected on the condition that the date reflects the offering of five or more tenders and at least one successful bid, for the firms to be extracted within each of the three sectors (extracted on the same condition as adopted by Drew *et al.* 1993):

1. The bridge-building sector (33 companies) – these companies were extracted from the sector list in which the surcharge orders of payment issued by the Fair Trade Commission pursuant to certain bid-rigging affairs. Medium- and large-scale companies are included.
2. The road paving sector (84 companies) – companies evidently constructing roads were extracted (i.e. firm names containing the word "road" was picked up). Small through large-scale firms were included.
3. The sector of major general contractors (47 companies) – the top 50-company list of the construction industry sales data, based on some trade paper surveys, is used, and companies with achievements shown in this data are extracted. All firm represent major corporations only.

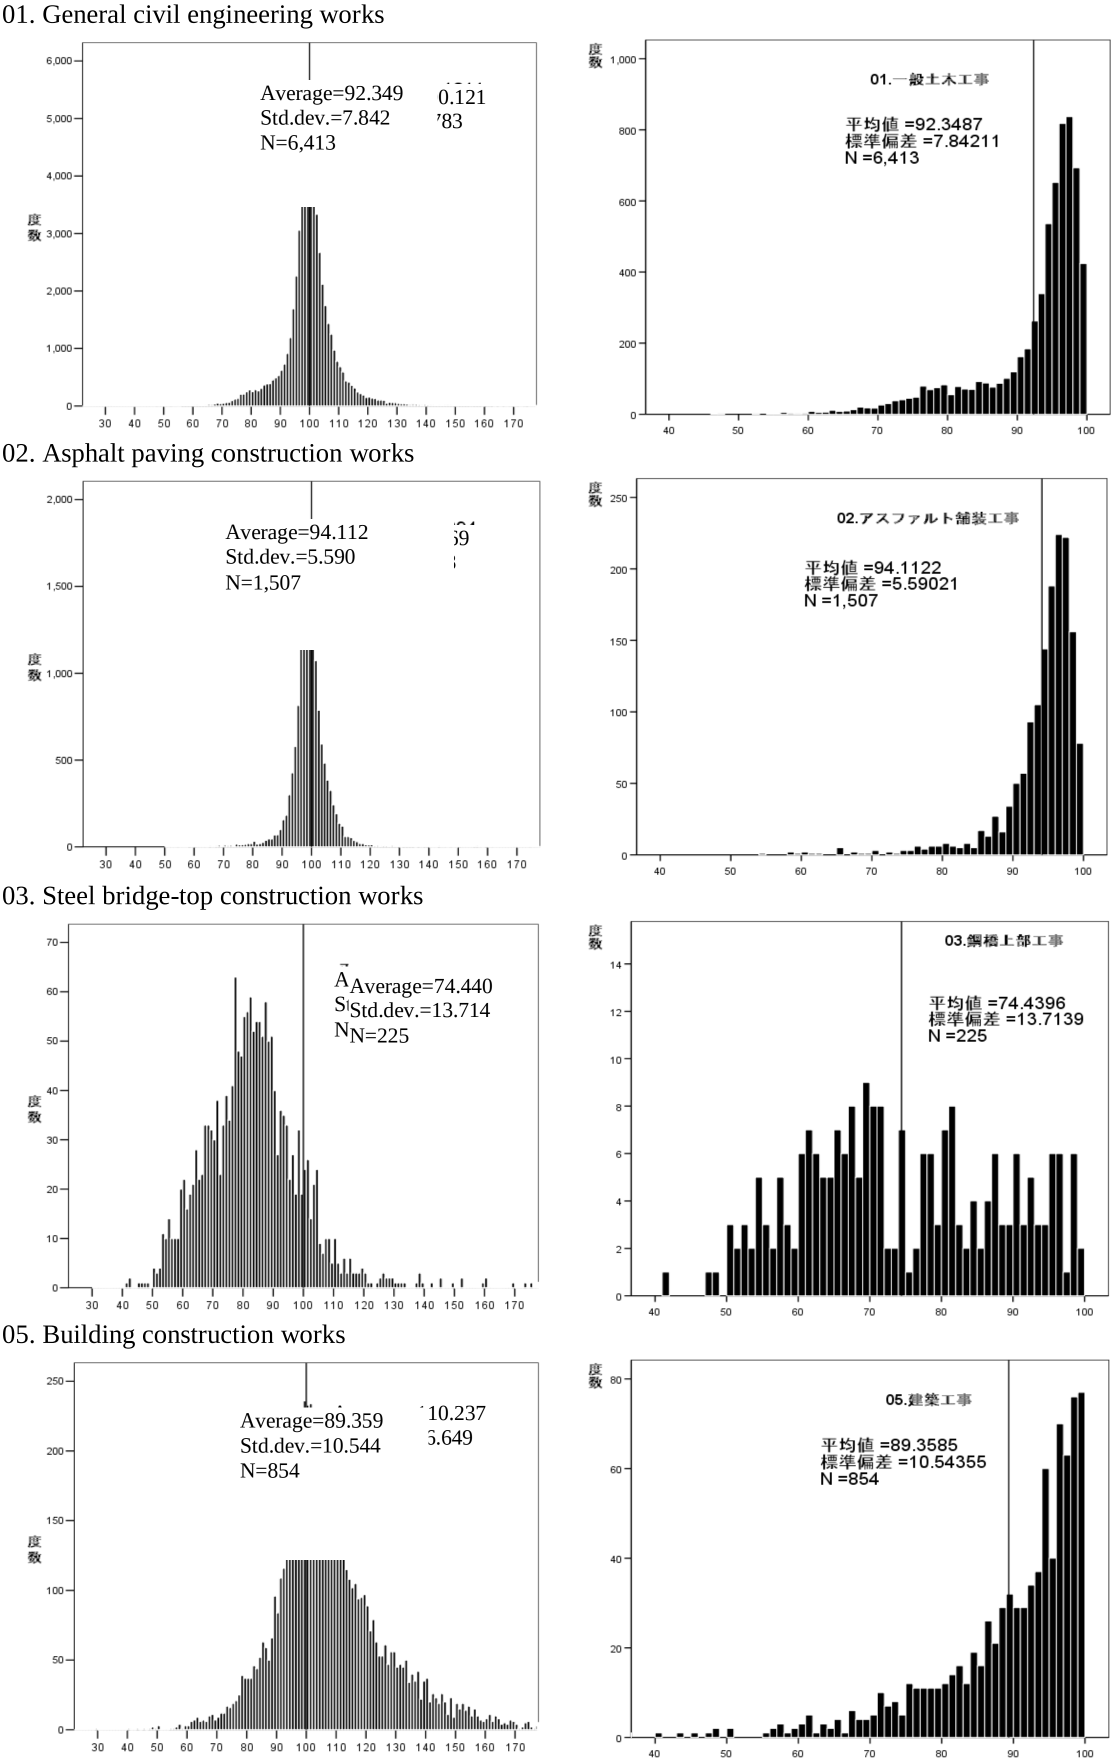

Figure 5: Histogram of ratios as the result of dividing the first-time tender value by estimated price (left side) and histogram of successful bid rates of some construction work types (right side)

Table 3: Outline of corporate behaviour data of the three sectors of construction industry

	Sector 1 Bridge-building	**Sector 2 Road repairing**	**Sector 3 Major GC**
Total no. of companies.	33	84	47
Aggregate total no. of tenders	1,522	8,387	3,258
Aggregate total no. of successful tenders	159	826	381
Average successful bid (1000 yen)	235,221	148,614	412,868
Average successful bid rate (%)	74.65	94.86	90.57
Standard deviation of above value	17.03	4.86	9.40
Average value of average competitiveness (the 1st time)	21.96	5.79	10.26
Average value of the standard deviation	19.44	6.36	13.13

(Note) These analytical data represent a total aggregation, in which number of “declined tenders” is not included.

Table 3 outlines the result of an analysis of corporate behaviours, as observed from the extracted data. Here, the word "competitiveness," as used in this analysis with each tender (by noting each company’s 1st tender only), is defined in the following equation:

Competitiveness = (Bidding price minus Contract price) / Contract price x100

The "Average Competitiveness" in Table 3 means an arithmetic average of competitiveness in all the tenders from each enterprise, and the Average Value means the arithmetic average of the average competitiveness values of two or more enterprises.

Bridge-building sector being shaken up upon disclosure of bid-rigging affairs (Sector 1)

In the steel bridge building sector whose main clientele is MLIT's Regional Development Bureau etc., there were two bid-rigging specialized organizations called 1_K-kai (old-Koyokai; 17 companies are members, a forerunner group of makers) and 2) A-kai (old-Azumakai; 30 companies are members, a late-coming group of makers). It became publicly clear in October 2004, as the result of an on-the-spot inspection conducted by the governmental Fair Trade Commission in October 2004, that these 47 companies of the two groups had been repeating bid-rigging practices (refer to http://ja.wikipedia.org/wiki in Japanese only).

This incident has resulted in the dispersal of the bid-rigging organizations, with some companies having had to withdraw from bridge building. Such confusion also affected the ordering side of the bridge building. In FY 2005, the order number of cases and the amount of order have fallen greatly, and this sector of industry has to face a severer competitive environment. In these study data, the situation surrounding about 33 companies after the incident disclosure is acquired. Among the 44 companies for which the Fair Trade Commission had issued the surcharge order of payment in March 2006, 11 companies without a fixed number of tender achievements were removed from the study for the reasons of their withdrawal from the market etc.

Road pavement sector of construction industry (Sector 2)

Road investment occupies a big pie of Japan's civil engineering-works investment. Sector 2 includes companies who mainly engage in road paving work. Since 83 companies included in this data actually succeeded in receiving orders for the nation’s public work, they are comparatively large companies. Since road paving is a type of work that requires special technologies; business superiority is enjoyed only by the companies belonging to this sector.

The sector of major general contractors (Sector 3)

The top 50 companies in construction sales were extracted; this group represents Japanese construction industry. Many engineers skilled in various technical fields are employed by these firms, covering a wide range of construction works and enabling them to participate in the tendering practice. They tend to be more involved in comparatively large-scaled construction work in monetary terms as shown also in Table 3.

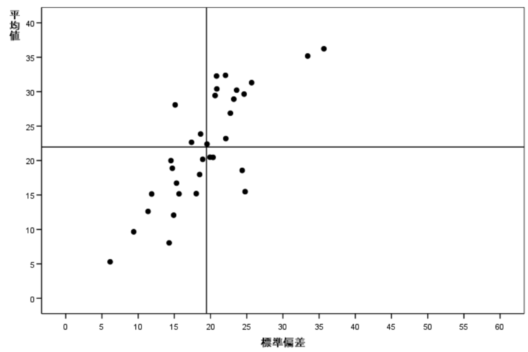
Comparative analysis of the three sectors using competitiveness indicators

The tendering behaviour of each enterprise as a member in each of the three sectors is plotted to the scatter diagram using competitiveness indicators as illustrated above (Figure 6). The vertical axis of the figure is the average value of competitiveness obtained from the accumulated tender result data of each enterprise, and the horizontal axis is the standard deviation of the value. It reflects that the closer a vertical axis is to the zero position of the chart, the more powerful the competitiveness is, and that the horizontal axis shows it being in a stable position.

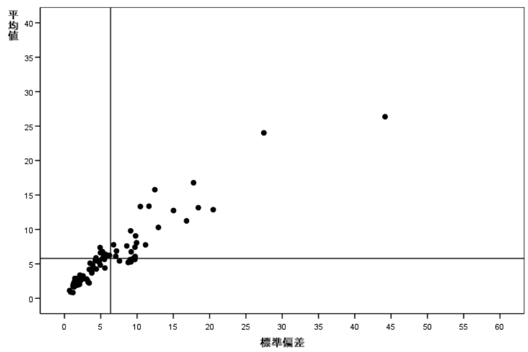
Classifying each sector's data of both axes with the arithmetic average values, the chart can be divided into four quadrants within each sector. Companies belonging to the first quadrant are companies characterized as "silly." Similarly, those in the second quadrant are named as "non-serious", the third quadrant as "sensible", and the fourth quadrant as "suicidal." These classification names and the analytic method used are based on Drew *et al*. (1993).

Figure 6 is plotted on the same scale for the three Sectors, enabling straight comparison with each other. In Sector 1 (bridge building), both average competitiveness and its standard deviation show high values and indicators are far from the zero position on the graph. Since Sector 1 is known to have rushed into severe dumping competition caused by the incident of bid-rigging exposure, this graph matches with such situation. Conversely, Sector 2 (road pavement) turns out to be closest to the graph's axis-zero position, and their competition is severe by a narrow margin. Sector 3 (general contractors) sits in between Sectors 1 and 2.

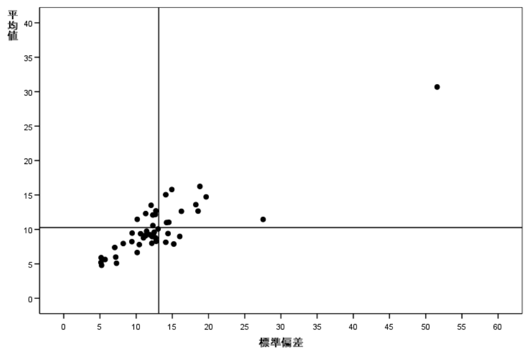
(1) The bridge building sector of industry



(2) The road pavement sector of industry



(3) The major contractor sector of industry



Legend:

Average	(ii)non-serious	(i)silly
	(iii)sensible	(iv)suicidal
	Standard deviation	

Figure 6: Company typology within each sector of industry reflecting average competitiveness and its standard deviation (the average line value of in each of above shown figures is shown in Table 3) (Cf. Drew *et al*. 1993)

Drew *et al*. (1993) analysed the data obtained from the housing industry of Hong Kong. They reported that its average competitiveness was 14.13 and its standard deviation was 13.79, and their indicators appear a little less distant from the axis-zero position, as compared with Sector 1 in this analysis. Meanwhile, Akiyama *et al*. (2002) etc., dealt with the similar situation of 118 companies by using the tender data of MLIT for the years 1998 through 1999, clarifying that their average competitiveness was 4.24 and the Standard deviation at 4.33. This means that they are almost the same as in Sector 2's case in this analysis. Since many of the 118 companies are major general contractors, these present-time values, if re-estimated now (i.e. 7 to 8 years thereafter), should be a little higher. Therefore, it can be concluded that what was once a competition with narrow margins is changing toward a severer competition with a recognizable variation at this moment.

As stated in the beginning, Japanese construction business has faced a comprehensive scale of reducing construction investments, leading to a more competitive market environment. Therefore, it can be conclusively said that the average competitiveness and its standard deviation values are leaving further from the axis-zero point in this analysis. This should also mean that the construction enterprise in present-day Japan is undergoing considerable differentiation in their competitive environments depending on what sectors the individual companies belong to.

CONCLUSION

This paper widely analyses the competitive environment surrounding the construction tender business in Japan using the published data on tender results in the construction industry. It also included past cases of authors' analysis as well as the data of some precedent researches so far made outside Japan. Therefore, this paper should clarify some specific characteristics of Japanese construction industry and related ongoing changes. However, since this study is still in process in that the "consultancy services" for the tendering entities, for instance, has not been covered yet, and that authors intend to pursue this aspect in future research. Furthermore, since more up-to-date data of accessible tender results keeps being accumulated, the authors will continuously monitor such up-to-date information for our study.

SOME NEGLECTED VARIABLES IN CONSTRUCTION MANAGEMENT RESEARCH CONTRIBUTING TO A COMPETITIVE ADVANTAGE RESEARCH APPROACH

Vernon Ireland[1]

[1]*Education Centre for Innovation and Commercialisation, The University of Adelaide, Adelaide, SA, 5005, Australia*

The purpose of the research was to identify variables or concepts which have had inadequate attention by construction researchers and practitioners, these being: CMMI, Enterprise architecture, Entrepreneurship, Operational Excellence rather than sustained competitive advantage, PMBOK, Portfolio, PRINCE2, Requirements and Vision. All appear to have relevance in construction.
A second purpose was to examine the relationship between the three types or levels of variables or concepts: external competitive strategy of a firm, the business environment in which the firm operates and the internal strategies chosen by the firm to achieve the external competitive strategy. Case studies were conducted on a group of mostly non-construction firms operating in a technology environment.
The methodology used included a major survey questionnaire and the use of principal components analysis to clarify variables. Correlations were then demonstrated between the three groups of variables.
Minimising cost within a niche and minimising time of delivery, segmenting the market and fit, were shown to be key competitive strategies. All internal strategies examined supported at least one external objective.

Keywords: business strategy, CMMI, enterprise architecture, entrepreneurship, requirements.

INTRODUCTION

Competitive strategy of firms has always been important and is becoming more so with globalisation. Construction research and practice can benefit from examining other disciplines which have similarities.

The research had two purposes:

1. Outline a number of concepts or variables which construction researchers could investigate more thoroughly, which are relevant in other areas of technology business and management, but which appear to have received little consideration in construction management research and practice;

2. More formally explore the relationships between the three classes of variables, these being the competitive strategy of the firm, the business environment in which the firm operates and the internal strategies which facilitate achievement of the external competitive strategy.

[1] vernon.ireland@adelaide.edu.au

With regard to the first objective, construction practitioners could benefit from greater awareness of these approaches in other industries and trial them in construction to assess their suitability.

With regard to the second objective, consideration of the approach of recognising these three levels of variables could contribute to a more formal definition of a research area in construction and lead to greater effectiveness of construction firms.

The reasons for conducting the study on competitive success stemmed from the view of the 6 sigma and CMMI enthusiasts that there is wastage in managerial effort in the majority of companies approaching 40–50%. The experience of practitioners working to assist companies improve their performance bears this out. These claims are discussed under the topic headings.

The use of these variables or concepts in other industries is based on a larger study of the competitive strategy of the firm, the business environment in which the firm operates and the internal strategies chosen to facilitate achievement of the external competitive strategy (Ireland 2007:1). The other industries on which this currently reported study was based are shown in Table 1.

Issues of whether the product manufacture and the building industry are part of construction are relevant. However, the processes used in construction, of feasibility, planning and design, production, commissioning and hand-over, and possibly operations, are similar to those in a number of other industries such as defence equipment development, shipping design and construction, and often conversion, and production of new products. Even development of software solutions uses similar processes. All companies studied were engaged in a technology environment and under competitive pressure.

The other concepts or variables which are examined have been chosen because they are generally not readily discussed or assessed by construction researchers, which relates to objective 1. These are as follows:

1. CMMI;
2. Enterprise architecture (Cronbach α of 0.7 or greater);
3. Entrepreneurship (Cronbach α of 0.7 or greater);
4. PMBOK versus PRINCE2 (Cronbach α of 0.7 or greater);
5. Portfolio (Cronbach α of 0.7 or greater);
6. Requirements;
7. Vision.

Competitive strategy and business environment are described below because of objective 2.

The concept of competitive strategy of the firm, the business environment and the internal strategies chosen to facilitate achievement of the external competitive strategy has certainly been addressed by many CME papers, even if not quite so formally. The larger study (Ireland 2007: 1), of which these variables form a part, considered the relative effect of many other internal strategies on the achievement of the firm's competitive success, including customer understanding, process management, process reengineering, the use of core competencies, innovation, risk management, leadership, staff development and staff motivation.

The variables have been defined, measured by survey, and those shown above have tested for reliability; they were then shown to correlate with competitive strategy at the 5% level of significance or better.

CONSTRUCTION COMPARED WITH OTHER INDUSTRIES

Many authors have described the construction industry including Ofori (1990), Nam and Tatum (1989) and Hillebrandt (1984). Hillebrandt defines construction as including the organisations involved in the construction process and this process aspect of feasibility, planning and design, implementation and commissioning, has been used as a basis for accepting the validity of comparison with other industries.

Some major industry bodies of knowledge such as the Project Management Body of Knowledge (PMBOK) include construction with defence, IT and manufacturing.

USE OF THE VARIABLES IN OTHER INDUSTRIES

Competitive strategy

Andrews (1991: 44) says corporate strategy is the pattern of decisions in a company that: determines and reveal its objectives, purposes, or goals; produces the principal policies and plans for achieving those goals; defines the range of business the company is to pursue; and the economic and non-economic contribution it intends to make to its shareholders, employees, customers and communities.

Porter (1980: 35) proposed that there are three potentially successful strategic approaches to outperforming other firms in an industry:

- Overall cost leadership;
- Differentiation;
- Focus or cost and differentiation within a niche.

Dikmen and Birgonul (2006), in their review of international construction research, both examine competitive advantage of firms and endorse the role of the business environment. Bassioni *et al.* (2005) support the need for strategic management. Ofori (2003) looked at factors leading to international competitiveness: using Porter’s diamond framework items, the demand conditions and related and supportive industries, the context for firm strategy and rivalry, and even the role of government and culture, are supportive ideas to business environment of this study. Oz (2001) is also supportive.

ISO 9000 is directed at quality and quality is a reasonable basis for competitive strategy.

Stalk and Hout (1990) make a strong case for competing by using time as the competitive weapon. This can take a number of forms such as reducing delivery time of the completed product, reducing response time of enquiries for proposals and reducing response time while operating a project. As all projects require a period of investment, usually without returns during the life of the project, shortening the project duration can significantly increase return on investment.

Hamel and Prahalad (1994: 146) outline the concept of ‘fit’ as being important in successful competion strategy. Fit is a good relationship between strategic intent and the resources available to achieve the strategy. Fit is embedded in the strategic tools of the organisation. Short term fit may be more loose but long term fit needs to be tighter. The concept of strategic tools is related to the concept in this study of internal strategies chosen to achieve the external competitive strategy. Porter (1996) also endorses fit.

The competitive strategies assessed in this study are shown in Table 1.

Business environment

Michael Porter (1980: 4) proposed his famous five forces which drive industry competition, these being Rivalry among existing firms, Threat of new entrants, Bargaining power of suppliers, Bargaining power of buyers and the Threat of substitute products or services.

There are significant differences between the forces which drive various industries. These include: rate of change of technology; the degree of mechanisation versus craft production; the extent to which competition is local versus global; degree of specialisation of key players; and, inherent complexity of tasks.

Mintzberg and Quinn (1991) see technology including scientific discoveries and the impact of related product developments, and the less dramatic process improvements and the progress of automation and data processing.

Political forces are relevant to how well a company survives. The fact that so many corporations make donations to political parties suggests there is value in political connections and power. Advance notice of changes in government priorities are essential to good planning. Key issues are: sensitivity to political issues, political connections; resources committed to political connections. Li *et al.* (2005) support the need for political support.

Businesses are influenced by consumer attitudes and behaviour and this depends on such factors as the age structure of the population and the nature of work. Porter (1980: 238–241) sees industry maturity providing significantly different conditions under which businesses operate. Changes occur to competitive forces, customer experience, the emphasis on costs and service, the marketing and distribution methods required and falling profits, among other effects.

An organisation’s environment can range from stable to dynamic (Mintzberg 1979: 268). Operating a business in rapidly varying business conditions produces very different people and business systems than in a stable environment. It also reduces the ability of a company to use stable and even automated processes.

An organisation’s environment can range from simple to complex. Mintzberg (1979: 262) points out that the more sophisticated the technical system of an organisation, the more elaborate will be the administrative structure, the more professional the workforce and the more liaison devices are required to coordinate the work of the specialists.

Market diversity may result from a broad range of clients to a narrow one. Clearly market diversity affects the structure through a third variable, the diversity of the work to be done (Mintzberg 1979: 269). Thompson *et al.* (2005: 248–279) outline differences between various industries, which are a recognition of the business environments in which the industries are operating. While it may be considered that construction has a reasonably uniform environment, economic cycles in each country, the different stages of development between countries, and other factors ensure that the business environment is a factor in competitive success.

INTERNAL STRATEGIES CHOSEN TO FACILITATE ACHIEVING THE EXTERNAL COMPETITIVE STRATEGY

A number of authors have commented on choices by firms to achieve their external strategy. Porter (1996) speaks of a number of management tools being spawned to achieve competitive success including, total quality management, benchmarking, time-based competition, outsourcing, partnering, reengineering, change management and others. Objective 2 of this paper is to illustrate a more formal comparison of these management tools in order to identify which are more suited to achievement of a firm's particular competitive strategy.

The main approach in Hamel and Prahalad (1994) is based on the notion of firms choosing internal actions in order to achieve external strategic objectives. Kaplan and Norton (1996) also address these internal strategies in proposed a simple approach that firms would achieve financial results if they focused on customers, their internal processes and the learning and growth of their staff. By implication the organisations proposing tools to assist the industry, such as ISO 9000, CMMI, PMBOK (PMI, 2004) and SWEBOK (IEEE 2004), are directly addressing the need for internal processes and competencies in firms to assist their performance.

The following concepts or variables are outlined by discussing how they are used in other industries and then by considering the possible benefits in construction.

CMMI

Capability Maturity Model® - Integration and (CMMI℠) are registered in the US Patent and Trademark office; CMMI is a service mark of Carnegie Mellon University; CMMI℠ was sponsored by the US Department of Defence in order to capitalise on process capability.

A key reason for adopting CMMI in organisations is the contention of Carnegie Mellon that the following savings for organisations operating at CMMI Level 5 can occur (CMMI 2006 associated presentation) with schedule savings of up to 50%, cost reductions of up to 34% and productivity improvement of 61%.

The point is made that process improvement activities compete for corporate resources therefore the most effective need to be chosen. The Defence Materiel Organisation of Australia are encouraging contractors to adopt CMMI in order to improve project consistency (Defence 2003). CMMI is an extension of earlier work by Deming (1986).

CMMI (2006: 3) comments that capability maturity is set in ‘the high velocity environment of the twenty-first century …. in which nearly all organisations have found themselves building increasingly complex products and services’. No single organisation is responsible for all of the product in manufacture, defence, software and IT&T. Therefore all of these stovepipe organisations need to be integrated by a common set of processes. However, this is the world construction has operated in for some time, so the arguments of need should equally apply to construction.

The definition of a CMM allows the community to develop different models supporting different approaches to process improvement CMMI (2006: 6).

CMMI is consistent with other capability maturity models such as Armstrong (2001) and Kerzner (2001) in defining five levels of achievement of processes of Level 1 Initial; Level 2 Managed; Level 3 Defined (and managed with a consistent process across the organisation CMMI (2007:33); Level 4: Quantitatively Managed (a level 3 process, which is controlled using statistical and other quantitative techniques); and Level 5: Optimising (continual improvement of a level 4 process).

There are 22 process areas in CMMI (2006: 18), most of which appear relevant in the construction industry. These include:

1. Causal analysis and Resolution (tracing the cause of defects);
2. Organisational process definition;
3. Project planning;
4. Risk management;
5. Project monitoring and control;
6. Organisational innovation;
7. Supplier agreement management;
8. Validation ;
9. Verification;
10. Organisational training.

Sarshar *et al*. (1999) investigated capability maturity in construction under their SPICE research (Standardised Process Improvement for Construction Enterprises). Their conclusion was that many of the basic process concepts are applicable in construction but problems may occur from supply chain arrangements. Voordijk *et al*. (2003) have briefly discussed a Capability Maturity approach.

The question remains of whether the construction industry in most countries is too unsophisticated for capability maturity. While this may be so for many of the smaller contractors it should not be true for the larger and multi-national contractors. While the aim of CMMI is to integrate CMMs, it could be more appropriate to produce a construction CMM.

Enterprise architecture

Schekkerman (2004) sees enterprise architecture as a complete expression of the enterprise’s masterplan, which acts as a collaborative plan between aspects of business planning such as: goals, visions, strategies, governance principles, aspects of business operations, such as business terms, organisation structures and processes and data, aspects of automation, such as information systems, databases, and the enabling technological infrastructure of the organisation, such as computers.

The Zachman Framework, developed in I987 at IBM, is an early version of Enterprise Architecture as shown in Schekkerman (2004: 133). Schekkerman also outlines a number of organisations which have some form of enterprise architecture, including a number of US Department of Defence architectures (145–182). Purdue University have an architecture for implementing computer aided manufacturing projects (183) and the German Federal Government has standards for implementing e-commerce applications (191).

While all organisations have a set of rules, either explicitly written or implied, to exercise direction and control of its units, the issue is how formally this architecture is stated and the composition of it. Simple examples are planning for future work, the rules for delegation, the capability of computing systems and the quality procedures.

Enterprise architecture does occur in the construction industry although it is not given this name except by a few consultants offering services. Research could be conducted to identify the common elements of a construction enterprise architecture, which should at least include: firm vision and mission, value propositions, target customer information, distribution channels, links with various customers, the value configuration, core competencies, the partner network, cost and schedule data, the revenue model for the company, rules for operating the business, including delegations, firm processes, position descriptions, and salary scales, and lessons learned, among others (Osterwalder *et al. 2005: 18).* The configuration of IT to support these functions is crucial.

Entrepreneurship

Bolton and Thompson (2000) see entrepreneurship in terms of what entrepreneurs do: they are individuals who make a significant difference, they are creative and innovative, they spot and find the resources to exploit opportunities, they are determined in the face of adversity, they manage risk, put the customer first and create capital.

Timmons (2002: 37) sees the entrepreneurial process as a value creation process by a team identifying an opportunity and then providing the resources to develop the opportunity. Uncertainty is involved. The process requires creativity, leadership and communication (2002: 41). The process of creating, shaping and recognising opportunities is assisted by differentiation and foresight, concepts which have been well explored (Peansupap and Walker 2006). Timmons, like a number of other authors, including Bollier (2006), see the internet creating more democratic opportunities.

Dollinger (1995: 78) sees entrepreneurs reacting to political, economic, industry, environmental, ecological, sociological and technological issues.

Obvious examples of entrepreneurship in construction industry are identification of new business directions, product development and property development, especially the use of different styles, building forms, residential densities.

Operational excellence and sustained competitive advantage

The concept of operational excellence versus sustained competitive advantage was initiated by Porter (1996). His contention was that operational excellence is not adequate for a company to pursue. In fact Porter's view is that pursuit of operational excellence is not even strategy.

Osterwalder *et al.* (2005: 18) suggest aspects of sustained competitive advantage include value propositions, target customer information, distribution channels, links with various customers, the value configuration, core competencies, the partner network, and the revenue model for the company. More detailed examination of value propositions, value configuration, core competencies and other bases for sustained competitive advantage would be of significant value in construction.

PMBOK versus PRINCE2

The Project Management Institute (USA based although there are offices in many cities worldwide) now has over 250,000 members and over 700 Registered Education Providers, suggesting a strong following. PRINCE2 was developed in the UK. Both are models used to manage projects, although the models are quite different is their structure. PMBOK (PMI 2004) and PRINCE2 (Bentley 2002) are the two most popular models of project management.

PRINCE2 is a layered approach of looking at a number of processes at the top level, then drilling down to a second and then a third level. The PRINCE2 processes are: directing a project, start-up, initiating a project, controlling a stage, managing stage boundaries, closing a project, managing product delivery and planning. This is within a broad context.

The PMBOK model is easy to understand based on three key variables of project phase, nine knowledge areas and five processes. The knowledge areas are: integration, scope, time, cost, quality, risk, human resources, communication and procurement. The processes are initiating, planning, control, executing and closing (PMI 2004).

Given the success of both models and the fact they are quite different, a comparison of each and in which circumstances either is more applicable, could be of value.

Portfolio

Schekkerman (2004) sees enterprise portfolio management falling directly below Mission, Vision and Strategy, in that order. Portfolio management is responsible for determining investment strategy, asset management, risk management and environment management; these sit above enterprise architecture; this is a form of enterprise investment management.

Some of the key activities that are essential to portfolio management are: translating organisational strategies into specific initiatives or business cases that become the foundation for programs and projects; identifying common systems to assist the projects in the portfolio, identifying and initiating programs and projects; providing, allocating and re-allocating resources to programs, projects and other activities; maintaining a balanced project portfolio; and, supporting the organisational project management environment.

Portfolio management promotes understanding of the interrelationship between organisational processes and the successful completion of programs and project processes. Blismas *et al.* (2004) recognise programs and portfolios and found value in optimising them.

Further research work could explore the more important aspects for relating project results to firm goals, other than financial.

Requirements

A requirement is a condition or capability that must be met or possessed by a system, product, service, result or component, to satisfy a contract, standard, specification or other formally imposed documents. Requirements include quantified and documented needs, wants and expectations of the sponsor, customer and other stakeholders, which are testable (PMI 2004).

SWEBOK comments: ‘Software requirements express the needs and constraints placed on a software product that contribute to the solution of some real-world problem’ (IEEE 2002: 2.1).

A requirement is the identification of a need, want or desire, which an installed system must satisfy. Key issues to consider are: ‘what is the system to accomplish in terms of operations and functional performance: when is the system needed, what are the consumer requirements, what is the expected operational life of a system; what effectiveness requirements should the system exhibit, and how is the system to be supported in terms of its life cycle (Blanchard & Fabrycky 1990: 35).

In software terms functional requirements describe the functions that the software is to execute; for example formatting some text’ non-functional requirements act to constrain the solution’ (IEEE 2004: 2.2).

A key issue is if a specification directly prescribes a solution (eg 220mm brick wall), it limits the supplier’s scope to innovate. By comparison, the specification of requirements, which do not specifically describe the solution, but describe the functions of the solution, lead to greater innovation, even if it is more difficult to use such descriptions. Use of requirements is more applicable in state of the art work such as defence equipment and IT. However, construction projects in which needs were expressed more in purely capabilities of the solution terms, should produce more innovation.

Shen *et al* (2005) examine requirements in construction, which are supportive of the view of this study.

Categorisation of standard requirements applicable to construction, development of standard tests for these, and a traceability system similar to defence, could be a worthwhile research area.

Ireland

SUPORT FROM ANOTHER STUDY

Ireland (2007: 1) conducted a broader research study which investigates the relationship between the three groups of variables which have been outlined however this broader study also included a number of other internal strategies in order to determine the relative merit of each.

The research was conducted on a group of firms operating in a technology environment. The relationships between the three variables shown in Figure 1 were investigated.

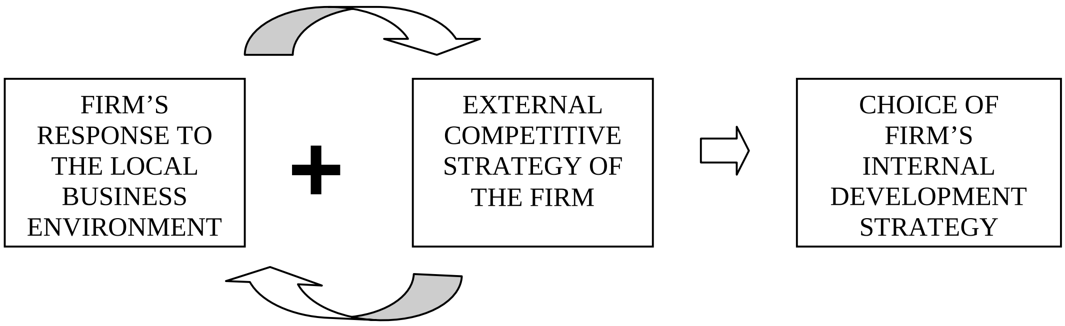

Figure 1: Firm's response to the local business environment leading to an external competitive strategy, which then leads to choice of the internal development strategies of the firm chosen to support the chosen external strategies

Hypotheses
This broader study had the following hypotheses:

1. Choice of a firm's external competitive strategy recognises the local business environment (as illustrated in Table 2);
2. Achievement of a firm's external competitive strategy in enhanced by encouragement of internal firm development strategies (as illustrated in Table 2);
3. The local business environment influences choice of internal firm development strategies (as illustrated in Table 2).

De Haan *et al.* (2002) considers internal and external conditions and fit as a related concept. De Haan is generally supportive.

Sample
Forty eight organisations took part in the survey from over 100 offered.

The firms were in the following roles:

Table 1: Firm types in the sample

Firm Type	Number
Air system control	2
Architectural design	1
Construction	3
Defence	10

Film	1
Finance	1
Health	1
Human resources (the technology to support the business)	2
Logistics	1
Manufacturing	12
Non-construction technology consulting	7
Oil well manufacture	2
Rail	2
Real estate	1
Technology entrepreneurship	1
Wholesale trade (the technology to support the business)	1

Only the variables relevant to this paper are reported.

Research method

Components of competitive strategy were not subjected to principal components analysis as competitive strategies need to be clearly different.

Elements of business environment were treated by principal components analysis and three components emerged, these being:

Environment 1 = (0.870Rivalry determinants, + 0.740Price sensitivity + 0.646Threatsubstitutes + 0.595Entry barriers);

Environment 2 = (0.859Politicalissues + 0.783Socialissues);

Environment 3 = (0.853Execbargaining + 0.853Industrels).

External strategies and some aspects of the internal strategies shown in Table 2 were surveyed by a single measure. Items 3.1 to 3.6 of the internal strategies were analysed by principal components analysis and all had Chronbach α of over 0.7. The others had a single measure. The correlations are shown in Table 3.

Table 2: Proposed relationships examined between external competitive strategy, business environment and the internal strategies chosen to support the external strategies

External Strategy	Business Environment	Internal Strategies used to Achieve External Strategies
1. Minimal cost;	2.1 Technology;	3.1 Vision
2. Minimal cost within a niche;	2.2 Industry;	3.2 Entrepreneurship
3. Adequate quality;	2.3 Economic conditions;	3.3 PMBOK
4. Innovation;	2.4 Ecology;	3.4 PRINCE2
5. Responsiveness;	2.5 Politics;	3.5 Portfolios
6. Time of delivery;	2.6 Social and cultural;	3.6 Enterprise architecture

Ireland

7. Customer value; 8. Market share; 9. Segmenting the market; 10. Fit.	2.7 Demographic; 2.8 Industry profitability; 2.9 Industry growth; 2.10 Industrial relations climate; 2.11 Executive bargaining; 2.12 Complexity; 2.13 Hostility; 2.14 Diversity; 2.15 Stability.	Further parameters were extracted from the above: 3.7 CMMI; 3.8 Requirements; 3.9 Operational excellence versus sustained competitive advantage.

It is probably not surprising to find that minimum cost within a niche and minimum delivery time were indicated as the most important competitive strategies with this small sample.

Table 3: Correlations between the external strategy chosen and the measures of the internal strategy of the firm: note ♦ indicates correlations of 5% significance or better.

External Competitive strategies from Table 2 ⇒	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**

Table 4: Correlations of business environment and external strategies.

External competitive strategy	**Business environment units correlated at 5% level of significance or better**
Minimal cost within a niche	Supplier power Buyer power
Segment the market	Industrial relations Environmental complexity Hostility
Fit	Ecological issues Demographic changes

Furthermore, based on the relationships shown in Figure 1 and illustrated in Table 2, correlations at the 5% level of significance or better are shown in Table 5.

Correlations between External strategy and Business environment
Recognising that firms concentrate on external strategies of minimal cost within a niche and segmenting the market, the correlations with business environment and these external strategies revealed the following correlations:

CONCLUSIONS

The research has shown that there are a number of concepts or variables which construction researchers could investigate more thoroughly, which are relevant in other areas of technology business and management. The research has also indicated that a more formal approach to considering three classes of variables, the competitive strategy of the firm, the business environment in which the firm operates and the internal strategies chosen to facilitate achievement of the external competitive strategy, appears worthwhile to be investigated in a larger sample.

Table 5 correlations between measures of business environment and measures of internal strategy of the firm at 5% level of significance

Correlations between measures of business environment and measures of internal strategy of the firm at 5% level of significance		
Env 1	**Env 2:**	**Env 3**
Nil	Vision* PMBOK** Enterprise Architecture*	Enterprise Architecture*

All of the variables investigated, these being CMMI, Enterprise architecture, Entrepreneurship, Operational Excellence rather than sustained competitive advantage, PMBOK, PRINCE2, Portfolio, Requirements and Vision were shown to support particular competitive strategies. Minimising cost within a niche and minimising time of delivery, segmenting the market and fit, were shown to be key competitive strategies.

MANAGEMENT FUNCTIONS AND COMPETITIVENESS IN THE PORTUGUESE CONSTRUCTION INDUSTRY

Brígida Pires[1], José Cardoso Teixeira[1] and Hélder Moura[2]

[1]*Department of Civil Engineering, University of Minho, Campus de Azurém, Guimarães, 4800-058, Portugal*
[2]*Estradas de Portugal, EPE, Almada, Portugal*

The construction industry faces a wide range of challenges that ought to be addressed if it is to maintain and, if possible, improve its competitiveness. The key interrelated elements of competitiveness have been the focus of many international research projects and studies. The measurement of this success and the quality of the project's performance depends on the achievement of the main construction management function objectives, namely time, cost, quality and safety, which are the focal indicators for a healthy and a competitive construction sector. However, frequent delays, cost overruns, insufficient quality and lack of safety are symptoms of the lack of competitiveness recognized in most construction projects concluded in the last years in Portugal. As a result, a research project has been launched to better understand and clarify the reasons behind the lack of achievements of these management functions that affect the competitiveness of the Portuguese construction industry. Results of the survey obtained so far indicate that the main causes for the lack of achievement of the construction functions are due to design and client responsibilities, inadequate construction management and lack of specific training.

Keywords: cost overruns, delays, quality, health & safety, Portugal.

INTRODUCTION

The approach to assess competitiveness is multi-faceted. It can be evaluated at different levels – national, firm or economic activity — as well as domestically, regionally and internationally. At each level, there are different indicators for competitiveness. For a nation, competitiveness is the capacity to achieve sustained economic growth and employment while remaining open to international trade. For a firm, being competitive involves increasing market shares over competitors, through either more competitive pricing or quality improvement of products (Reinaud 2005). Measuring competitiveness is a key issue in any economic activity and construction is not an exception.

Different frameworks have been suggested to measure competitiveness for countries, economic activities and single firms. Obviously, the ways this may be achieved is highly dependent on the purpose and aim of the study but the so-called Porter's diamond seems to be in widespread use. The diamond (Porter 1990) has been used to explain each country's industrial trends, depending on four major determinants (factor conditions, market conditions, industrial environment and corporate strategy) and two external factors (government and chance).

[1] brigidapires@civil.uminho.pt

Recent critical reviews suggest new factors and a different organization of Porter’s Diamond to better suit the construction industry (Ofori 2003), for instance the Hexagon framework proposed by Flanagan *et al*. (2005). This report considers that the industry is competitive if it satisfies the national needs of the four main stakeholders: shareholders, clients, employees and the overall society. To achieve these goals, it must be profitable, predictable in time and cost, innovative, achieves harmonious relationships, achieves competitive wages, has a safe and healthy work environment, behaves ethically and complies with environment and sustainable regulations.

However, to be effective these goals should be measured in order to evaluate the industry’s performance. The most common approach to measure the performance of a project is with the use of key performance indicators if comparable data on similar projects is available. An alternative quantitative approach is to measure the three fundamental indicators at project level: time, cost and quality, commonly known as the iron triangle (Atkinson 1999). More recently, the consolidate framework for measuring project success also includes health and safety (Chan and Chan 2004).

The lack of fulfilment of cost and time management functions often leads to project overruns producing immediate effects on construction stakeholders and on the country’s economy and competitiveness. National construction projects that have experienced extreme cost overruns and delays include a performance hall in Porto (Casa da Música, 2005), a bridge in Coimbra (Ponte Europa, 2004), an urban tunnel in Lisbon (Túnel Rodoviário do Marquês, 2007) and an underground railway tunnel in Lisbon (Metro do Terreiro do Paço, 2007).

Cost and time overruns have been thoroughly studied internationally but unfortunately, at national level, research results on these overruns continue to be very rare. Only recently did the Board of Engineers submit to the National Court of Audit a proposal with recommendations for the reduction of cost and time overruns in public works construction projects (OE 2006). Simultaneously, the Board of Architects also decided to take affirmative action by undertaking a project with the National Court of Audit regarding the identification of situations that originate cost overruns in public works construction projects (OA 2006).

Another issue reportedly pointed out in the media is the lack of safety in the Portuguese construction sector that continues to lead the number of work-related accidents and fatalities. Although responsibilities of all who intervene in the construction process have been reinforced by recent law amendments on risk prevention at work, numerous violations continue to occur with dramatic consequences. Costs related to work accidents as well as health problems related to this profession affect not only injured workers but also the employer, insurance companies and society in general.

According to the General Labour Inspection, 157 fatalities occurred in all the economic activities in Portugal during 2006. The construction industry was accountable for 71 (or 45%) of those fatalities (IGT 2007). But more important than statistical data on labour fatalities is the analysis of available information on the causes for these unfortunate events and find solutions for their mitigation. In 2005, the incidence rate of work-related fatalities in the Portuguese construction was 30.5 per 100,000 workers.

A further aspect regarding the need for better quality in the Portuguese construction sector has impelled proposals for the revision of legislation, namely increasing the guarantee period of buildings. Shorter life cycles of construction materials and components cause unexpected expenses that new end-users have to endure. However, to help mitigate these intolerable costs leaving end-users more satisfied, it is necessary to improve the quality of construction materials and its components.

In brief, cost and time overruns, the lack of safety during the construction phase and insufficient quality of the final built facilities have diverted the industry from fully advancing towards a more competitive ground in this country. A number of explanations have pointed out for these situations: the specifics of the industry, the production structure, the phased development of projects, the lack of adequate labour training, the weather conditions, etc. However, these do not explain why it evidences the above symptoms in national territory while it seems to be more competitive in the international market.

Therefore, in order to better understand and clarify the reasons behind the lack of achievements of the main management construction functions, a research project was launched, entitled “Reasons for lack of accomplishment of schedule, costs and safety objectives in construction”, financed by the Science and Technology Foundation (FCT). Comprehending the causes and formulating methods to better manage and control these issues is essential for improving the competitiveness of the Portuguese construction industry, influencing the credibility of professionals and the country’s image in this sector.

Results from the project will be used to recommend measures to increase competitiveness of the Portuguese construction industry. Work accomplished so far over the last two years is presented in this paper.

RESEARCH METHODOLOGY

The inquiry

Prior to the creation of the inquiry, specific boundaries were set to define the cluster of information that would be gathered from the industry and compiled in a database for subsequent treatment. Consequently, only information regarding construction projects launched between 1998 and 2004 and with an initial contract value over €10,000,000 was gathered.

Gathering information on public projects was unproblematic due to the available information on the procurement phase of these projects in Official Journals. Information on approximately 500 public projects had been collected. However, efforts to gather information on private projects were abandoned due to the scarcity of available data.

Opinions were collected from relevant client and contractors involved in the projects previously assessed through an internet-based questionnaire available on the project’s website. This was created with the intent of disseminating the project and its objectives and encouraging respondents to take part in it.

Clients and contractors involved in the projects assessed were contacted by email and fax. These included information on the ongoing project, link to the project’s website, questionnaire and its direct internet link and also an individual database that contained only the projects that respondent had been involved in the specified time period.

The questionnaire focused on the characteristics of each project and evidence of the lack of achievement of cost, time, safety and quality management functions. The first part of the questionnaire aimed at gathering specific information on the project under assessment (project description, client and contractor(s) identification, initial contract value, type of contract, starting date and initial project duration).

Subsequently, respondents were asked to quantify the lack of fulfilment of each management function. Consequently, information was requested on the final cost and duration, number of accidents (fatal and non-fatal), number of workers, number of work-hours, days lost and the number of quality non-compliances and claims).

For each project, respondents were asked to point out and graduate in a scale of 1 (less important) to 4 (most important) the possible causes for the lack of fulfilment of each management variable:

- Main causes for delays: materials, equipment, workforce, contractor management, client responsibility, design, project managers, financial problems, contract, institutional relations, project specifics, external factors.
- Main causes for cost overruns: design errors and omissions, site conditions, client responsibility, cardinal changes imposed by third parties, external factors.
- Main causes for lack of safety: lack of individual protection, lack of collective protection, lack of specific training, high risk activity, lack of equipment maintenance, insufficient and inadequate task preparation, direct orders from client/client representative, inadequacy of selected materials and/or equipments, force majeure.
- Main causes for poor quality: inadequate design solutions, poor work execution or construction errors, inaction or errors in clients decisions and performance of project managers, inaction or errors in clients decisions and performance, inadequate materials, products or construction processes, inadequate or poor inspection to site conditions, external factors

Respondents were given also the opportunity to indicate other causes not mentioned in the questionnaire and possible actions for mitigating these.

Reply from the industry

Although approximately 500 projects had been previously identified, only 66 answers were received after a six-month period of inquiry. Additionally, two global responses representing 53 projects were also received. Therefore, analysis will only be based on the 64 individual answers. Table 1 illustrates the distribution of answers by types of projects ands respondents.

Table 1: Distribution of projects by type of construction

Type of projects	Distribution of answers (%)	Clients	Contractors
Civil works (buildings, urban development)	19%	58%	42%
Infrastructure (water, gas, sewer)	17%	64%	36%
Industrial	8%	60%	40%
Dam/maritime	16%	70%	30%
Roads/highway/railway	36%	48%	52%
Environment	5%	33%	67%

Responses were only obtained after several diligences. Persisting phone calls, emails, faxes, letters to the board of directors and personal contacts with key personnel of contractors and clients were strategies adopted by the research team. A large number of the companies inquired had no available data readily available to provide. In other cases, although data was available, it had not been adequately treated. This lack of relevant records on past projects has been identified as the first reason for the lack of competitiveness of Portuguese construction industry (Moura and Teixeira 2006).

The conservative behaviour of the industry, key personnel involved in the projects no longer with the company, fears that data would be misused against respondents, and that records were too hard to retrieve or missing were just a few aspects that led to the lack of response from the industry.

ANALYSIS OF RESULTS

Information gathered from the industry was quantified by measuring the frequency and the intensity of the causes pointed out by the clients and contractors. In order to measure the importance and the intensity of these causes, an index (*I*) is used given by the expression $I = \sum_{i=1}^{4} x_i a_i$ where a_i is the constant that expresses the weight given to I (ranges from 1 = less important to 4 = most important) and x_i is the frequency of the answers.

The following results emerged from this analysis.

Time function

The quantitative measure for the time function was the delay in each project, expressed in calendar days, in relation to the initial duration. The average initial contract duration was 512 calendar days and the actual duration was 713 days. Therefore, the average delay was 201 days approximately 40% above the expected duration period.

Aggregate answers point out client (61%) and designer responsibility (59%) as the most frequent delay causes, followed by project specifics, contractor responsibility and external factors, with 47%, 41% and 34% of responses.

Compared to the overall results, the clients surveyed firstly point out designer responsibility (61%) and only afterwards client responsibility (58%) as the most frequent delay causes. Contractor responsibility was ranked third with 50% of responses and project specifics ranked forth with 44% of the responses.

As for the contractors' response, the most frequent delay causes ranked similarly as the overall results. Contractors mostly blame the clients (64%), designer responsibilities (57%) and project specifics (50%) as the most frequent delay causes. Contractors blame themselves with only 29% of responses, taking up fifth place. The frequencies of these causes are represented in Figure 1.

	Material	Equipment	Workforce	Contractor responsability	Financial problems	Client responsibility	Designer	Project Manager	Contract	Institutional relations	Project specifics	External factors	Others
□ Total response	22%	20%	23%	41%	25%	61%	59%	23%	23%	23%	47%	34%	23%
■ Client response	19%	19%	25%	50%	28%	58%	61%	19%	19%	19%	44%	36%	22%
□ Contractor response	25%	21%	21%	29%	21%	64%	57%	29%	29%	29%	50%	32%	25%

Main causes for delays

Figure 1: Frequency of delay causes

According to Figure 2, the intensity of delay causes ranks similarly to the frequency causes pointed out by participants for the lack of achievement of project's time management function.

Aggregate answers show that client and designer responsibility reach 116 and 104 points, respectively, followed by project specifics with 71 points (third place) and contractor responsibility with 66 points (forth place).

Contrary to the most frequent cause for delays, previously identified by the clients (designer responsibility), client responsibility has been ranked the most intense cause and designer responsibility second. In the clients' perspective, although designer responsibility contribute more frequently to delays, its **intensity** on the lack of achievement of the project's time function **is not as significant** as the client's responsibility. This is an interesting detail because clients are actually aware that they contribute significantly to the delays and thus low performance of the project.

Compared to the overall response, clients point out contractor responsibility as the third most intense reason for delays (47 points) and only after projects specifics as the forth reason (38 points).

Contractors rank the same causes for delays as the overall response: client responsibility (56 points), designer responsibility (47 points); project specifics (33 points). Results distinguish slightly from the overall response since their responsibility only ranks sixth with 19 points. Figure 2 illustrates the intensity of the main causes for delays.

Cost function

Analysis of the cost function was done by comparing the final cost of the project with the initial contract value. The average initial cost of the 64 construction projects surveyed was €16.183.327 while the average final cost reached €18.384.341. As a result, the average cost overrun was € 2.201.014 or 14% of the initial average cost.

Traditionally cost overruns in public projects normally reach the maximum permitted by law: 50% for projects launched up to 1999 and 25% afterwards. However, some caution must be taken when analysing these results, as the reasons behind this low rate of cost overruns can be due to scope changes especially on those projects experiencing final cost reduction.

	Material	Equipment	Workforce	Contractor responsability	Financial problems	Client responsibility	Designer	Project Manager	Contract	Institutional relations	Project specifics	External factors	Others
□ Total response	20	18	23	66	30	116	104	25	24	33	71	54	56
■ Cliente response	10	9	14	47	22	60	57	9	10	17	38	30	30
□ Contractor response	10	9	9	19	8	56	47	16	14	16	33	24	26

Figure 2: Intensity of delay causes

The aggregated answers from respondents revealed that design errors (56%), direct changes ordered by clients (56%) and different site conditions (55%) are the most frequent causes for cost overruns in construction projects.

Moreover, the clients' point of view and the contractors' point of view on this issue barely diverge (see Figure 3). Design errors have been ranked by both groups as the second most frequent cause for cost overruns in the projects surveyed with 56% and 57% of responses. While clients rank site conditions (58%) as the most frequent cause for cost overruns, contractors rank direct change orders from clients (61%) as the most frequent cause. On the other hand, whereas direct change orders (51%) ranks third for clients, site conditions fill the spot with 50% of responses from contractors.

	Design errors	Diferent Site Conditions	Direct change orders	Cardinal changes	External factors	Others
□ Total response	56%	55%	56%	39%	30%	13%
■ Client repsonse	56%	58%	51%	42%	25%	8%
□ Contractor response	57%	50%	61%	36%	36%	18%

Figure 3: Frequency of cost overrun causes

According to Figure 4, the intensity of these causes rank similarly when compared to the frequency causes previously pointed out. Aggregate responses portray design errors (100 points), direct change orders (97 points) and site conditions (86 points) as the most intense causes for the lack of achievement of the project's cost management function.

Clients rank the same causes as the overall response while contractors position direct change orders instead of design errors as the most intense cause.

On the other hand, different site conditions, previously ranked first by clients as the most frequent cause, ranks third as the most intense cause. In the clients' perspective, although site conditions contribute more frequently to cost overruns, its **intensity** on the lack of achievement of the project's cost management function **is not as significant** when compared to design errors and direct change orders.

	Design errors	Diferent Site Conditions	Direct change orders	Cardinal changes	External factors	Others
□ Total response	100	86	97	55	40	30
■ Client response	57	45	50	28	19	11
□ Contractor response	43	41	47	27	21	19

Main causes for cost overruns

Figure 4: Intensity of cost overrun causes

Safety function

The number of fatal and non-fatal accidents, number of workers involved in the projects, number of work hours and the total working days lost due to accidents occurred was the data surveyed for the safety management function. However, the most reliable data is in fact the labour accidents that are reported to the authorities: 3 fatal and 159 non-fatal accidents occurred in the 66 projects surveyed.

According to the aggregate answers, the most frequent reasons for the occurrence of labour accidents are the lack of specific training, insufficient task preparation, high-risk activities and lack of individual protection.

Separate analysis of clients' and contractors' responses showed an equal understanding on the causes for the lack of safety in construction, although more severely classified by contractors. Contractors insist on the high risk of the activities (36%), an issue that normally is beyond their control, while clients attribute a higher degree of severity to contractors as they indicate insufficient task preparation (22%) and lack of specific training (22%). Contractors also hold themselves liable having reported the lack of specific training and insufficient task preparation with 32% of responses. The lack of individual protection and inadequacy/lack of material/equipment are other causes summoned by contractors.

The frequency of the main causes for the lack of achievement of the safety function is represented in Figure 5.

	Lack of individual protection	Lack of collective protection	Lack of specific training	High risk activity	Lack of equipment maintenance	Insufficient task preparation	Due to a direct order	Inadequacy of materials/equipm.	Force majeure events	Other cause
Total response	24%	17%	27%	27%	16%	27%	13%	16%	13%	9%
Client response	20%	11%	22%	19%	6%	22%	6%	6%	6%	8%
Contractor response	29%	25%	32%	36%	29%	32%	21%	29%	21%	11%

Figure 5: Frequency of accident causes

The intensity of these causes rank similarly when compared to the frequency causes previously specified. However, contractors rank insufficient task preparation as the most intense cause whereas it was ranked second as the most frequent cause. In their opinion, although the high-risk activity contributes more frequently to the lack of safety, its **intensity** on the lack of achievement of the project's safety management function **is not as significant** when compared to insufficient task preparation and lack of specific training. Thus, this only comes to show that contractors acknowledge their own fault in contributing to the lack of safety in construction.

The intensity of the main causes for the lack of achievement of the safety function is represented in Figure 6.

	Lack of individual protection	Lack of collective protection	Lack of specific training	High risk activity	Lack of equipment maintenance	Insufficient task preparation	Due to a direct order	Inadequacy of materials/equipm.	Force majeure events	Other cause
Total response	23	17	42	37	17	44	8	12	8	20
Client response	10	7	19	16	2	20	2	2	2	8
Contractor response	13	10	23	21	15	24	6	10	6	12

Figure 6: Intensity of accident causes

QUALITY FUNCTION

The number of non-compliances presented during the construction and operation period of the constructed facility was used to analyse the project's quality function. Table 2 illustrates an abnormal frequency distribution of non-compliances that vary from zero non-compliances in 27% of the projects to more than 1000 non-compliances in 3% of the projects, whereas 44% had no available data.

This abnormal frequency distribution must be handled with some care as it might not explain the real situation of the Portuguese construction projects. Instead, it might explain the consequences and the inexperience in dealing with the recent implementation of Quality Management Systems, which is not compulsory for construction companies in Portugal.

Table 2: Weight of non-compliances

Number of non-compliances	Distribution of answers (%)
0	27%
1	6%
2	5%
3	6%
4–10	5%
100–1000	5%
>1000	3%
No answer	44%

Poor work execution (31%) and inadequate design solutions (27%) are the most frequent causes of poor quality of Portuguese construction projects. The same causes identified in the aggregated answers have also been pointed out in the separate answers given the by clients' and by contractors'. Contractors acknowledge their own low performance identifying poor work execution with 39% of responses and inadequate design solutions with 32% of responses while clients consider these causes to be less frequent (see Figure 7).

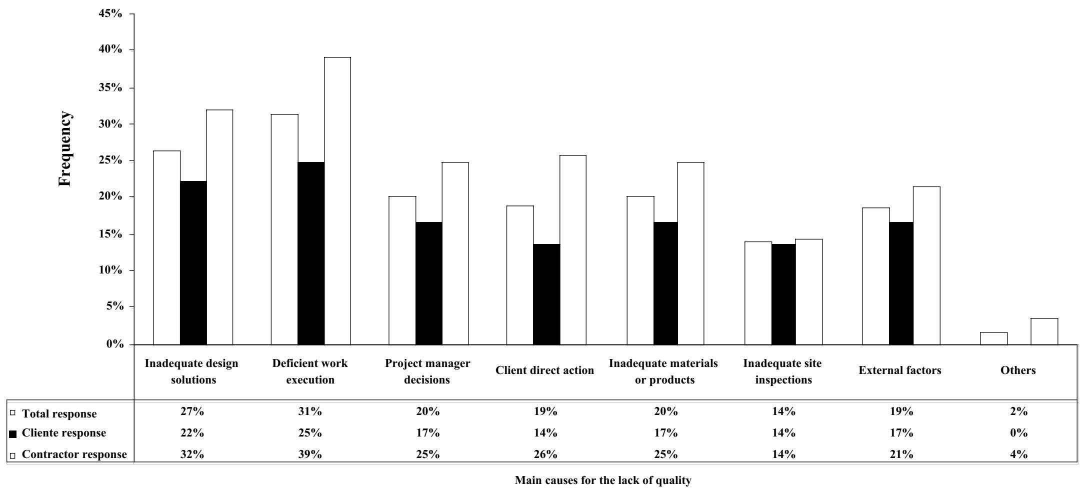

Figure 7: Frequency of causes for the lack of quality

As for the intensity of these causes, poor work execution and inadequate design solutions are more emphasized with 46 and 40 points, respectively. Clients maintain the preceding rank but with less intensity: poor work execution (24 points) and inadequate design (21 points). Contractors also weighed these causes with approximately the same intensity as clients along with external factors (21 points) and inadequacy of materials/products (18 points). Figure 8 illustrates these aspects.

	Inadequate design solutions	Deficient work execution	Project manager decisions	Client direct action	Inadequate materials or products	Inadequate site inspections	External factors	Others
Total reponse	40	46	18	18	28	14	32	2
Client response	21	24	8	5	10	9	11	0
Contractor response	19	22	10	13	18	5	21	2

Main causes for the lack of quality

Figure 8: Intensity of causes for the lack of quality

CONCLUSIONS

Results from an ongoing research project on the lack of achievements of the cost, time, safety and quality management functions in the Portuguese construction sector have been reported. These results are an outcome of a survey to the industry involving clients and contractors but the number of replies obtained was bellow expectations, therefore limiting their significance.

The results of the survey on project delays indicate that both clients and contractors agree that major causes have to do with client responsibilities and designer responsibilities followed by inadequate construction management (for clients) and project specifics (for contractors).

Both clients and contractors ascribe major causes to design errors, different site conditions and direct change orders as the main causes for cost overruns.

Lack of specific training, insufficient task preparation, lack of individual protection and the high risk of the activities are the main reasons pointed out for the lack of safety. Contractors indicate the high risk of the activities as the major cause for the lack of safety while clients blame contractors for the lack of specific training and insufficient task preparation.

Poor work execution and inadequate design solutions are the most ascribed reasons by clients and contractors for the lack of quality. External factors and the use of inadequate materials or products have also been pointed out by contractors.

Further results and proposed measures to improve achievements in the cost, time, safety and quality management functions, positively influencing the competitiveness of the Portuguese construction industry, will be presented. The results of this research will be used to establish a set of recommendations for achieving better performance of the industry.

FORECASTING THE HONG KONG CONSTRUCTION DEMAND – A PILOT STUDY

Ryan Y.C. Fan,[1] S. Thomas Ng and James M.W. Wong

Department of Civil Engineering, The University of Hong Kong, Pokfulam Road, Hong Kong

The construction industry is one of the main pillars of Hong Kong's economy. In recent years, however, the demand for construction activity has been changing dramatically, in terms of both volume and market structure. These changes in the construction industry, together with the rapid economic growth and liberalization of markets in mainland China and Macau, have had a serious impact on both the level of activity and type of work available to the construction. Forecasting construction demand in Hong Kong, therefore, has been recognized as an important indicator for industry development and for various industry stakeholders to formulate their short to medium-term procurement strategies and corporate development plans. This paper aims to present succinctly the trends of various construction activities in Hong Kong, and discuss preliminary findings of an ongoing research study on predicting the Hong Kong construction demand. Relevant forecasting methodologies and rationale for building demand-forecast models are explored via an extensive literature review. Empirical analysis and robust modelling will be undertaken in order to generate reliable construction demand forecast for the industry. The research findings of this study are expected to capture the output behaviour of the local construction industry and that of each sub-sector for facilitating the industry's sustainable development.

Keywords: forecasting, construction demand, construction industry, Hong Kong.

INTRODUCTION

The construction industry has long been one of the main pillars of Hong Kong's economy. It essentially serves as a regulator of an economy, and its importance and impact to the economy is undeniable (Ball 1988). However, it is well recognized that construction industry is volatile and may fluctuate dramatically according to the general economic conditions (NEDO 1978; Hillebrandt 2000). The fluctuations in the level of construction output can cause significant rippling effects to the economy (Chan 2001).

The Hong Kong's construction market has indeed experienced severe recession after the Asia region being profoundly hit by the economic turmoil in 1997. Despite seeing signs of recovery lately, the future of the industry remains rather uncertain. The industry lacks a coordinated effort to monitor changes in existing market and predict future demand for construction thus resulting in an imbalanced and distorted production capacity. Construction-related organizations need to respond to fluctuating market demand to survive, and work within a tradition of competitive tendering and small profit margin (Soetanto *et al*. 2006).

It is therefore valuable to develop forecasting models using statistical techniques to predict the construction demand in the next 3–5 years, so that both policy-makers and industry practitioners can formulate appropriate short to medium-term strategies to

[1] h0389349@hkusua.hku.hk

cope with any undue fluctuations in construction. A number of reports scrutinizing the performance of the sector (e.g. Egan 1998; Hampson and Brandon 2004) have also called for the industry to extend their orientation by looking ahead and to prepare themselves to respond to potential future events and trends.

This paper presents preliminary findings of an ongoing Hong Kong construction demand forecasting study. First is a review of the current situation of the Hong Kong construction industry. A theoretical framework is then proposed to account for recent developments and possible future trends. Following that, the need for construction demand forecast is discussed, and suitable forecasting methodologies are evaluated. The expected findings for the study are highlighted before the concluding remarks.

OVERVIEW OF HONG KONG CONSTRUCTION INDUSTRY

According to the Census and Statistics Department (C&SD) of the HKSAR Government, the construction industry produced a total gross value of work of nearly HK$90 billion in nominal terms in 2006, accounting for around 6% of total local Gross Domestic Product (GDP). It ranked third in terms of percentage contribution to total GDP from 1980 to 2004, after the largest services sector and the manufacturing sector. During the third quarter of 2006, the construction industry in Hong Kong employed more than 280,000 people, representing 8.1% of total labour force.

Residential building construction output was about HK$15.5 billion (at current market price) in 2006. Other buildings, including commercial, industrial and storage, and service buildings added up to a similar gross value of HK$13.9 billion. The value of work in civil engineering sector was over HK$12.3 billion, while the value of non-site activities (including decoration, repair and maintenance, construction work at minor work locations, carpentry, electrical and mechanical fitting, plumbing and gas work etc.) was over HK$48.3 billion. The four categories contributed approximately 17%, 15%, 14% and 54% respectively to the total construction output in 2006.

The general construction industry not only provides strong value added to the local economy, but also supports the economy by high level of consumption. The building and civil engineering establishments consumed over HK$30 billion in materials and supplies, fuels, electricity and water, and maintenance services in 2005. The real estate development, leasing, brokerage and maintenance management establishments and architectural, surveying and project engineering establishments spent over HK$10 billion and HK$200 million on the same items respectively.

Most of the construction companies in Hong Kong are small in size, as 82% of the total establishments in building and civil engineering discipline were producing less than HK$5 million of turnover in 2005. These small companies hired only 37% of total workforce in the discipline though, while a substantial portion (about 30%) of workforce was engaged in companies producing work valued at more than HK$100 million in 2005 (Census 2005b).

In addition, Hong Kong has been exporting its construction and engineering services to overseas markets, especially China and Macau, primarily due to the shrinking local construction expenditure. In 2005, the export of construction services alone was almost HK$2.5 billion, along with over a billion dollars export in architectural, engineering and other technical services. Of which, all the construction services were exported to Asian countries, whereas majority of architectural, engineering and other technical services were exported to Asia (i.e. 88%), with the rest to North America, Western Europe, Australasia and Oceania (Census 2005a).

RECENT TRENDS

Hong Kong was one of the countries being profoundly hit by the Asian economic turmoil in 1997. Its GDP growth rate at constant market price once became negative since 1998. The recession propagated through all business in Hong Kong and, inevitably, the construction industry was also severely affected. The construction output has been declining since 1998 (Figure 1). The total construction work volume has shrunk by over 30% in 2006 compared to its peak in 1997. The decrease in the percentage contribution to the total GDP (Figure 2) made the construction sector being overtaken by the electricity, gas and water sector and only ranked fourth in terms of importance among all sectors in 2005, for the first time since 1980.

The construction site works, both the public and private projects, followed a declining pattern in the last few years. However, the non-construction site works, representing the repair and maintenance sector, has been on an upward trend since 1980s. The sector climbed even faster since 2004, while the other sectors of construction industry were still deeply caught in the recession.

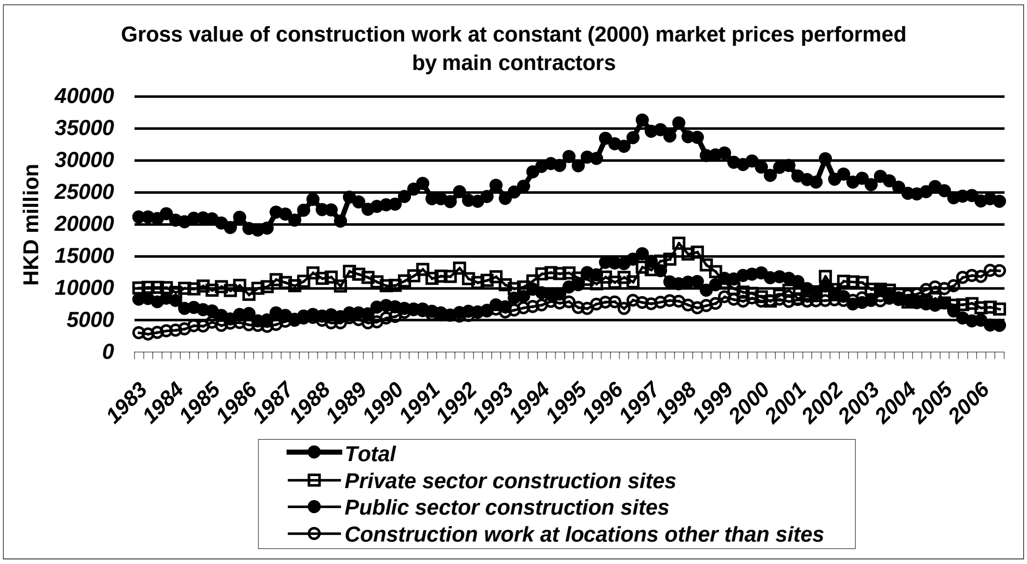

Figure 1: Quarterly gross value of HK’s construction work at constant (2000) market prices (Source: Census and Statistics Department)

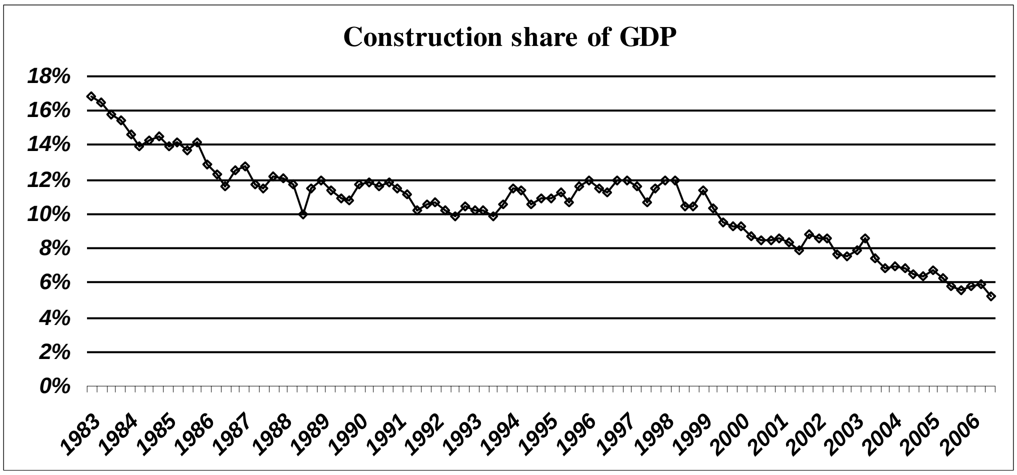

Figure 2: Contribution of Hong Kong’s construction activity to GDP (Source: Census and Statistics Department)

THE OUTLOOK

Bon (1992) discussed the changing role of the construction sector in different stages of economic growth. He pointed out that both the construction sector's contribution to the countries' GNP as well as the absolute construction volume would follow an inverted U shape as a country moves from being a less developed country (LDC) to newly industrialized country (NIC) and finally to advanced industrial country (AIC). His ideas were reflected in Figures 3 and 4.

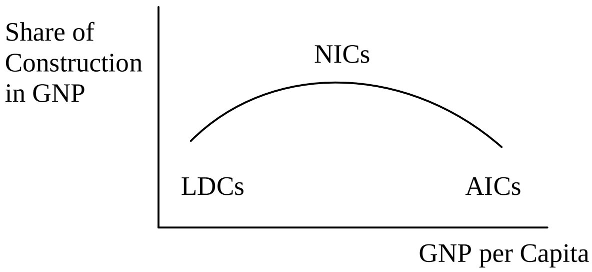

Figure 3: Share of construction in GNP vs. GNP per capita (Source: Bon 1992)

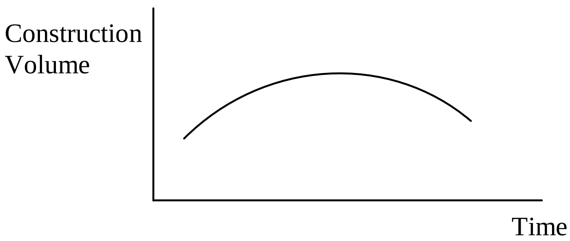

Figure 4: Construction volume over time (Source: Bon 1992)

Bon also suggested that, as time moves on, the repair and maintenance sector and some new construction work would eventually form the lower bound of the declining half of the U-shape curve, which is obvious because the capital stock that generally built in the early stages of economic growth tends to age over time. The model holds for any one country over time, as Bon stated, since economic development is unidirectional and must go through the three stages mentioned above.

It is not difficult to match the Hong Kong's situation with the Bon's model. The GDP growth rate has slowed down in 1990s while services sector contributed to the total GDP for more than 90% in 2005, indicating Hong Kong's transformation into an AIC. The construction sector's contribution to GNP (GDP is identical to GNP for non-tradable goods such as construction goods, according to Bon) and the construction output have more or less followed an inverted U-shape (Figures 1 and 2).

The repair and maintenance sector is gradually taking up a larger portion of the total construction output. Hence, the construction demand and output in Hong Kong may continue to shrink as Hong Kong moves gradually towards economic maturity. An accurate forecast on the future construction demand in the next 3–5 years will be able to better illustrate the trend, hence preparing the local industry for the coming challenges.

THE RESEARCH FRAMEWORK

In view of the recent slump experienced by Hong Kong construction industry as well as the various calls for better insight into future construction trend, a research study that aims to forecast the Hong Kong construction demand is being carried out. The research adopts statistical means, of which will be explained below, to establish a rigorous forecasting models suitable for the local situation. The models built are expected to capture the future demand pattern for Hong Kong construction industry in each of the detailed sector such as residential/commercial/industrial in medium to long-run, based on the historical trend as well as the contributing social and economic factors. The predicted future pattern will then be compared with the model suggested by Bon (1992). The identified contributing factors to construction demand will help verify the demand theories proposed by various scholars (e.g. Ball 1998; Hillebrandt 2000). These theories will finally be combined and modified to illustrate the Hong Kong situation.

CONSTRUCTION DEMAND FORECASTING

Construction demand forecast studies have been carried out in many countries. For instance, Goh (1999) forecasted for sectoral construction demand in Singapore using a multi-regression model, while another model using Box-Jenkins approach for the forecast of construction industry demand, price and productivity in Singapore was built by Goh and Teo (2000). Akintoye and Skitmore (1994) predicted the UK private sector construction demand by building multi-regression models using quarterly output data. Tang *et al*. (1990) adopted regression technique to forecast the total construction activities in Thailand. In the US, Killingsworth (1990) developed a demand-forecasting regression model for industrial construction.

Causal forecasting approach and time-series models are indeed the most common techniques for the forecasting of construction demand. To produce a more accurate and meaningful forecasting model, construction demand should be further classified into detailed categories of residential/commercial/industrial construction demand, building/civil/repair and maintenance works demand, public/private sector construction demand, etc., so that the specific contributing factors accounting for each of the category can be selected and the uncertainties in future trend can be minimized (Goh 1999).

Amongst the available causal forecasting approaches, the regression model is the most common and versatile causal technique, applicable in every facet of business decision-making, due to its relative simplicity in both the concept and application (Goh 1999). The regression model also has its strengths in outlining the contributing factors towards the variable being studied and, hence, allowing a more comprehensive theoretical framework to be established. On the other hand, it means that information on the possible contributing factors needs to be gathered and a selection process of the more influential factors is involved. Lack of information can be critical and intuitive judgment involved while selecting parameters for the final model may contribute to discrepancies in the final model. Therefore, all possible contributing factors affecting construction demand will be identified prior to the model building. Factors considered by previous literature are summarized below.

FACTORS AFFECTING CONSTRUCTION DEMAND

A brief summary of the factors being considered in previous literature for forecasting construction demand is shown in Table 1. Not all of these factors were found to be significant in the final models of the literature of where they are extracted. However, as the construction market is unique in each country, these possible factors should be considered and carefully selected when developing the regression models.

The reviewed literature usually distinguishes construction demand by residential/industrial/commercial/public utilities/repair and maintenance sectors. Akintoye and Skitmore (1994) focused their study on the private sector construction demand only, while the other scholars included both public and private sector works in their analysis. For residential construction demand, population, interest rates and construction approval/completion/transaction volume were the most commonly considered factors. National economy indicators like GDP, tender price index and unemployment rate were also used in some models.

Table 1: Factors affecting construction demand

	Residential Demand	Industrial Demand	Commercial Demand	Public Utilities Demand	Repair and Maintenance Demand
Population Structure	O, TA, G, TS, H	K, G	O	O, H	
GDP, GNP, National Income	TA, A	TA, A, G, H	TA, A, G		H
National/Corporate Savings	G	TA, G	TA, G		
Government revenue/expenditure				O, TA, H	
Interest Rate	O, TA, A, TS, H	K, A, G	A		
Export Value		TA, B, G	TA, B		
Tender Price Index	A, G	A	A		
Labour Cost Index		G			
Income	O, H				H
Housing Loans	G, H				
Property Price	O, TS	B	B		
Land Price			O, G		
Consumer Price/Spending	TA	B	B		O
Money Supply		G			
Employment/Unemployment Rate	A, G, H	A, B, G	O, A, B		
Orders for plant and equipment		K, O, H			
Productivity		G	G, H		
Composite index of leading indicators		K, G			
Construction approval/completion/transaction	O, TA, G, TS	K, G	G	TA	O
Industrial/Manufacturing output/investment/utilization rates	A	K, O, TA, A, B, G, H	TA, A, B	H	
Manufacturing/Trade/Retail Sales		K	G, H		
Visiting Tourists		TA	TA		

Note: K=Killingsworth (1990); O=Ofori (1990); TA=Tang *et al.* (1990); A=Akintoye and Skitmore (1994); B=Ball *et al.* (1998); G=Goh (1999); TS=Tse *et al.* (1999); H=Hillebrandt (2000)

For industrial construction demand, national economy indicators and the performance of the manufacturing and industrial sector were the most popular factors considered.

Population, national savings, interest rate, export performance, unemployment rate and orders for plants and equipments were the less mentioned factors. For commercial construction demand, national economy indicator, employment distribution and industrial sector performance were the more prevailing factors, while national savings, export value, land price, productivity and sales were considered as well.

When forecasting for public works and utilities, government revenue and expenditure was the most important factor while population structure was also incorporated into the models. For repair and maintenance work, as it was seldom being considered in previous studies only a few factors including national economy performance, household income, purchasing power and new construction completion which may all have impact on the level of work in the sector were considered.

TIME SERIES MODELLING TECHNIQUES

Time-series models, in contrast, predict the future values of a time series solely based on the historical trend of the variable. It treats the underlying trend of the series as a "black box" and makes no attempt in trying to discover the factors contributing to the trend (Goh and Teo 2000). In other words, a time-series model attempts to describe the random nature of the process, which is also known as the stochastic process of time series that generated the observations of the variable being studied (Pindyck and Rubinfeld 1998).

As the model assumes repetition of similar patterns over time, it is only suitable for short-term forecasting (Goh and Teo 2000; Wong 2006) and large forecast errors may arise if discontinuities occur within the projected time period (Wong 2006). Despite these constraints, the time-series model is considered an accurate model due to its emphasis on investigating the stochastic process of the variable rather than adopting a deterministic approach.

The simplest form of time-series modelling is to fit the data series by the exponential smoothing technique (Ng *et al*. 2004). Bowerman and O'Connell (1993) described the method as "not based on any formal statistical model or statistical theory". The intuitive model is studied below; as a test of whether more sophisticated methodology would be needed for the construction demand forecasting study. The model describes the time-series by the no trend equation

$$y_t = \beta_0 + \varepsilon_t \tag{1}$$

where β_0 can be represented by the least point estimate, i.e. the mean of y_t for $t = 1 \ldots n$, being denoted $a_0(0)$.

Hence, the update of estimate from $a_0(T-1)$ to $a_0(T)$, in a time period T, can be obtained by using the smoothing equation of

$$a_0(T) = \alpha y_t + (1-\alpha)\, a_0\,(T-1) \tag{2}$$

where α is the smoothing constant being selected between 0 and 1 following a iterative process to minimize the model's sum of squared errors; and α represents the rate of the previous observations of also represents the rate that the older observations of y_t being dampened out of the current estimate of β_0 as time advances.

In other words, for α closer to 1, the remote observations are dampened out quickly and the recent observations would be weighted more heavily in estimating β_0.

Applying exponential smoothing technique in predicting construction demand

The time-series data of the gross value of total construction work, the gross value of public sector construction site work and the gross value of private sector construction site work, all at constant year 2000 market prices, were computed for modelling. The quarterly data from 1983 to 2005 were used, representing a total of 92 data points. The earlier 80 quarterly data points from the first quarter of 1983 the fourth quarter of 2002 were fitted into the model to produce forecast values for the next 12 periods, i.e. quarterly construction output from the first quarter of 2003 to the fourth quarter of 2005.

The forecast values were then compared to the actual data of the same period, by using the Mean Absolute Percentage Error (MAPE). Wong *et al.* (2005) suggested using the MAPE for testing time series models and recommended using 10% as the acceptable level of accuracy. The MAPE is computed as follow:

$$MAPE = \frac{1}{T}\sum_{t=1}^{T}\left|\frac{Y_t - F_t}{Y_t}\right| \times 100 \qquad (3)$$

where Y_t is the actual value of the series at period t; F_t is the forecast value at period t; and T is the total number of periods.

The developed exponential smoothing models are summarized in Table 2. Despite the high significant levels for the α parameters that were found, it should be noted that the α values ranged from 0.67 to 1. The result calls for methods other than the exponential smoothing to be adopted to forecast the time series. As Bowerman and O'Connell (1993) pointed out, if the α value exceeds 0.3 the current model may not be appropriate or the parameter β_0 may be changing quickly over time. On top of that, the models, especially for the more detailed categories of construction demand such as the public sector output and private sector output, do not perform satisfactorily in terms of MAPE. The MAPE becomes even larger when the longer term forecast values were compared with the actual ones.

Table 2: Results of simple exponential smoothing model by JMP

Forecast variable	α	**MAPE (%)**
The Gross Value of Construction Work as constant (2000) market prices (A)	0.67	7.05
The Gross Value of Public Sector Construction Site Work at constant (2000) market prices (B)	1	15.47
The Gross Value of Private Sector Construction Site Work at constant (2000) market prices (C)	0.82	32.08

It supports that simple exponential smoothing technique might be adequate only for short-term forecasting. For medium to long-term forecasts involving predicting values more than three years ahead, such as our Hong Kong construction demand forecast study, the exponential smoothing technique may not be the best choice (Table 3). Furthermore, Ng *et al.* (2004) discussed another major shortcoming of simple exponential smoothing technique being the method's assumption of uncorrelated errors, which in turn means that observations over time are uncorrelated. While collecting time-series data in practice, serial correlation is often anticipated.

Table 3: Absolute percentage errors for the forecast and out-of-sample data points

Out-of-sample data	A	B	C
2003Q1	3.62	11.1	3.67
2003Q2	1.45	11.1	19.7
2003Q3	1.29	12.8	10.5
2003Q4	5.13	20.5	5.4
2004Q1	9.15	40.0	4.3
2004Q2	9.63	38.2	0.8
2004Q3	8.02	39.3	3.9
2004Q4	4.66	29.8	6.6
2005Q1	7.32	42.0	1.9
2005Q2	12.4	48.8	21.9
2005Q3	11.3	47.9	47.0
2005Q4	10.8	43.6	60.2

Therefore, a more sophisticated model with a strong theoretical background is recognized as crucial for forecasting construction demand. Among all the possible models, Goh and Teo (2000) confirmed the accuracy of the Box-Jenkins approach in handling construction demand forecasting. The Box-Jenkins approach has been regarded as an accurate, reliable and widely applicable time-series model by researchers (e.g. O'Donovan 1983; Wheelwright and Makridakis 1985; Goh and Teo 2000; Ng *et al*. 2004). Bowerman and O'Connell (1993) introduced the Box-Jenkins methodology as an iterative procedure involving the transformation of data series into a stationary and non-seasonal series for the Auto-Regressive Integrated Moving Average (ARIMA) modelling process. The tentative model is then evaluated for its goodness of fit against the historical data using the Akaike's Information Criterion (AIC) and the Bayesian Information Criterion (BIC) (Maddala 2001). Should the tentative model be acceptable in fitting accuracy, the process would be repeated with different models until a satisfactory model is identified. Forecast of the data series will then be produced based on the final model.

FUTURE WORK

The present research study aims to forecast for Hong Kong's construction demand, classified into categories of residential/commercial/industrial construction demand, building/civil/repair and maintenance works demand as well as public/private sector construction demand. The classification will be as detailed as possible, depending on the availability of data. Multi-regression models and time-series models will be built for each of the classification and compared with historical data by error estimators to ensure their accuracies. A combination of the two models may be proposed, as Ng *et al*. (2004) reported in their study that the combined regression analysis and time series model outperformed each of the individual one. The results are expected to offer a better picture to the local industry about the future work volume and distribution of workload in each discipline, such that the policy-makers and industry practitioners can formulate strategies to find sustainable work source.

Apart from being practically informative, the regression model shall provide evidence for establishing theory of construction industry supply and demand in the local context. The technique can also be compared to the time-series model in terms of forecasting accuracy, as most of the earlier construction demand forecast studies were based on the regression techniques. Furthermore, a combined model involving the two approaches has not been applied in construction demand forecast before. Hence, it is worth investigating the possibility of developing a new direction for construction demand forecasting. Lastly, forecasting repair and maintenance works has not been extensively conducted before, and hence the study will also attribute to verify the suitably of demand theories as proposed by scholars (e.g. Ofori 1990; Hillebrandt 2000) in various sub-sectors.

CONCLUSIONS

Hong Kong's economy has been suffering from a deep recession since 1997. The Asian economic turmoil and overheated property market contributed to a sharp downturn from the earlier economic boom in 1990s. There are evidences suggesting that Hong Kong has transformed into a rather mature economy in which the services sector would become the most important economic pillar while the construction industry fades out. Together with a slow down in population growth rate, Hong Kong's construction industry may inevitably be going through a structural change. The impact from the recession in construction sector could further propagate to other sectors as construction sector has extensive connection with a lot of other sectors. The plunging construction volume has not been showing signs of stabilizing yet. Despite the rather discouraging signs, scholars have suggested that there will be a growing demand for repair and maintenance, together with some new construction orders, to sustain the construction industry. On top of these works, the industry may seek alternative opportunities, for example the overseas markets or other construction-related business, to find sustainable paths for growth.

Under such a severe situation, the construction demand forecast can serve as an important guideline when planning for the construction companies' operations as well as formulating future business strategies. Government can arrange its public investment in a way that provides maximum benefit and minimal disturbance to private sector developments. Having a foresight into future construction market is also important to avoid being caught up in possible recessions. Before building the forecast models, construction demand data are collected and classified into various disciplines by job nature. Multi-regression and time-series model are both adopted. Possible underlying factors affecting construction demand considered in previous multi-regression models have been summarized, and similar Hong Kong data will be collected. A simple exponential smoothing technique has been studied and proven insufficient in precisely forecasting for short to mid-term construction demand. Hence, the more sophisticated Box-Jenkins model is proposed for carrying out time-series analysis. The two models may be combined, if the integrated model can provide better performance than any of the individual ones. It is anticipated that the study will capture Hong Kong's construction demand in different disciplines during the next 3–5 years.

ACKNOWLEDGEMENT

The authors are grateful to the Construction Industry Institute – Hong Kong for funding this study. Financial support from The University of Hong Kong through its CRCG Seed Funding for Basic Research (grant no. 10207434) is also gratefully acknowledged.

FROM DEMAND-DRIVEN SUPPLY TOWARDS SUPPLY-DRIVEN DEMAND IN CONSTRUCTION

Hennes De Ridder[1] and Ruben Vrijhoef

Faculty of Civil Engineering, Delft University of Technology, Delft NL-2600 GA, The Netherlands

The ‘living building’ concept (LBC) represents a new approach to the delivery and life cycle of built objects. The idea of dynamic control of LBC respects the fact that the function and circumstances of built objects are constantly changing. This is in full contrast to the traditional building paradigm and current practice, which are based on a static approach to the performance of buildings. In traditional practice the demand is fixed at the start of a project and supply is only mobilized to meet the initially established requirements. This demand-driven supply results in supply of standard products and prevents innovation. LBC aims to change this into supply-driven demand involving all parties in the supply chain to supply an integrated product and dealing adequately with changing technology, regulations and demands throughout the entire life cycle of buildings. As a result the application of LBC concept reduces risks and transaction costs substantially. In order to do so the concept must be the basis for life cycle contracts. Following a previous application of LBC to a school building, LBC has recently been applied to the redevelopment of a hospital building in the Netherlands. The application of LBC has proved to be beneficial developing a facility that will be flexible to future changes, and has led to a movement from traditional demand-driven supply towards supply-driven demand, implying that the client’s demand remains on a high aggregation level, and supplying parties offering an integrated solution to this demand.

Keywords: benefit, dynamic control, life cycle, living building concept.

INTRODUCTION

Society and technology are changing continuously. This subsequently induces changes in the activities of human beings. As a result, the goods needed for human activities alter frequently owing to the modified wishes and requirements. The consumer market for goods is fully equipped to anticipate and meet such changing conditions. Products and services such as electronics, cars, bicycles and healthcare are renewed continuously. This is possible because consumers and producers are geared to one another. The essence is that demanders are meant to be surprised by the products and services provided by innovative suppliers: demand is following supply. The supply chain needs to develop activities like marketing, research, product development, branding in order to stay in touch with the consumers (De Ridder and Vrijhoef 2003).

The construction industry is totally different. The majority of people working in that sector assume that the world does not change during the lifetime of a building. This can be concluded on the basis of the trend in construction to award contracts,

[1] h.a.j.deridder@tudelft.nl

covering the outsourcing of multiple tasks like construction, design, maintenance, operation and financing, over a long period (up to 40 years) with fixed output and fixed price. In such a top-down approach the contractual parties create high risks for themselves by fixing the future, excluding both end-users as well as innovative suppliers, and giving way to financiers and lawyers as the new leading parties in the built environment. In short, to a larger extent we build structures and buildings with yesterday's technology, with today's ideas for tomorrow's people.

On the other hand, when observing the building sector more carefully, we could identify some similarities with the consumer market. Obviously, the world in and around buildings changes faster than buildings themselves. And the speed of changes increases more and more. These changes not only relate to users and stakeholders with their own respective interests on the one hand, and technology on the other. Changes also relate to climate, regulations, resources and financial/economical conditions.

For instance the changing climate will definitely lead to new standards for cooling in public buildings. The 'living building' concept (LBC) (Living Building Concept®) transforms the 'top-down' organized pull market of the construction sector into a 'bottom-up' organized push market enabling buildings to be and stay fit for purpose and up to date. In the paper the main principles of LBC will be explained and discussed.

AIM OF LBC

Construction implies complex product development in a changing context, involving many parties, delivering products with value to society, pulling high levels of resources from the economy. Construction projects often take a long time, and the life cycles of built services are lengthy. During the construction process, the level of information and knowledge grows, on the side of both the client and the supplier. Demand and supply influence each other. So requirements of buildings change over time. Demand must be adaptable and supply must grow along. Procurement and supply strategies as well as project and life cycle management arrangements must be able to cope with these dynamic mechanisms.

The rationale of LBC is based on two underlying problems in construction: perception and 'process statics'. The problem of perception is caused by the fact that the first demand specification is basically always incorrect or incomplete, because it is impossible to demand before knowing what is available and possible. Supplying without knowing what is basically wanted is impossible as well. So demand and supply are intrinsically connected, and this should be reflected in the process towards delivery of any product such as built services. However in current construction practice, this is often not the case. Demand and supply are relatively disconnected. This is basically the result of the tension between value and costs, and thus between the client's interest in added value versus the supplier's interest in profit. The problem of 'process statics' makes this worse while in most cases the construction process is fixed from the start of a project, making it impossible to cope with change effectively.

LBC aims to increase the benefit for both demanding and supplying parties, by focusing on the maximization of the gap between value and costs of the built object (Figure 1). The costs are determined by the suppliers of a built object jointly. The value includes a wide spectrum of types of value (financial, sustainable, etc.) which are determined by the client and the users in the first place, who can decide to involve a larger stakeholder group to help determine the total value. This is considered to be a dynamic process, meaning that both demanders and suppliers get involved in this process with a ‘control budget’ from both sides, which is used to find the optimal solution for additional demands collaboratively. These can fluctuate between the minimum and maximum boundaries set by both parties. The main criterion is that the additional demands and solutions proposed must have a positive effect on the benefit.

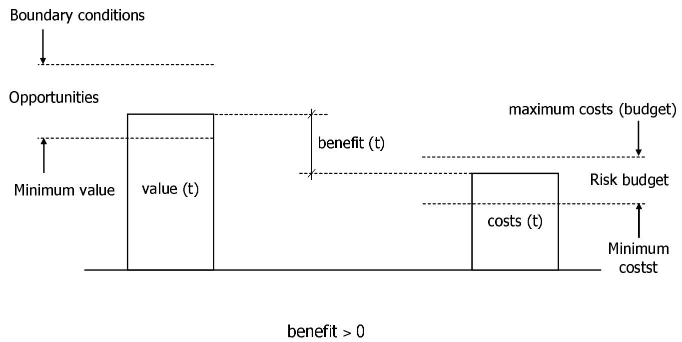

Figure 1: Essence of delivering value in the built environment

PRINCIPLES OF LBC

Partnering aimed at maximum benefit

Mostly construction is a joint activity involving multiple parties. LBC stimulates parties to find ways to maximize the collective benefit, i.e. the gap between value and costs. All parties are challenged to find solutions to either increase the value and/or decrease the costs. Ideally, the collective contributions of parties to do so must lead to a total value that exceeds the sum of values, and a total costs that is lower than the sum of all costs (Figure 2). This process is organized in a dialogue form that requires that all parties involved are open in their communications. The process as well as the information shared are monitored and checked by a third party. And in the end it is the client who decides after having consulted experts. The end result is the start of the rest of the process which is flexible and thus capable to cope with possible changes. This approach is illustrated later in this paper by an experiment applying LBC to the redevelopment project of a hospital building, which is currently ongoing.

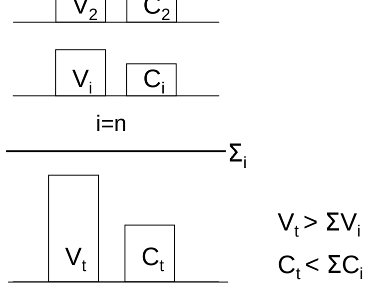

Figure 2: Basic partnering model between demanding and supplying parties

Transaction connecting value and costs

For many reasons there is always a need for some kind of change during the process, so there is a need for a dynamic approach. This is particularly true in construction. The 'natural response' in construction has been to isolate and fix various aspects as much as possible, including the price and the design early in the process. This leads to quasi-certainty, 'process statics' and disproportional additional transaction costs. Owing to this kind of fragmented and delegated control, and long demand and supply chains, changes come often too late to be effectively and systematically dealt with. Instead the total value should be interconnected qualitatively and quantitatively to the total costs by means of an algorithm between value and costs. Then demanding and supplying parties can collaborate to achieve the highest possible benefit to the mutual advantage of both demanding and supplying parties (Figure 3).

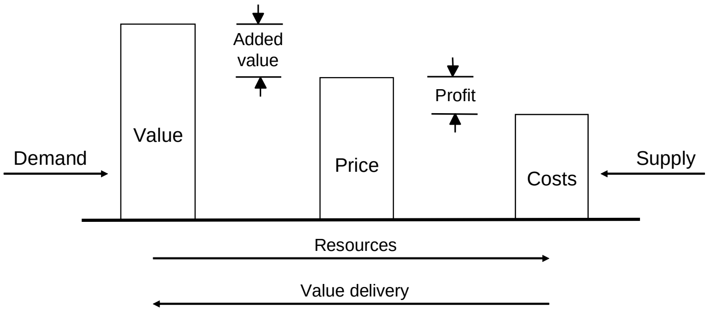

Figure 3: Basic transaction model between demanding and supplying parties

Dynamic control

Instead of enforcing the initial planned performance against a fixed price calculated in the first phase of the project, the price is based on the actually delivered performance at the end of the project. The final price goes up to the initially set maximum guaranteed price, not exceeding the planned budget of the client. The range between initial price and maximum budget is the client's 'control budget' for dealing with problems of perception and additional value to be delivered during the process. In addition, the contractor is able to reserve budget for investments to reduce costs or increase value (Figure 4). This approach can be defined for the project only, but can be extended to the whole life, and can be applied to a variety of contract formats, from build-only contracts to more integrated DBFMO contracts (design, build, finance, maintain, operate).

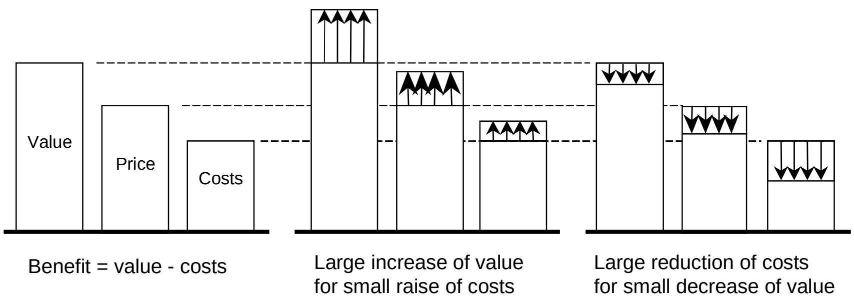

Figure 4: Dynamic control strategies to increase the total benefit

Consumer market approach
In contrast to the construction market, consumer markets consist of consumers and producers. Producers develop and sell products proactively anticipating the wishes of consumers. In construction, broadly, there are contractors and clients. Normally, clients start a project, and contractors build it based on the client's design. The concept of LBC represents a consumer market approach to construction. In those terms, consumers in the construction industry are interested in value for money. That means that they get value and spend money for it. Their requirements and wishes are highly dependent on what producers have to offer. As the offer changes, the requirements and wishes change as well. Producers in the construction industry are interested in money for value. That means that they generate value and get money. The value to be produced against the price is the core of competition and is subject to change due to innovation. Bottom-up organized supply chains consist of partners, which use research and development to generate supplier specific systems. These supply chains and use branding and marketing in order to know the consumers' wishes and satisfy their demands proactively (Figure 5).

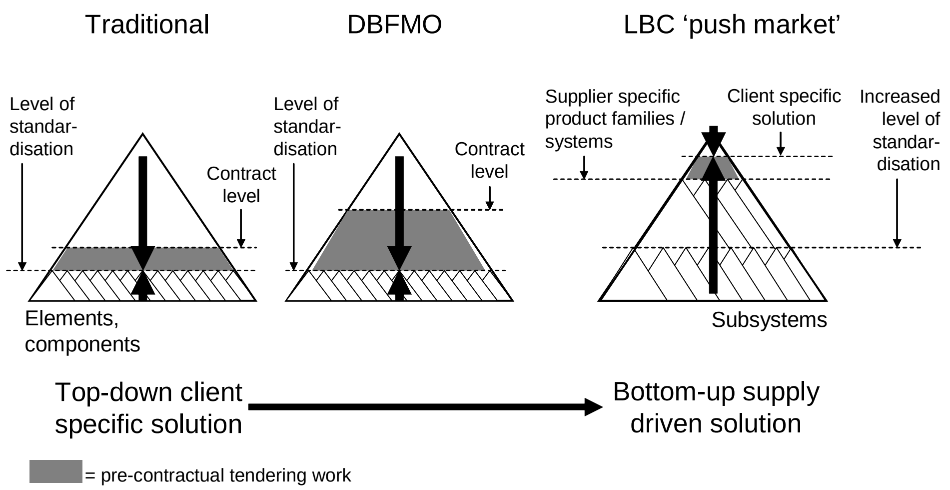

Figure 5: From demand-driven supply towards supply-driven demand

DEMAND AND SUPPLY STRATEGIES OF LBC

Demand strategy
Particularly in the public sector many clients have fixed and restrictive budgets, and public projects are subjected to investigation by government agencies to ensure value for money, control over public funds and public interest in general. Within LBC the client's budget, public or private, is always higher than the price and includes a buffer for dynamic control by the client. The supplier (e.g. contractor) sets an initial price for the basic solution and the possible scenarios. The buffer between the budget and the price is used for unforeseen changes: changing demands, requirements, regulations, standards, technology, finance, etc. The following procurement process is based on a continued process of 'price development': it starts with an initial price for initial design, through a final price for actually measured additional output at the moment of delivery, and next constant measurement of delivery of life cycle value. This process can be capped, e.g. by means of a guaranteed maximum price, which in

this case equals the budget set at an earlier stage. Similar concepts of target price, guaranteed maximum price and budget allowance for extra risks and changes have been introduced previously (e.g. Boukendour and Bah 2001; Cain 2003).

Hence the lowest price is not necessarily the client's main selection criterion and driver. Rather it is necessary to realize that the price has to be related to the value delivered in a constant manner, and value for money has to identified, to ensure that clients get the best possible life cycle value from suppliers (contractors, etc.) (Wong *et al.* 2000). However, in current practice, criteria for selection and bid evaluation of contractors are often still aimed at mere project delivery capabilities. For LBC, a wider range of criteria is needed to evaluate suppliers' capabilities against the needs of clients and other stakeholders (Hatush and Skitmore 1997). Thus the procurement system must be linked to the client's priorities. The priorities and the procurement system are influencing the team selection, and thus the project outcome and performance level (Kumaraswamy and Dissanayaka 1998). The use of 'sound' selection criteria and application of a 'best value based contractor selection framework' are essential to achieve the desired project outcome and 'best value' (Luu *et al.* 2003).

In a dynamic approach, the client will not put a lot of effort into a complete formulation of the demand and fixation of the price in an early phase of the project, but rather starts with setting boundary conditions, defining the 'procurement space' for an adequate solution to be delivered by the contractor. Negotiation and collaboration have been advocated rather than competition and relying on market mechanisms to achieve best value for money. However, it has also been argued that competitive procurement methods achieve better value for money than negotiated procurement methods (Abrahams and Farrell 2003).

Supply strategy

Most supply strategies in construction are restricted to project delivery only. Few advanced supply strategies are extended beyond project delivery, including facility management, maintenance and refurbishment, to ensure the functionality and serviceability of the built service. This implies 'continuous value delivery' or 'life cycle value delivery', instead of project delivery. This approach requires dynamic control capabilities of the whole life cycle by suppliers of built objects, and parts of those objects. The industry needs to broaden its approach to value delivery, and apply the concept of value delivery proactively vis-à-vis construction clients (Thomson *et al.* 2003). In general, LBC requires the industry to move from a delivery system within a price-based environment towards higher level of performance-based competition (Parmar *et al.* 2004).

Industry partners must adopt the use of integrated value delivery to facilitate collaborative working to resolve current industry inadequacies regarding design, construction and facility management (Austin and Thomson 1999). Integration of the team to the client's value system is essential to capture client value from the beginning of the project and informing further decision making during the project, and continued value delivery through the value chain (Kelly and Male 2001). Therefore, contractors and other suppliers in construction must develop and improve their marketing strategies, their costing capabilities and their financial risk management (Xu and Tiong 2001). This must result in advanced supply strategies ensuring the positive balance between price and costs.

DYNAMIC OUTSOURCING AND PARTNERING APPROACH

In construction, projects often start with the arrangement of legal matters in order to prevent claims and disputes. After that the organizational issues with regard to the project are arranged, and then the relationship between parties is established. LBC is based on a reverse sequence. It starts with the relationship between parties, then the organizational issues and finally the legal aspects are arranged. This means that partnering comes first to achieve common understanding of all demands and possible solutions, before the project is actually organized and the contract is made. The contract and procurement are based on outsourcing rules; however, the relationship between parties remains based on partnering rules (Table 1).

Table 1: Outsourcing versus partnering

Outsourcing	**Partnering**
Unequal	Equal
One party pays, one delivers	Mutual cooperation
‘Closed book’	‘Open book’
Working on different levels	Working on same level
Different interests	Joint interests
Transaction costs	No transaction costs

In order to build up the partnering relationship, both demanding and supplying parties join in separate partnering arrangements first in order to make an optimal business case on the demand side (e.g. value–revenues–price), as well as on the supply side (value–price–costs). Those business cases are the basis for the integrated business case for the project (value–revenues–price–costs), and an envisaged optimal benefit for the project as a whole (value–costs) (Figure 6).

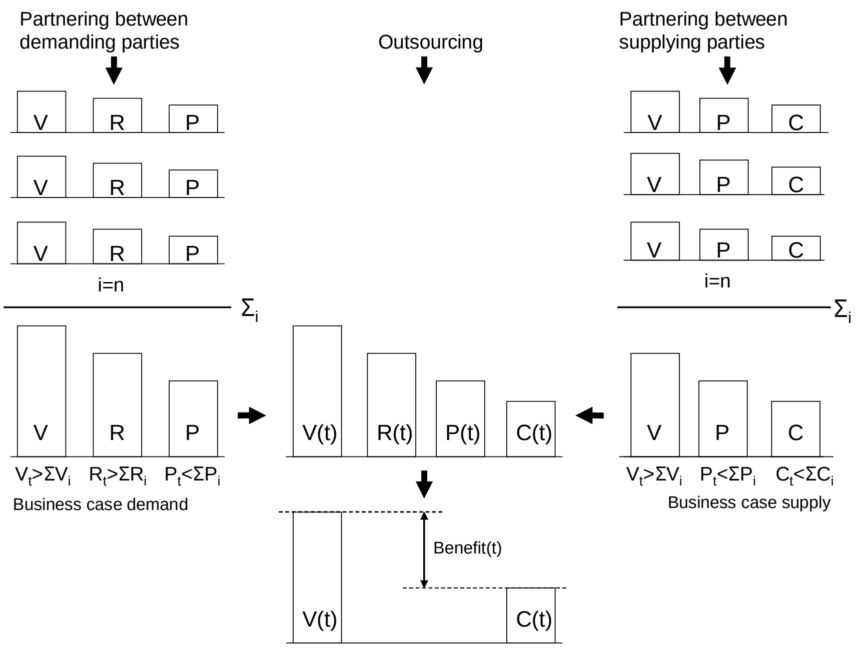

Figure 6: Integrated partnering and outsourcing approach

After the partnering phase, the project organization and contract should be arranged. This process contains three steps (Figure 7). The first step is the determination of the initial area of interest based on the previously established integrated business case. The second step is the selection of the producer based on the best value–price offer. For instance, in this case, producer 2 has the best value–price offer, i.e. the largest angle alpha. So he is the winner of the competition. Step three is to settle an agreement based on the relation between value and price in the area of the producer's offer, i.e. the initial design, and thus the initial value and initial price. The contract area around this point is the 'dynamic control space', in order to be able to change and improve the built object during the contract period when changes occur, e.g. changing regulations, demands from new users and availability of new technology.

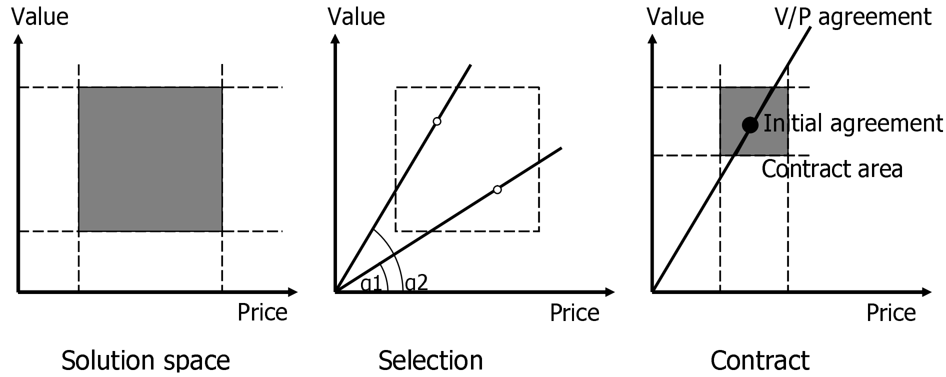

Figure 7: Enabling dynamic control

Next the legal issues are arranged in a contract including responsibilities, liabilities, obligations and risks. For dynamic control it is necessary to know what value against what costs is delivered, but leave open the way how this is achieved. In the present situation however, contractors should comply with drawings and specifications which have been made by the owner and his advisors for a fixed price. In an LBC situation, the big change for the industry is reversing the supply chain that is capable of delivering buildings proactively as if they were consumer goods, that are totally pre-designed and pre-developed, and still flexible enough to be customized to clients' wishes.

EXAMPLE: APPLYING LBC TO A HEALTHCARE FACILITY

In 2006 LBC has been applied to the redevelopment of an existing hospital which was built before in 1983. Owing to changing policy by the national and local government, changing finances of healthcare and increased commercial possibilities in the healthcare sector, the management of the hospital decided to rebuild the hospital and change it into a healthcare centre with multiple services added to it. Application of LBC and its benefits have been studied for this particular case, particularly because healthcare policies are bound to be changing considerably during the coming years. This calls for flexibility of the building and the services in and around the new healthcare centre, and the contractual setting too. Besides, healthcare demand and technology change fast. LBC has been particularly beneficial because client requirements and wishes were captured only in a minimum brief. In this particular case, a traditional briefing process would have taken too much time. The LBC consortium was invited to develop an integrated solution for a new hospital, including all services and technology, and offering solutions to keep the building flexible. In order to increase the commercial possibilities and to ensure sufficient resources for the project, the main solution was found in physically disconnecting core facilities of the total centre from additional services, and reconnecting parts of them flexibly to the hospital. This enables the hospital to flexibly make use of the additional services, and enables it to deliver services to others at the same time too, which increases financial benefits (Figure 8).

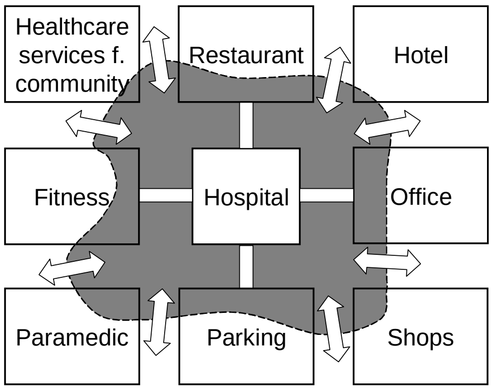

Figure 8: Schematic layout of the flexible healthcare centre

The schedule for this project is rather tight. In the first half of 2007, the brief will be developed further. By the summer of 2007 the tender will be issued, in order to start construction by the end of 2007 or beginning of 2008. The entire project should be delivered in 2010. This requires a fast process, particularly at the start, to ensure the parties go ahead with their parts of the project, and be sure everyone understands the project, and feels comfortable with it.

CONCLUSIONS

The idea of LBC represents a new and comprehensive approach to demand and delivery of built services, based on a dynamic approach to the construction process and the life cycle. The main advantage of the dynamic approach is that an agreement between client and supplier/provider, focusing on measuring the value against price under fast changing circumstances, gives both parties opportunities. The client can easily adapt his facility to new demands, changing regulations, changing circumstances, new education systems, etc. The supplier is able to introduce new technologies, new materials, new concepts, etc. during the contractual period and will be awarded in a corresponding way. However, the client will always decide about new solutions proposed by the supplier/contractor, and these must comply with the performance contract, and always lead to more value than costs. In addition, the decision making is easier and more suitable compared to the current practice in which scope and price are mostly fixed at the start against high transaction costs. By contrast, LBC starts open and ends with a target price within the budget, by means of an open process where client and contractor are equal partners, interacting based on clear agreed-upon rules about the measurement of value and costs, and the establishment of a corresponding price as a result. Such an approach implies a reduced role for the client compared to traditional construction practice, where demand is leading supply. Instead, LBC is based on the idea that supply is leading demand, in a sense that suppliers are able to respond adequately to demands on high aggregation levels, and offering integrated solutions, i.e. a built facility including the services that will keep it 'fit for purpose' during the life cycle, under changing circumstances. The case of the healthcare centre demonstrates that LBC can be beneficial, particularly for healthcare facilities because of the dynamic character of healthcare demands and its context (interest of society, regulations, technology). LBC has offered solutions to cope with the changes and accommodate these in the built facility.

IMMIGRATION AND THE CONSTRUCTION INDUSTRY: EFFECTS OF IMMIGRANT HIRING PRACTICES AND PENDING IMMIGRATION REFORM LEGISLATION ON CONSTRUCTION INDUSTRY ECONOMICS IN THE UNITED STATES

Sabrina K. Golden[1] and Mirosław J. Skibniewski

Project Management Program, Department of Civil and Environmental Engineering, University of Maryland, College Park, MD 20742-3021, USA

Current estimates indicate an illegal immigrant population of over 11 million residing in the United States; an estimated 19% of this total works in the construction industry. There are several draft bills currently making their way through the US federal legislative process. All of them tighten immigration rules and enforcement, which will ultimately affect the available immigrant workforce. Enforcement of current law will no doubt have a measurable impact on the availability of illegal immigrant workers. Amnesty or some version of a “guest-worker” program would also have a significant impact on the immigrant workforce. Regardless of the scope and breadth of immigration reform, there will be a considerable impact on labour resources for the construction industry. The research will analyse the current hiring practices of immigrants within the construction industry and predict the effects of impending immigration reform on industry economics. Initial predictions of the direction of immigration reform indicate that labour shortages are unlikely; however, increased labour costs are likely due to a prevailing wage provision in the proposed law. Increased costs of around 1% are predicted for projects in the DC metro region.

Keywords: Immigration, labour, project costs.

INTRODUCTION

Current estimates indicate an illegal immigrant population of over 11 million residing in the United States. Almost 40% of this total has been in the US less than five years. An estimated 19% work in the construction industry, which comprises approximately 14% of all construction workforces. Detailed analysis of the Current Population Survey (CPS) conducted by the US Census Bureau reveals that illegal immigrants make up about one-third of the insulation workers, roofers, and drywall installers, and one-quarter of all construction labourers, masons, painters, cement and concrete workers, and carpet and tile installers. This is a significant portion of construction labour resources.

Immigrants, legal and illegal, have migrated to the US in droves over the last five years. As a matter of fact, from 2000–2005, almost 8 million immigrants settled here; it is the highest five-year period of immigration in the nation’s history. Most of the immigrants lack higher education attainment. Almost one-third of all immigrants over 18 and in the labour force have not graduated from high school. For those arriving in

[1] sabrinagolden@gmail.com

the United States since 2000, the estimate is over 34% (Passel 2006). For these poorly educated immigrants, mostly men, willing to work long hours for mediocre pay, the construction industry is an ideal place to find employment. Likewise, the construction industry is in position to receive, employ, and train this abundant work force.

The construction industry, according to the US Department of Labour, Bureau of Labour Statistics, employs over 6 million people, accounting for nearly 5% of the entire US labour force. The value of construction in the US topped $1 trillion in 2004, amounting to 5% of the gross domestic product (Bureau of Economic Analysis, 2007). Additionally, the construction market can be entered with little capital investment, enticing a large group of competitors into the field. As a result, profit margins for construction projects are typically rather small, 5 to 10% or less, with substantial risk for loss.

Between this abundant, low-skilled, highly motivated work force and this enormous, hyper-competitive industry a synergy has developed. This synergy buttressed the industry during the construction boom and labour shortages experienced in the first half of this decade, but promises significant turmoil within the industry given pending immigration reform by the US Congress.

There are several draft bills currently under consideration, which are at various stages in the legislative process. A commonality among the proposals is that they would all tighten immigration rules and enforcement, which will ultimately affect the available immigrant workforce. Research indicates that only about half of all illegal immigrants are paid within the confines of current law. Another 3 million or so have illegally acquired documents authorizing them to work. Estimates also indicate that about a third of all foreign-born workers are illegal immigrants. Enforcement of current law will no doubt have a significant impact on the availability of illegal immigrant workers. Amnesty or some version of a “guest-worker” program will also have a significant impact on the immigrant workforce supply. No matter the scope and breadth of immigration reform, there will be a significant impact on labour resources for the construction industry.

The study’s aim is to analyse the current hiring practices of immigrants within the construction industry and predict the effects of impending immigration reform on industry economics. There are four main objectives:

1. To analyse, by discipline, the current makeup of construction industry workforce, native-born vs. immigrant, and legal vs. illegal immigrant.
2. To assess the pay differential between immigrant workforces (legal and illegal) and native-born workers.
3. To examine the effects of immigration reform policy on the makeup of the construction industry workforce.
4. To predict possible effects on industry economics, including demand, labour costs, project costs and profits.

LEGISLATION

Currently, there are two versions of immigration reform legislation: one bill proposed and passed in the US House of Representatives and one bill proposed and passed in the US Senate. Few issues are as politically charged and garner such widely diverse, intense opinions in the country as immigration. There are two basic philosophies on immigration reform that dominate the scene in the United States: amnesty and enforcement. Following this pattern, the House and the Senate have proposed their own version of immigration reform, one favouring enforcement and the other tending toward amnesty. In effect, there are two bills concurrently making their way through the convoluted legislation process. The first bill introduced in the House of Representatives on December 6, 2005; HR 4437, is titled The Border Protection, Anti-terrorism, and Illegal Immigration Control Act of 2005. Technically, once passed by either House of Congress, a bill becomes an 'act,' but not yet law. The bill passed the House on December 16, 2005, with amendments. It was forwarded to the Senate on 17 December 2005 and the Senate referred the bill to its Judiciary Committee on 27 January 2006. The major provisions of the House bill of particular interest to the construction industry include:

- Requirement for construction of 700 miles of fencing along the border with Mexico in conjunction with deployment of surveillance technology in order to detect and prevent illegal border crossings. This fence is estimated to cost almost $4 million per mile. The cost of 700 miles of fence would amount to almost $3 billion. This indicates a tremendous opportunity for construction companies working in the border area.
- Mandating the use of the Employment Eligibility Verification System by employers. The Department of Homeland Security (DHS) is directed to establish and administer an employment eligibility status database through which an employer can verify the eligibility for employment of potential employees. This system is to be administered in consultation with the Commissioner of Social Security. The system is to be phased in over several years for previously hired individuals. There is also a provision that establishes a responsibility of DHS to investigate possible fraudulent use of Social Security numbers when identical numbers are submitted by multiple employers. Over 20 years ago, the Immigration Reform and Control Act of 1986 made it unlawful for employers to hire illegal aliens and required employers to verify eligibility by a review of an employees documents. Prevalent document fraud has made a mockery of this law. It is estimated that almost two-thirds of immigrant documentation in use today is fraudulent. The Illegal Immigration Reform and Immigrant Responsibility Act of 1996 established three pilot programs of this Employment Eligibility Verification System, whereby Social Security numbers and alien identification numbers of new hires are checked against Social Security Administration and DHS records in order to verify the validity of an employee's documents. Under The Border Protection, Anti-terrorism, and Illegal Immigration Control Act of 2005, this pilot program would be extended and immediately viable for all new hires. Employers would be required to check the eligibility status of all new hires within two years of enactment. On a voluntary basis, employers could check the eligibility of previously hired employees two years following enactment. By three years following enactment, all employers of immigrants working for federal, state, and local governments or in government buildings, on military bases, nuclear energy sites, weapons sites, airports, and other critical infrastructure sites must have verified the eligibility of employees through this system. Six years following enactment, all employers of all immigrants must have completed this verification. This requirement applies to day labour sites

and hiring halls as well. If the estimates are accurate, this requirement by itself could reduce the immigrant workforce by two-thirds over six years.

- Prohibiting grants to state and local governments that harbour illegal aliens through a sanctuary policy. This requires the federal government to take custody of illegal immigrants apprehended by local officials. Sanctuary policies are usually adopted by local governments, i.e. cities or counties. No state, yet, has broadly adopted a sanctuary policy. The policies basically direct local officials not to notify the federal government of illegal immigrants living in their cities. Since immigration is a federal concern, the federal government has jurisdiction. Some policies also eliminate the distinction between illegal and legal immigrants, which allows illegal immigrants to benefit from state services. This provision in the House bill will, in the simplest of terms, make it harder for illegal aliens to live and prosper in the United States. Sanctuaries allow illegal immigrants to live without fear of being caught and deported. With the requirement of local officials to notify the federal government of their knowledge of the presence of illegal immigrants in their localities, this freedom of existence is diminished. This would of course extend to health and human services officials as well as law enforcement officials. So, not only are criminals affected, those seeking assistance or medical treatment will be scrutinized as well. The House bill also makes it illegal to give aid to illegal immigrants, prohibiting charities from giving aid to illegal immigrants without notification to the federal government of their presence. This is another provision discouraging the presence of illegal immigrants.
- Increase in penalties for production and use of fraudulent documents and establishment of a Fraudulent Documents Center within DHS to better track the sources of fraudulent documents. This requirement would also reduce the ability of illegal immigrants to procure documents for employment, thereby reducing the number of illegal immigrants in the workforce.
- Increase in penalties for employing undocumented workers to $7,500 for first offence, $15,000 for second offences, and $40,000 for subsequent offences. In essence, the House bill makes it harder for employers to plead ignorance for hiring illegal immigrants and makes it fiscally prohibitive to get caught doing so.

One of the more politically volatile aspects of the bill is its exclusion of any type of guest worker program. The House bill focuses primarily on enforcement and discouraging illegal immigration. The enactment of this bill would certainly reduce the immigrant workforces available within the construction industry, creating labour shortages in certain disciplines. There is no relief available in this bill for such shortages.

The second bill, introduced in the Senate on 7 April 2006; S 2611, is titled Comprehensive Immigration Reform Act. The bill passed the Senate on May 25, 2006, with amendments. The House bill, The Border Protection, Anti-terrorism, and Illegal Immigration Control Act of 2005 mentioned earlier has been stalled in the Senate Judiciary Committee. Rather than annihilate the House bill, the Senate chose to establish its version of immigration reform and proposed this alternative bill. The major provisions of the Senate bill of particular interest to the construction industry include:

- Requirement for reinforcement of several miles of fencing along the Mexico border and the construction of 370 miles of additional fencing. At an estimate of $4 million per mile, the total cost would amount to almost $1.5 billion of construction.
- Mandating an expanded use of the employment verification system. The system must be in use by all employers for new hires 18 months after the necessary appropriations are made to fund the system, an estimated $400 million. There is no mention of employment verification for existing employees.

Overall, enforcement is not the essence of the Senate bill. The two key provisions in the Senate bill that would drastically impact the construction industry are amnesty for illegal immigrants and the guest worker visa program.

- Amnesty: illegal immigrants present in the United States for more than five years could apply for citizenship. A penalty and back taxes would apply. Illegal immigrants present in the US for 2–5 years would be allowed to remain in the US without fear of deportation and apply for citizenship in 3 years at one of 16 ports of entry. Illegal immigrants present for less than two years would be required to return to their original nations. Amnesty, therefore, would be available to approximately 85% of illegal immigrants. This would significantly reduce the labour shortages experienced in the construction industry.
- Guest Worker Program: the Senate bill establishes the H-2C visa or “blue card.” Companies would be allowed to recruit foreign workers for positions where there are a shortage of U.S. workers available. The employer will be allowed to petition the Department of Labour (DOL) for permission to hire foreign workers after they have shown reasonable effort to recruit US workers. All foreign workers under this program shall be paid prevailing wages. Workers would be allowed to work under this program for 3 years with one 3-year extension. After returning to their home countries for one year, they could reapply. This provision alleviates the labour shortages experienced in some construction disciplines, but makes the cost of recruiting and hiring foreign workers prohibitive.

The Senate bill takes a much softer stance on enforcement and allows provisions for amnesty and guest workers, which would alleviate the strain on current labour resources within the construction industry. However, the guest worker program could prove cost prohibitive.

CURRENT ESTIMATES

Among illegal Hispanic immigrants in the Washington DC metro region, one in three is employed by the construction industry. According to information provided by the Center for Immigration Studies, the construction industry employs more illegal immigrants than any other industry in the US Immigration and illegal immigration, in particular, are hugely important issues within the construction industry.

Analysis of the Current Population Survey (CPS) for 2005 reveals an illegal immigrant population between 11.5 and 12 million. Of those, 7.2 million are employed in the US labour force, with 1.4 million in the construction industry, which comprises 14% of the entire construction workforce. Since guest worker provisions and legalization paths being discussed in Congress differentiate between long-term illegal immigrants (those that have resided in the US more than five years) and short-term illegal immigrants (those that have resided in the US less than five years), it is helpful to break these numbers down accordingly. Again, from an analysis of the March 2005 CPS, 4.4 million illegal immigrants arrived in the US between 2000 and 2005. Another 2.9 million arrived between 1995 and 1999, and approximately 4 million before 1994. By these estimates, the short-term illegal immigrants make up over 35% of the total illegal immigrant population. Of those, approximately 550,000 have found employment within the construction industry (Pew Hispanic Center, 5 &13 April 2006).

Table 1: Illegal immigrant share of specific occupations, March 2005 (in thousands)

Detailed occupation	Total Workers	Illegal Immigrant Workers	
		Number	Share
Total, Civilian Labour Force (with an occupation)	148,615	7,255	4.9%
Insulation workers	56	20	36%
Roofers	325	93	29%
Drywall installers, ceiling tile installers, and tapers	285	79	28%
Construction helpers	145	40	28%
Construction labourers	1,614	400	25%
Brick masons, block masons, and stone masons	198	49	25%
Painters	768	167	22%
Cement masons, concrete finishers and terrazzo workers	141	29	21%
Carpet, floor and tile installers and finishers	330	66	20%

Source: Passel (2006)

Overall, almost 14% of the construction industry workforces are comprised of illegal immigrants. This trend in hiring practices will have a significant impact as the industry braces for immigration reform.

THE NEW FACE OF THE WORKFORCE

Based on this information, how will immigration reform change the make-up of the US construction workforce? Following, we consider each element of reform and anticipate its impact on the labour force.

The Employment Verification System will be mandated for new hires and existing employees. New hires will require immediate verification and existing employee verification will be phased in over several years.

This aspect in itself will have huge impact. There have been several studies that conclude approximately half of illegal immigrants have provided valid Social Security Numbers (SSN) in order to obtain employment. There are two ways that an illegal immigrant can obtain a valid SSN: (1) the SSN was stolen or otherwise illegally obtained from someone who is authorized to work in the US or (2) the SSN was issued by the Social Security Administration. There are some illegal immigrants that are authorized to work in the US, for instance, asylum seekers whose cases have not yet been adjudicated. Thus, it is not clear how many illegal immigrants have illegally acquired SSNs, but the number is likely to be significant (Camarota 2004).

The mandated use of the employment verification system will make it more difficult for illegal immigrants to deceive employers who are attempting to comply with the law. The immediate deployment of the system for new hires will deter the influx of illegal immigrants directly. The phased deployment of the system for existing employees will likely encourage the departure of illegal immigrants before they are apprehended.

Document fraud will be more strictly enforced in conjunction with the Employment Verification System. Harsher penalties will be levied against those found to be involved.
This is likely to deter illegal immigrants from improperly obtaining worker authorization documents and decrease the number of illegal immigrants in the workforce.

Higher penalties will be enforced for unlawful employment of illegal immigrants, probably along the lines of the House bill.
This appears positive, but without enforcement, it means little. Penalties for hiring illegal immigrants already exist in the law. Enforcement will be the key for this component of the bill to have any effect.

Amnesty will be allowed for those illegal immigrants living in the US for longer than five years.
This element will have far reaching effects: 60%of illegal immigrants have resided in the US. more than 5 years. Thus, they would be eligible for legal residency under this provision. Approximately 7 million illegal immigrants would be eligible for Legal Permanent Resident (LPR) status under this provision. In addition, another 3 million family members living abroad, spouses and minor children, will be eligible for LPR status.

The H-2C visa program for guest workers will be included with the prevailing wage provision intact to discourage use by employers and protect US workers.
The guest worker program will allow another 19% of illegal immigrants currently residing in the US to remain. Illegal immigrants that have lived in the US for 2–5 years are eligible for Deferred Mandatory Departure (DMD) for up to three years. Within those three years, they will be allowed to return to a port of entry and apply for the H-2C visa program. The H-2C visa program has a cap of 200,000 admissions annually; however, DMD applicants are exempt from this cap. Through DMD and H-2C visa program, another 2.2 million illegal immigrants would immediately be eligible for legitimate worker status, but at a price (Camarota June 2006).

Employers of guest workers will be required to pay prevailing wages to these employees. There is still some discussion of whether to use the wage determinations from the Department of Labour as required by the Davis-Bacon Act of 1931 or wage data garnered from information and data collected by the Bureau of Labor Statistics (BLS). Either way, the cost of immigrant labour will increase.

In summary, immigration reform will deter hiring practices of illegal immigrants, but will allow the vast majority of illegal immigrants a path to legal status. Thus, this does not represent a true zero-sum game. Nearly 80% of illegal immigrants are likely to be granted some form of amnesty and be allowed to continue to work in the US. However, employers will see a rise in the cost of immigrant labour.

LABOUR COST FOR CONSTRUCTION PROJECTS

Labour costs account for over half the direct costs of construction projects in the US. Table 2 is a comparison of hourly wage estimates for immigrant-intensive disciplines taken from Davis Bacon Wage Determination and BLS data. These data will be used in determining prevailing wage rates paid to newly eligible immigrants who qualify for the guest worker visa program. The BLS data is the median for wages paid for the detailed occupation category listed. The Davis Bacon wage listed comes from the wage determination from the DOL. There is considerable controversy within the industry over the validity of the prevailing wage determination made by the DOL. DOL collects data from employers in order to determine the prevailing wage. Many feel that labour unions, who offer their wage data more freely than private industry, skew the numbers towards union rates and, therefore, the prevailing wage determination is not an accurate reflection of prevailing wages in the region. BLS data comes from annual surveys of employees. Currently, "prevailing wage" language means Davis Bacon wages as determined by DOL wage determinations. Lobbyists are working hard to change this generalization and hope to replace DOL wage determinations with BLS median wage data. However, for the purposes of this research, we consider prevailing wages to be predominantly union-scale wages based on provisions of the Davis-Bacon Act and BLS median wages to be the average wage for that particular construction labour specialty.

Table 2: Hourly wage determinations for Montgomery County, Maryland

Construction Labour Specialty	**Davis-Bacon**	**BLS**
Insulation workers	$30.58	$20.11
Roofers	$29.56	$16.25
Drywall installers, ceiling tile installers, and tapers	$17.44	$15.84
Construction helpers	$11.48	$11.65
Construction laborers	$11.74	$12.69
Brick masons, block masons, and stone masons	$22.69	$19.88
Painters	$29.37	$16.80
Cement masons, concrete finishers, and terrazzo workers	$17.44	$16.15
Carpet, floor, and tile installers and finishers	$20.76	$18.59

THE IMPACT ON PROJECT COSTS

Scarcity of labour is not a likely result of the pending immigration reform. The Electronic Verification System will allow existing illegal immigrant employees to remain employed without detection for up to six years. Eighty percent of illegal immigrants will be allowed some form of amnesty, either through access to LPR status immediately available to those that have resided in the US over five years or DMD status for those that have lived in the US for 2–5 years. DMD immigrants will be eligible to apply for guest worker status with little effort, so the industry is not likely to suffer further labour shortages as a result of immigration reform.

However, the attractiveness of immigrant labour will subside slightly due to the prevailing wage requirement included in the reform bill. Currently, immigrants earn approximately 75% of native-born wages, (Kochhar 2005). This difference is not due solely to the foreign-born factor, or to legal or illegal immigration status. The primary driver of depressed wages is the lack of high school and higher education among the construction workers. Over one-third of all immigrants lack high school education. Education is the best predictor of economic success for individuals, regardless of immigration status, (Camarota 2004).

Additionally, only about 55% of illegal immigrants are paid "on the books", i.e. payroll taxes are deducted and matched by the employer. Payroll taxes include income, Social Security, Medicare, and Workman's Compensation (Camarota 2004). Depending on the discipline, this could account for half of the cost of the employee to the employer.

To quantify the effect, the following analysis was conducted on cost data for five commercial construction projects. The projects were all from the DC metro area, so prevailing wage determinations were collected from DC, Northern Virginia, and Maryland. The projects were all commercial construction: three high-rise office buildings, one high-rise condominium structure, and one institutional structure. Labour burden was estimated to be 33.6%: 17% worker's compensation insurance, 16.6% unemployment costs for federal and state and Social Security taxes. These are national averages for labour burden taken from BLS.

Table 3 shows an analysis of cost data in five construction labour specialties saturated with immigrant labour: concrete, masonry, drywall, painting, and flooring. Terrazzo installation was included for the projects for which there was data. Overall, the impact appears less than 1% of total project cost, but with profit margins on the order of 5–10%, 1% would certainly become a noticeable impact.

Table 3: Estimated increase in project costs

	% Illegal Immigrant Workers	% DMD	Median Wage	Prevailing Wage	% Payroll Taxes	% Increase in Total Labour Cost	% Increase in Total Project Costs
Project 1: Virginia							
Concrete	21%	4%	$14.18	$30.91	9%	1.66%	
Masonry	25%	5%	$19.57	$22.69	11%	1.13%	
Drywall	28%	5%	$15.24	$30.91	13%	2.72%	
Terrazzo	21%	4%	$14.13	$30.91	9%	1.66%	
Painting	22%	4%	$14.10	$29.37	10%	1.73%	
Flooring	20%	4%	$14.68	$20.76	9%	0.92%

Project Totals						2.28%	0.93%

To reach the above conclusions, the following assumptions were made:

- The estimates of illegal immigrant workers are accurate for these projects. Pew Hispanic Center believes that these estimates for the Washington, DC metro area may be low. Additional research is ongoing to determine better estimates for this region.
- Of those illegal immigrants eligible for DMD, all will apply for guest worker visas. Employers will be required to pay these employees prevailing wages. The inflationary impact of this action on other wages for these projects was omitted. Further research will be necessary to quantify this impact.
- Payroll taxes for 45% of illegal immigrants are not currently being paid. Following immigration reform and the instatement of the Electronic Verification System, employers will experience more difficulty in paying employees "off the books." Therefore, payroll taxes will be paid by employers for these existing employees currently being paid "off the books".
- Labour accounts for 65% of subcontract costs. This is a rule-of-thumb used by estimators, and more detailed estimates should be addressed for affected construction labour specialties.
- All other factors affecting construction economics have been ignored. Immigrant labour supply and immigration reform have been isolated in order to analyse impact. Construction demand has been assumed to be stable and immigrant labour has been assumed to be plentiful. Economic expansion or recession has not been addressed. Additional research is required to include these factors in a more detailed analysis. Inflationary impact as a result of prevailing wage legislation has also been omitted thus far.

CONCLUSIONS

The research in this area continues. Currently, specific trades in the Washington DC metro area are being studied to determine the ratio of workers that will be affected by the pending reform. Increased project labour costs of 1% are estimated thus far, assuming the most likely political scenario related to the passage of the reform measures under consideration. It is predicted that this estimate will rise with more detailed and accurate data regarding worker demographics. Further study will address: (1) specific trades affected most dramatically by anticipated reform; (2) the amplitude of the effect based on the possible extreme scenarios of the reform; and (3) proposed mitigating efforts by the construction industry itself.

THE ROLE OF DEFECTS AND REWORK IN THE DRIVE FOR SUSTAINABLE CONSTRUCTION

James Sommerville[1] and Nigel Craig

School of the Built and Natural Environment, Glasgow Caledonian University, Glasgow, G4 0BA, UK

Various reports have identified the need for a consistent reduction in the level of construction defects. The reality of course is that little has been done to improve the industry's record with regard to the origins and causes of defects, nor their eradication. The research aimed to determine the role actors in a range of defects and the impact of the defects on sustainable construction. Detailed analysis of defects found within the house building sector shows a continuing trend towards acceptance of the inevitability of defects.. Analyses of some 200,000 defects in 3696 new homes shows that whilst there are a number of prime origins, the actual cause of the defects on site can be attributed to a single entity – the humans. Discussion is given to the impact of the defects and the need for management of the causal agent. These initiatives are then contextualized within the drive for sustainable construction. The figures and analyses from this research represent the most accurate statistics on snagging in the UK. What is clear from the research is the failure to grasp a significant opportunity to improve sustainability performance and at the same time bring about a significant increase in customer satisfaction.

Keywords: building defects, customer satisfaction, sustainability, new homes, snagging.

INTRODUCTION

The last decade has witnessed a constant clamour from both clients and government for improvements in the quality of the finished product delivered by the house building sector of the UK construction industry. The UK government's ambitions to improve the quality of new homes have prompted a number of house builders to consider the implementation of quality initiatives such as Total Quality Management (TQM) and ISO 9000 (Sommerville 1994). The use of these quality initiatives is at best questionable and their adoption does not appear to be a guarantee of an improvement in the quality of the finished article (Sommerville *et al*. 2004).

In the house-building arena, the house builder sets the specification requirements (finished product), the customer is perceived as a simply a 'buyer' that purchases the final product with its inherent defects or 'snags'. The importance of snagging is shown by the fact that the last three Housing Forum/MORI customer satisfaction surveys carried out in 2000, 2001 and 2003 and the House Building Federation customer satisfaction survey in 2006 report an increasing number of new home purchasers as being unhappy with the finished quality of their new home, with the recorded levels of satisfaction showing a downward trend.

The volume of research specifically related to snag levels or indeed quality in new-build housing is remarkably scant given the size of the industry. The research that is

[1] jso@gcal.ac.uk

there focuses predominantly on regulatory defects, i.e. contraventions to either building regulations or the warranty providers' standards. Whilst researchers have made some inroads into describing and understanding the phenomenon of defects and rework, the literature available has tended to concentrate upon the major project environment. There is limited literature that incorporates current knowledge of not only snags and snagging but the quality problem within new build housing, more work needs to be done to unite the disparate research areas.

Initial analysis of snag data from 3696 new homes built by 420 UK house builders demonstrates the levels of snags a home buyer could expect to find when purchasing a new home. It is clear that snags are a major problem within the industry and one that requires major attention if Egan's (1998) dream of reducing defects at handover by 20%, year on year is to become reality.

EGAN – NEGATIVE IMAGE AS A DRIVER

As a result of the perceived negativity hovering around the image of the UK housing industry, the government published two significant reports in an attempt to drive up the quality of the final product. The reports themselves (Latham 1994; Egan 1998) were mainly focused upon the commercial sector although they have strayed into the speculative house building sector (Sommerville and McCosh 2006). Egan (1998) argues that quality must be fundamental in the design process and that defects and snagging need to be designed out on the computer before work starts on site. He also proposes that by achieving a reduction of 20% in the number of defects found in handover annually that the goal of zero defects is achievable across construction within five years. In spite of this, he fails to provide any clarity as to how this recommendation was generated, let alone any approach to the attainment of the 20% reduction; further, he fails to provide evidence to suggest that his theory of a five-year time scale in achieving zero defects will be obtainable. It can also be argued that if a timescale and factor of improvement figure had been provided then a benchmark defects figure for the construction industry to use to measure performance should also have been provided. The Modernizing Construction Report (2001) rightly highlights that there is a serious lack of reliable and quantified information that can be used to evaluate the performance of individual projects never mind the industry. Such information is essential for setting reliable targets and estimates for future performance

The reports focus on the need to reduce the number of defects in construction and highlight the increasing importance of after-sales customer care. Sound after-sales customer care is an integral part of overall quality that exceeds customer expectations and provides a real service benefit to the end user. Given the discussion above, it becomes apparent that The Egan Report (1998) may not be directly applicable to the speculative house-building sector of the construction industry.

THE PROBLEM WITH DEFECTS/SNAGGING AND REWORK

The ongoing quality problem within the industry suggests that one of the main drivers of the Egan report (reduction in defects of 20% p.a.) has been ignored and a golden opportunity missed.

Understanding defects and rework in new UK houses strikes at the very heart of the wider construction industry since the contribution to the UK construction industry's output made by the new private-housing segment is significant, as shown in Figure 1.

The data shown in Figure 1 has been drawn from the UK's DTI (2005) statistics on the industry and shows, in relative terms, that the private new-housing segment is the largest of the three segments, which coalesce to make up the new-works section of industry output. Even though this new private-housing segment is the largest element in the composite new-works section, it is often ignored due to its fragmented nature and its myriad of clients – the individual new house buyers.

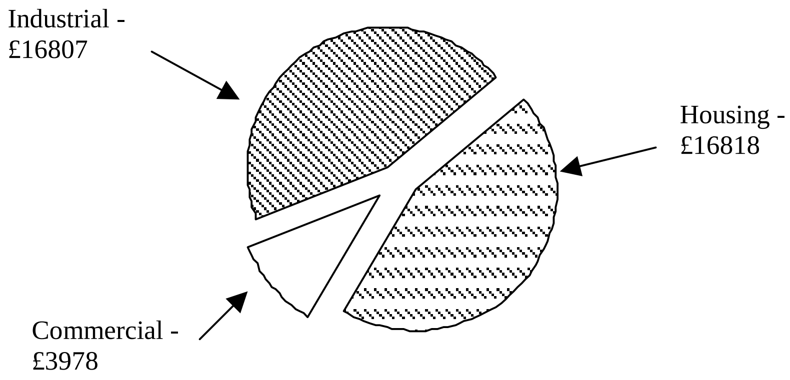

Figure 1: The distribution of UK new works: £ Millions (source: DTI 2005)

With this multiplicity of clients, there is an implicit argument that the house builders will focus on the quality of the product they offer in order that they differentiate themselves from rivals and attract buyers. These house buyers of course have their own set of quality expectations, i.e. requirements, which are often at odds with those of the house builder.

QUALITY EXPECTATIONS OF UK NEW HOUSE BUYERS

The quality drive in the UK new-housing sector arises not only from the buyer, but also from two main industry forces: firstly, the marketing efforts of the individual house-builders, which sees the house-builder trying to convince a fickle buying public that their product is as good as, or superior to, that offered by the rivals and therefore the one to have; and, secondly, the need for the house builder to reach various minima dictated by a range of regulatory bodies such as Building Control or the National House Building Council (NHBC).

Against this drive for pluralistic client satisfaction, we have to balance a multi-billion pound industry within which one of the largest companies sees their core business as being a retailer, rather than a house-builder. Lorentzen (1996) argued for this underlying presumption, that new houses are now consumer products, with his contention that a home could be seen as a consumer product, albeit a very expensive one. Thus we have a multi-billion pound industry, manufacturing and producing very expensive consumer products, but with little research on the end-customer's requirements and scant consumer legislation to protect the buyer (Mills 2000). The Barker Review (2004) reinforces the view that more has to be done to raise the quality standards of a number of the leading house building companies, noting that "the need to improve standards applies right across the industry".

This need to improve quality standards is in part driven by the levels of defects and rework found in new houses and also through various reports (e.g. Ball 1996; Barker 2004), which clearly indicate that all is not well with the products currently being delivered (i.e. the mismatch between Technical and Functional Quality). A number of high-profile instances have shown that the quantity of defects and rework, on relatively small new houses, can be enormous. The case of Langridge (2005) illustrates this point: after the buyer moved in to a one-bedroom house, valued at £500,000, it was found to have 86 defect items requiring rework. Whilst this case appears on the surface to be ‘cut and dried’, it highlights the need to define precisely what the defects are, what the associated rework is and the defects’ root causation.

MEASURING USING KEY PERFORMANCE INDICATORS

Key Performance Indicators (KPIs) are a form of benchmarking that has been adopted in construction allowing performance to be measured and analysed, thus enabling continuous improvement to be developed and implemented. KPI charts rate defects from 1–10 on the y-axis as can be seen in Figure 2. This scoring indicates the level of defects in construction: the higher the rating the lower the number of defects there are. If the contractor or house builder receives a low rating, it indicates that the end product is riddled with defects upon handover. This rating is determined by the client but in the speculative house building sector it will be the home builder who applies the final rating. Constructing Excellence characterize the ratings as follows:

“**Definition**: Condition of the facility with respect to defects at the time of handover, using a 1 to 10 scale where:

10 = Defect-free.

8 = Some defects with no significant impact on the client.

5/6 = Some defects with some impact on the client.

3 = Major defects with major impact on the client.

1 = Totally defective. (Constructing Excellence 2006)

An organization can then use the KPI charts to gauge how their own performance compares to their competitors. This is carried out by rating a building at handover using the above rating system and plotting the result onto the graph. By marking the rating with a horizontal line, the performance is identified at the point where this line intercepts the curved line and a percentage identified. An example could be where a defect performance rating of 9 is achieved. This score of 9 is plotted horizontally (see Figure 2) and this would provide an organization with a benchmark score of 85%. A rating of 85% would indicate that 85% of companies are achieving equal or lower than this and 15% are achieving higher. The above scoring format for rating performance is adequate; however, the rating process itself has inherent issues in that it is highly subjective in nature. Therefore, for the data that is produced by this process to be accurate, a considerable responsibility lies with the home builder to be completely truthful when rating their products (new homes) and they are more likely to rate their products higher than the end customer would. For example, the terms major and minor impact are not defined and the home owner may interpret these terms in a different way. The reality is that a completely different set of results would be produced if it was the home owner who was rating the new home as opposed to the home builder. This demonstrates that there is a degree of one sidedness embedded within the current process and is a process that does not take into account customer satisfaction information obtained from the most important member of the house buying process “the customer”.

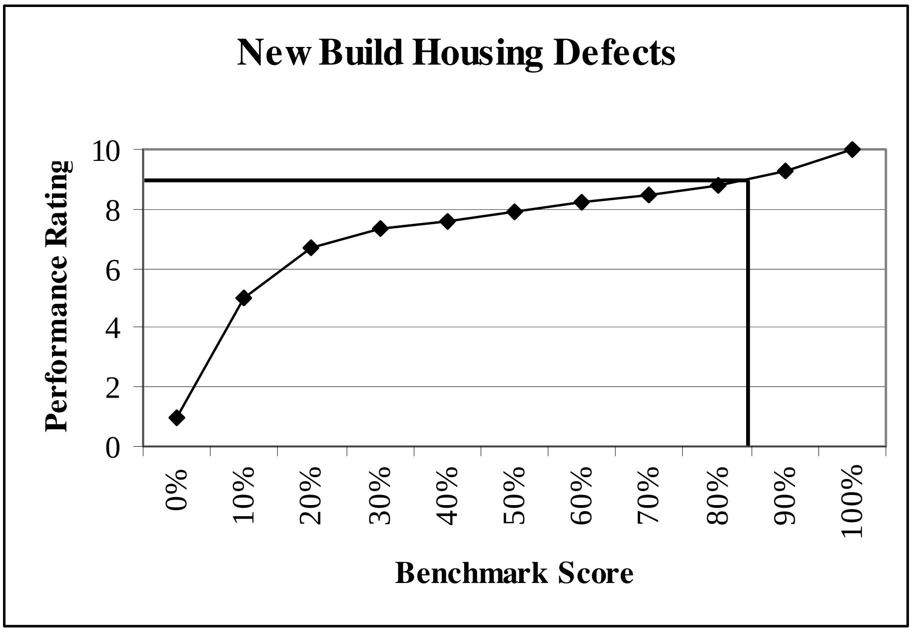

Figure 2: KPI graph indicating the benchmark score for defects within new homes in the UK (adapted from Constructing Excellence, 2006)

MEASURING INDUSTRY PERFORMANCE – NATIONAL CUSTOMER SATISFACTION SURVEYS

The UK Housing Industry performance has also been measured in recent years using national surveys. Surveys carried out by the Housing Forum in 2000, 2001 and 2003 and the House Building Federation in 2006 have focused upon the customer in order to generate results that reflect the customer's opinion of their newly built home. On the face of it, these surveys are sporadic, in that they are not carried out annually; unlike KPI data, which is now produced on a constant basis. However, when these customer surveys are carried out, very similar questions are asked each time. Since the same questions have been utilized in each survey, it is possible to agglomerate the results for the national surveys of 2000, 2001, 2003 and 2006, and from this agglomeration to identify trends from within this enveloping period as displayed in Figure 3.

What is evident from Figure 3 is that the overall levels of quality, finish and condition of the new home display downward trends whilst, at the same time, the amount of home owners reporting snags within their new homes is on the increase (having risen by 12% over the last six years). The apparent misnomer in that the overall quality is falling and yet the buyers are happier would perhaps lie in the improvement in the approach to Functional Quality being implemented by the house builders (Technical Quality being taken for granted). If no action is taken to prevent this trend continuing, it can be assumed that the overall quality of new build homes will continue to decrease. In comparison, however, the new build housing KPIs taken over the last six years show an increase in the number of organizations scoring 8/10 or better from a figure of 50% in 2001 to a figure of almost 78% in 2006. We thus have an industry which indicates that performance levels are increasing with regards to overall satisfaction and reduction in defects levels, but end customers who indicate that the overall quality of their new homes is decreasing whilst snagging levels have risen dramatically. The snagging process or indeed the collection of snagging data has rarely been written or reported upon within the UK construction and housing industry which has resulted in a dearth of literature and data sets available to the authors of this paper. The data sets available for analysis within this research are limited: both in terms of the actual quantity of data available and the access to such data sets from different members of the snagging process chain.

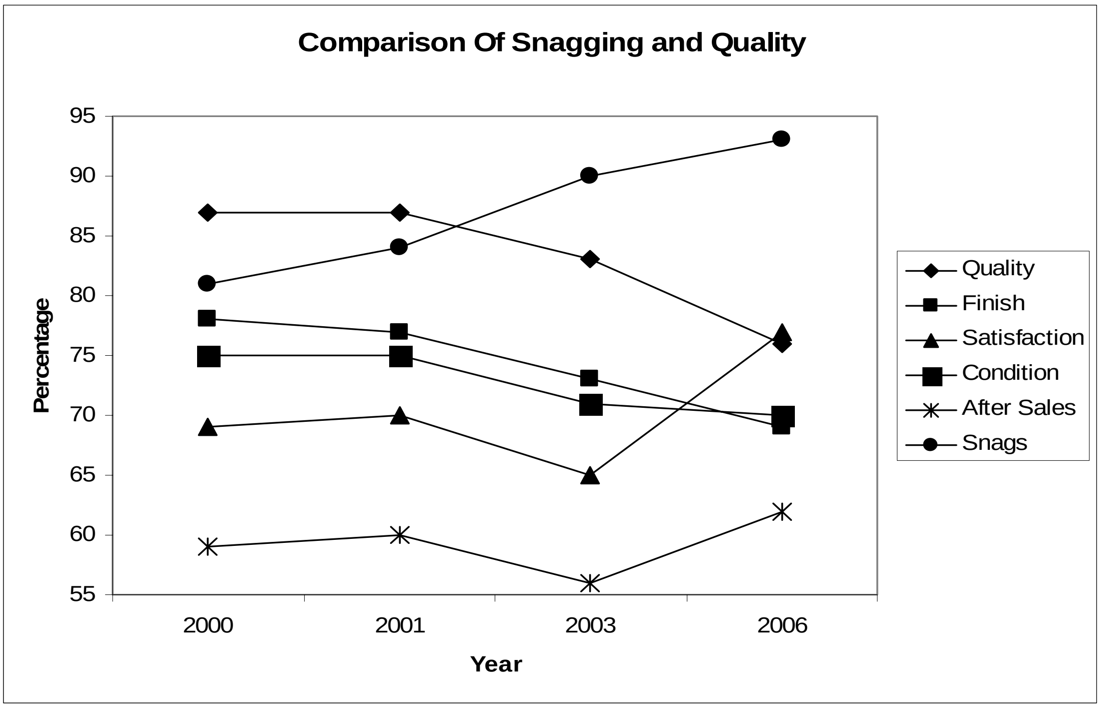

Figure 3: Trends from housing surveys 2001–2006(adapted from Constructing Excellence 2000, 2001, 2003 and HBF 2006)

AIM AND OBJECTIVES OF THE RESEARCH

The research aimed to determine the role actors within a broad spectrum of defects and the impact of the defects on sustainable construction.

Objectives: to determine the level of snags prevalent within new homes in the UK; to discern the link between snags and a sustainable industry; to discuss the industry's utilization of KPIs; and to disseminate the findings form the research.

In order to achieve the stated aim and objectives, a robust methodology is required, the discussion of which follows.

METHODOLOGY

There is an implicit constraint within the methodology that the data used in this research was extracted from a data set provided by the UK's leading independent new home snagging company. The argument would be that this is a biased population. Indeed the contrary may be argued since it is the only detailed independent dataset available and as such, is deemed to be robust until new data sets are made available within the public domain.

A comprehensive snagging report has been produced for each of the 3696 new homes; these reports being generated over a period of 5 years (under the instructions of the home buyer) through 57 inspectors based around the UK. The reports have been formatted and analysed with the resultant dataset containing detailed information on 200,000 snagging items found within the 3696 properties built by some 430 house builders.

Data available for extraction from the inspection reports included a host of detail on: the name of the client, the location of the property, the type of property, the house builder, the independent inspector, date of inspection, number and type of snag and so on. For the sake of clarity in this paper, the list noted above has been truncated. The variables within the datasets were numerically coded for statistical analysis. The names of 'clients', 'inspectors' and 'building companies' are not specified for confidentiality reasons.

After the initial examination of the data, it was clear that for many of the factors, such as builders and inspectors, there were a number of categories with very little data. These categories with low frequencies were then excluded from further analysis. The formatting of the data involved the examination and analysis of over 2m individual data cells. This paper will include analysis on select variables contained in the dataset, which will give an initial picture of the extent of snagging in the UK house building sector of the UK construction industry.

DATA ANALYSIS

All of the new homes inspected on behalf of homeowners, property investors and developers were inspected after the properties had been checked and verified by the appropriate warranty provider and passed over by the developer to the new home owner. Over 90% of properties were checked in the week prior to completion. This is an extremely important aspect as the figures demonstrate a true reflection of the current industry quality standards, rather than just a reflection of all the worst properties in the UK.

There is a considerable range between the highest and lowest number of snags found within a new home. For the first time during this research project a new home (One bedroom flat) has been accredited with having zero snagging items. However, the highest number of snagging items found within a new home has dramatically increased from a figure of 389 to a new level of 452 (six-bedroom house located in the south of England).

The first factor considered during the analysis of the 200,000 snagging items was the average number of snags across the 3696 properties over a five-year period 2002–2006. A decrease in the average number of snagging items found within new homes in 2002–2004 can be seen in Figure 4. The average for 2005 increased by some 19% although the overall performance for 2006 shows a marked increase in overall quality with an average figure found of 46.3.

Considering the average number of snagging items for all house types, further analysis was undertaken to identify the average number of items found within house types of a particular size, in this case by the number of bedrooms. The results of this can be seen in Figure 5. From the analysis of the 3696 new homes, it became clear that as the number of bedrooms in a property increased, so did the number of snagging items associated within each property type, although over time the number of items found within particular house types is slightly decreasing. Although it might be reasonable to expect an increase in the incidence of snags as the bedroom number increases, the full extent of this increase was not expected. The fall in the average number for 1 and 5

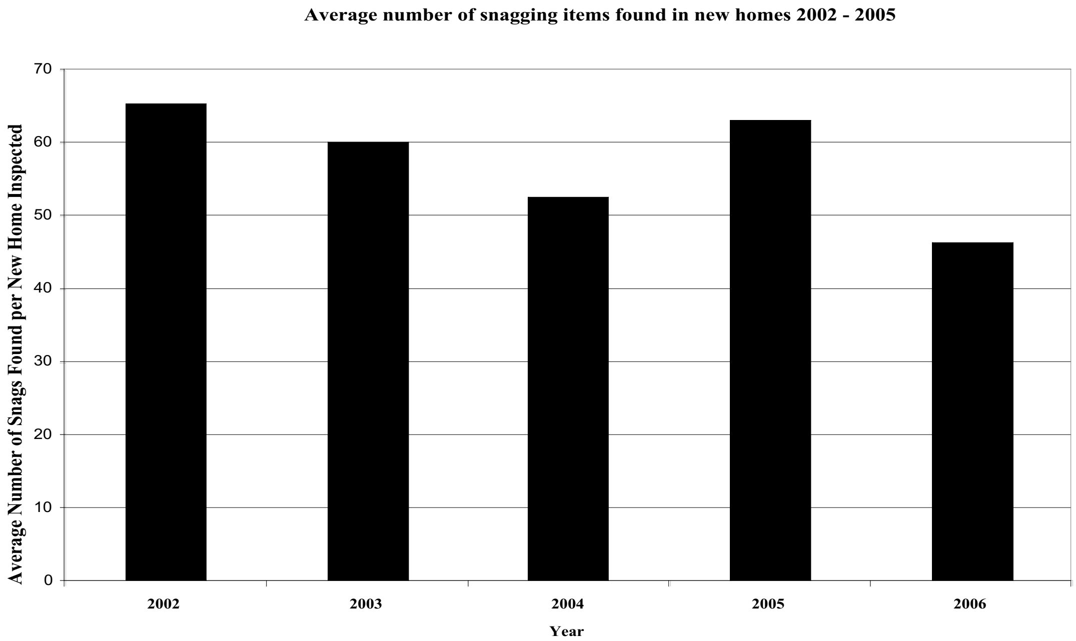

Figure 4: Average number of snagging items per property 2002–2006

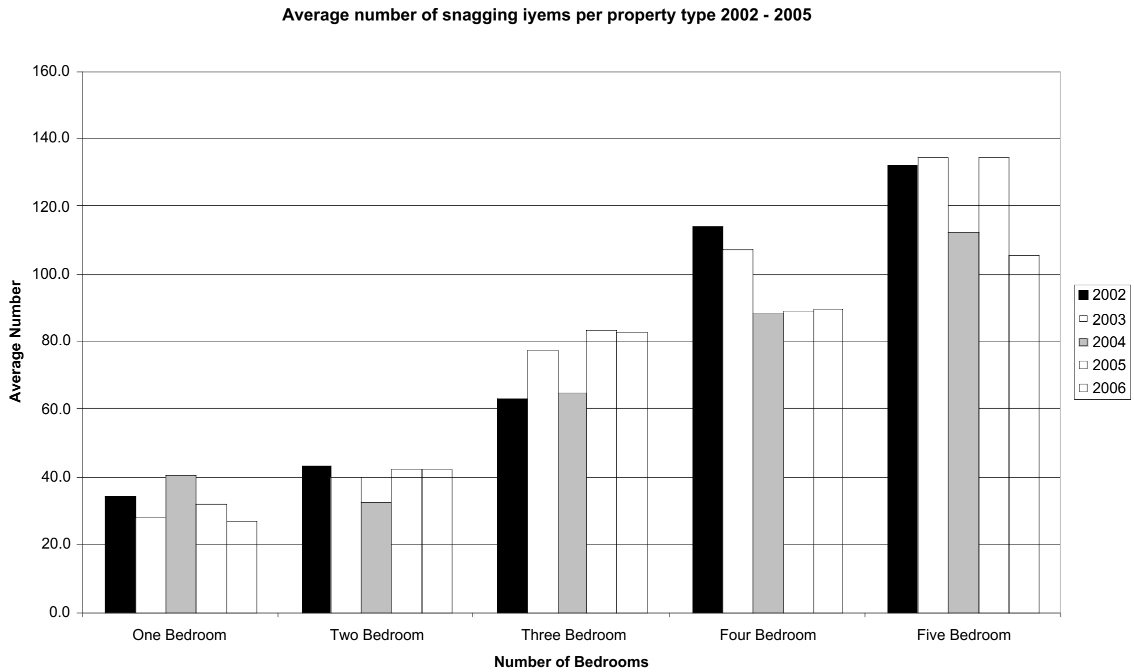

Figure 5: Average number of snagging items per property type 2002–2006

bedroom properties in particular follows the general trend set within the average figure for the whole of 2006. The figures for 2006 are a marked improvement on the overall figures for 2005 although the overall performance levels of the house building industry still have a long way to go in order to achieve Egan's dream of zero defects.

The apparent dichotomy in Figure 3 may arise from significant efforts by a number of the major house builders to improve their Customer Satisfaction activities. These activities are in effect masking the buyers underlying perception of the quality of the product and at the same time embedding the losses to be sustained by the house builder during the construction phases. These losses of course detracting from the industry's sustainability drive.

CONCLUSION

The lack of detailed research in this area prohibits us from discussing these findings directly with prior work/s. However, previous research in associated areas has shown the loss to the industry has a direct impact on its sustainability. Whilst this work is centred on new housing, a full-scale industry wide research effort is required to delve into the issues and arrive at a broadly meaningful set of conclusions.

New homes within the UK are being repeatedly handed over to the end customer with very high levels of snagging items that cause the customer to be dissatisfied with overall quality. The research within this paper has demonstrated that current snagging levels found within new homes in the UK are at a level that must be perceived as damaging to the house-building sector's image and they detract from customer satisfaction. The house-builders of course could be asked to shoulder some of the blame for this lack of quality focus but the responsibility may better sit on the shoulders of the numerous buyers who have accepted products with lower than anticipated quality standards.

Quality initiatives within the industry have been promulgated and implemented under a number of guises and yet the end product – the new home is still sadly lacking in quality. The investigations have also shown to some extent that the dream of zero defects within five years, proposed by Egan, was in reality unachievable and this research has been undertaken nine years after this proposition was made.

The problem of managing performance has also been examined and links have been found which have displayed a total lack of agreement between the parties involved in house building. The KPIs are indicating that 78% of all new house builders (self rating) are achieving performance measures of between 8/10 whilst at the same time overall customer satisfaction within the industry continues to drop at an alarming rate and snagging items reported continue to rise.

Modern house builders and developers ought to feel the effects that new services such as snagging surveys are having on the industry. There may eventually have to be a change with regard to the snagging process, as the process already implemented is not addressing the problem adequately. If the construction industry is able to produce an improved way of monitoring errors, defects and snags when constructing then hopefully this will be implemented and the dream of zero defects, if not realized, then the number of items can be dramatically reduced. This in turn would boost customer satisfaction figures.

Future work will examine in further detail the snagging data already collected from the independent surveys. This data will be mined and analysed in order to determine what snagging items are Functional and what items are Technical which will give an overall view of the types of snagging items currently found within new homes. By determining the Technical and Functional aspects of snagging, it will be possible to identify which items can be avoided and removed from snagging lists at the point of handover. This will not only improve industry performance and sustainability but also result in customers being more satisfied with the overall quality of their new home.

DRIVERS FOR IMPLEMENTING SUSTAINABILITY INITIATIVES: AN EMPIRICAL STUDY

Suresh Renukappa[1] and Charles Egbu

School of the Built and Natural Environment, Glasgow Caledonian University, Glasgow G4 0BA, UK

In the early part of this 21st century, global competition, the knowledge economy and the potential offered by emerging technologies along with commitment to the principle of sustainability pose profound strategic challenges for business. Sustainability concerns the management of an organization's total business impact upon its immediate stakeholders, the society, and the natural and built environment within which it operates. For businesses, the very concept of sustainability is elusive and defining sustainability in general terms does not easily translate into individual responsibility or appropriate action. Businesses today have to amend many of the principles that have guided generations of managers, and develop a new set of objectives and rules that will enable them to successfully manage sustainability issues in the next decade or so. As organizations try to meet these change challenges, executives face conflicting pressures. The issue is not whether companies will engage economically viable, environmentally sustainable, and socially responsible activities, but why should they do so. For most companies, the central challenge is how best to achieve the maximum environmental and social benefits from a limited amount of resources available for sustainability programmes. Many organizations are convinced that they are likely to financially benefit from encouraging socially and environmentally sustainable business practices. This paper primarily reports on the findings of an ongoing research study, which is focused on how organizations are managing change and knowledge associated with sustainability initiatives so as to improve their competitiveness. The findings are in the main, based on semi-structured interviews with 59 professionals from 40 UK organizations in four sectors: energy and utility, transportation, construction and not-for-profit organizations. It reviews the concept of sustainability and the key drivers for implementing sustainability initiatives in organizations. The paper concludes that identifying and understanding drivers for implementing sustainability initiatives is a complex process. The key drivers for implementing sustainability initiatives as revealed by the study are reducing operating costs, enhancing reputation, stakeholder pressure, Government regulation/legislation, and top management commitment.

Keywords: corporate social responsibility, environmental sustainability, managing change, sustainability initiatives.

INTRODUCTION

Reports in the academic, business and popular press make it clear that the world in which business operates today is different from the world of two to three decades ago. This is primarily due to meeting increased demands and expectations of stakeholders; protecting degradation of natural resources; the knowledge economy; managing crisis and remediation while defending the organization; and diminishing social and community structures (Connor and Mackenzie-Smith 2003). These complex issues involve numerous processes carried out and influenced by many stakeholders to set

[1] Suresh.Renukappa@gcal.ac.uk

the tone and guide corporate level decisions. Nevertheless, to businesses these are formidable environmental and social issues that have evolved over time and that must be addressed (Carroll and Buchholtz 2006). To address the above issues and challenges, sustainability (or sustainable development) offers business leaders a 21st-century management framework. Sustainability is a management principle that aims to create long-term shareholder value by seizing opportunities and managing risks related to the economic, environmental and social impact of doing business (Savitz and Weber 2006).

The World Commission on Environment and Development has defined "sustainability" as "economic development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs (Brundtland 1987). However, this macroeconomic definition does not provide much guidance on how this concept should be put into operation at the company level, and managers still question how to implement a strategy to encourage corporate sustainability when there are many competing organizational constraints and numerous barriers to address (Epstein and Roy 2001).

The recent GlobeScan (2005) report states that: "societal expectations for corporate social responsibility have grown across the world. At the same time, corporate social responsibility performance ratings for industry sectors have been consistently decreasing since 2001". Sustainability has significant implications for all businesses. In particularly, it necessitates the need for a decision-making process that balances the impacts associated with environmental, social and economic issues. In order for this to occur, however, the principles of sustainability must be incorporated into existing management systems. Rather than being seen as just another "add-on", sustainability must be viewed as an essential business value that requires full integration into core business strategies (Johnson and Walck 2004).

From a more general perspective, in recent years there has been increasing attention on the drivers of value in organizations. To improve sustainability performance, executives have recognized that it is necessary to better understand the drivers of both costs and revenues and the actions that they can take to effect them. However, the identification and measurement of social and environmental strategies is particularly difficult as they are usually linked to long-term time horizons, a high level of uncertainty, and impacts that are often difficult to quantify (Epstein and Roy, 2001).

Few researchers posit that it is crucial to understand the reasons why corporate decision makers adopt the sustainability initiatives (Hahn and Scheermesser 2006; Dunphy *et al.* 2003; Morrow and Rondinelli 2002; Bansal and Roth 2000; Sharma *et al.* 1999; Henriques and Sadorsky 1999). Even though few authors argue that it is crucial to understand the reasons for transition toward sustainability, there is little empirical research on "why organizations are implementing sustainability initiatives", which is the aim and the research question posed by the authors of this paper.

Understanding the drivers for implementing sustainability initiatives is critical for four reasons. First, this understanding could help business leaders to identify the resulting sustainability-related drivers in their industry and organization. Second, this understanding could act as a much-needed catalyst for stimulating internal discussion and debate about sustainability threats and opportunities in the market and society. Third, this understanding could assist decision makers to develop sustainability strategy based on the drivers. Fourth, this understanding could expose the mechanisms that foster sustainable organizations, allowing managers and decision makers to determine the relative efficacy of actions, market measures and voluntary measures (Grayson and Hodges 2004; Bansal and Roth 2000).

This paper is part of an ongoing research study, which is focused on the management of change and knowledge associated with sustainability initiatives for organizational competitiveness. In the study reported here, four standard industry classification sectors are identified based on the environmental, social and economic accounts of the urban environment. The sectors considered for this study are energy and utility, transportation, construction, and not-for-profit organizations.

For the purposes of this research, sustainability initiatives are defined as “key practices undertaken by an organization to support environmental, social and economic causes and to fulfil organization’s commitments to sustainability”. Causes most often supported through these initiatives are those that contribute to community health (e.g. HIV/AIDS prevention), safety (e.g. crime prevention), education (e.g. job training), and employment (e.g. hiring practices), the environment (e.g., waste recycling), reducing natural resources (e.g. reducing energy consumption) and reducing carbon emission (e.g. minimizing logistics operations).

The paper is organized in the following manner. The next section presents the research aim and method employed for this research. The key drivers for implementing sustainability initiatives are then presented. Finally, the paper concludes with the conclusions and recommendations.

RESEARCH AIM AND METHOD

This paper draws from an ongoing doctoral study entitled “managing change and knowledge associated with sustainability initiatives for organizational competitiveness”. The aim of this research is to investigate how companies are managing change and knowledge associated with sustainability initiatives so as to improve their competitiveness. In order to achieve the aim and objectives of this research, a robust methodology is essential. Broadly, the research process is identified into three key phases within its flexible boundaries. The three phases are the literature review, the pilot study and the main study. The development of the research work started with the literature review. The review of literature involved background study on change management, knowledge management and in varied areas of sustainability. This resulted in the development of a theoretical framework.

In this research study, prior to the main study, a pilot study was undertaken which helped with refining data collection plans with respect to both the contents of the data and the procedure to be followed. As Denzin *et al*. (1998) suggest, when there is a high degree of unpredictability, a pilot study is a good means to add value to the research. A pilot study allowed the researcher to focus on particular areas that may have been unclear previously (Yin 1994). The initial time frame of the pilot study allows the researcher to develop and solidify a rapport with the participant as well as to establish effective communication.

This paper is based on the results from both the pilot (26 interviews from 17 organizations) and the main (33 interviews from 23 organizations) study. Therefore, a total of 59 professionals from 40 UK organizations across 4 industry sectors – energy and utility, transportation, construction and not-for-profit organizations – were interviewed. The current study, which is reported in this paper, was interview-based and semi-structured in format. Semi-structured interviews provide some flexibility and it is one of the ways to obtain a realistic picture of an individual’s view (McCormack and Hill 1997). Those who participated included board members, directors, advisers and managers responsible for corporate environmental, social and economic sustainability initiatives in organizations. The interviews in the current study lasted between thirty and ninety minutes. The format of these interviews was face-to-face. All face-to-face interviews were recorded with permission and later transcribed.

As part of the analysis of the interviews, content analysis was employed. The content analysis begun as a tool for quantitative researchers, now it is increasingly being used in the qualitative studies (Silverman, 2004). Weber (1990) defined content analysis as “a research method that uses a set of procedures to make valid inferences from text”. Applications of content analysis show three distinct approaches: conventional, directed or summative. All three approaches are used to interpret meaning from the content of text data and, hence, adhere to the naturalistic paradigm. The major differences among the approaches are coding schemes, origins of codes, and threats to trustworthiness (Kondracki and Wellman 2002). In conventional content analysis, coding categories are derived directly from the text data. With a directed approach, analysis starts with a theory or relevant research findings as guidance for initial codes. A summative content analysis involves counting and comparisons, usually of keywords or content, followed by the interpretation of the underlying context. The current study adopted a conventional approach to content analysis. Using content analysis enabled the researcher to include large amounts of textual information and systematically identify its properties, e.g. the frequencies of most used keywords in context by detecting the more important structures of its communication content. This paper presents the results from both the pilot and main study on the key drivers that have fuelled the need for implementing sustainability initiatives in the UK organizations.

KEY DRIVERS FOR IMPLEMENTING SUSTAINABILITY INITIATIVES

Table 1 shows the key drivers for implementing sustainability initiatives as revealed in this study.

Table 1: The key drivers for implementing sustainability initiatives as cited by interviewees

Sl. No	Key driver for implementing sustainability initiatives	Percentage of interviewees cited
1	Reducing operating costs	97 %
2	Enhancing reputation	90 %
3	Stakeholders’ pressure	83 %
4	Government regulation/ legislation	76 %
5	Top management commitment	73 %

From the data in Table 1, it is evident that the key drivers for implementing sustainability initiatives are reducing operating costs, enhancing reputation, stakeholders’ pressure, Government regulation/legislation, and top management commitment. It should be noted that for some organizations, the key drivers may be all of these drivers or combination of some of these drivers.

Reducing operating costs

Regardless of industry, the main aim of any organization is to: create compelling new product and service offerings; provide service quality and value as defined by customers; generate attractive returns for shareholders; be the best place to work for employees; operate mutually value-creating partnership with supply chain; and act in an ethically, socially and environmentally responsible way (Hayler and Nichols 2007). Running the business includes reducing the costs, improving productivity, eliminating needless waste and obtaining capital at lower cost.

In the current study, 57 of the 59 (97%) interviewees agreed that the key driver for implementing sustainability initiatives is to reduce operating costs. A number of interviewees raised the concerns for increasing fuel price, amount of money they are paying for managing waste, and difficulties in recruiting skilled employees. One of the interviewees noted:

> "One of the key drivers for our business is to minimize operating costs. Therefore, we implemented sustainability initiatives like energy savings and waste management initiatives five years back".

Furthermore, this interviewee noted how their organization is experiencing cost savings particularly from energy savings and waste recycling. In response to the above, it is clear that if firms persist with the win-win business logic of 'natural capitalism', profiting from increasing the productivity of natural resources, closing materials loops and eliminating waste, shifting to biologically inspired production models, providing their customers with efficient solutions, and reinvesting in natural capital, they can gain a commanding competitive advantage (Lovins *et al.* 1999).

A longitudinal study of the Canadian oil and gas industry showed that proactive strategies of environmental responsiveness were a reflection of managerial interpretation of environmental issues as opportunities (Sharma 1997). Embracing environmental and social issues as opportunities enables managers to reap benefits in terms of lower costs, higher process efficiencies, reuse and recycling of resources, and a positive reputation (Sharma and Vredenburg 1998; Post and Altman 1994).

Eco-efficiency and socio-efficiency are the basic components of sustainability (Savitz and Weber 2006). For example, eco-efficiency initiatives can allow the firm to reduce the amount of resources used to produce products and services, which in turn decreases an organization's operating cost while decreasing its environmental impact. Also, it will coordinate the environmental activities of the firm to achieve greater organizational efficiency and effectiveness. The underlying theme of eco-efficiency is simple: pollution is waste, and waste is anathema because it means that organization is paying for something it did not use.

Enhancing reputation

The motivation from the corporate sector to take part in sustainable development may come from several concerns, such as branding and reputation (Fombrun 1996), enhancing competitive advantage (Porter and Kramer 2002), embracing stakeholders that are key to success and long-term value maximization (Freeman 1984).

The PricewaterhouseCooper's (2002) survey report found that 90% of companies believe that sustainability is important to their reputation. The results of this current study support PricewaterhouseCooper's (2002) global survey findings.

In this research, 53 of the 59 (90%) interviewees agreed that another key driver for implementing sustainability initiatives is to enhance their organization reputation. Due to the recent spate of worldwide corporate scandals, most of the interviewees highlighted the risks of irresponsible behaviour and governance to damaged reputations, brands and, in some cases, the demise of companies. This was the second most important driver identified by the interviewees in this research. None illustrates this point better than the response by the corporate responsibility director who said:

> ‘‘We merely realize that our image could be adversely affected if we were seen to conduct our business in socially irresponsible way. There is no doubt sustainability offers terrific opportunity for us to create and maintain positive image in the society. Acting in an environmentally sustainable and socially responsible way is one of our organization’s values and is firmly anchored in our culture. …we touch millions of lives everyday because of the nature of the industry we are in. Acting responsibly should be fundamental to how we carry out every aspect of our business. To deliver a sustainable future, we are investing in new technologies such as clean coal and carbon capture, as well as in the next generation of renewable energy sources. We provide extra support for our customers facing fuel poverty, and those who are particularly vulnerable. We aim to encourage employees’ development, recognize their achievement and look after their wellbeing. We have in place a number of policies that seek to foster and maintain our well-earned reputation for integrity and responsible business conduct”.

From the above statement, it is clear that some businesses are facing threat from the so-called ‘bottom-line’ backlash, which can adversely affect corporate reputation, especially when profits and the levels of executive compensation that accompany them are seen to be gained at the expense of other stakeholders (Porritt 2005). It is just such a situation that underlay scandals like Enron and has led the financial services industry in the UK into a soul-searching exercise over its governance models and compensation strategies (Gordon 2004).

Regardless of how the balance between environmental, social and economic responsibility issues is struck and changes over time, core items on this agenda for most organizations will include building and maintaining strong corporate reputations and corporate brands. These issues are especially important among economies and companies that rely on intangible assets such as creativity, innovation, intellectual capital and high levels of service as the basis for competition (Kay 2004).

Balmer and Greyser (2003) noted “corporate reputation is a window to the fundamental character of a company and its leaders, and as such is relevant to all stakeholders”. Management can choose to proactively shape and nurture its corporate reputation or become the victim of assailant’s negative reputational arrows.

Stakeholder pressure

In recent years, business stakeholders of all kinds have become increasingly interested in and engaged with businesses to address environmental and social issues. Despite the poor image and bad press of business in recent times, a recent survey suggests that people retain a faith in the ability of businesses to provide a positive contribution to society (Business in the Community 2005).

The most significant change in recent time is the emergent role of stakeholders, beyond shareholders, in defining the roles and responsibilities of business in society (Frooman 1999; Harrison and Freeman 1999; Goodpaster 1991). Many stakeholders have interests far beyond the traditional ideas of corporate philanthropy and the prevention of negative business impacts (Frooman 1999). Indeed, such stakeholders increasingly requiring businesses, especially large organizations, to be a positive force, to contribute to broader societal development goals and to work in partnership with others to solve humanitarian crises and endemic problems facing the world such as disease and poverty, climate change and environmental stewardship (Godet 1998).

In this current study, 49 of the 59 (83%) interviewees agreed that the stakeholders' pressure is a key driver for implementing sustainability initiatives. The most concerned stakeholders are employees, trade unions, suppliers, customers and NGOs. Each group has its own concerns for society and the environment. One of the respondents stated:

> "It is certainly important to recognize the needs of the stakeholders. In recent time, there is a strong environmental and media lobby against our industry. Some of the pressure can be extreme and disgraceful claims…. To mitigate business risk, management expects us to provide more and more information about the environmental and social impact of our business than our financial performance".

A number of interviewees highlighted the difficulty in prioritizing the interests of stakeholders. If organizations have to react to external pressures there is a greater sense of conflict between economic and social objectives. As McWilliams and Siegel (2001) noted, if the firm is functioning properly with respect to prioritizing the interests of stakeholders, then management should pursue only those strategies designed to enhance or protect the firm's position across its relevant markets.

Government regulation/legislation

Governments clearly plays a major role in environmental and social sustainability by the provision of environmental and social standards and regulatory frameworks to conserve productive inputs and the quality of life, in an economic environment where such action may be regarded as cost enhancing and detrimental to industrial competitiveness. Such additional costs no doubt cause very real problems to industry in the short term, particularly if adequate preparatory work has not been completed, but in the longer term: properly designed environmental standards can trigger innovations that lower the total cost of a product or improve its value. Such innovations allow companies to use a range of inputs more productively – from raw materials to energy to labour thus offsetting the costs of improving environmental impacts and ending the stalemate (Porter and Van Der Linde 1995).

Regulatory pressure to cut waste and emissions is one of the main drivers for business interest in sustainability. For example, the UK landfill tax was introduced at £7 per tonne for active waste and £2 per tonne for inert waste in October 1996. In the 2000 Finance Act, the UK Government introduced the climate change levy as part of its wider climate change programme. It was regarded as the 'UK's most significant green tax to date' and was estimated to raise £1 billion in revenue and save 2 million tonnes in carbon dioxide emissions per year by 2010 (Varma 2003). In this research, one of the interviewee stated that:

> ''The greatest impact on us recently has come through the UK government climate change policy".

In this current study, 45 of the 59 (76%) interviewees agreed that another key driver for implementing sustainability initiatives is due to government regulation/legislation. For example, one of the managing directors noted:

> "…the organization has got climate change and waste management pressures that we have to deal with. We also have issues around things like using

> renewable energy and fuel cost. Along with this is the huge government legislation around things like gender, age, race and employment".

A UK-based study (Faruk 2002) had similar findings: 79% of 700 senior business managers surveyed cited government legislation or threat of legislation, as the main reason for implementing environmental sustainability initiatives. The results of this current study support Faruk (2002) findings.

In the current study, many organizations are regulatory compliance by voluntarily developing and certifying their environmental management systems under ISO 14001 guidelines.

Top management commitment

An organization's sustainable operation requires strategies and policies that result in fully integrating the organization's social and environmental functions with business management systems. The ultimate success of any sustainability initiative is found when sustainability-based thinking, perspective and behaviour are incorporated into the everyday operating procedures and culture of an organization (Doppelt 2003). Therefore, the role of senior management is important.

Porter (1991) noted that strategy is the act of aligning a company with its business environment to maintain a dynamic balance. Thus, leadership strategy will be the key. For developing, implementing and sustaining the sustainability-related strategy that changes systems or transitions from traditional resource-intensive to an approach that uses fewer resources and maximizes benefits to both organization and stakeholders requires leadership, culture, management commitment, resources and innovation (Placet *et al.* 2005).

Also, Henriques and Sadorsky (1999) suggest that what an organization is actually doing, or has done, in relation to environmental issues can describe its commitment to the natural environment. Previous researchers suggest that socially proactive companies have top management support that is involved in environmental issues, utilize internal and external environmental reporting, and employee environmental training and involvement is encouraged (Bansal and Roth 2000; Clarkson 1995; Hunt and Auster 1990; Carroll 1979).

In this research, 43 of the 59 (73%) interviewees noted that another key driver is top management commitment. One of the senior board members noted that "sustainability initiatives are driven 80% by head office and 20% by individuals within the company".

To achieve sustainability goals, there is a need for a strong agenda to support sustainability initiatives in a more holistic and integrated approach to environmental, social, and economic concerns. In particular, business leaders will need to reassess their role, specifically their responsibility in persuading organizations to adopt practices that support a sustainable approach. Therefore, leadership from top plays an important role in addressing sustainability issues and concerns. At all levels, advocates of sustainability need to be co-ordinators, mentors and integrators, linking capabilities into organizational structure, technologies and practices of organizations (Doppelt 2003).

CONCLUSION

Sustainability is about building a society in which a proper balance is created between economic, social and environmental aims. For businesses, effectively managing sustainability initiatives could lead to the creation of new ways of working, new products, services, and new market space. To improve organizational sustainability performance, executives have to recognize and better understand the drivers of both costs and revenues and the actions that they can take to address them.

This paper has outlined the key drivers that increasingly fuel the need for implementing sustainability initiatives. A background to sustainability, research aim and method has also been documented. The current study findings suggest that a significant change in organizational strategy toward sustainability was triggered by political, economic, social and environmental changes. As revealed from this study, a complex mix of forces drives organizations to implement sustainability initiatives. The key drivers that have fuelled the need for implementing sustainability initiatives are reducing operating costs, enhancing reputation, stakeholder pressure, Government regulation/legislation and top management commitment. It should be noted that for some organizations the key drivers may be all of these drivers or combination of some of these drivers.

The current study reveals that, even though, most businesses now recognize that sustainability is conceived as a holistic and integrative concept, there are considerable ambiguities and interconnectivities among various facets of environmental, social and economic sustainability issues. The paper concludes that identifying and understanding drivers for implementing sustainability initiatives is a complex process. Given that the research reported on in this paper was largely exploratory in nature, the results presented here are only tentative and of limited value for the purpose of generalization. Therefore, additional research with more elaborate and better-articulated designs is therefore called for to explore further the complex mix of key drivers that have fuelled the need for implementing sustainability initiatives.

ASSESSING ATTITUDES TO SUSTAINABILITY IN CONSTRUCTION AND PROPERTY MARKETS

Danny Myers[1] and Mutale Katyoka

Faculty of the Built Environment, University of the West of England, Bristol, BS16 1QY, UK

In the last 25 years, sustainable development has emerged as an important international issue, and most Governments have adopted a policy to meet the agenda. On the basis of public disclosures made by major construction and property companies, this research reviews current attitudes to sustainability and corporate social responsibility. The bulk of the sample is derived from companies listed on the UK Stock Exchange; however, for comparative purposes, a smaller subset is examined from equivalents in Brazil and South Africa. The main findings suggest that construction and property companies do not positively embrace new ideas; consequently, relatively few have changed their business paradigm to one that is heavily influenced by sustainability. An argument that emerges is in favour of a broader industrial category to integrate construction, real estate and management of built facilities, at both the intra and international levels. The paper concludes that it is the fragmented, diverse and heterogeneous nature of the construction and property sectors that presently restricts the transition towards the adoption of sustainable practice. This is the crux of the problem to resolve in the future.

Keywords: construction sector, corporate social responsibility, integration, real estate, sustainable development.

INTRODUCTION

In December 1983, the Secretary-General of the United Nations set up an independent commission to address the long-term environmental strategies for achieving sustainable development by the year 2000 and beyond. The subsequent World Commission on the Environment and Development (WCED), chaired by Gro Harlem Brundtland, published its report *Our Common Future* in 1987.

The Commission's hope for the future was conditional on immediate political action to manage environmental resources to ensure both sustainable progress and human survival. As stated in the foreword: “We are not forecasting a future; we are serving a notice - an urgent notice based on the latest and best scientific evidence - that the time has come to take the decisions needed to secure the resources to sustain this and coming generations. We do not offer a detailed blueprint for action, but instead a pathway by which the peoples of the world may enlarge their spheres of cooperation” (WCED 1987: 2).

Interestingly, nearly 25 years later the landmark Stern Review (2007) reiterated similar messages. It highlighted the global problem of greenhouse gases and encouraged society to move from a business as usual model towards a strategy aimed at guaranteeing a future for the planet earth. The crux of the argument was based on a risk analysis where Stern recommended that we need to spend 1% of world GDP

[1] Danny.myers@uwe.ac.uk

immediately to avert a 20% decline in world GDP in the next 25 years. As he expressed it in the introduction to his report: “The scientific evidence that climate change is a serious and urgent issue is now compelling. It warrants strong action to reduce greenhouse gas emissions around the world to reduce the risk of very damaging and potentially irreversible impacts on ecosystems, societies, and economies. With good policies the costs of action need not be prohibitive and would be much smaller than the damage averted” (Stern 2007: xiii).

The implication of the calls for sustainability for the construction and property sector are immense, as they both make such large and important contributions to the economic and social character of society. These industries not only help to determine the nature, function and appearance of our towns and countryside, but also they influence the levels of productivity achieved in commercial settings, contribute to the formation of communities and have significant environmental impacts. The importance of the sustainability messages for property and construction, therefore, cannot be overstated.

The business strategy that is firmly imbedded in both sectors, however, appears in many instances to be more than 50 years out of date. Evidence of the conservative and traditional nature of the construction and property sectors are frequently made in government reports and sponsored commentary. For example, Fairclough (2002: 30) accused the construction industry of being “dirty, dangerous and old fashioned”; the property sector was warned of the need to “make a prompt effort to ditch the cynicism that has typified the sector to date, and acknowledge that the business environment has changed significantly in recent years” (SCTG 2001: 1). In other words: the sectors can easily be singled out from the rest of the economy by attitudes, technologies, processes and cultures that are at least half a century old (Dulaimi *et al*. 2001: 1).

Consequently, there are relatively few companies in the real estate or construction sectors that genuinely embrace sustainability, corporate social responsibility (CSR) socially responsible investment (SRI) or any of there equivalents; and this inertia has survived despite the fact that explicit strategies to promote sustainable construction have emerged across many European, American and African states (Myers 2004: 236). The Government-led strategies have occurred for two reasons, firstly because of the significant environmental and social impacts created by the industry and secondly, and more importantly, because it always lags so far behind all the other sectors. A similar case could be made for property but in some ways this gets subsumed under the heading construction.

The intention of this paper is to argue that for a sustainable built environment (and, by default, sustainable development) to become a reality, it is necessary to promote more than just policy aimed at the construction stage. The built environment clearly straddles a number of disciplines and it seems ironic that, to date, most related government policy and academic research has primarily focused on the construction of new buildings. As a general rule of thumb, new builds only represent around 1% of the total stock in any one year, so it could take at least 100 years to completely replace current stock. Even more worrying is the fact that, although the technology exists to design new stock in ways that could reduce the waste stream and energy consumption by 50% or more, most new builds (about 0.9%) achieve little more than the minimum standards laid down in the building regulations. Thus, without a cultural shift and interventions from governments, it could take 1,000 years to replace the stock with the best possible performance at today’s standards! Consequently, there is an argument that favours the retention of existing buildings on the basis that they can be retrofitted and this process is less polluting than the construction of new buildings.

THE RESEARCH METHODOLOGY

The research involved a systematic review of the contents of annual reports (public disclosures) published by major construction and property companies during the financial year of 2005. The objective was to determine attitudes to sustainability and in a large part this was gauged by the reporting of corporate social responsibility and associated issues. In some cases, the related strategy was fully disclosed (revealed) in a separate report.

All public limited companies (PLCs) are legally obliged to produce and make available to the public an annual report and set of accounts. Over time, the publication of these disclosures has become a public relations exercise in which the company details it achievements to date and clarify its future missions. In short they are documents published to inform, and impress, interested stakeholders; in particular investors (shareholders).

As a research metric, the process of content analysis of company disclosures is objective, consistent and repeatable; and it avoids the problems of subjectivity associated with other methods of research. It is, in fact, the dominant method used to inform the *Global Reporters* series. This biennial survey of corporate sustainability is coordinated by Sustainability (an international consultancy promoting the business case for sustainable development) with support from the United Nations Environment Programme (UNEP), and Standard and Poor’s (the international risk assessment and credit ratings agency). Together they have produced four reports since the series commenced in 2000. Each publication in the series uses content analysis to identify best practice in corporate accountability across the triple bottom line of sustainable development to select the top 50 international companies. (The only construction or property company listed to date in this top league is Lafarge, the French materials and construction company.) It is also interesting to note that a third of the Dow Jones Sustainability Index assessment criteria are based upon “disclosures written by the company themselves” (Cerin 2002: 50). Those seeking inclusion in the FTSE4Good index are also subject to: “scrutiny of annual reports, and research of company websites” alongside company questionnaires and direct contact (FTSE 2006: 4).

Content analysis of public disclosures also formed the basis of the World Wildlife Fund (WWF) research that was associated with their campaign for one million sustainable homes to be completed by 2012. The aim was to move sustainability from the fringes to the mainstream of UK housing, and the study restricted itself to 13 UK listed house-builders (WWF 2004). The majority of their findings were based on the examination of public disclosures for the financial year ending 2002. These showed house-builders to be slightly ahead of the game and this relative position could be equally inferred from the 2005 data. Regardless it would appear that none of them has embraced sustainability in its entirety.

A firm that genuinely embraced the idea of CSR would use it to: manage the effects of globalization, to cut environmental costs, raise productivity, and improve staff recruitment and retention rates (Hancock 2005: 6). They would be wholly committed to sustainability in so far as they would seek to grow the business by integrating the environmental, social and economic dimensions of their corporate activities. More importantly, from the view of measuring this commitment, they would be able to cite examples of good practice and refer to third party certification to confirm their social and environmental credentials. In Henriques and Richardson's (2004: xix) words, they would be "connected and responsive to shareholders, suppliers, communities and customers". In short, there is no 'one-size-fits-all' guide for what CSR should mean – but firms embarking on the commitment would innovate and think beyond the traditional business paradigm.

Most firms involved in the built environment, however, have not progressed much beyond the starting line, where they simply pay homage to the environment and community by entering into a passive box ticking exercise that implies some awareness but is lacking in evidence. In other words, CSR has not yet developed to the point where it is linked to corporate performance.

For example, in a pilot survey based on company reports published in 2003, there appeared to be very few PLC's listed in the UK construction and building sector that fully embraced or even addressed CSR issues. From the sample of 42 companies, the majority appeared completely traditional in the sense that they only reported financial information. In sharp contrast, however, there was a small emergent group of companies who produced some kind of "stakeholder reports" to address their commitment to the environment, the community, employees, customers, suppliers and/or investors. This group only accounted for approximately one quarter of the sample and interestingly the majority of them were in fact companies that gained more than 25% of their turnover from house building. Overall, the percentage of material relating to CSR in the pilot sample was found to be less than 5% (Myers 2005).

The construction and property research findings for 2005 are dealt with as discrete parts in the following sections

CONSTRUCTION FINDINGS

A sample of 31 companies was selected on the basis that they were listed in the FT 'building and construction' sector and subscribed to the *Financial Times* service between March and August 2006. This number represented 42% of the 74 companies listed in the sector by the Stock Exchange at that time. Alongside this core information, any supplementary information, available from the companies' websites, was also reviewed. The results are summarized in Table 1

Table 1: Construction 2005 – UK

Number of sample companies	31
Total page count of annual reports	3036
Proportion of pages relating to CSR	5.8%
Companies publishing a separate CSR report	55%

As the data in Table 1 suggests, in quantitative terms the construction and building sector appear to be modernizing. According to 2005 data, more than half of the sample produced a separate report on issues of CSR – and a significant proportion actually allude to it, albeit quite briefly in the main report.

A further audit of the construction and building sector was carried out in Brazil as a kind of control, and this revealed a far lower degree of participation in CSR, as summarized in Table 2.

Table 2: Construction 2005 – Brazil

Number of sample companies	14
Total page count of annual reports:	374
Proportion of pages relating to CSR	0.8%
Companies publishing a separate CSR report	21%

As the data in Table 2 suggests, in a developing country such as Brazil (adopting World Bank classifications) the construction and building sector are still relatively traditional as less than 1% of the reports allude to CSR and only 21% of the companies examined actually produced a separate report on these issues.

PROPERTY FINDINGS

A sample of 46 companies was selected on the basis that they were listed in the FT 'real estate sector' and subscribed to the *Financial Times* service between March and May 2006. This number represented 37% of the 125 companies listed in the sector by the Stock Exchange at that time. Alongside this core information, any supplementary information, available from the companies' websites, was also reviewed. The results are summarized in Table 3.

Table 3: Property 2005/06 – UK

Number of sample companies	46
Total page count of annual reports	3865
Proportion of pages relating to CSR	1.5%
Companies publishing a separate CSR report	13%

As the data in Table 3 suggests, the UK property sector appear in relative terms to be lagging behind the profile suggested for construction. Many companies were still only providing traditional financial reports with some token references to CSR made here and there. The sample only showed 13% of the companies producing a separate report in 2005.

A subsequent audit of the property sector was carried out in South Africa and the results are presented in Table 4.

Table 4: Property 2005 – South Africa

Number of sample companies	22
Total page count of annual reports	1293
Proportion of pages relating to CSR	0.8%
Companies publishing a separate CSR report	5%

The data in this final table shows the weakest position regarding CSR reporting. South Africa (classified as a developing country by the World Bank) has a traditional property sector. Less than 1% of the reports allude to CSR and only 5% of the companies examined produced a separate report on the issue.

Overall, the percentage of material relating to CSR in the samples was found to be less than 3%; in short, no more than 'window dressing'.

CSR findings

The main purpose of CSR reporting is to inform stakeholders of a company's environmental, social and economic performance, and the argument being pursued in this research is that it can be used as a means of measuring a company's progress towards sustainability. The problem, however, is to differentiate between those who approach sustainability as a PR exercise and those who are genuinely committed; a line needs to be drawn between those who ‘green-wash’ their products and those who actually ‘walk the talk’.

As the data in the tables suggests, in the property sector there are very few on either side of that divide line; real estate companies appear to be traditional with a majority reporting only financial information. In contrast, the construction sector is relatively further along the spectrum, with some companies offering a separate report on issues of CSR and, in some exceptional cases, making real inroads with evidence and examples of best practice. Carillion PLC, for example, refers to a sustainability policy that dates back to 1994, and this has been continually revised and influenced by the Natural Step Framework, an international system designed to achieve sustainable development. Sustainability has clearly become an integral part of Carillion’s business plan as it states: “it is as important to deliver the intangible issues, as it is to deliver hard-nosed cash backed business objectives. In fact it has been seen that community and environmental objectives both enable and legitimize the success of our business objectives in a process of continual improvement” (Carillion 2006). Likewise Skanska, the Swedish construction firm, has adopted four ‘zero’ targets to focus its sustainable development achievements: zero loss-making projects, zero environmental incidents, zero work site accidents and zero ethical breaches. Also in the 2005 annual report, it proudly details its association with the development of housing that uses environmentally sound materials and production methods to significantly lower the life cycle costs of the buildings (Skanska 2005: 40).

Between the two extremes, in all continents are companies that are just beginning to engage in social and environmental issues. This might amount to no more than a couple of sentences on CSR whilst others would have as many as 10 pages; contributing from as little as 1% to as much as 20% of the content, in South Africa and the UK respectively.

The lack of engagement is not particularly surprising as the conventional goal of any company is to maximize profits. As the supporters of traditional market economics are keen to emphasize, ‘There is one and only one social responsibility of business – to use its resources and engage in activities designed to increase its profits’ (Friedman 1962). CSR, however, does not seek to challenge this convention but to create conditions where social and environmental benefits can simultaneously help to drive the business forward. In Elkington’s (1994) elegant phrase, “triple bottom line accounting” must find resonance with the business community for sustainability to be realized. Interestingly triple bottom line accounting have been undertaken for two of Carillion’s PFI projects and these clearly demonstrate the financial gains that can be made from accounting for the social and environmental impacts made during the long concession periods (Casella Stanger 2002).

CIRCLE OF BLAME

Construction work inevitably involves the assembly of a range of materials and services from a broad range of sources. In turn, each of the material inputs is subjected to different types of processing according to their particular use on a specific project. Assembling the materials are teams of subcontractors gathered for the sole purpose of completing the project. As a result, the labour force is often more than one stage removed from the agreement made between the client and the developer; in fact, the whole process is characterized by its temporary and relatively short-term nature. A common analogy that is used compares the process of construction to film production to emphasize that each project involves gathering together a different team to build a 'unique' product (Ive and Gruneberg 2000: 149). It is this diverse and fragmented nature of the industry that constrains the opportunities to improve performance, learn from experience and introduce innovation. Furthermore, the division of labour in the industry leads professions to defend their traditional interests against emergent trends and this hinders communications and the transfer of knowledge. As Gann (2000: 237) observed: "professions and industry associations are just as likely to cause inertia to change as they are to promote innovation". It is clear to see how these aspects of construction and property development lead to difficulties in approaching sustainable development in a coherent manner.

No one specific sector should be allowed to carry all the blame for the failings of this system, as it is some challenge to integrate all the related sectors in a common vision – especially as there is a lack of joined-up thinking across the various related government departments. The problem is compounded further by a mindset that tends to fragment the responsibility for sustainable development. Construction firms argue that they can only adopt holistic approaches if clients ask for them; since builders carry out the instructions of their paymasters. Property developers are often restricted by the conditions imposed by investors or banks, and they tend to be risk-averse and hesitant to fund new ventures. Architects are constrained by planners and the users of buildings have their own specific requirements. The so-called 'circle of blame' that perpetuates the existing traditional approach highlights the conservative nature and adversarial tendencies that make up the relationships in the property and construction markets.

CONCLUSIONS

It is important to emphasize that the survey data referred to above, is based on publicly available information from: the *Financial Times* Annual Report Service; ShareData online, a database of companies listed on the Johannesburg Stock Exchange; and Bovespa, the Brazilian stock exchange in Sao Paulo. This enabled an audit of 31 construction and 46 property majors listed on the UK Stock Exchange and 22 property and 14 construction companies listed on stock exchanges in developing countries.

The largest part of these two markets, however, always comprises small firms; far smaller than those audited. For instance the DTI register lists more than 183,000 private construction contractors working in Great Britain – and approximately 85% of them employ less than eight people with a significant proportion being self employed (DTI 2006). The nature of the property sector is different, the smaller firms are usually partnerships and the larger ones are PLCs employing thousands of people; the common structure for the majority of real estate firms will be some form of limited liability, and there are currently more than 153,000 companies listed in the sector in Great Britain (Companies House 2007). These statistical portraits appear to be very similar to the structure of firms that make up construction and property across other continents (Carassus 2004). The important point of these statistics, however, is to highlight that the typical firm in the property and construction sector is the small private firm and they are quite likely to have incomplete records and far less grand corporate strategies. The government will be lucky if they report fully on their financial position let alone their social and environmental progress.

On the basis of publicly available information, and related literature, the survey suggests that some of the exceptionally large companies in the construction sector are beginning to acknowledge sustainability; and to a lesser degree the same applies to real estate. These firms, at the forefront of the sectors, recognize that a business is no longer judged solely on the economic value added by a company's activity, it is also judged on the social and economic value they add (or destroy). Examples of best practice to minimize the negative impacts and develop the obvious business opportunities are stated in their reports. However, it also clear that many companies, particularly the small, unlisted ones, have a long way to go, before they can effectively manage the opportunities that emerge from the sustainability agenda.

This rather negative portrait is partly due to the inefficiency of construction and property markets. Construction tends to be short-term in outlook, slow to innovate and hesitant to adopt best practice. Compounding the problem, the market for tenants of property in the commercial sector is subject to long-term leases, with large developers supplying a standardized product on a kind of 'let and forget' basis. In the residential sector, market conditions are little better, because in most instances, occupiers have limited control of the design and build specifications of the homes they buy or rent. In consequence, the users of buildings – the real customers – have become disconnected from the development process.

Compounding the problem is the diverse nature of these two sectors in terms of both the associated processes and the related professions. Indeed, when Professor Pearce, an environmental economist (and Government adviser on sustainable development), was commissioned to investigate the social and economic value of construction, he was struck by the complexity of the sector and its lack of comparable international data. His report argued that before the industry can proceed towards contributing to sustainable development it needs to adopt a more holistic definition to include property and its management. He stressed that sustainability is concerned with the complete life cycle, so a building needs to be considered from its design and construction, through the operational stage, to its deconstruction. To make meaningful recommendations, therefore, "it is necessary to understand the nature of the industry – its size and structure" (Pearce 2003: ix).

The need to broaden the approach to the construction and property sectors has been reiterated by the International Council for Research and Innovation in Building and Construction. Carassus (2004) and his team, reviewed nine countries, employing a new systems approach to all that construction entails. The case was made to broaden the approach, to emphasize the importance of repair, maintenance, and management of existing structures and buildings. To paraphrase their conclusions: the requirements of sustainable development call for a new approach to the economic analysis of the construction and property markets to take into account all the participants involved in the life cycle of building structures; not only design and construction but also operation, maintenance, and the management of services provided by built facilities. This new broad approach would provide a framework for sustainable development, not only in terms of analysis but also in terms of public regulation. They then close with the apt remark that the separation of construction economics from property economics has become 'obsolete' (Carassus 2004).

To sum up, it is the existing systems of industrial classification (NACE, NAICS, ISIC) used for statistical and government purposes that restrict the interpretation of the construction and property industry to narrow separate and distinct sectors. For example, the European, North American, and United Nations systems all define construction activity as being site based; to include trades, subcontracted labour, repairs maintenance and demolition. Whereas real estate activity is usually classified as being associated with the buying and selling of land and property so it includes: development, estate agency and management services. This is an arbitrary divide that makes the idea of a sustainable built environment no more than an allusive dream. The integral role of construction and property to the economy is overlooked and government policies designed to create change lack the necessary coherence. Consequently, there is little evidence to suggest that the complex and fragmented nature of these two sectors will allow real progress towards sustainability until they are conceived and managed as one.

A BASIX TOOL FOR ENVIRONMENTAL ASSESSMENT OF RESIDENTIAL BUILDINGS – AN AUSTRALIAN APPROACH

Grace K C Ding and Goran Runeson

School of the Built Environment, University of Technology, Sydney, PO Box 123, Broadway, NSW 2007, Australia

The rapidly growing population in New South Wales (NSW) is the driving force behind the growth in new housing. The environmental impact in terms of land use, energy and resource consumption will significantly impede the supply of new housing. In NSW, sustainable housing has become an important focus of the government's housing policy. In response to the need for sustainable housing, the government launched a sustainability assessment tool called BASIX in July 2004 to assess and establish indoor thermal comfort, water and energy efficiency targets, and sustainability levels. The introduction of BASIX has had a profound impact on the construction industry. In order to ascertain the extent of impact, an online survey was conducted among construction professionals in NSW in March 2006. The tool has played a significant role in providing a general guideline for the sustainability performance of proposed developments. It serves as a means to make people think about water and energy saving initiatives, and to encourage good design practice without excessive additions to the cost of a new building. However, there is the opinion that there is more to be done such as control of waste and energy usage in the manufacturing of building materials.

Keywords: sustainability, performance evaluation, environmental impact, sustainable building.

INTRODUCTION

Global economic growth has increased the overall demand on energy and other resources. Unless the demand reduces significantly, resource scarcity will become a major issue in the international market and a major threat to the survival of the planet (IEA 2006). In response to the global environmental problems, the Kyoto Agreement was signed in 1990. The agreement requires countries to reduce greenhouse emissions by an average of 5% below their 1990 levels from 2008 to 2012 (McGovern 2006).

Buildings are major contributors to the environmental deteriorations and are uncaring to the environment (Levin 1997; Kein *et al*. 1999). Buildings consume approximately 30%, 10% and 40% respectively of the world's resources, water and energy (OECD 2003). Indeed, the construction and property industries have significant irreversible impacts on the environment across a broad spectrum of off-site, on-site and operational activities that alter the ecological integrity (Uher 1999). Sustainable housing has found its place in the construction industry. Local and international authorities have put environmental issues of housing development high on their agenda. The European Union will implement stricter regulations as well as financial incentives to promote sustainability in the housing sector. In other regions, similar initiatives have been introduced (IEA 2006).

The population in Australia is predicted to rise from 20 million in 2005 to 25 million in 2021 (Australia Bureau of Statistics 2005), and continue to create demand for new housing. According to the Department of Infrastructure, Planning and Natural Resources (DIPNR), currently a new dwelling is built every 14 minutes in the state of New South Wales (NSW). The increasing demand for new dwellings will no doubt increase the effect on the environment and sustainable housing has become a main focus of the government's housing policy (DIPNR 2004a). In terms of sustainability and environmental performance, these new houses were no different from houses built in the previous decade. In response to the need for sustainable housing, the NSW government therefore launched a sustainability assessment tool called BASIX in July 2004 to assess and establish indoor thermal comfort, water and energy efficiency targets and sustainability levels.

This paper provides an overview of the importance of sustainable housing in NSW and discusses the introduction of BASIX as the first government-implemented environmental assessment tool in Australia. This paper is based on an online questionnaire survey undertaken in March 2006 in NSW. The survey reviews the impact of BASIX in the construction industry since its introduction in July 2004. This paper also discusses the principles of BASIX, its implementation and its affect on sustainable housing in NSW.

BASIX – THE SUSTAINABILITY ASSESSMENT TOOL

Definition of sustainable housing

In recent years, a growing number of sustainable housing projects have been completed and sustainable construction is increasingly becoming part of the common building practice. Sustainable housing was one of the issues addressed in the United Nations Conference on Environment and Development at the Earth Summit in Rio de Janeiro in 1992 (Li and Shen 2002). Bhatti (2001) states that sustainable housing can make major contributions towards our environmental future. The methods by which housing is produced, consumed and managed, and the way it contributes to social and cultural life, have major impacts on the environment.

The issue of how housing can be made more sustainable has become a main focus of the government in Australia in relation to minimizing adverse effects on the natural environment (Gurran 2003; Department of Planning 2005). The purpose of sustainable housing is to raise the standard of living and to offer an opportunity for people to have a decent home, to enhance social unity, well being, economic growth and social improvement without adverse environmental impacts. Sustainable housing affects not only the fabric of buildings but also the social and environmental context of construction practices.

Due to population growth, the houses constructed during the next 15 years will form a considerable part of the future housing stock and there is therefore an important opportunity to improve the environmental performance of housing. Conventional housing construction has a far higher environmental impact than have new methods. Housing development is just as important as any other type of construction. The environmental impact of an individual house may be minimal but the construction of all houses together will make a significant impact on the environment. Continuous improvements are required to reduce the environmental impact of housing.

There is an increasing recognition that buildings cannot be designed without consideration for social impact (Cole 1999). Sustainable housing construction, as defined by Klunder (2004), reduces the environmental impacts of material use, energy and water consumption during the whole service life of the building. IEA (2006) further discusses how sustainable housing can be achieved in three main aspects:

- Low impact – preservation of global environment.
- High contact – harmony between the house and the environment.
- Health and amenity – health and pleasant living.

From this viewpoint, a sustainable house is characterized by futurity and equity issues which aims to ensure that everyone today and the generations to come have a decent place to live and one that is cheaper to run than most existing homes. In addition to considering land use, orientation, shadows and light, our concerns need to focus on the long-term costs: social, environmental and economic. Environmental impact depends on the population size, the average prosperity per person, and the environmental impact per unit of prosperity (Klunder 2004). In sustainable housing construction, the concept of eco-efficiency is important and implies that a reduction in the environmental impact of housing construction can be undone by trends such as an increase in the average size of houses, or a decrease in the average number of persons per house (Ding 2004; Klunder 2004).

Sustainable housing will be a growing part of the housing industry, making it a business opportunity waiting to be explored. There are multiple advantages to sustainable housing. Sustainable housing directly brings energy cost savings to owners. The lower energy consumption during the operating period contributes significantly to saving energy bills in the long run and will further save energy cost if energy prices continue to increase in the future. According to DIPNR (2004b), for the first 10 years after the introduction of BASIX, there will be accumulative saving of 9.5 million tonnes of greenhouse gas emissions, which is equivalent to removing 2.6 million cars from the roads. As compared to conventional housing, energy saving for sustainable housing can be as high as 75% with a payback period within two years (IEA 2006).

Other non-energy benefits include better indoor air quality, more marketability, reducing global warming and better living quality. Based on research in New Zealand and the USA in 2004, the non-energy benefits are more than twice as much as the energy savings (IEA 2006). Sustainable housing helps to address more directly social, economic and ecological realities. They also help to set up benchmarks for future projects as examples of best practice by moving into a social and ecological market of housing (Crabtree 2005).

Significance of BASIX in sustainability assessment of housings

Local governments in NSW have advocated sustainability in housing development for a long time (Department of Planning 2002). However, each local authority has its own environmental assessment measures in local planning tools, which vary greatly across the state. Some local authorities may be more pro-active than others, while some are still struggling to develop a single tool. The inconsistencies have caused frustration within the construction industry.

The rapid population growth in NSW has caused increasing demand for new dwellings with significant impact on water and energy consumption (Standing Committee on Public Works 2004). Design characteristics of individual homes can have a dramatic effect on the environment as well as water and energy use. For new homes, local government can specify design features including the use of insulated roof and external walls, sun shading and energy efficiency designs via its development approval powers (Department of Planning 2002).

BASIX was developed in response to the need for local governments to address these issues. BASIX was the first integrated web-based sustainability planning and assessment tool (http://www.sustainability.nsw.gov.au for full details on the BASIX assessment for new buildings as well as additions and alterations.). It was developed by DIPNR in consultation with industry and councils and is now a mandatory component of the development approval process in NSW under the Environmental Planning and Assessment Act 1979, through the Environmental Planning and Assessment Regulation 2004 and State Environmental Planning Policy.

BASIX is designed to provide a systematic assessment of the sustainability components of residential development, including regional sensitivity where appropriate and as a means of raising the awareness of sustainability in construction (Department of Planning 2002). BASIX measures energy efficiency in homes along with measuring other sustainability factors such as water usage and thermal comfort. BASIX assists councils, architects, builders and developers to standardize development practices in areas such as water, energy and land use. BASIX simplifies and improves the planning process and provides an easy and effective tool to enhance better sustainability outcomes in residential development. It also assesses the potential performance of residential developments against a range of sustainability indices. (In order to complete an assessment, log on to BASIX website at www.sustainability.nsw.gov.au and the website provides details of the proposed development as prompted by the BASIX tool. The project is assessed against the existing average and given a score. The project must demonstrate a reduction of 40% mains water and 40% energy to qualify for a BASIX certificate.)

It was first introduced in July 2004 with the aim to reduce water consumption by dwellings by 40% and energy use by 25%. In July 2005, it was applied to all new residential developments in NSW including new houses, dual occupancy and apartment buildings. In July 2006, BASIX has increased the energy reduction target to 40% and since October 2006 BASIX has become mandatory to alterations and additions to residential development across NSW.

SUSTAINABLE HOUSING – ASSESSING THE IMPACT OF BASIX

Research method

BASIX has been a mandatory requirement for development approval for all residential projects in NSW for over two years and yet no attempts have been made to ascertain its impact in the construction industry. In order to examine the impact of BASIX in promoting sustainability in residential developments, an online questionnaire survey was undertaken to investigate its role and impact. The survey was designed and distributed online so that it could obtain a wider coverage and provide a quick and easy platform for the return of the completed survey. The purposes of the survey were to examine the level of acceptance of BASIX since its introduction in July 2004 and to explore the role of BASIX in the construction industry in enhancing sustainability in residential developments. The survey also assesses the impact of its implementation as mandatory to development application for residential projects.

The questionnaire was divided into three parts. The first part was intended to obtain general details of the respondents and contains four questions. Information about the demographics of respondents and details of their professions and organizations are the main outcomes of this part. Part two was intended to obtain the viewpoint of respondents in respect to their understanding and acceptance of the tool, and it contains nine questions. The questions were designed as a standard Likert scale where respondents were asked to rate each questions from low to high or from strongly disagree to strongly agree. Part three contained 16 questions and was designed to identify the level of expertise the respondents have in the operation of the tool. The questions in this part were also on a standard Likert scale similar to the questions in Part two.

The online survey was assisted by the Association of Building Sustainability Assessors (ABSA) and Timber Development Association (TDA) in distributing the survey to their members. The anonymous questionnaire was sent to ABSA and TDA as well as to 85 practitioners in the construction industry in NSW via email with a URL containing the online survey in March 2006. Many participants also forwarded it to URLs of other practitioners in the industry. Therefore it was difficult to determine the exact response rate. At the end of May, 120 completed questionnaires had been received via online.

Observations and analysis

Generally

Of the 120 returned surveys, 80% were from male respondents. Although females are seriously under-represented, this is not surprising as construction has always been a male dominated field. Therefore, the survey results may predominantly represent opinions from male building professional but this should not have a significant impact on the outcomes. Approximately 40% of the participants have over 10 years work experience.

Respondents came from a variety of background. The design consultants and sustainability assessors contributed 56% and 24% respectively of the total returned questionnaires whilst the remaining 21% of the respondents were distributed amongst contractors/sub-contractors, project managers, developers and others. The sustainability assessors comprise of 89% of BASIX assessors and 11% of the energy assessment assessors. The design consultants are the main users for the tool and the participation of BASIX assessors can offer important feedback and opinions on the impact of BASIX in the construction industry due to their knowledge and expertise in the tool.

Approximately 85% have used BASIX before and 15% have not used it so far. Of the 85%, approximately 62% have used BASIX up to 15 times since its introduction, 11% between 15 to 35 times and 27% have used it more than 35 times. Approximately 46% of the respondents found out about BASIX from its website and 21% from BASIX consultants, 20% from company internal information and 13% from local councils. The BASIX website has fulfilled its original purpose in promoting the tool and providing information for its application.

The use of BASIX in the construction industry

Since the introduction of BASIX in July 2004, there have been substantial discussions about increased construction cost and time for development approval. However, the impact is yet to be ascertained. On one hand the mandatory use of BASIX in the development application process has created a new role of BASIX assessors and it will be one of the fastest developing services in NSW and may be throughout Australia in the near future. On the other hand, the design consultants and developers have been busy learning to use BASIX as it was designed for self-assessment on the internet.

Part two and three of the online survey were designed to obtain opinions and feedback from professionals in the industry with regards to the introduction of BASIX and the results are summarized in Table 1. The questions were designed using a standard Likert scale from strongly disagree to strongly agree.

Table 1: Summary of impact of BASIX in the construction industry

Proposition	Responses (%)				
	Strongly Disagree	**Disagree**	**No Opinion**	**Agree**	**Strongly Agree**
Online assessment tool is user friendly	6	21	13	55	6
Online help note is useful	3	13	14	58	12
BASIX helpline is useful	8	9	33	42	8
The resources on the BASIX website are sufficient	11	31	18	38	2
The 40% water target is achievable	8	15	7	58	11
The 25% energy target is achievable	3	14	3	64	16
The thermal comfort target is achievable	7	19	7	57	11
BASIX can help to provide better sustainability outcomes in residential development	12	10	6	56	16
BASIX has increased the overall construction cost	2	8	6	37	48
BASIX has increased the overall time for development application	2	20	36	27	15
BASIX should be applied to other types of construction	22	20	11	32	15
BASIX should be applied throughout Australia	17	8	19	37	19

Based on the returned surveys, the professionals in the construction industry are generally well aware of the importance of BASIX in the development of residential projects. The survey results indicate that 47% of the respondents (not including BASIX assessors) undertook BASIX assessment for the projects themselves, 15% engaged BASIX consultants and 13% used both. The results indicated that BASIX have been widely used by practitioners in the industry and has been successful for its ultimate purpose of self-assessment. Making the tool accessible via the internet has been successful and widely accepted. People can access the site anywhere in the world at any time at no cost. It is not like other energy assessment tools such as NatHERS that requires an accredited assessor and constant updates. The free access and self-assessment are the main features of BASIX that have contributed to the success of its implementation.

BASIX is regarded as user friendly and the resources are sufficient either on the online help notes or the helpline (see Table 1). Approximately 47% of the users that had assessed their projects themselves without engaging a consultant found the structure of the tool clear and 61% found it user friendly. However, some respondents consider the tool too simple and insufficient to capture sufficient sustainability issues.

With regards to the online resources, 70% and 50% found the online help notes and the helpline respectively useful in answering queries on the assessment tool (see Table 1). The helpline is arranged to provide support when needed but only 50% agree that the helpline has provided sufficient support to the use of the tool. Relating to the resources on the website, 40% agree that the resources on the website were sufficient whilst 42% disagree (see Table 1). However, there is no indication to the type of resources that are missing from the website.

With regards to assessment criteria, 72% believe that BASIX can help to provide better sustainability outcomes in residential developments (see Table 1). The majority of respondents found the assessment criteria of thermal comfort, a 40% reduction in water and 25% reduction in energy consumption achievable (see Table 1). After the survey was completed, in July 2006, the energy target was increased to 40%. There is no information as yet about whether the new target of 40% reduction in energy consumption is achievable and further investigation in this area will be undertaken later. Some respondents worry that they may struggle to achieve the 40% energy saving targets. Others also suggest that embodied energy needs to be addressed in the manufacturing process of building materials and components as well as the on-site process.

As discussed earlier BASIX has impacted on the overall construction cost as additional elements such as sun shadings, insulations to walls and ceilings, water tanks for recycling storm water and so on are required in order to satisfy the requirements. With reference to Table 1, approximately 85% of the respondents agree that the implementation of BASIX has increased the overall construction cost of residential developments by about 10%, which is different from the DIPNR report of BASIX-compliance cost of 3–4% (BMT & Assoc 2005). The economic savings may take a few years to come to fruition and this is why this system is not popular with developers. Only 42% of the respondents agree that BASIX has increased the overall time for development application approvals (see Table 1). They suggest that the time required for approval has increased by about 10%.

With reference to Table 1 only 47% of the respondents agree that BASIX should be applied to other types of construction and 56% agree that BASIX should be applied throughout Australia. However, many believe that the tool needs further development to improve it usefulness. Thermal comfort is one of the variables that are assessed within the BASIX programme. It addresses insulation, heat transfer through glazing, shading and active heating and cooling. There is a field of thought in the industry that this section should have given attention to the thermal mass, which also has a major effect on the indoor environment of a dwelling. In their opinion, the thermal comfort section of BASIX is not a true representation of the actual thermal properties of the building and an accredited assessor may be required in this respect.

SUMMARY AND CONCLUSION

Construction is one of the largest users of environmental resources and one of the largest polluters of the man-made and natural environment. The improvement in the performance of buildings with regards to the environment will indeed encourage greater environmental responsibility and place greater value on the welfare of future generations. There is no doubt that BASIX contributes significantly to achieving the goal of sustainable development within construction. On one hand, it provides a methodological framework to measure and monitor environmental performance of residential development, whilst on the other it alerts the building profession to the importance of sustainable development.

Sustainable housing is multidimensional and the evaluation of sustainable housing cannot be achieved using a single criterion and single objective function. The decision-making process for sustainable housing uses multiple criteria and objectives and needs to be considered on a whole-of-life approach as it is not just considering economic and environmental problems. It also needs to include social and economic evaluations during the service life of the building. Therefore, a set of multiple goals and criteria needs to be considered simultaneously. The sustainable housing industry needs to appreciate the affordability for homebuyers especially those issues relating to design and cost. The reality is that homebuyers will respond to environmental issues providing it is affordable and does not come at a cost penalty compared with houses that deliver inferior environmental performance. Professional designers should maximize the environmental performance and concentrate more on achieving lower costs. If additional cost items are to be included, developers, builders and governments will need to consider introducing innovative financial incentives.

The accessibility of the tool via internet and free access are the main reasons for the success of the tool. It was generally accepted that the tool has played a significant role in providing a general guideline to the sustainability performance of a proposed development. It is a start but there is more to be realized. The key benefit of the tool is that it leads to better thermal comfort to users and to reduced water and energy consumption as well as less greenhouse gases emission. However, there is also the opinion that there is more to be done such as control of waste and energy usage at manufacturing of building materials for future development of the tool to be used in other types of construction. It serves as a means to make people think about water and energy saving initiatives and to encourage good design practice without excessive additions to the cost of a new building.

Irrespective of the advantages and disadvantages that the BASIX system may have, it has come into effect quite smoothly and with continued improvement and updating, it could become one of the most important planning and design tools in the construction industry. There may currently be shortfalls in the system and eventually they will be rectified, but the point is that new residential dwellings will have less environmental impact than their predecessors will. A step forward is better than standing still.

VALUE-ENGINEERING USING LINEAR PROGRAMMING: OPTIMIZING INDOOR AIR QUALITY (IAQ)

B.G. Celik,[1] K.R. Grosskopf[2], P. Oppenheim[2] and C.J. Kibert[2]

One of the key requirements of a high performance building is to create an efficient, healthy and comfortable indoor environment that provides measurable performance benefits. Unfortunately, traditional value engineering tools often lack the flexibility to efficiently "screen" the seemingly endless combinations of alternatives to those few that are most likely to provide the highest level of performance relative to cost. A mixed integer linear programming tool has been developed to determine optimal IAQ design parameters and equipment specifications for high performance commercial buildings. By expressing the dimensionless linear function of each benefit-cost objective and constraint in relation to one another, the linear model is capable of defining a boundary condition where the productivity benefits of added ventilation are maximized relative to added equipment and O&M costs. By applying operations research to value engineering, a mixed integer linear programming model has demonstrated the ability to select appropriate high performance technologies far more efficiently than conventional time intensive value engineering techniques, especially for those alternatives whose costs and benefits are difficult to quantitatively define.

Keywords: cost, decision analysis, life cycle, value management.

INTRODUCTION

Value is the ratio of function to cost and can be increased by either improving function relative to cost or reducing cost while maintaining function. There exists a tenet within the paradigm of value engineering that quality must not be compromised in the pursuit of value. Yet, too often, value engineering results in little more than an exercise in cost cutting and scope reduction, resulting in less than optimal building performance. One of the key requirements of a high performance building is to create an efficient, healthy and comfortable indoor environment that provides measurable performance benefits. Traditional value engineering tools often lack the flexibility to efficiently screen alternatives that are most likely to provide the highest level of project specific performance benefits from among the many that are commercially available. As a result, only a limited number of high-performance alternatives are ever considered, usually as a product of the intuition or bias of the architect or engineer. Nowhere may this condition be more evident than in the assessment of IAQ management options, where in addition to the costs associated with inefficient mechanical systems and building operations, specific levels of indoor air pollutants may adversely affect the health and comfort of workers, resulting in lost productivity, increased absenteeism and added health care costs.

[2] kgro@ufl.edu

Value-engineering (VE) was developed during World War II by the General Electric Company to retool production processes affected by shortages in labour and materials. During this time and for nearly 30 years thereafter, value was defined as the lowest unit cost of production. Although VE had migrated to transportation, building construction and other industries, the value paradigm changed little until the energy crisis of the 1970s when building owners and operators were suddenly faced with soaring operation costs, interest rates and inflation. As a result, the focus of value in the building industry began to shift away from the initial cost of production (e.g. construction) and toward the total life-cycle cost of the building. A new generation of VE methods soon emerged in an attempt to quantify the total cost of building ownership during the design phase, where design changes could be most cost effectively implemented.

Among the most widely used tools today, *life-cycle cost analysis* (LCCA) considers all significant costs of competing design alternatives and chooses the alternative that meets functional requirements at the lowest total cost of ownership. Among these traditional costs of ownership are initial design and construction costs, operations, maintenance, and repair costs, replacement costs (less residual salvage or resale values), disposal costs and financing (interest) costs. The LCCA method escalates all costs to their future year of occurrence and discounts them back to present values (Fuller 2007). The discount rate can be as low as the general rate of inflation for essential building systems or as high as the building owner's minimal acceptable rate of return (MARR) for building systems that are considered non-essential, discretionary investments. Building systems that provide essential safety or reliability functions may be selected based on lowest life-cycle cost, whereas non-essential systems must generally provide operational savings on added first-cost investment that meet or exceed the MARR or "hurdle" rate established by the building owner (Grosskopf 2006).

Yet, the definition of value continues to evolve. No longer is value defined in terms of achieving minimum performance benchmarks or functional requirements at lowest cost, but rather maximizing life-cycle productivity of the building relative to life-cycle costs. One indication of this change is the apparent shift away from lowest-bid award to negotiated "best value" delivery. In 1985, 82% of all construction projects in the US were awarded based on lowest "hard" bid, compared to less than 5% design-build delivery based on flexible design and negotiated project costs. Today, more than 50% of all construction in the US is let using the "best value" approach (Good 2006). Increasingly, building owners and operators are factoring the qualitative benefits of design, such as aesthetics, employee comfort and performance, environmental impact and historic preservation, into their definition of value. For example, worker productivity can significantly influence the economic analysis and decision-making process. Over a 30-year period, operations costs account for approximately 1–2% of the total cost of ownership, while initial building costs total 6–8%, and personnel costs total 90% or more (USDOE 1996). As a result, a 1% increase in productivity could nearly offset the building's total energy cost.

Although LCCA can be modified to account for qualitative or "soft" costs, it becomes inherently less stable as each new variable is added and as the level of uncertainty associated with each variable increases. In addition, LCCA is generally limited to evaluating individual systems under steady state conditions. As a result, mixed integer linear programming has been identified as a multivariate analysis technique that can not only evaluate multiple interdependent building systems, but also define *optimal* combinations of building systems or design parameters within a functional range of user-defined project constraints and operational conditions. Unlike traditional LCCA, linear programming does not provide a finite output, but rather identifies building systems and design parameters that fall within a feasible region where all of the dimensionless, linear functions that represent each economic and operational constraint are satisfied. The feasible region or "objective function", bounded on all sides by the project constraints, often takes the form of a two-dimensional polygon, which can be expanded or contracted based on acceptable levels of risk and uncertainty.

To demonstrate the linear programming approach to value engineering, a hypothetical case study has been developed to define optimal IAQ design parameters and select optimal IAQ equipment options for a commercial office building. IAQ options are among the most complex of building systems to value engineer since IAQ benefits often require substantial capital investment, are difficult to quantify (e.g., improved worker health and productivity, reduced absenteeism, etc.) and may result in added operations and maintenance (O&M) costs. The purpose of this research is to develop a simplified decision tool for building designers, builders, operators and owners to screen a large number of value-engineering options and design parameters to those most likely to provide the greatest level of performance benefits in relation to costs.

BACKGROUND

IAQ, along with lighting, acoustics, and vibration, are a few of many indoor environmental quality (IEQ) issues that can affect the well-being and productivity of building occupants. US Environmental Protection Agency (EPA) studies of human exposure to air pollutants indicate that indoor levels of many pollutants are often 2–5 times higher than outdoor levels (USEPA, 1993). Indoor air pollutants are of particular concern because it is estimated that most people spend as much as 90% of their lives indoors.

Although providing a healthy indoor environment can be achieved in part by selecting appropriate interior finish materials and managing sources of indoor pollutants such as cleaning agents, process chemicals, dust, moulds, pollen, dander and smoke, HVAC systems must be designed, operated and maintained to provide adequate air ventilation and filtration. According to a US National Institute of Occupational Safety and Health (NIOSH) survey, 52 out of 100 US office buildings with IAQ problems suffered from inadequate ventilation. Building code compliant levels of indoor ventilation air and filtration in the US are largely determined by the American Society of Heating, Refrigeration and Air-conditioning Engineers (ASHRAE) Standard 62-2001. Minimum ASHRAE standards require 0.57m^3/min/person (20ft^3/min/person) of fresh air ventilation for typical office environments having on average, seven workers per 92.9m^2 (1,000ft^2) of air-conditioned floor area.

Monitoring indoor contaminants and pollutants such as $C0_2$ for example is important since studies have shown that levels of $C0_2$ above 1,000ppm can cause drowsiness and general discomfort, making it more difficult for building occupants to think and work (Bas 1993). Although efforts to identify and reduce sources of indoor pollutants are generally the most effective alternative, not all sources can be eliminated by source management. Some non-particulate contaminants are too small and the volume of re-circulating air too great to be cost-effectively filtered, absorbed or *ad*sorbed. $C0_2$, a by-product of human respiration, is a prime example. As a result, outside air (OA) ventilation in combination with source management and filtration is commonly used to dilute pollutants within the indoor air and exhaust contaminated air to the outside.

Ventilating conditioned indoor spaces with unconditioned outside air often requires additional equipment size and cost, energy consumption and maintenance. An investigation into a "typical" 10-storey office building determined that OA ventilation alone resulted in a 2.8% increase in heating energy costs and a 6.3% increase in cooling costs (Bas 1993). However, improved worker health and productivity resulting form improved indoor air quality may provide substantial payback. In 2000, three studies were conducted to determine the increase in productivity, if any, associated with added levels of OA ventilation using 90 human subjects. By doubling OA ventilation from the minimum ASHRAE standard of 20cfm to 40cfm, productivity improvements of nearly 2% were observed in test subjects performing simulated office tasks. At present, however, there exist limited tools to quickly and efficiently evaluate OA ventilation design parameters and equipment options that maximize these and other performance benefits whilst minimizing incremental equipment and O&M costs.

METHODOLOGY

To demonstrate the linear programming approach to value engineering, the model will attempt to determine the optimal rates of OA ventilation for a hypothetical commercial office building in Miami, Florida (USA). For the purposes of this study, "optimal" is defined as a rate of OA ventilation that meets or exceeds the ASHRAE 62-2001 standard of 0.57m^3 (20cfm) per building occupant and maximizes worker productivity returns on added equipment and O&M investments.

Estimating the costs of improved ventilation

The first step in assessing the costs associated with increasing the OA ventilation rate is to estimate the OA increase that will be required. The following equation presents a procedure for estimating the needed increase, assuming that dilution is the sole mechanism which reduces the contaminant concentration. It is assumed that the concentration of the contaminant of concern in the outside air is zero.

$$C = \frac{d \times (a - b)}{b}$$

where,

C = Incremental increase in outdoor airflow rate required to achieve the desired reduction in contaminant concentration (m^3)

a = Current average concentration of the contaminant of concern in the building (ppm)

b = Average concentration to which "a" should be reduced (ppm)

d = Current flow of OA into the building (m^3).

Next, the incremental increase in equipment and life-cycle O&M costs must be considered. Depending on the climate, added fresh air ventilation will generally require additional equipment capacity to condition and circulate the added volume of unconditioned outside air. The values presented in Table 1 represent the incremental increase in heating and cooling capacity required to condition each additional 28.3m^3 (1,000cfm) of outdoor air to an indoor temperature of 21°C (70°F) and 50% relative humidity for five geographic regions in the US.

Table 1: Incremental increase in heating, ventilation and air-conditioning (HVAC) capacity by geographical location (Henschel 1999)

City	Required increase in cooling capacity, 3.5kW (ton) per 28.3m^3 (1,000cfm) OA	Required increase in heating capacity, 1.0kW per 28.3m^3 (1,000cfm) OA
Chicago	3.3	22
Miami	4.6	6
Minneapolis	2.7	26
Washington, DC	3.9	16
Seattle	0.5	13

To provide the added heating and cooling capacity needed to condition the added OA ventilation, the existing HVAC system design must either be modified (enlarged) or a dedicated OA ventilation and conditioning system must be installed. The values presented in Table 2 represent the incremental increase in installed HVAC system equipment costs per incremental increase in resistance (strip) heating and air-to-air direct expansion (DX) cooling capacity for new construction (not retrofit).

Table 2: Incremental increase in heating and cooling equipment costs for modified HVAC systems and dedicated OA systems (USEPA 2005)

System	Cooling capacity range, kW	Heating capacity range, kW	Incremental cost, $US/kW
Central HVAC system	0–70		355
	>70		318
		0–10	95
		11–20	75
		21–40	50
		41–100	30
		>100	18
Dedicated OA system	0–18		426
	>18		355
		0–10	125
		11–20	80
		21–40	50
		41–100	30
		>100	18

To determine the added operations costs, the incremental increase in OA ventilation is factored by the added energy necessary to condition and circulate each cubic metre of added outside air. The total number of heating and cooling degree-days is used to determine how much energy is needed to condition each cubic metre of OA ventilation. A degree-day is defined as each 24-hour period that the outside temperature is one degree above the cooling set-point (22°C) or one degree below the heating set point (12°C) within a given year. However, a calculation of energy consumption that is based only on the total heating or cooling degree-days in a specific geographical location may be misleading as the mechanical system may not be supplying OA ventilation into the building during the night, usually the coldest period of a day or during weekends and holidays. The modified energy use values (kWh/yr/m^3) presented in Table 3 assume that OA ventilation is being supplied for 13 hours per day (6:00 a.m.–7:00 p.m.) and 5 days per week for the specified US locations.

Table 3: Incremental increase in annual heating and cooling energy use per unit increase in OA ventilation rate by geographical location (Henschel 1999)

City	Increase in cooling energy use, kWh (3,413Btuh) per m^3 (28.3cfm) OA	Increase in heating energy use, kWh (3,413Btuh) per m^3 (28.3cfm) OA
Chicago	107.8	340.0
Miami	555.6	1.7
Minneapolis	107.8	522.4
Washington, DC	165.8	207.3
Seattle	24.9	232.2

By factoring the annual energy required to condition each unit of OA ventilation in each geographic region by the total incremental increase in OA ventilation required, the total increase in energy consumption (kWh/yr) can be determined. For electric cooling systems using direct expansion (DX) of a refrigerant, the efficiency of the cooling system must be considered. The efficiency of the cooling system, commonly referred to as the coefficient of performance (COP), calculates the amount of heat transfer output for each unit of electric energy input. A COP of 2.9 for example, means that the cooling system can remove 2.9W (10Btu) of heat within the building for every 1W of electric input energy. The efficiency of electric heating systems using resistance coils is approximately 0.9. The efficiency of gas or fuel oil heating systems is approximately 0.85.

In most cases, marginally increasing the capacity of an existing HVAC system to accommodate added OA ventilation will not substantially increase maintenance costs. However, if additional intake or exhaust fans are required or if dedicated OA units are added to the original design, maintenance labour costs can be expected to increase. Each additional intake or exhaust fan will on average, require an additional 5 hours of maintenance labour per year. Dedicated OA units will require 20 hours of maintenance labour per year.

Most buildings are financed by bonds, bank loans or venture capital. Consequently, the cost of the construction, including the cost of OA ventilation equipment, is usually amortized over the service life of the equipment, usually 10–20 years. Depending on the interest rate at which funds are burrowed (*i*) and the amortization period (*n*), a capital cost recovery factor (*CRF*) can be used to annualize the added cost of OA ventilation equipment.

$$CRF = [i(1+i)^n]/[(1+i)^n - 1]$$

The *CRF* can be multiplied by the total added equipment cost to determine the annualized installed cost of the equipment. Combined with the added operations and maintenance cost, if any, a total annualized cost for added OA ventilation can be determined.

Estimating the benefits of improved ventilation

In 2000, three studies were conducted to determine the increase in productivity, if any, associated with added levels of OA ventilation using 90 human subjects. By increasing OA ventilation from 0.60m^3 to 5.05m^3 while holding all other indoor climate conditions constant, the subjects' performance of simulated office tasks were observed. Results found that doubling OA ventilation can initially increase overall performance by 1.8%. However, the rate of increase in performance benefits declines with respect to additional increases in OA ventilation beyond approximately 1.56m^3.

In fact, as presented in Table 4, increasing OA ventilation another five-fold to 5.05m^3 results in only another 1.9% increase in worker productivity (Wargocki 2000).

Table 4: OA ventilation rate (m^3/min/person) vs. worker performance index (Wargocki 2000)

OA (m^3)	PI	OA (m^3)	PI	OA (m^3)	PI	OA (m^3)	PI	OA (m^3)	PI
0.60	0.9900	1.56	1.0220	2.51	1.0289	3.46	1.0330	4.42	1.0358
0.71	1.0000	1.67	1.0230	2.62	1.0294	3.57	1.0333	4.52	1.0361
0.81	1.0069	1.77	1.0240	2.72	1.0300	3.67	1.0337	4.63	1.0364
0.92	1.0110	1.87	1.0249	2.83	1.0305	3.78	1.0340	4.73	1.0366
1.03	1.0139	1.98	1.0257	2.93	1.0309	3.89	1.0344	4.84	1.0369
1.13	1.0161	2.08	1.0264	3.04	1.0314	3.99	1.0347	4.95	1.0371
1.24	1.0179	2.19	1.0271	3.15	1.0318	4.10	1.0350	5.05	1.0374
1.34	1.0195	2.30	1.0277	3.25	1.0322	4.21	1.0353		
1.45	1.0208	2.40	1.0283	3.36	1.0326	4.31	1.0356		

Using the Wargocki data, the incremental performance benefit or performance index (PI) of each added cubic metre of OA ventilation can be determined by multiplying the worker's fully burdened labour rate or salary by PI minus one. This value (PI-1.0) represents the incremental performance "profit" index (PPI). For instance, if the average cost of the employee to the employer is $US 30,000 per year, then increasing the employee performance index to 1.02 could improve the value of productivity $US 600 per year per employee. By multiplying the average benefit per employee by the total number of employees, a total annualized benefit for added OA ventilation can be determined. If the total annualized benefit for added OA ventilation is greater that the total annualized cost, then a positive return on investment can be realized.

Benefit-cost optimization using mixed integer linear programming

To simplify the relationships of two or more non-linear functions, such as the relationship between OA ventilation and worker performance, linearization tools can be used. One such tool, *piece-wise* linearization, divides non-linear functions into linear segments. A decision can be made to either "segment" underneath the curve and thus, underestimate values or segment above the curve and overestimate values. Also, the greater the number of linear segments used to represent the a non-linear function, the greater the accuracy. The slope of each linear segment (m) can be calculated by finding the tangent of the angle (θ).

$$\mathrm{Tan}(\theta) = \frac{(\text{Max PPI - Min PPI})}{(\text{Max OA - Min OA})} = m$$

By applying the point-slope method $y = mx + c$, the relationship of the performance profit index (PPI) and OA ventilation can be linearized. In other words, performance profit index values (y) can be approximated for each linear segment by factoring the segment slope (m) by corresponding rates of OA ventilation (x) in cubic metres per person.

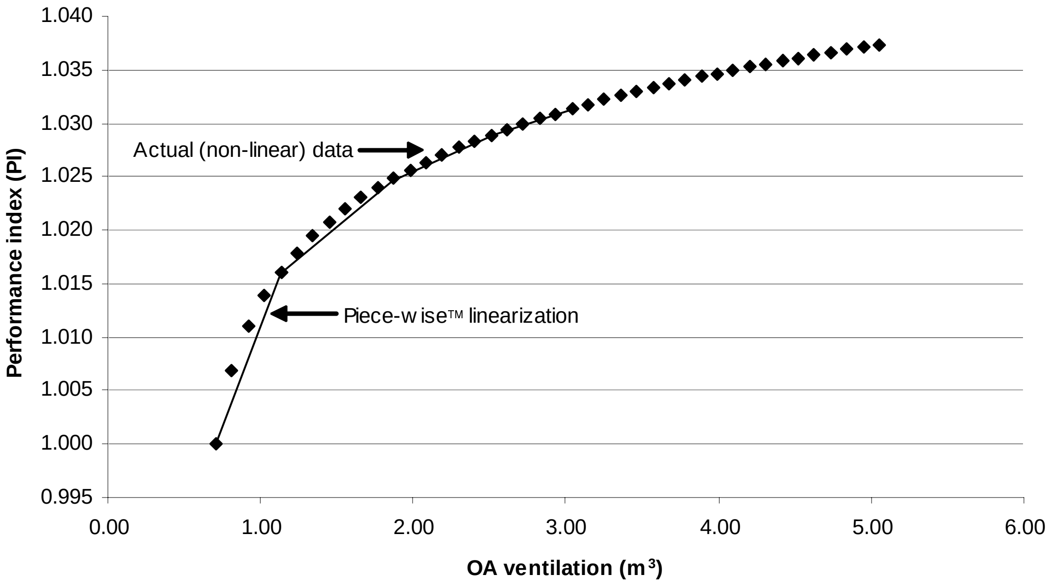

Figure 1: Linearization of OA ventilation rate (m^3/min/person) vs. worker performance index

Having expressed all incremental equipment costs and performance benefits as linear functions, a mixed integer linear expression (e.g. *objective function*) can be derived to determine the optimal rate of OA ventilation.

$$\text{Min}\, z = \sum_{i=1}^{2} (A_i X_i Y_i) - W$$

where,

z = Total annual benefit (or cost) of the incremental OA ventilation system ($US)

A_1 = Variable cost of air by central unit ($US/person/$m^3$)

A_2 = Variable cost of air by dedicated unit ($US/person/$m^3$)

X_1 = Amount of OA supplied by a central unit (m^3/person)

X_2 = Amount of OA supplied by a dedicated unit (m^3/person)

Y_1 = "1" if central unit is used, "0" if not

Y_2 = "1" if dedicated unit is used, "0" if not

W = Profit generated by increased productivity by using PPI function ($US).

Constraints

$X_1 + X_2 \geq 20\text{cfm}; \leq 140\text{cfm}$

Requires that the total amount of added OA ventilation supplied by enlarged central unit(s) or dedicated unit(s) should be at least 20cfm per person and the amount of OA does not exceed 140cfm since the Wargocki study finds little or no increase in performance for OA ventilation above 140cfm.

$Y_1 + Y_2 = 1$

Requires the selection of at least one or a combination of both, enlarged central or dedicated HVAC systems.

$X_1 - 140Y_1 \leq 0$

Requires that X_1 (added ventilation air from enlarged central unit) will be zero if Y_1 (enlarged central unit) is equal to zero (not used).

$X_2 - 140Y_2 \leq 0$

Requires that X_2 (added ventilation air from dedicated unit) will be zero if Y_2 (dedicated unit) is equal to zero (not used).

RESULTS

Case study office building

A 670m^2 (7,200sf) office building in Miami, Florida (USA) with 50 employees requires 0.57m^3/min (20cfm) per person of outside air ventilation or 28.3m^3/min (1,000cfm) total to adhere to the ASHRAE 62-2001 standard. The average cost of the each office worker to the employer is $US 20,000. As a result, the employer incurs approximately $US 1,000,000 in fully burdened labour expenses (salaries, payroll taxes, fringe benefits, etc.) each year. Using the values presented in Tables 1–4, and the incremental cost assumptions below, the *objective function* determines that the optimal rate of outside air ventilation is 1.25m^3/min/person or 62.5m^3/min total, achieved by modifying (enlarging) the design capacity of the existing, central HVAC system prior to construction.

- Interest rate (*i*) = 8% APR.
- Service life (*n*) = 15 years.
- Cooling efficiency = 2.9 (DX).
- Heating efficiency = 0.9 (electric strip heat).
- Electric rate = $US 0.09/kWh.

The *ratio* of total annualized performance benefits ($US 21,972) in relation to total annualized performance costs ($1,672) is maximized at 1.25m^3/min/person (44cfm/person) OA ventilation. However, the model indicates that the *net* benefit of added OA ventilation continues to increase well beyond 2.83m^3/min/person (100cfm/person). Again, the optimal rate of OA ventilation is highly dependent on a number of independent variables and functions. As electric rates approach $US 0.12/kWh for example, the optimal rate of OA ventilation drops to 1.08m^3/min/person (38cfm/person) whilst holding all other variables constant.

In summary, the following research has demonstrated that optimizing indoor air quality through outside air ventilation is at least dependent on the following primary variables:

- Number of employees.
- Outside air ventilation requirements.
- Added capacity of HVAC equipment per climate.
- Added installed cost of HVAC equipment per location.
- Energy efficiency of HVAC equipment.
- Added energy use of HVAC equipment per climate.
- Added energy operations cost of HVAC equipment per location.

- Added maintenance cost of HVAC equipment per location.
- Improved performance index.
- Total annualized installation, operations and maintenance cost.
- Average annual salary of the employees.

CONCLUSIONS

One of the key requirements of a high performance building is to create an efficient, healthy and comfortable indoor environment that provides measurable performance benefits. Yet studies of human exposure to air pollutants indicate that indoor levels of many pollutants in the US are often 2–5 times higher than outdoor levels, resulting in worker discomfort, potential health risks and loss of productivity. Unfortunately, IAQ improvements are among the most complex of building systems to value engineer since IAQ benefits often require substantial capital investment and may actually result in added operations and maintenance (O&M) costs. The reductions in “soft costs” such as reduced absenteeism and health care costs, as well as gains in worker comfort and productivity, are difficult to quantify.

As shown, nearly a dozen independent variables may influence the design of an optimal ventilation system alone. By applying a linear programming approach to value engineering, the annualized costs and performance benefits of added outside air ventilation have been successfully transformed into linear functions using “piece-wise” linearization. A mixed integer model was then developed to determine the optimal rate of outside air ventilation, as well as the type of equipment that will most cost effectively provide the optimal level of ventilation in terms of benefit-cost ratio. As shown, the primary advantage of the linear programming method is the speed and simplicity of the solution generation and the potential of the mixed integer model to value engineer optimal combinations of integrated IAQ solutions (e.g. ventilation, filtration, source management, etc.) as well as other building design elements.

VIRTUAL FRAMEWORK FOR PROJECT MANAGEMENT EDUCATION – EXPERIENCES FROM TEACHING-LEARNING PERSPECTIVE

Hemanta Doloi[1]

Faculty of Architecture, Building and Planning, University of Melbourne, Victoria 3010, Australia

This research presents a self-learning model, to ensure participants address and meet project challenges with their inherent professional and managerial skills. Flexible delivery and self-learning mechanisms have proven to be one of the best learning approaches among professional project managers within dynamic corporations. The model facilitates project management education at a higher level than commonly available. Progressive learning and competency development for effective utilization of project management knowledge and methodologies has been redesigned to match the needs of the future. Research-based, team-learning exercises, coupled with peer-assessing and self-learning exercises have facilitated such development, within a controlled learning process. This distinct learning mechanism aims to educate professional project managers, at a superior level, across various project management disciplines, while referencing to the global competency frameworks from major professional bodies. The outcomes and validity of the pedagogy have been demonstrated using a hypothetical case study.

Keywords: education, future studies, globalization, project management.

INTRODUCTION

The continuous development of the multifaceted character of the project management (PM) profession has increasingly been a focus of attention over the past few decades. Project managers are responsible for the overall control of projects and are concerned with delivering on time, within budget and to the appropriate quality (Manivong *et al*. 2004). Organizations in many industry sectors are moving away from traditional forms of management towards a more project-oriented culture. This requires a combination of technical interpersonal skills for managing projects in diverse contexts (Marton and Saljo 1976; Dooley *et al.* 2005).

While continuous development in the PM profession is on the increase, the relevant educational model with appropriate delivery strategies becomes the point of major concern among the higher education industries (Munns 2001). Recently, many universities have been trying to adopt a distance educational model using an online delivery platform. The US set the trend in the early 1990s that resulted in a mass education system being born (Manivong and Doloi 2004). The trend was primarily caused by the birth of distance learning programmes and institutions and the needs of individuals for higher degrees to keep pace with the dynamic corporate culture.

Traditional delivery practices in the classroom environment do not provide sufficient flexibility in terms of time and locations for global audiences (Nunan 1994). Such

[1] hdoloi@unimelb.edu.au

factors predominately must have been contributing to education sectors becoming adaptive to terms such as globalization, internet technology, virtual conferencing systems, cultural empathy, international workforce, and so on. Emeritus Professor Wells (1998) asked critical social questions about the current direction of universities: ‘how are we going to manage higher education, maintain standards, be innovative and serve the students?’. He also raises the question of how the so-called ‘emerging nations’ are going to provide the educational infrastructure for their growing middle classes in a way which will satisfy the rapidly increasing demands. Another aspect of such movement is the ever-increasing pressure on university funding (Doloi and Stevens 2004). Western governments have had continuing political debates on their roles in developing and funding universities. For example, currently in Australia, the federal government has enforced a policy on reducing higher education funding and increased places for full fee paying students (Davis 2005).

RESEARCH HYPOTHESES AND ADOPTED METHODOLOY

Today’s higher education providers are seen to be a more strategic venture where multi-disciplinary dependencies contribute to the fulfilment of strategic objectives of the entire educational system (Munns 2001; Williams 2003; Manivong and Doloi 2004). In current educational practices, the challenging complexities of an institution are typically due to the following reasons:

- the presence of uncertainty and risks affecting virtually all aspects of knowledge creation, delivery and operations;
- multifaceted curriculum requirements and associated functional integration;
- complex and changing business environments with highly networked stakeholders;
- multiple choices, change of priorities and global audiences with free market ventures;
- global competition, internationalization and competitive market demand.

Given the profound changes in educational environments and the increasing evidence of the shift of current practices, this paper seeks to address the following research questions:

- How does the diversity and complexity of today’s practices impact on establishing next generation educational delivery platform?
- How can the advancement of information technology (IT) and information services (IS) be used for the strategic existence of an educational organization?
- Will the framework be seen as a core capability in delivering required competency in project management education and supporting the flexibility, reflectivity and adaptability across the global boundary?
- How will the delivery of knowledge be relevant to ensure diagnostic cross-communication between current industry practices and educational institutions?

Focusing on the above questions, this research aimed to define an advanced online delivery framework and underlying strategies in a proactive and explicit manner. Results of the market research conducted at the University of Melbourne has shown that there is a need for innovative design and flexible delivery of professional courses for busy corporate professionals to keep pace with business dynamics and progressive competency development in their areas of expertise (QBrand Consulting 2005). The research investigates the robustness of using an Internet-based platform as core functionality for designing and delivering a course targeting global audiences. A case study is used to demonstrate how the framework has been used to effectively deliver the knowledge and ensure the appropriate practice-based educational outcomes in a virtual learning environment.

COMPETENCY-BASED LEARNING AND HIGHER EDUCATION

An effective learning environment relies on the competencies of those who are going to use such education in practice. Regardless of infrastructure and other associated delivery factors, the competency framework is the key to delivering practical knowledge in the higher education sector (Williams 2003; Crawford 2004; Morris 2004). Figure 1 shows a high level competency development framework integrating environments and associated business roles.

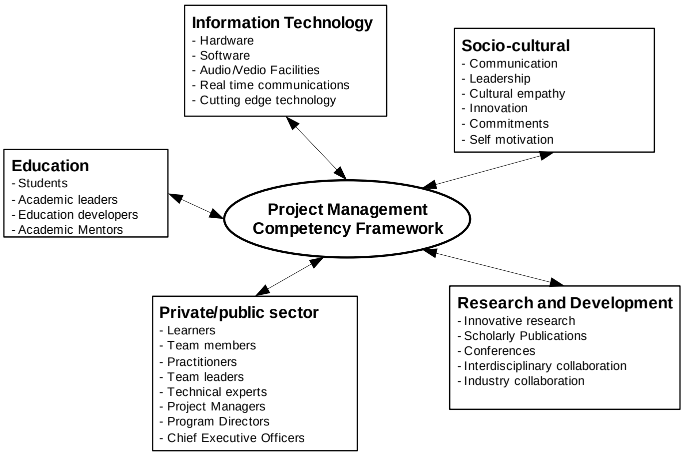

Figure 1: Competency development framework

As seen, the framework comprising practice roles and competencies associated with the educational model must be designed thoughtfully with full understanding of curriculum objectives and technological balance. While discussing competency-based education, the underlying characteristics associated with the term ‘competency’ must be understood. These characteristics lie mainly among the people and their behaviour or thinking patterns across any situation over a reasonable time period (Saba and Shearer 1994). The term ‘competency’ usually refers to the skills, knowledge, personal characteristics and behaviours needed to effectively perform a role in an organization in order to contribute to meeting the strategic business objectives (Roschelle and Teasley 1995).

There is an essential need for educators to clearly understand the related roles and competencies for professionals in applied fields (Crawford 2004). The development of educational models especially for the distance delivery model must integrate the roles of key stakeholders or target audiences with their business roles and responsibilities facilitated by the emerging pedagogy and technology. As shown in Figure 1, five major drivers such as education, information technology, socio-cultural aspects, research and development and private/public sector business practices have been integrated in developing the competency framework in the model. In the flexible delivery model, competency-based learning plays a great role in realizing an appropriate educational outcomes.

THE VIRTUAL PEDAGOGY MODEL

Figure 2 shows the pedagogical model of the distance learning framework. The model has been developed by integrating the views of a number of stakeholders from the teaching and leaning points of view, such as students, tutors, course advisers and course designers.

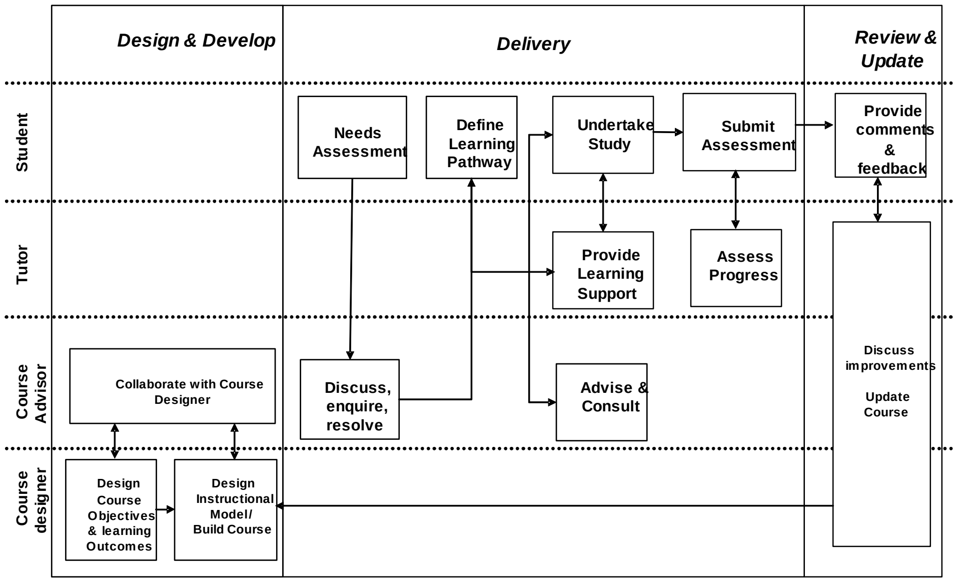

Figure 2: The pedagogical model

The overall model comprises three major phases: Design and Development, Delivery and Review and Updates. The Design and Development phase focuses on design and staged delivery of the module-specific technical contents. In a typical module, closed interaction is required between the course adviser and the course designer or content provider for the seamless integration of the technical contents within the target competency framework.

The focus of the Delivery phase is on the student's learning where actual learning takes place through rigorous interaction within the structured learning programme and learning pathways, assisted by the course adviser as well as the respective tutors. The computer-based self-assessment toolkit allows students to assess their strengths and weaknesses against given target outcomes. A customized learning programme and the specified learning pathways ensure progressive development through a peer feedback mechanism within the team-learning environment.

In the Review and Update phase, all the stakeholders interact closely in reviewing and providing feedback for continuous updates. Self- and peer-reflection reports are the key to achieving target outcomes in this process. Moreover, such dynamic interaction and continuous reflection allow for the integration of student feedback for further model enhancement.

MODEL FRAMEWORK

Figure 3 shows a high level framework of the model. As seen, there is an entry level compulsory module followed by a few performance parameters, such as understanding of the professional strength, gap analysis and progressive development towards meeting a specific target outcome at the end.

The entry level module, 'Project Management Framework', allows students with cognate as well as non-cognate professional backgrounds to develop an understanding of the global standards of the project management competency framework (Crawford 2004; Project Management Institute 2004).

A computer-based in-house self-assessment toolkit facilitates students' self-assessment of their generic and technical strengths. A notional professional development plan then allows the students to evaluate knowledge and competency gaps and benchmark the self-learning and progressive development curves towards the target competencies. The target competency may vary from student to student and depends on the relevant business roles of a given organization (Figure 2). The overall competency matrices have been developed based on the organizational and project management competency standards set by the leading professional associations (e.g. Project Management Institute, International Project Management Association, Australian Project Management Association, etc.) (Crawford 2004).

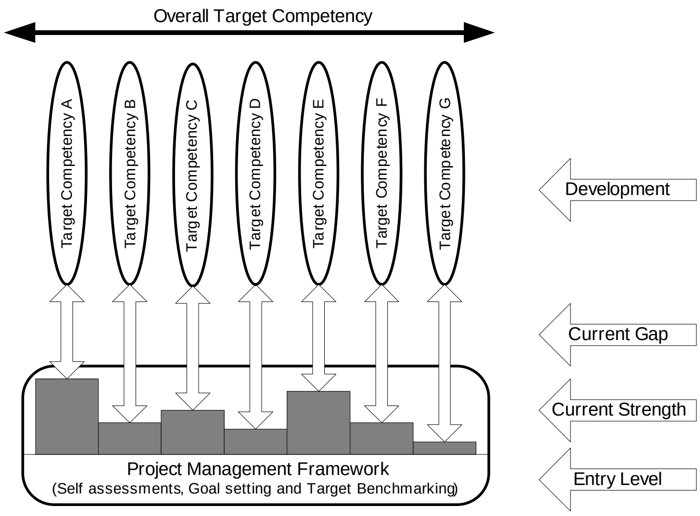

Figure 3: Broad architecture of the framework

LEARNING PATHWAYS AND SYSTEM CAPABILITY

The overall model facilitates dynamic interaction and communication where learning takes place. A typical module aims to capture all the learning and teaching components from the students' perspectives. Some of the key features of a typical module are discussed below:

- *Introduction* – outlines the profiles of the module's educators and available teaching assistance, if any. This section also provides a brief on what to expect in the course module, any textbooks, and special requirements, e.g. a spreadsheet program.
- *Assessment* – outlines the academic assessment criteria and the assessment structure of the course module. A major assessment component is the participation rate of students within the virtual team learning environment facilitated by the system.
- *Activities* – depicts the learning activities and tasks that need to be conducted by students or groups to gain academic credit. Typically three to six assignments are given in any course module. The learning activities are

typically threefold: start-up exercise, case-based application and individual reflection and demonstration. The start-up exercise is designed for students to expedite learning of the fundamental knowledge. The case-based application allows students to apply the fundamental knowledge to devise an appropriate solution to their own case projects. Individual reflection and demonstration allows students to demonstrate their progression and achievements in a personalized, guided environment. Each assignment has guidelines and relevant learning notes which can be downloaded.

- *E-library* – for students to conduct further research and information gathering which may or may not be relevant to the subject matter. Students are able to access all documents provided by this service.
- *Submission* – allows students to upload and submit their assignments online to educators for assessments.
- *Discussion forum* – allows students and educators to interact by posting public or private messages with attachments to other colleagues in the module or for a particular group.
- *Team/group evaluation* – this feature allows confidential assessments to be made between students in a group. The submitted report allows educators to individualize students' marks from the group study.
- *Teaching assistant assessment* – this feature allows educators/teaching assistants to mark and upload detailed comments to students. Marks are not finalized until the end of semester examiners meeting.
- *Team/group discussion forums* – for educators to create groups or teams of students and create private discussion forums for every group in the class.
- *My transcripts* – allows students to download and print their current academic transcripts.
- *Audio-conferencing system* – allows for synchronous virtual communication between teaching teams and students to conduct regular discussion sessions throughout the academic semester.

As can be seen from the above sample of a typical online course, it is obvious that a dedicated online system is required to deliver the embodied education/training philosophies. Since one of the main goals of virtual delivery is to extend education globally, and reach out to untapped world markets, it is prudent for these education systems to be accessible over the Internet. Today the Internet offers a very cost-effective solution to online education delivery. All types of media (e.g. word processing documents, video clips, picture files, sound files, etc.) can be transmitted, viewed, edited and played over Internet.

APPLICATION OF THE MODEL

As mentioned earlier, this model has been designed based on the author's experience with delivery of online education over a number of years. Though no systematic documentation or recording was taken during the time, observations and experience have provided the following proven successful teaching and delivery approaches:

- *Group learning and independent learning* – Group/team learning provided a means for students to learn more effectively resulting in a network of cooperation and collaboration. Independent learning proved effective where educators did not provide a 'cookbook' approach to learning. As it was a graduate level programme the key was to provide challenging tasks for different minds and to perhaps change old mindsets via challenging tasks.

- *Competency-based learning* – Proved successful in this type of management programme. A 'hands-on' application of PM theory to workplace integration proved effective. Just relying on a 'body of knowledge' was not good enough. Rather, it was the exchange of information, concepts, ideologies, and so on that were more important.
- *Educator responsiveness and feedback* – Since students came from all corners of the world it was imperative that students receive feedback on questions they posted and more importantly receive assignment feedback rapidly. Since the Internet and computers are what students physically interact with and see, it was imperative that communication would occur through the system's email and discussion forum without relying on external means, which was efficient and spontaneous.
- *Real-time (audio/video) conferencing* – To counteract the asynchronous mode of interaction, a dedicated audio/video conferencing system was useful for students to get together to work on real-time tasks. This system is also useful for live seminars or lectures if students need it.
- *Focus on asynchronous delivery* – Because of student time commitment to family and work, asynchronous learning was the most effective means to deliver this type of online education. It was also more cost-effective. Studying at your 'own pace' proved to be what students wanted.

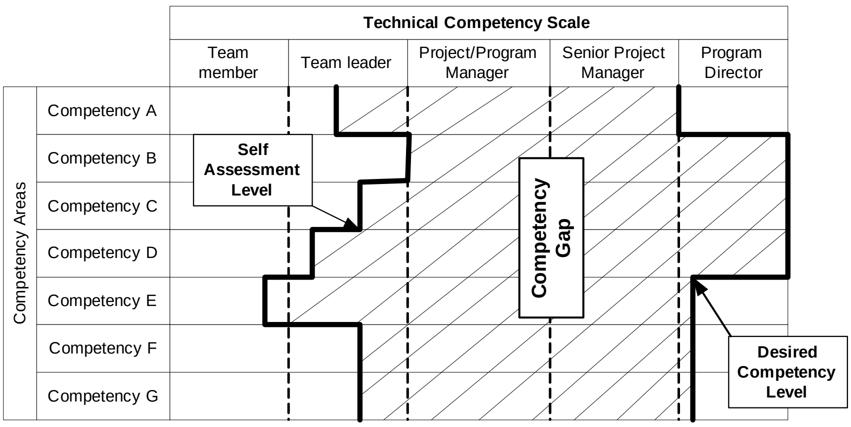

Figure 4: Goal-setting framework

The case study showed that success of an online programme can be attributed to the delivery mode and design of a self-driven learning programme. There is no doubt that the IT systems form an integral part of the education service and must be considered carefully before being implemented. The system itself, if not properly implemented, could 'bog down' key resources, and the focus may be turned away from delivering a quality education in the process.

Figure 4 shows an outcome of a goal-setting exercise that students need to perform before entering any formal module. The model allows students to work through a number of project management competency matrices such as socio-cultural, technical and organizational competencies, assessing strengths and weaknesses in the area. The result of this goal-setting exercise allows students to feel the competency gap between the current and desired competency levels. The assessments are then combined to get a holistic evaluation of personal as well as professional attributes before selecting subject matter for further developments.

Such assessment exercises can be undertaken from a distance using a secured IT platform. A notional professional development plan is then developed setting up the desired competency levels across the global competency matrix and relating to the respective business roles.

CASE STUDY

Though the paper claims that competency-based education is possible by advocating an appropriate distance learning educational model, questions persist regarding the parallel evolution of related roles, a curriculum supporting the development of professional skills and finally formal degree programmes. Researchers have provided both positive and negative insights regarding competencies associated with distance learning. These discussions are important in understanding the perspectives of both emerging and new professionals in the field and provide implicit signals as to the ways in which the mature professionals can be trained. The aim of the case study is to further clarify the model in terms of distance learning roles and competencies through the exploration of a typical graduate student perspective. It is worth mentioning that the output chart provided in the paper is hypothetical because of sensitivity in publicizing the original student’s result.

Self-assessment and professional development planning

As mentioned earlier, the overall competency framework for each module comprises three broad categories of competencies relevant to the target knowledge areas of the project management profession. These are: general management, functional management and socio-cultural aspects. The general management functions are generic and focus on the generic managerial aspects in the project context. Functional management focuses mainly on the project management functions specific to the technical competencies. Socio-cultural management functions are based on soft competencies associated with project management practice.

Table 1 shows the levels of self-assessment along with the expected goals against some of the general management functions. There are six attributes against each management function showing an incremental order of 20% progression towards the completion. As can be seen, students’ competency levels at the beginning are assessed and target outcomes are set identifying the gaps for further development.

Similar outcomes of self-assessments are expected along target competencies in both project management functional and socio-cultural aspects. The outcomes of such self-assessment exercises entirely depend on students’ professional as well as relevant academic backgrounds. Targets are also set as per the personal as well as professional requirements associated with any business roles. While the learning road map may be similar across a given class size, the target achieved or reported at the end depends on students’ personal and professional judgements.

Table 1: Beginning and target competencies in general management

General Management		Learner / Understanding / Developing / Practicing / Competent / Leading (0% to 100%)	Begin	Target
Integration Management	Beginning			
	Target		20	80
Business Management	Beginning			
	Target		0	60
Procurement Management	Beginning			
	Target		40	80
Technology Management	Beginning			
	Target		20	100
Stakeholder Management	Beginning			
	Target		20	80
System Management	Beginning			
	Ending		0	60

Competency report

Table 2 shows the comparative report with the analysis of learning progression within a set boundary. As can be seen, the competency achieved (refer to the rows denoting 'ending' against each management function) is shown along with the levels at the beginning as well as targets. For instance, beginning and target competencies of a given student on technology management in the general management aspect are 20% and 100% respectively. After completion of the module, the student reports that he/she has acquired up to 40% against the target of 100%. In this case, there is a need to undertake further action in developing and closing the gap by an additional 60%. The strategy for such development is normally tracked through a professional viva presentation and final report with an idea that a solution may be devised in the model in its dynamic review process.

Table 2: Acquired competency in general management

General Management		Learner / Understanding / Developing / Practicing / Competent / Leading (0% to 100%)	Begin	End	Target
Integration Management	Beginning Ending Target		20	40	80
Business Management	Beginning Ending Target		0	60	60
Procurement Management	Beginning Ending Target		40	80	80
Technology Management	Beginning Ending Target		20	40	100
Stakeholder Management	Beginning Ending Target		20	80	80
System Management	Beginning Ending Target		0	60	60

The model advocated in the paper emphasizes heavily self- and team-learning aspects as opposed to the traditional lecture-based approach. Academic research is the key to developing the knowledge of the subject matter. Hypothetical analysis allows students to devise solutions for given problems facilitated by the educators as part of pilot exercises. Once the level of knowledge has been built up to an appropriate level, the same needs to apply on a real case project in team environment to devise the best solutions with a complete holistic approach. The required technical competencies are assumed to be achieved by such exercises throughout the module. Similarly, socio-cultural competency is developed through mechanisms such as peer discussion, group discussion and self-reflection.

CONCLUSION

This paper highlighted the fact that true educational outcomes experience in traditional teaching model can well be replaced with appropriate pedagogy for flexible delivery. The rapid growth of virtual/online programmes has changed the way education is being taught and delivered. The validity of research-based pedagogical development is becoming important in the value addition process of the delivery of knowledge to the wider community. This is because of increased demand for continuous professional development to gain competitive advantage in the corporate business environment. A model has been developed and validated as a major tool to exploit a virtual teaching philosophy and delivery strategy using online platforms. A pedagogical approach of flexible delivery of academic project management education has been demonstrated. The model is purely competency based with appropriate reference to leading project management bodies across the globe and has proved to be quite successful integrating educational principles and industry practices within the project management profession.

MANAGEMENT AND ECONOMICS EDUCATIONAL PROGRAMMES AS A CONSTRUCTION INDUSTRY DEVELOPMENT SUPPORT

Zoran Cekic[1]

Department of Construction Management, Union University Faculty of Construction Management, Sarajevska 20, Belgrade, Serbia 11000

Considering the latest dynamical changes in knowledge and technologies it is very important for higher educational institutions to develop and implement a strategy for the continuous enhancement of quality of their programmes and awards, supported by the results of educational research projects. Educational programme integrated database and knowledge base is suggested as an IT support for programme development, monitoring and renewal. In order to become a mirror industry image educational programmes have to respond to industry requirements for broader construction management and economics competencies. The Delphi method is applied to find which competencies industry experts consider most important for competitiveness and industry development. Needs for project management competencies are based on the traditional industry belief that successful project execution is the fundamental key to corporate success. Requirements for specific business and economics knowledge and skills are based on the belief that management education is a critical issue for sustainable long-term corporate success and industry development. Construction management and economics knowledge and skills are very important for integrated innovation processes in construction companies and could foster organizational improvement and sustainable industry development.

Keywords: education, industry development, knowledge-based systems.

INTRODUCTION

In the near future great investment activity is planned in South-East Europe. Many large construction projects are now funded by international financial institutions and private investors, and constructed and supervised by international companies. That is why engineers employed in construction companies need additional knowledge and skills in project and corporate management to successfully manage complex construction projects with short duration and strict quality requirements. In this dynamic situation it is clear that construction companies are strongly oriented towards employing educated, skilled and experienced engineers.

In order to develop and implement a strategy for the continuous enhancement of the quality of their programmes and awards, an educational research project *Construction Management and Economics Education Programmes as a Construction Industry Development Support* is organized in cooperation with the Faculty of Construction Management, Union University, Belgrade, the Higher School of Civil Engineering and Geodesy, Belgrade, and the Association of Civil Engineers, as a professional institution at a national level. Construction management and economics (CME) educational programmes in these institutions, with some

[1] cekicz@eunet.yu

similarities and differences, were specially designed and adapted to the construction industry's specific needs. At the beginning of this research, which is scheduled from September 2006 to May 2008, the Delphi method is applied to find which competencies (learning outcomes of formal, non-formal and informal education process) industry experts consider most important for construction companies' competitiveness and industry development.

An important research phase is development and implementation of an integrated education programme database and education programme knowledge base, as an IT support for education programme development, monitoring and renewal.

The next generation of civil engineering professionals is similarly witnessing the emergence of knowledge-based tasks as a central focus of organization operations (Chinowsky and Guensler 1998; Drucker 1993). The industry is slowly adopting the concept of learning organizations (Cayes 1998), and still has not come any closer to arriving at a consensus on education requirements appropriate for new managerial challenges (Chinowski 2000). The challenge to organization leaders is to develop knowledge dissemination mechanisms that retain a focus on individual enhancement while enhancing distribution to the overall organization (Stata 1989).

It is very important for higher educational institutions to carefully examine the educational needs and opportunities within construction companies and set the education objectives required to create an innovation corporate culture and civil engineering learning organization. The new civil engineers combine university education with professional experience and are entering the engineering industry with a broader educational perspective that includes influences from economics, marketing, management and computing (Grant 1996).

In an attempt to respond to industry requirements for specific educational skills, university programmes have slowly emerged as a mirror image of the construction industry (Long 1997; Singh 1992; Lowe 1991; Wadlim 1985; Hancher 1985; Grinter 1955). University programmes have followed project management tradition as they have prepared each succeeding generation of industry managers (Oglesby 1990; Betts and Wood-Harper 1994). According to the results of many studies in this field (Chinowsky and Paul 1997; National Academy of Sciences 1995; National Science Foundation 1996), management education is a critical issue for the long-term success of the civil engineering industry.

EDUCATIONAL PROGRAMME QUALITY ENHANCEMENT STRATEGY RESEARCH

If Europe is to achieve its aspiration to be the most dramatic and knowledge-based economy in the world (Lisbon strategy), then European higher education will need to demonstrate a policy and associated procedures for the assurance of the quality and standards of their programmes and awards. In order to develop a quality enhancement strategy and formal mechanism for the approval, periodic review and monitoring of higher educational programmes and awards, educational research is based on the following framework:

- Definition and analyses of all phases of CME education programme life cycle.
- Industry influence in education programmes development, monitoring and renewal.
- System for regular industry feedback (cyclical monitoring and periodic review by employers, labour representatives and professional organizations) of competencies and learning outcomes of CME department graduates.
- Development of education programmes information system (IS) which can be considered as an IT support in programme development, monitoring and renewal.

- Data and information from all phases of the education programme life cycle could be stored in an integrated educational programme database (IEPDB).
- IEPDB could form a construction industry education programmes knowledge base, as a subsystem of a construction industry knowledge base.
- An education programmes knowledge base could be used in programmes development.
- It is possible to apply principles of lifelong learning (LLL) in the field of CME.
- Development and dissemination of CME knowledge and skills could foster innovation in corporate culture, integrated innovation processes and organizational improvement.
- Managing the integrated innovation processes could foster industry development.

External quality assurance of institutions and programmes should be undertaken on a cyclical basis. The life cycle of the education programme is shown in Figure 1.

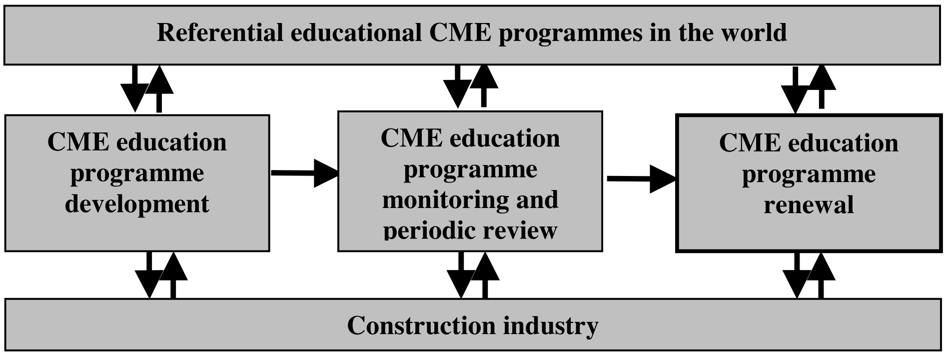

Figure 1: Life-cycle of CME education programme

The confidence of students in higher education is more likely to be established and maintained through effective quality assurance activities which ensure that programmes are well designed, regularly monitored and periodically reviewed. Quality assurance of programmes and awards are expected to include regular feedback from employers, labour representatives and relevant organizations. Learning outcomes are sets of competencies, expressing what the student of the department will know, understand or be able to do after the completion of a process of learning, whether long or short. In the final analyses the aim of the education programme is to prepare learners for an active and positive role in the construction industry (DGEC 2005).

The use of learning outcomes represents a shift in thinking from a stuff-based input-oriented system to a student-centred output-oriented approach. Learning outcomes are expressed in terms of competencies. Competencies represent a dynamic combination of attributes, abilities and attitudes, and can be subject-specific or generic. Programme monitoring and periodic review is shown in Figure 2.

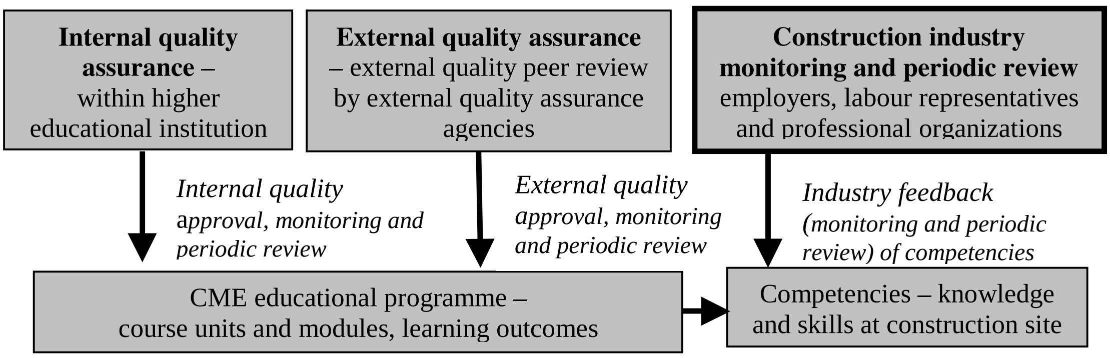

Figure 2: CME programme monitoring and periodic review

Ensuring CME educational programmes' quality assurance is not a static but a dynamic process. It should be continuous and not 'once in a lifetime'. Outcomes analysis can provide very useful information about developments, trends, good practice and areas of persistent difficulty of CME programmes and can become useful tools for quality enhancement.

IT SUPPORT IN EDUCATION PROGRAMME DEVELOPMENT, MONITORING AND RENEWAL

The higher education institutions in the field of CME should collect, analyse and use relevant information for the effective management of their programmes of study and other activities. The quality-related education programme information systems (IS) are expected to cover the institution's own key performance indicators to compare themselves with other similar organizations and to extend the range of their self-knowledge. Integrated education programme database (IEPDB) is an integrated database containing data from the design, operational and renewal phases of the education programme life cycle (Figure 3).

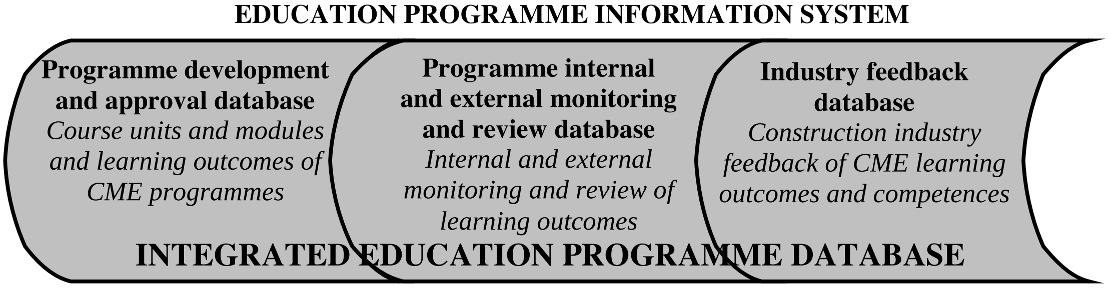

Figure 3: Integrated CME programme Database

In order to preserve, spread and manage the knowledge accumulated in previously realized CME education programmes, all IEPDB can be gathered and stored in a newly created education programmes knowledge base (EPKB). Knowledge-based systems (KBS) should preserve developed and rare knowledge in such a form that can be efficiently distributed to anyone who needs it (Dutton *et al.* 1996). EPKB, as a subsystem of the industry knowledge base, is shown in Figure 4. The education programmes information system is intended to be developed at the Faculty of Construction Management and Higher School of Civil Engineering and Geodesy, as an IT support in CME education programme development, monitoring and renewal. EPKB is intended to be developed at the Association of Civil Engineers, as a longstanding national professional organization.

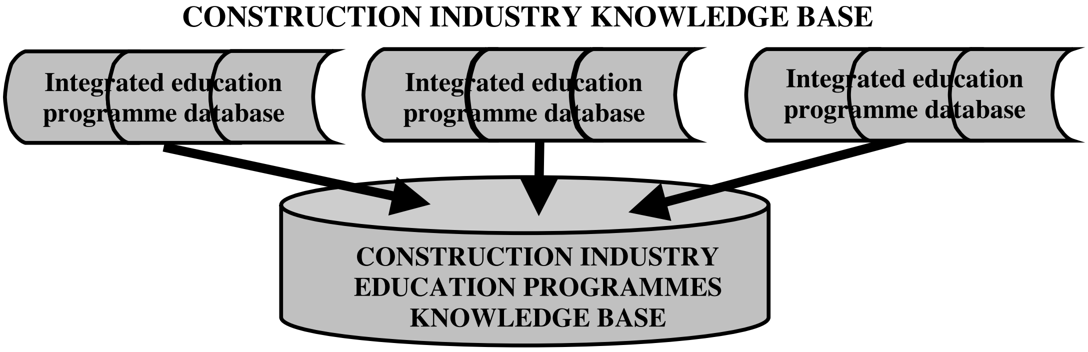

Figure 4: Construction industry education programmes knowledge base

LIFELONG LEARNING, INTEGRATED INNOVATION PROCESSES AND INDUSTRY DEVELOPMENT

The successful construction companies are increasingly facing the need to establish lifelong learning – LLL as a centrepiece of strategic management. Updating core engineering knowledge or expanding skills to areas such as management and technology, education is the emerging avenue to organization improvement (Chinowski 2000).

LLL comprises all types of learning and training within any type of institution or company, or outside in the field, i.e. formal, non-formal and informal learning. Where formal learning takes place in CME education and training institutions and leads to recognized CME diplomas and other types of documented qualifications, non-formal learning occurs outside mainstream education and training and does aim at formalized certificates. Informal learning is a natural consequence of everyday life. CME lifelong learning as an organization improvement and industry development support is shown in Figure 5.

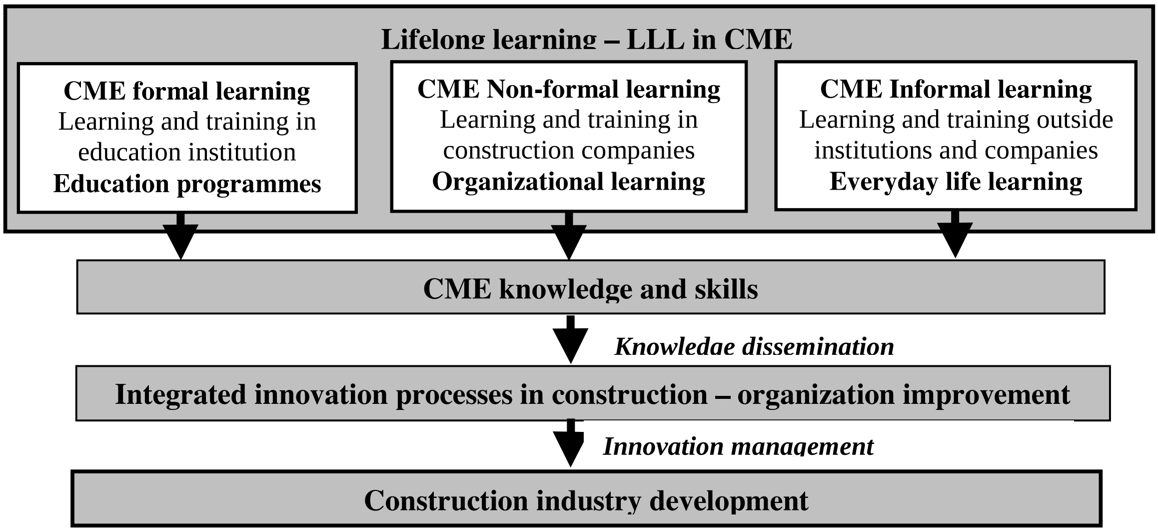

Figure 5: LLL as a support for organizational improvement and industry development

Construction companies face many challenges owing to the changed technical, economic and social conditions inside and outside the sector. Raised environmental demands can be identified as challenges for a change. As soon as such a change is an economically successful novelty for the company, it can be considered to be an innovation. However, in order to innovate successfully, it is necessary to create efficient innovation processes. Organizational learning (OL) is one of the mechanisms that facilitate innovation.

The chief aim of innovations is to contribute to meeting the needs of the clients, providing for the quality of the services offered and gaining advantages in competition. Using the available knowledge is one of the main components of the innovative strategy. It is possible to group justification for lifelong education of civil engineering organizations into four categories (Chinowski 2000): bridging the management knowledge, enhancing career advancement opportunities, enhancing personnel and professional development and ensuring competency in discipline knowledge. With the focus on long-term benefit, a strong organization knowledge base is a foundation to retain competitive advantages.

RESEARCH METHOD AND METHODOLOGY

The main goal of the first part of educational research is to find which CME competencies (as a learning outcome of education process) leading construction companies in the market consider most important for competitiveness and future industry development. The need to introduce new education opportunities to address emerging business environments is a significant challenge. Once an organization establishes the need for a professional education programme, the next issue that arises is what topics should be studied. This research explores the essential CME knowledge and skills that the successful project and corporate manager in the industry should possess.

The result of Delphi surveys is a statistically significant consensus about necessary CME knowledge and skills. Delphi is an iterative forecasting procedure characterized by three features (Chan *et al.* 2001): anonymity; iteration with controlled feedback; and statistical response. The iterative nature of the procedure generates new information for panellists in each round, enabling them to modify their assessments and project them beyond their own subjective opinions (Corotis *et al.* 1981). The success of the Delphi method depends principally on careful selection of the panel (Edmunds 1999). The Delphi method adopted in this research consisted of four rounds (from September 2006 to January 2007).

RESEARCH RESULTS

Ten panel members represent a wide distribution of top managers from internationally successful Serbian companies, providing a balanced view for the Delphi survey. In the first round of Delphi, experts were asked to provide at least five competencies they considered important for projects and corporate success. In the second round experts were asked to indicate the relative importance using a simple three-level scale: very important, important and not important. Competencies that attracted 50%, or below, in the category of ‘very important’ or ‘important’ were removed. As a result, only 12 (of 17) were included in the round 3 study (Table 1).

In round 3, experts were asked to enter a utility factor against each competence. A utility factor is a factor to indicate the degree of suitability for different learning methods (1 – undergraduate studies; 2 – graduate studies; 3 – learning and training in companies; 4 – internet-based learning; 5 – books and journals-based learning). To obtain a measure of consistency, a statistical test was applied involving the calculation of a coefficient of concordance (W) for the utility factor provided by experts (Siegel and Castellan 1988) using the SPSS computer package. Utility factors of competencies are sufficiently consistent at 0.05 level of significance ($\alpha < 0.05$) or smaller for all suggested competencies. For the round 4 survey, the experts were asked to reassess their score in the light of the average values scored by the panel.

Table 1: Results of round 2 – relative importance of competences

CME competencies as a learning outcomes of education processes	(%)
1. **Project management** (scheduling techniques, alternative procurement, WBS, CAP)	100
2. **Cost engineering** (techniques, modelling, planning, control, estimating and tendering)	100
3. **Construction law** (contract law, claims, forms, alternative dispute resolution, mediation)	100
4. **Production management** (concurrent eng., lean production, supply chain management)	100
5. **International construction** (market entry, growth, profitability and survival, local government and regulatory bodies, market trends)	100
6. **Risk and value management** (risk identification and quantitative approaches, integrated value and risk engineering and management)	100
7. **Development and investment** (valuation, NPV, rate of return, discounted cash flow)	100
8. **TQM** (TQM, sustainable construction, built environment, ISO 9000 and 14000)	88,88
9. **Accounting and financial analysis** (balance sheets, profit measurement, cash flow, profit and loss, financial ratios, budgeting)	88,88
10. **Business management** (organizational structures and culture, leadership, marketing, taxation, processes improvement, partnering)	77,77
11. **Human resources management** (organizational behaviour, innovation, market, recruiting, performances, learning)	55,55
12. **Strategic management** (planning, diversification, competitiveness, markets, portfolio)	55,55

The first seven competencies are project oriented, following industry project management orientation and tradition, and the last five are business and corporate oriented, with a broader educational perspective in the fields of business management, economics, finance and investment.

A set of utility factors from rounds 3 and 4 are shown at Table 2.

Table 2: Concordance coefficient of utility factors in rounds 3 and 4

Selection criteria	Kendall coefficient of concordance – W			Significance level – α	
	Round 3	Round 4		Round 3	Round 4
1.	0.551	0.639	16.0%	0.005	0.001
2.	0.513	0.507	—	0.009	0.009
3.	0.426	0.438	2.8%	0.030	0.025
4.	0.509	0.472	—	0.009	0.016
5.	0.904	0.929	2.8%	0.000	0.000
6.	0.638	0.739	15.8%	0.001	0.000
7.	0.741	0.802	8.2%	0.000	0.000
8.	0.735	0.755	2.8%	0.000	0.000
9.	0.690	0.899	30.3%	0.001	0.000
10.	0.387	0.475	22.7%	0.050	0.015
11.	0.545	0.540	—	0.005	0.006
12.	0.663	0.696	5.0%	0.001	0.001

Industry needs for project management competencies are in accordance with project management-oriented educational programmes (analysed by Oglesby (1990) and Betts and Wood-Harper (1994)) and educational research studies (Long 1997; Singh 1992; Lowe 1991; Wadlim 1985; Hancher 1985; Grinter 1955) which have shown strong industry and educational institutions belief that project management knowledge and skills and successful project execution are the fundamental key to corporate success.

Industry requirements for specific business management and economics competencies beyond a project management level is in accordance with many educational research studies (Chinowsky and Paul 1997; National Academy of Sciences 1995; National Science Foundation 1996), which have considered management knowledge and skills as a critical issue for long-term corporate and sustainable industry success.

CONCLUSIONS

Educational research in the field of programme quality enhancement strategies, IT support for programme development and monitoring, and adaptation of educational programmes to the construction industry needs, are important activities for programmes developers and educational researchers.

Research results have shown industry requirements for broader construction management and economics competencies. In order to successfully respond to industry requirements management and economics educational programmes have to become a mirror image of construction industry needs.

Considering the latest dynamic changes in contemporary business methods, and bearing in mind that lifelong learning is at the heart of the contemporary educational process, educating engineers to successfully manage their projects and companies could foster integrated innovation processes, organizational improvement and sustainable industry development.

AN OVERVIEW OF CONSTRUCTION MANAGEMENT EDUCATION AND RESEARCH AT CENTRAL AND SOUTH-EASTERN EUROPEAN UNIVERSITIES

Anita Cerić[1] and Mladen Radujković

Faculty of Civil Engineering, University of Zagreb, Kaciceva 26, Zagreb, Croatia

The field of construction management has never had an adequate role in educational and research programmes at civil engineering faculties, especially in former socialist countries where all the attention was directed on the technical aspects of engineering. This paper will show how the restructuring of civil engineering curricula according to the Bologna Declaration affects the status of construction management education and research at the universities of central and south-eastern Europe. The research includes twelve universities from nine countries. The results show that there are significant differences within the region reflecting specific features of each country, and that the role of construction management has been increased.

Keywords: civil engineering, developing countries, education, learning, organization.

INTRODUCTION

The 25th anniversary of *Construction Management and Economics* is a good occasion to analyse the position of this field in some central and south-eastern European countries. Many of these former socialist countries have changed their political and economic systems and some of them became part of the European Union. As a part of the European community, they signed the "Bologna Declaration". Despite the fact that a few former and now lately independent Yugoslav countries have not yet joined the EU, they signed this Declaration on higher education as well.

The Bologna Declaration is an obligation undertaken by 29 countries to reform the structures of their higher education system in a convergent way. This commitment is freely taken by each country to reform its own education system. A set of specified objectives of the Declaration are: the adoption of the common framework of readable and comparable degrees; establishment of a system of credits (ECTS-European Credit Transfer System); students', teachers' and researchers' mobility; and quality assurance.

A few years have passed since signing the Bologna Declaration. At the South Eastern Network (SENET) conference held in Croatia earlier this year, the top experts from the fields of organization, management and technology in civil engineering came together to report on new educational programmes developed according to the research projects and the Bologna Process, and to comment on the implementation of the Bologna Declaration. Those reports were used to analyse the condition of construction management in this region.

[1] anita@grad.hr

METHODOLOGY

To get the insight into the status of construction management at the universities, the participants reported on their individual experiences. Representing their countries, the participants of the SENET symposium took part in the section "Education and Research in Construction". This paper reports on the experiences of twelve universities from nine countries. The reports analysed with regard to each individual country aimed to answer the following questions:

- Which institution organizes educational and research work for construction management?
- Which unit within the institution organizes educational and research work (an institute, department, chair)?
- Has the Bologna Process started and when?
- At what level is the construction management course being held within the undergraduate programme, i.e. is there any field connected with construction management or are there only construction management-related subjects?
- At what level is the construction management course being held within the graduate programme – i.e. is there any field connected with construction management or are there only construction management-related subjects?
- Has a postgraduate programme in the construction management field been organized?
- Do organization units conduct, prepare and take part in national and international research projects?

The answers served as a basis for the comparative analysis of construction management's position in the central and south-eastern European region.

ANALYSIS OF REPORTS WITH REGARD TO UNIVERSITIES

The reports covering twelve universities from nine countries were analysed. The participating countries were: Austria, Bosnia and Herzegovina, the Czech Republic, Croatia, Greece, Hungary, Kosovo (Serbia), Republic of Macedonia and Slovakia. Twelve universities were analysed in total (Table 1).

Table 1: Analysed universities

Country	City	University
Austria	Vienna	Vienna University of Technology
Bosnia and Herzegovina	Sarajevo	University of Sarajevo
Czech Republic	Brno	Brno University of Technology
Croatia	Rijeka	University of Rijeka
Croatia	Split	University of Split
Croatia	Zagreb	University of Zagreb
Greece	Athens	National Technical University of Athens
Hungary	Budapest	Budapest University of Technology and Economics
Kosovo (Serbia)	Pristina	University of Pristina
Republic of Macedonia	Skopje	Ss. Cyril and Methodius University, Skopje
Slovakia	Kosice	Technical University of Kosice
Slovakia	Bratislava	Slovak University of Technology, Bratislava

Table 2 shows which institution and unit organizes educational and research work for construction management and whether the Bologna Process has started and when.

Table 2: Institutions, units and starting time of Bologna Process

City	Institution	Unit	Bologna Process
Vienna	Faculty of Civil Engineering	Institute of Interdisciplinary Construction Process Management with three Departments: Department of Industrial Building and Interdisciplinary Planning, Department of Construction Management and Department of Construction Economy	2005/2006
Sarajevo	Faculty of Civil Engineering	Department of Technology and Organization	2006/2007
Brno	Faculty of Civil Engineering	Institute of Structural Economy and Management and the Institute of Technology, Mechanization and Construction Management	2004/2005
Rijeka	Faculty of Civil Engineering	Department of Construction Management, Technology and Architecture	2005/2006
Split	Faculty of Civil Engineering and Architecture	Department of Construction Management	2005/2006
Zagreb	Faculty of Civil Engineering	Department of Construction Management and Economics	2005/2006
Athens	Faculty of Civil Engineering	Department of Construction Engineering and Management	Not yet started
Budapest	Faculty of Architecture and Faculty of Civil Engineering	Department of Construction Technology and Management	2005/2006
Pristina	Faculty of Civil Engineering and Architecture	Chair for Organization and Road Construction	2001/2002
Skopje	Faculty of Civil Engineering	Department of Technology and Organization	2004/2005
Kosice	Faculty of Civil Engineering	Department of Building Technology and Building Materials	2005/2006
Bratislava	Faculty of Civil Engineering	Department of Building Technology and the Department of Economics and Building Industry Management	Report does not state clearly

Table 3 shows at what level the construction management course is being held within the undergraduate, graduate and postgraduate programmes, i.e. is there any field connected with construction management or are there only construction management-related subjects.

Table 4 shows teachers’ activities in conducting, preparing and participating in national and international research projects.

Table 3: Fields and subjects in undergraduate, graduate and postgraduate programmes

City	Undergraduate programme	Graduate programme	Postgraduate programme
Vienna	no field, six compulsory subjects	Field: construction management and geotechnics	Not yet established
Sarajevo	No field, four compulsory subjects	No field, one compulsory subject	Not yet established
Brno	Field: civil engineering management	Field: civil engineering management	Field: civil engineering management
Rijeka	No field, two compulsory and two optional subjects	No field, two optional subjects	Not yet established
Split	No field, two compulsory and one optional subject	No field, two compulsory and three optional subjects	Not yet established
Zagreb	No field, three compulsory and five optional subjects	Field: construction management	Field: project management in construction
Athens	No field, five compulsory subjects	No field, three compulsory subjects	Not established yet
Budapest	No field, five compulsory and two optional subjects	Field: construction management in the graduate programme of both faculties	Not established yet
Pristina	No field, one compulsory subject	No field	Not established yet
Skopje	No field in, one compulsory and one optional subject	No field, two optional subjects	Not established yet
Kosice	Field: construction management	Field: building technology and realization	Field: building technology

COMPARATIVE REPORTS ANALYSIS

Research and educational activities in the field of construction management are being organized at all universities by the faculties of civil engineering except for the faculties at Priština and Split where civil engineering and architecture are taught at the Faculty of Civil Engineering and Architecture.

The faculties organizational structures is quite different. The Brno faculty has two institutes specializing in construction management. The Vienna Institute comprises three departments specializing in construction management. There are two departments specializing in construction management in Bratislava. Athens, Budapest, Sarajevo, Skopje, Split and Zagreb all have a construction management department. There are no independent departments specializing in construction management in Kosice, Pristina and Rijeka.

The implementation of the Bologna Process in undergraduate study began with many difficulties at all analysed universities, except for the one in Athens. It started earliest in Pristina in 2001, whereas it began at other faculties between 2004 and 2006, which means that there are no finished undergraduate students yet enrolled on the graduate study.

The most complete undergraduate programme in the field of construction management is to be found at the universities of Bratislava, Brno and Kosice. Their students can enrol on programmes that are entirely focused on construction management. Students at other faculties can enrol within the existing undergraduate programme on 1–6 compulsory and 1–5 elective subjects. The acceptable level of undergraduate education in construction management can be obtained at the faculties in Athens, Budapest, Vienna, Sarajevo and Zagreb, while the undergraduate level education should be necessarily raised at the faculties of Pristina, Rijeka, Skopje and Split.

The most comprehensive graduate programme in the construction management field is to be found at the Bratislava faculty where students can enrol in two exclusively construction management programmes. At the faculties of Brno, Budapest, Košice and Zagreb, there are graduate programmes specializing exclusively in construction management. The Vienna faculty has a graduate programme in construction management combined with geotechnics. Students at other faculties can enrol in 1–3 compulsory and 1–3 elective subjects within the existing graduate programmes. The education level should be raised here.

Postgraduate PhD programmes in the field of construction management are to be found at the faculties of Bratislava, Brno, Košice and Zagreb. The other faculties have no PhD programme, so should be planned for in the future.

The faculties at Athens, Bratislava, Vienna and Zagreb conduct, prepare and participate in national and international research projects in the field of construction management. The faculties at Brno, Budapest and Kosice conduct, prepare and take part in national research projects while preparing international ones. The faculties at Split, Pristina and Skopje conduct, prepare and participate in national research projects, but do not take part in international research projects, their preparation or implementation. The faculties at Sarajevo and Rijeka do not carry out, prepare and participate in national and international research projects. Except for the latter two faculties, this situation is satisfactory with a continually increasing number of research projects and inter-faculty collaborations on new projects.

CONCLUDING REMARKS

The Bologna Process started in central and south-eastern European Countries. It is too early to draw conclusions on the implementation results, as there are no finished undergraduate students to date. Nevertheless, there are already some inadequacies that should be overcome in future. Construction management education is fundamentally different between the faculties within the region, which essentially makes one of the basic fundamentals – allowing student mobility while ensuring corresponding quality – of the Bologna Process difficult.

The pioneering of new curricula according to the Bologna Declaration led to the significantly more vital construction management role at most faculties. The most complete construction management education at all levels within the region can be obtained at the faculties of Bratislava, Brno, Košice and Zagreb. A high construction management education level can be attained at the faculties of Athens, Budapest and Vienna. The construction management educational level should be raised at the faculties of Sarajevo, Split, Rijeka, Skopje and Pristina.

The researchers from the region are sufficiently and increasingly involved in national and international research projects. The teachers' and researchers' mobility as the prerequisite of the Bologna Process will inevitably lead to ever increasing collaboration and involvement in research projects including those faculties that currently fail to keep pace. Despite some vagueness and difficulties following the implementation of the Bologna Process, the teachers and researchers in the field of construction management at the faculties of civil engineering can be satisfied with the construction management's increasing role with regard to technical aspects of engineering.

WORK–STUDY CONFLICT: MANAGING THE DEMANDS OF WORK AND STUDY IN BUILT ENVIRONMENT UNDERGRADUATE EDUCATION

Anthony Mills,[1] Helen Lingard and Ron Wakefield

School of Property Construction and Project Management RMIT University Melbourne Victoria 3000, Australia

Excessive work demands cause students to have less time available for study, which results in them missing lectures and tutorials. In addition, full-time students appear to be increasingly uninterested in connecting with the broader university experience, and are instead seeking to adopt a minimalist approach to education. This study seeks a more accurate understanding of why students undertake part-time work to the level that they do. This paper examines the extent of employment of undergraduate students enrolled in property and construction at RMIT University Australia. Students responded to a questionnaire on the duration and nature of their part-time work. The results indicate that students are working on average three days per week during semester time. Past research suggests that there is sufficient evidence that this will create work–study conflicts. However, the paper suggests that one of the major issues facing educators is that students themselves believe that part-time employment within their discipline benefits their long-term career. Hence they are reluctant to reduce their work commitment. The paper concludes by suggesting that some form of work-integrated learning process may benefit both the students' learning and their need to obtain work skills.

Keywords: learning, work–life balance, work study, workforce.

INTRODUCTION

In recent years, the cost of personally funding education has increased to such an extent that combining work and study is a necessity for many students (Curtis and Lucas 2001; Curtis and Williams 2002). In fact, Curtis and Williams (2002) write of the 'routinisation' of students combining study and part-time work, suggesting that this is now the norm.

Students seem to accept a view that education is subordinate to employment, and that a university exists to prepare individuals for the world of work. This statement is based on a study of over 500 students who were enrolled in construction-based undergraduate courses in five universities across Australia conducted by the authors a few years earlier (Lingard *et al.* 2003; Mills and Ashford 2004).

Graduates of construction courses enter an industry which is under-supplied with tertiary trained people and salary prospects are very good. This research asked students about their long-term motivations for work and contrasted this with their short-term financial imperatives. In addition, this research considers whether

[1] anthony.mills@rmit.edu.au

universities have a responsibility to their students to assist them in obtaining the best educational outcomes and not just provide them with pathways to a job.

The changing attitudes of students towards their own education are having an impact on the ability of universities to offer broad educational experiences. Past research by the authors (Mills and Ashford 2004; Lingard *et al*. 2003) has shown that students now adopt a minimalist attitude to tertiary education because they have become aware that a degree alone will not guarantee entry to a profession. The value of an undergraduate education is less than it once was. In addition, students are spending larger amounts of time undertaking part-time work. The paper suggests that professional work experience should be included in undergraduate courses in a more formalized manner.

Aims and objectives

This paper builds on previous work which measured the amount of paid work being undertaken by built environment students, comprising quantity surveying and construction and project management. The paper presents an exploratory analysis of the factors predicting construction undergraduates' work conflict with university study. The aims of this paper were to:

- explore the extent to which students work and study; and
- develop a model of the work–study interface, describing the conflict between paid work and study due to time commitments.

The conflict between one's work role and other life roles is an important aspect of the relationship between work and non-work life. Much research and theory building has focused on the conflict between work and family. For example, Greenhaus and Beutell (1985: 77) defined work–family conflict as 'a form of inter-role conflict in which the role pressures from the work and family domains are mutually incompatible in some respect'. In adult life work and family are primary life domains and researchers have developed and tested various models of the antecedents (e.g. work hours, number of children, etc.) and consequences (e.g. absenteeism, low job satisfaction) of work–family conflict. Very little theory development has related to the forms of inter-role conflict affecting adolescents or young adults in full-time education. However, the work–family literature provides a useful basis for this development.

Markel and Frone (1998) suggest that that, in adolescent life, work and education are likely to be primary life domains. Empirical evidence indicates that the number of hours spent in paid employment each week is positively associated with a sense of conflict between work and education among adolescents and young adults (Markel and Frone 1998).

Student attitudes to education

McInnis (2003) stated that the results of various studies over a number of years showed that undergraduate students are unclear about their obligations to the university, and tend to spend less time on tasks that improve their learning experience. Instead, students are more pragmatic about their study and view learning as a vehicle to obtain work. The emphasis is now focusing on the universities who are beginning to detect that modern students have lower expectations of higher education and consequently there is a lower demand for full educational experiences. This according to McInnis (2003) has reduced the student incentives to be engaged in the education process.

Other studies (e.g. Curtis 2000) have found that many students do not consider university to be a full-time occupation and that when not in class they are available to work. This attitude can have a detrimental effect on the cohesion of group work performed outside class and can consume the time available for extra reading around subjects (Watts 2002). This can lead to a climate of individuals straddling their academic work and the labour market while not being fully committed to the cultures of either (Hodgson and Spours 2000).

A model of the work and university interface

For the purposes of this study a model of the work–university interface was developed based upon a model of the work–family interface, proposed and tested by (Frone *et al.* 1997). This model uses work–study conflict as a key mediating variable in the relationship between the time demands of both work and university, students' satisfaction with work and university life and burnout. Thus it is suggested that time demands impact upon students' work–study conflict.

Work–university conflict represents the extent to which involvement in one role (e.g. work) interferes with students' ability to participate in the other role (e.g. university). However, consistent with the research on the work–family interface, work–university conflict is conceptualized as a bi-directional phenomenon. Therefore, a distinction is made between the extent to which participation in paid work interferes with students' ability to meet university responsibilities (work–university conflict) and the extent to which participation in university life interferes with students' ability to fulfil the requirements of their paid work (university–work conflict).

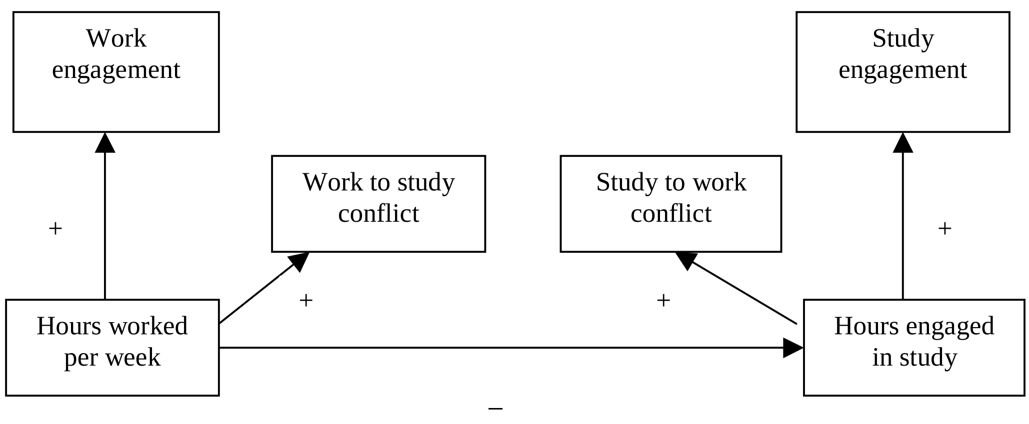

Figure 1: Hypothesized model of work–study interface

In the model (Figure 1), role-related time commitments are regarded as predictors of work–university conflict. Time is a limited resource and university students' time commitments to paid work reduce the time available to fulfil duties required of another role. It may therefore be expected that excessive time involvement in paid work would make the fulfilment of university requirements more difficult for students, giving rise to a sense of work–university conflict. Conversely, the time requirements of university might negatively interfere with students' work responsibilities, for example when a lecture clashes with a scheduled project meeting. Thus it was expected that there would be a positive relationship between the number of hours spent at university and university–work conflict.

This research focused on the motivations of students to seek work during semester time. The hypothesized model in Figure 1 has been used to validate work–study conflicts of construction students. The next section of this paper outlines the research instrument used to collect the data on student attitudes to work.

METHOD

The research was based on a paper-based questionnaire, which was adapted from similar studies of work–family conflict. Three academic members of staff from RMIT University were contacted; each was asked if they would assist by offering a questionnaire to their students enrolled in the RMIT University, property construction and project management courses. Students were asked to respond to questions on a number of issues including: the reasons for seeking work, the type of work undertaken, and the amount of time spent in paid employment and the amount of time spent studying during semester.

The survey forms were given to each course coordinator for distribution to students in class. The completed survey forms were returned anonymously into a closed box. The data were entered into an Excel spreadsheet, which was later converted in to SPSS for analysis. In addition, each course coordinator was asked to specify the total number of students enrolled in their courses. The overall response rate was 23% (104/450) indicating that the survey represents a sufficiently large sample of the courses (Table 2).

One of the principal aims of the research was to explore more deeply the impact of paid work on the undergraduate student study experience. Past research by the authors (Mills and Ashford 2004; Lingard *et al*. 2003) indicated that students were working sufficiently long hours to experience conflicts with university study. Work to study conflict was measured using a modified version of the bi-directional work–family conflict scale developed by Netemeyer *et al.* (1996). Items were reworded to replace aspects of family life with study or university life. For example, 'the demands of my work interfere with my home and family life' was changed to 'the demands of my work interfere with my study'. Items were rated on a seven-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree).

The next section presents the results of the questionnaire, including the amount of time students spend on work and study. In addition, the respondents were quizzed about their perceptions of their work–study conflicts, these data were then analysed to produce a model of the work–university interface.

RESULTS

The number of hours students work during semester time was relatively high. Table 1 indicates that students spend on average 24 hours per week engaged in part-time work during semester. This is slightly higher than the amount of time spent by students in a prior study of built environment courses around Australia. The results of previous research conducted by the authors (Mills and Ashford 2004; Lingard *et al*. 2003) showed that other university students averaged 18 hours of paid industry work per week during semester time.

Table 1: Average number of hours worked per week (Semester 2) by type and year

	Casual work	Industry-based work	Average
Year 1	19.0	5.3	17.1
Year 2	17.5	23.3	20.2
Year 3	19.8	17.1	17.7
Year 4*	26.2	41.1	38.1
Total	19.7	27.1	24.0

Note: * 4th year students are only enrolled in research projects that require only limited class attendance.

Table 1 shows the average number of hours worked each week by type of employment. Industry-based work comprised employment in junior positions in quantity surveying, construction and project management. Casual jobs were those that were not related to the construction industry, and did not have a career dimension that was relevant to the student's course of study.

Casual work (i.e. non-industry work) consumes the fewest hours each week (19.7 hours), while working in industry-related jobs consumes more time (27.1 hours). An independent sample t-test was conducted to assess whether there were significant statistical differences between the work types. Students working in industry-based occupations do work significantly more hours per week than those in casual employment at the 5% level ($t = –0.2.882$, $p = 0.005$).

As expected, the results of Table 2 shows that most students tend to work in industry-based jobs in the latter stages of their course. The results show that only 14% of Year 1 students work in industry; this rises to 80% by Year 4. This shift begins to occur from about the third year when students reduce their preference for casual-based work. This indicates that students perceive there is more benefit in pursuing industry-based work compared to casual work when it becomes available.

Table 2: Number of students undertaking work by type and year (Q6)

	Casual work	Industry-based work	Total
Year 1	19 (86%)	3 (14%)	22 (100%)
Year 2	12 (52%)	11 (48%)	23 (100%)
Year 3	6 (21%)	23 (79%)	29 (100%)
Year 4	6 (20%)	24 (80%)	30 (100%)
Total	43 (41%)	61 (59%)	104 (100%)

Motivations for seeking work

The survey asked respondents about their reasons for seeking work; the questions were based on a similar study by Lucas (1997). The students were offered a limited list of seven reasons for work. The results of the study (Table 3) indicate that financial gain was not the most important reason why students work. Instead, students believed that work was mostly undertaken because it benefited their long-term career, as well as their undergraduate studies.

The results of present research support the work of Lucas; students work for a variety of reasons but financial imperatives are not the main motivation. This result indicates that students perceive industry-based work is of greater educational/career development value than its ability to provide financial reward. This also supports the work of Micklewright *et al.* (1994) who suggested that the unknown future state of the industry encourages students to seek work as soon as possible.

Although the students stated that the most important reason they seek industry work is because it benefits their long-term career, it may be reasonable to suggest that the benefits may be due to maintaining industry contacts and developing a stronger resumé for future job applications. This may be occurring in spite of the negative impact on their educational experience at university.

Table 3: Indicate the extent to which the following statements relate to your reasons for work (disagree 1 to agree 5) (Q17)

Reason for work	Mean score	Rank
It benefits my long-term career	2.3	1
Because it is beneficial to my studies	2.7	2
To pay for my essential living expenses	2.7	2
To provide income for my social activities	2.7	2
To save money for special purposes	3.0	5
I feel it necessary to have a job in industry	3.1	6
The rates are better than for casual employment	3.8	7

An independent sample t-test was conducted to assess whether there were significant statistical differences between the reasons for work (Q17) between various groups within the survey. The results of Q17 were analysed by university, gender and course, and no statistical difference was evident at the 5% level. This indicates that student motivations for work are essentially the same across all major subgroups within the sample.

The overall results indicate that students engaged in a significant amount of paid work while enrolled as full-time students. There appears to be sufficient evidence that students may experience work–university conflicts. The next section of the paper examines students' perception of that conflict and whether it can be predicted by the time spent at work or engaged in university learning.

Factor analysis of work and study

Past literature on work–family conflict suggested that there were a number of issues that resulted from the amount of time students spent working and studying. A set of questions were devised to examine the effects of:

- work to study conflict;
- study to work conflict;
- work engagement;
- study engagement.

The questions in Table 4 show factor loadings that applied to the above aspects of work–study interfaces. A principal components factor analysis with varimax rotation confirmed the discriminant validity of the four dimensions. The results of this analysis are presented in Table 4. Items loaded clearly on the four factors which explained 76% of the variance.

The factor loadings were saved and correlated with the time spent in work and time spent engaged in study. The next section of the paper examines the correlations of each of the components and offers some possible explanations of the results.

Table 4: Factor analysis of work–study conflict

Survey question	Component			
	1	2	3	4
I am enthusiastic about my paid work	0.066	–0.072	0.812	0.136
My job really inspires me	–0.026	0.065	0.930	0.040
I find my job full of meaning and purpose	0.032	0.118	0.881	0.091
I am enthusiastic about my university study	–0.014	–0.012	0.187	0.861
My study really inspires me	–0.115	0.053	–0.052	0.936
I find my university study full of meaning and purpose	0.018	–0.183	0.153	0.868
The demands of my work interfere with my study	0.875	0.126	0.053	0.043
Because of my job I can't involve myself as much as I would like in my study	0.913	0.094	0.063	0.017
The things that I want to do at university do not get done because of the demands my job puts on me	0.864	0.213	–0.018	–0.140
There is conflict between my job and the commitments I have as a university student	0.831	0.319	–0.039	–0.076
The demands of my study interferes with work-related activities	0.463	0.618	0.122	–0.017
I sometimes have to miss work so that study responsibilities are met	0.422	0.691	0.182	0.046
Things I want to do at work do not get done because of the demands my university study puts on me	0.307	0.827	0.077	–0.064
My study interferes with my responsibilities at work, such as getting to work on time, accomplishing daily tasks and working overtime	0.251	0.833	0.058	0.026
My employers and/or co-workers dislike how often I am preoccupied with university life	–0.162	0.623	–0.186	–0.145

Notes: Extraction method: principal component analysis. Rotation method: varimax with Kaiser normalization. A rotation converged in 5 iterations.

Correlations

Bivariate Pearson correlations between the variables measured in the research are presented in Table 5. Inter-correlations between the factors and the work and study hours showed that little conflict seems to exist. Surprisingly only work to study conflict was significant. Contrary to expectations, neither the number of hours students spent in paid work nor the number of hours per week engaged in learning were significantly correlated with the study to work conflict dimension.

The results (Table 5) indicated that work to study conflict was also positively correlated with hours engaged in learning ($r = 0.264$, $p = 0.010$). Hours worked per week was negatively correlated with work to study conflict ($r = –0.371$, $p = 0.000$). And also hours work per week was also negatively correlated with hours engaged in learning ($r = –0.434$, $p = 0.000$).

Table 5: Bivariate correlations between the variables

	Factor	1	2	3	4	5	6
1.	Work to study conflict	1					
2.	Study to work conflict	0.000	1				
3.	Work engagement	0.000	0.000	1			
4.	Study engagement	0.000	0.000	0.000	1		
5.	Hours worked per week	–0.371**	–0.075	–0.016	0.170	1	
6.	Hours engaged in learning per week	0.264**	–0.063	0.152	–0.071	–0.434**	1

Note: ** Correlation is significant at the 0.01 level (2-tailed).

The results of the survey have shown that students seemingly work long hours in industry-based jobs while also engaged in full-time study. Past research indicated that this mix was a recipe for conflicts. The incidence of high levels of work does translate into work to study conflicts, but surprisingly not into study to work conflicts. This suggests that students are concerned more about meeting work obligations, and less worried about missing learning opportunities and study. The next section of the paper discusses the above findings and draws some conclusions.

DISCUSSION

Past research has shown that work in excess of the 10–15 hours per week is believed *not* to be beneficial to student learning (Curtis and Lucas 2001). The results of this research showed that students appear to be working longer than what may be considered useful to gain work skills. Instead, students appear to be increasingly uninterested in connecting with the broader university experience, and instead seek to adopt a minimalist approach to learning.

The results of the RMIT study validate the previous studies of other built environment courses across Australia. Students in built environment courses tend to work longer than average for all students in Australia which is 14.7 hours per week (Mcinnis 2003).

This seems to be supported by the results of Table 3 which shows that highest ranked reason for work was that it benefited their long-term career. The results show that students change their preference from casual work in the early part of their course to industry-based jobs in the later years. It seems that over time the benefits of casual jobs become more limiting because it is not possible to obtain career experience while undertaking non-industry work. The undergraduates in the study seek property- and construction-related positions as soon as they can in order to begin their careers.

The study confirmed that many students were working and studying for long hours during a typical semester week. This suggested that there is some evidence to suggest that work–study conflict exists, although the conflict seems to be asymmetrical and does not seem to affect students' ability to meet the demands of study. The next section explores some aspects of the conflicts as perceived by the student respondents.

Work to study conflict

Past research based on work–family conflicts suggested that impacts were expected to be bi-directional in nature. In other words, there should be both study to work conflict, and work to study conflict. The results of this research were somewhat surprising.

Students' experiences at the work–university interface are presently asymmetrical with students indicating a greater tolerance for the time demands of paid work than those of university study. Overall these findings suggest that the students in the present sample resent the time commitments required by university.

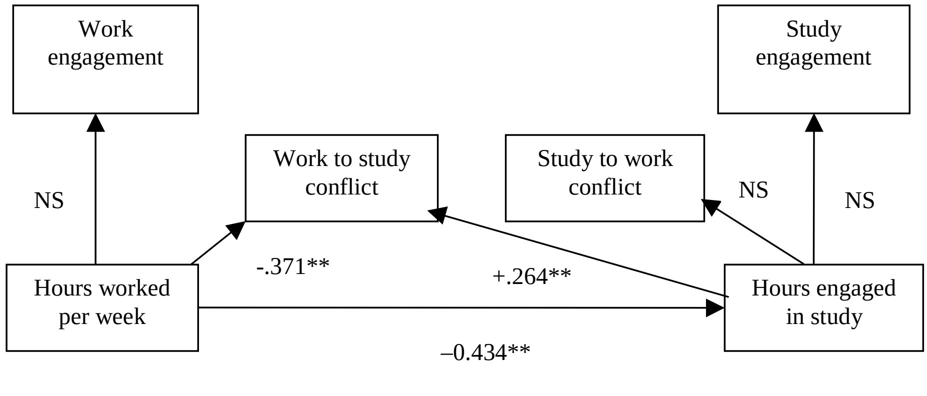

Figure 2: Correlation coefficients for work–university interface

Notes:** Correlation is significant at 0.01 level (2-tailed). NS Correlation is not significant.

Students who spend more time at work seem to spend less time at university engaged in study. The results of correlation analysis in Table 5 have been used to form the model in Figure 2. The model indicates that when students worked longer hours it reduced the time available for university but that contributed to less work to study conflict. In addition, there were no significant correlations with the study to work conflict.

The non-significant relationship between time involvement and students' perceptions of work–university conflict was unexpected. This finding indicates that work–university conflict does not mediate the relationship between time demands of work or university and the outcome variables measured in the study. This is in contrast to the role played by work–family conflict, which mediates the relationship between time demands of work and burnout in employed adults. This result also suggests that, among the students in our study, the amount of time spent in paid work may be a less significant source of work–university conflict than other variables. This finding is similar to a report by Ackerman and Gross (2003) that marketing students in an American university were less affected by a perceived scarcity of free time than by an individual's emotional reaction to work and university commitments.

Future research should examine the extent to which variables other than time involvement predict students' work–university conflict. Other variables of interest may include subjective perceptions of the qualitative and quantitative workload, available resources and support and the amount of control that the students are able to exercise over their work and university arrangements. Students' commitment to their work and/or their university education was not measured in this study but it is possible that these findings reflect that the role of employee is more salient to property and construction students than the role of university student.

CONCLUSIONS

In higher education research there is a growing interest in the importance of work-based learning, which is defined as linking learning to the work role. The significance of this research was that it demonstrated that when students worked longer hours it reduced the time available for university, but that it also contributed to less work to study conflict. In addition, there were no significant correlations with the study to work conflict suggesting that students placed greater value on work experience than on study, particularly in the final years of their course. If this is the case universities should consider whether the length and type of education on offer is still appropriate to students intending to enter the construction industry.

Garavan and Murphy (2001) suggested that work-based learning requires consensus and agreement from key players in the learning process, namely: the individual student, the employer and the higher education institution. Work-based learning helps to bridge the gap between theory and practice by permitting reflection on actions and the testing out and reapplying of theories when faced with dilemmas and when confronting new situations in the workplace. The results of this research suggest that some form of work-based learning may provide the necessary link between the students' need for work and the necessity for deeper educational experiences as a student.

Past research (Garavan and Murphy 2001) identified a number of different models of work-integrated learning, none of which has been examined in this research. For example, one model explores how each course could develop an alternative model of assessment so that students can choose to do either the standard piece or an equivalent work-based one, which draws on and uses their paid work experiences/activities. In other words, students could either do the assignments as set by their lecturer, or alternatively negotiate with the lecturer to undertake work-based tasks that can be used for academic assessment. This requires great care to ensure that lecturers can assess the work-based experiences against rigorous academic standards rather than just industry custom and practice, i.e. the alternative assessment must capture students' independent reflection and learning. This is also likely to require some cooperation and commitment from the students' employers.

Another model identified a set of capabilities in the programme which could give credit for a portfolio of evidence that documents the development of these capabilities from work-based activities. Multiple assessment options could be developed and spread across the programme or be clustered around discipline-specific capabilities. In this way recognition of concurrent relevant industry-based learning will be acknowledged and formalized. In other words, academic credit may be given to the acquisition of broad professional competences gained in the workplace. The research by Sher *et al.* (2004) matched work-based learning experiences with the development of professional competence of the Australian Institute of Building.

However, is unclear whether universities should require industry experience as a formalized component of the course. University policies generally do not allow students to be remunerated while undertaking practical work experience that is assessed as part of an undergraduate degree. While industry would readily accept free student practical experience labour, this may be an unreasonable expectation on the student as well as a financial burden. In addition, university monitoring of student experiences would then be necessary as part of the package for quality assurance purposes which leads to higher educational costs to the university.

Although there is substantial past research that shows that work can provide very positive benefits for obtaining employability skills, this study suggests that there are three major challenges. First, to identify the employability skills and attributes that students need to obtain. Secondly to identify the model for learning that best integrates their work and study experiences. Thirdly, to develop tools that allow students access to the learning experiences.

The development of a partnership between the university and the industry in providing work experience that complements the programme of study would be helpful. Without this partnership, students may not get the range of experience they need and may struggle to find the linkages between theory and practice. More research is needed to determine the form and structure of the work-integrated learning programme. Nevertheless the results of this research show that such a programme is likely to be very well received by students. Universities have a responsibility to their students to assist them in obtaining the best educational outcomes from their degree courses. Given the reality of student employment, this must include being flexible and supportive of students in paid work.

LEADERSHIP RESEARCH IN THE CONSTRUCTION INDUSTRY: A REVIEW OF EMPIRICAL WORK AND POSSIBLE FUTURE DIRECTIONS

Shamas-ur-Rehman Toor[1] and George Ofori

Dept of Building, School of Design and Environment, National University of Singapore, Singapore 117566

Researchers have traditionally focused on technical and managerial features of construction projects and have largely ignored the subject of leadership. However, recent interest in the subject has resulted in global research initiatives that aspire to understand leadership in a more holistic manner. To further the research on the subject, it is important to review the existing body of knowledge and draft a road map for the future. For this purpose, a review of empirical works on leadership in the construction industry is reported in this paper. Findings reveal that most empirical studies focus on behavioural dimensions of leadership while ignoring numerous important dimensions, particularly leadership development. For future research, leadership studies need to improve quality in terms of research design, level of analysis, developmental perspective of leadership and objective measurement of leadership outcomes. Along with past and ongoing research trends, a brief agenda is discussed for further research in the area of leadership in the construction industry.

Keywords: construction industry, future studies, leadership, project management.

INTRODUCTION

For several years, the mainstream paradigm of construction industry leaders has been technology and project oriented (Pries *et al*. 2004) and focused on management, to the exclusion of leadership (Skipper and Bell 2006a). This conventional orientation of construction firms and conservative culture of the industry is resulting in a shortage of skilful ‘project leaders’ although it has produced a large number of ‘project managers’ (Toor and Ofori 2006). Other studies have noted that construction managers are hardly perceived as leaders and are often considered as managers (Russell and Stouffer 2003). The prevailing situation is, therefore, regarded as ‘leadership crises’ by some scholars who believe that construction leaders should be capable of changing the conventional paradigm of management in the industry and setting exemplary standards for other businesses to follow (see Toor and Ofori 2006).

The lack of focus on leadership is not only the case in practice; academic research also seems to have done little in the area (Odusami *et al*. 2003; Chan and Chan 2005). Langford *et al*. (1995) opine that the low volume of leadership studies in construction is due to the lack of knowledge of the industry on the part of social scientists and a lack of understanding of social sciences by those in the industry. In the construction literature, studies on leadership mostly concentrate on investigating the motivational factors and the personal characteristics of project managers (Dulaimi and Langford

[1] shamas@nus.edu.sg

1999). However, in recent years, there has been an increase in the number of publications with an expanded range of topics related to leadership in the construction industry.

The latest initiatives of the International Council for Research and Innovation in Building and Construction (CIB) have also resulted in formation of a task group on leadership in construction (TG64), which has released its ambitious plans. The introductory statement of TG64 articulates that "the challenges of globalization, new markets, changing demographics and new technologies are transforming the focus of construction leaders and require the implementation of new competitive strategies, forging of international alliances and the adoption of new practices. The industry needs to develop, implement and support the leadership required to successfully lead construction projects and organizations in the new construction environment."

To carry out more work on leadership in the construction industry and achieve the objectives of TG64, it is important to review the work that has been done on different sub-topics of leadership and consider where the state-of-the art research stand today. In the light of past research and ongoing changes in the global construction environment, a broader road map for leadership research in the construction industry can be prepared to meet the current needs and the long-term development of construction industry leaders. To put forward a future research agenda for leadership research in the construction industry, this paper presents a review of empirical works that have been carried out in the past. The main objectives of this paper are: (i) to review the published empirical work on leadership in the construction industry research literature; (ii) to identify the past and current research trends on the subject; and (iii) to propose the future research developments.

METHOD

To review empirical studies on leadership in the construction literature, a search was carried out in various online databases. Combinations of several keywords were used to search publications on leadership in the construction industry, which resulted in a broad selection of a large number of works that included empirical, qualitative and descriptive articles, notes, features, book reviews and case studies. To separate the empirical studies from the larger pool, the following selection criteria were established: (a) the study principally focuses on the subject of leadership; (b) the study is empirical in nature; (c) the study is carried out in the domain of the construction industry; and (d) the study is peer-reviewed and published in an international journal.

In addition to searching databases, various internationals journals in the domain of construction, engineering and project management were also searched. Thus, it is pertinent to note that this review focuses only on empirical studies published in peer-reviewed journals, and does not include any conference papers, research reports, unpublished dissertations, feature articles, magazine articles, theoretical and conceptual papers, and any books or book reviews. Restriction of scope to empirical work is in order to avoid any possible confusion between theoretical and empirical work. This restriction is helpful to clearly define the scope of review, present explicable and objective findings, and make recommendations for future work. The review is also limited to studies in the English language. Considering the above criteria, studies were coded and further short listed resulting in a list of 39 articles. Reference lists in all the selected articles were again checked to circumvent the chance of missing any studies. Consequently, five more studies were included in the review list. In the second stage, these studies were further coded with respect to their research framework, study objectives, methodology, type of respondents, country of research, principal outcomes of study, future research directions, and so on. In the following sections, some findings from the review are presented.

Table 1: Summary of findings

Distribution of publications in JOURNALS		Distribution of Publications over YEARS		Distribution of studies over various FRAMEWORKS	
Journal Title	**N***	**Year**	**N**	**Framework**	**N**
International Journal of Project Management	12	Before 1990	2	Fiedler's Least Preferred Coworker (LPC) Scale	9

International Journal of Human Resource Management	1			Kouzes-Posner Leadership Practices Inventory (LPI)	1
Journal of Occupational Psychology	1				

* N denotes the number of studies

FINDINGS

Some general observations from the review are shown in Table 1. It indicates that most studies have been published in the *International Journal of Project Management* followed by *Construction Management and Economics* and ASCE *Journal of Management in Engineering*. It is also apparent from Table 1 that most studies have been carried out in the UK followed by USA, Hong Kong, Singapore and Thailand. Some studies are conducted in more than one country (e.g. Chan and Chan 2005; Powl and Skitmore 2005; Muller and Turner 2007). The distribution of the studies according to the time of publication reveals that very few studies are published before 1996. However, the last decade has witnessed a considerable increase in leadership studies in the construction industry.

A summary of the frameworks that researchers have employed in their investigations on leadership-related topics is summarized in Table 1. It can be seen that Fiedler's (1967) Least Preferred Coworker (LPC) scale has been used most frequently, followed by Blake and Mouton's (1978) nine-factor leadership grid. Despite its widespread use in the mainstream leadership studies, Bass and Avolio's (1990) transformational leadership (or MLQ) has been employed only in two of the studies considered. In most studies in this review, researchers have used their own questionnaires, interviews, or case studies to analyse and describe the leadership behaviour of their respective subjects. Table 1 also shows that studies included in the review target a wide range of construction professionals. Most studies have focused on project managers, site managers, project professionals, project engineers and building professionals. Few studies have been conducted on executive level managers and other professionals such as quality managers and quantity surveyors. In few studies, foremen have been either included as raters in a 360 degree loop (Ogunlana *et al*. 2002) or as principal subjects (Seymour and Elhaleem 1991).

RESEARCH TRENDS IN THE PAST

Dulaimi and Langford (1999) observe that most studies on leadership in the construction industry concentrate on investigating the motivational factors and the personal characteristics of project managers. This review also confirms that more than 30% of studies directly or indirectly address leadership dimensions such as behaviours, traits, characteristics and attributes (e.g. Seymour and Elhaleem 1991; Muir and Langford 1994; Dulaimi and Langford 1999; Fraser 2000; Cheung *et al*. 2001; Ogunlana *et al*. 2002; Carr *et al*. 2002; Odusami 2002; Dulaimi 2005; Butler and Chinowsky 2006; Skipper and Bell 2006).

However, recently some research works have been published on leadership development (Skipper and Bell 2006), emotional intelligence (Butler and Chinowsly 2006), superior-subordinate relationship (Lee *et al*. 2005), leadership in multi-cultural projects (Makilouko 2004), effectiveness of leadership and innovation (Bossink 2004; Nam and Tatum 1997), thinking style for managing change (Tuilett 1996) and emerging managerial competencies (Debrah and Ofori 2005). Research on factors that hinder the leadership performance of project managers also continues to attract researchers (see Mustapha and Naoum 1998; Zimmerer and Yasin 1998; Powl and Skitmore 2005; Low and Chuan 2006). Another research trend that continues to persist is power and authority of leadership in construction organizations (e.g. Feng and May 1997; Fellows *et al*. 2003; Anita and Fang 2006).

Some research endeavours have also been devoted to match project managers with projects based on various personality dimensions (Ogunlana *et al*. 2002; Muller and Turner 2007). The majority of the leadership studies selected in this review also focus on effectiveness, performance or simply the job-related outcomes of leadership (Chan and Chan 2005; Fraser 2000; Fraser 1999; Djebarni 1996; Mustapha and Naoum 1998; Seymour and Elhaleem 1991; Odusami *et al*. 2003; Carr *et al*. 2002; Bossink 2004; Powl and Skitmore 2005). Similar contemporary and nascent research trends on leadership in the construction industry have also been summarized by Goodman and Chinowsky (2000) and are shown in Table 2.

Table 2: Current and emerging focal areas in leadership research

Leadership	**Current Focal Area**	**Emerging Focal Area**
	Academic management curriculum	Decision making under uncertainty
	Developing leaders and managers	Negotiation
	Leadership skills and traits	Senior management teams
	Organization culture, structure and dynamics	Pricing
		World-place politics
		Working with investors
		Ethics
		Coaching
		Managing organizational change
Managing People	Benefits programmes	Career development
	Employee performance	Workplace diversity
		Manager performance
		Work-family conflict
		Women executives
		Recruiting and training
		Workplace regulations

IMPORTANT ISSUES AND FUTURE DIRECTIONS

Leadership constructs

From the review presented earlier, it can be noticed that leadership research in the construction industry has predominantly used very few leadership constructs that include contingency theory, leadership grid and transformational leadership. For example, no empirical studies have been carried out on charismatic, servant, spiritual, shared and authentic leadership. This review will help to comprehend what leadership style is most suitable under different circumstances and stages of a construction project. It will help to explore which leadership approach is most suitable for attaining particular objectives, such as to enhance construction productivity or the quality of the project management. It will also help to develop a framework that is most suitable for leadership development in construction industry professionals.

Level of analysis

Most studies have focused on leadership of project managers, site managers and construction professionals. However, studies have shown that foremen and supervisors also have a vital role in getting the job done on the construction site. Therefore, it is important to analyse the leadership at all levels of construction organizations. Examinations at dyadic, group and organizational levels also have the potential to enhance the understanding of leadership in the construction industry. Analysis should also be extended to examine the leadership issues in the cross-cultural and cross-organizational teams that have become a common feature on construction projects, especially those undertaken by joint ventures and consortiums.

Design of studies

In this review, it is noticed that most studies utilize the traditional approach of survey questionnaires and interviews. There are few case studies of firms and individuals; however, the methodology adopted in these does not go beyond interviewing the subjects or analysing some official documentation to capture certain leadership behaviours. Further, it is also found that the majority of the studies in this review are cross-sectional in nature. Leadership, being temporal in nature (Goodman *et al*. 2001; Avolio and Gardner 2005), must be examined through longitudinal studies. Particularly, in construction projects, some researchers have argued that project managers tend to employ different leadership styles during different stages of the project. This conclusion needs further exploration through longitudinal studies. Such studies can also explore how project managers adapt themselves to new projects and what influences their leadership styles in a new environment.

Multidimensional studies can examine the leadership style of those project managers who lead a number of projects at the same time. It is likely that they employ different styles in different situations, team composition and project variables that require a different leadership approach. It is pertinent to explore how they manage to perform under various situations and environments, through longitudinal and multidimensional studies.

Researchers in mainstream leadership research have used several innovative ways to study leadership. Particularly many have employed qualitative methods to analyse the leadership style and behaviour of their target subjects. Observational studies have also interested several scholars, especially in the case of transformational and charismatic leadership studies. Studying leadership through narratives, personal writing, stories or biographies has also been employed by many. Recently, psychometric neuro-scientific methods have also generated much interest in the study of leadership behaviour.

These studies can also focus on how the authenticity of leadership is perceived differently in different contexts such as: culture, religion, ethnicity and gender. Other dimensions on which project leadership research can focus are organizational culture (transactional, transformational etc.), type of organization (developers, contractors, architects, designers, quantity surveyors etc), size of organization (small, medium, large; local, multinational, etc.) and focus of organizational activity (building, roads, and so on). Such multi-level and multi-dimensional analyses can help to identify and explain specific leadership needs and demands of organizations in different contexts; and understand the tactics that leaders use to be more effective and successful in different contexts.

Leadership development

The review in this paper reveals that few leadership studies in the construction literature focus on leadership development and almost no works have considered designing effective interventions for leadership training and development of construction professionals. Industry has so far relied on professionals and managers educated on conventional academic curricula, and the organic growth of leaders through experience. However, in today’s competitive environment, there is a need to accelerate the leadership development process of capable individuals. Competitive advantage can be obtained by investing in leadership training and development of professionals at all levels of organizations. For this purpose, it is important to explore the antecedents that stimulate the leadership schema and result in leadership development. Research endeavours in this direction are likely to produce results that are useful for designing leadership development programmes for construction professionals. Future research can also focus on designing and testing interventions to develop special skills required to lead in the construction industry.

Leadership outcomes

The review in this paper shows that leadership studies mostly base their conclusions on perceptions of respondents without providing objective measurement of outcomes of leadership process. Hence, there is a need to evaluate leadership performance by objective measurements such as general effectiveness and performance, follower satisfaction, organizational and project performance, personal growth of leaders, influence on innovation, effectiveness in terms of cost, time and quality, management and satisfaction of stakeholders, decision making and dispute resolution capabilities, interface management, etc. Objective measurement of leadership outcomes will help to estimate return on the investment in leadership development programmes.

CONCLUSION

The principal purpose of this paper is to analyse key aspects of the published leadership research in the construction industry. The paper details various past trends, predicts several future trends and suggests certain areas in which future research on leadership in the construction industry could focus. The authors argue that leadership research and development should be undertaken at a macro-scale so as to transformation the industry's culture. It is also suggested that comprehensive analyses of descriptive studies, unexplored models and qualitative studies should also be performed to mark what has been done and what needs to be done on leadership in the future research.

The present authors hope that more studies on leadership in construction will be undertaken in the countries with mature construction industries such as Europe, the US and Japan, as well as those have, or are expected to have, large volumes of construction work such as Brazil, China, India, Russia, South Africa and the United Arab Emirates. Finally, it is hoped that CIB TG64 will provide the leadership in the work that is necessary in this important area.

LIVE YOUR LEGACY, THAT IS WHAT YOU LEAVE: FUTURE ASPIRATIONS OF LEADERS OF SINGAPORE CONSTRUCTION INDUSTRY

Shamas-ur-Rehman Toor[1] and George Ofori

Department of Building, School of Design and Environment, 4 Architecture Drive, National University of Singapore, 117566

Leadership has been looked at through various lenses such as behaviours, styles and skills. Recent works have attempted to view leadership from the lens of the legacies that leaders want to leave behind. The legacies of the leaders do not only provide a perspective about the impact they want to have on the people and organizations but also portray the future they want to see. Interviews with leaders of professional organizations and AEC firms in Singapore show their desires for developing their followers as leaders and turning their firms into successful organizations. The interviews also reveal the anxiety of the leaders about issues in the industry such as lack of professionalism and adversarialism. Thinking about leadership purpose and leaving a legacy is not something the leaders should be doing in the last stages of the careers. Rather, the leaders should be clear about what they want to achieve from their leadership and what impact they want to have on their followers and organizations. This can help the leaders to understand and then live the legacies they want to leave behind.

Keywords: construction leaders, leadership, legacy, purpose, Singapore.

INTRODUCTION

Good leaders live the legacies they wish to leave behind. In their daily actions, decisions, interactions and communications, intentionally or otherwise, they demonstrate their inner values, beliefs and motivations. With every passing day, they leave an impression and make an impact on others; this may be positive or negative. Thus, Blanchard (in the foreword of Brooks *et al*. 2004) notes: ‘The legacy you live is the legacy you leave’. One common desire among good leaders is that they want to have a lasting impact on their followers and organizations. Some who are involved in social activities also wish to influence society in the long term. They want to be remembered in good lexis.

Galford and Maruca (2006) note that good leaders want to achieve success while looking into the future, whereas looking into the past, they would like to know that their efforts were appreciated and perceived positively by their followers and colleagues. They wish to think that they influenced people in a constructive manner and their efforts made a difference. They like to be remembered for the accomplishments they attained for their organizations and their people. Although ‘leadership legacy’ carries a positive connotation, it is important to acknowledge that a legacy does not have to be necessarily positive. However, good leaders want to leave good legacies.

[1] shamas@nus.edu.sg

This study seeks to discover the legacies which leaders in the construction industry of Singapore would like to leave behind. The articulation of such legacies would indicate: the future the construction leaders foresee; the changes they desire to occur in their own organizations and the construction industry; and what the leaders wish to leave behind in their organizations, their professions and the construction industry.

WHAT IS LEADERSHIP LEGACY?

Galford and Maruca (2006) consider a legacy as the enduring impact which a leader has on colleagues, followers, successors, organizations and external stakeholders. A legacy is the scale and scope of a leader's influence on others during the leader's period of time in a given position or in a given company, all these coloured by the judgment, or guiding principles, that the leader applies most consistently in his/her decisions (Galford and Maruca 2006). Brooks *et al*. (2004) consider leadership legacy as the 'sum of total difference' a leader makes in people's lives. This 'difference' can be direct or indirect, intentional or unintentional, short-term or long-term. Freeman (2004) maintains that the 'true legacy' a business leader leaves behind 'is what happens to the company' after the leader has completed the term of office, or departed. Nash and Stevenson (2004) note that legacy is a way to establish values or accomplishments so as to help others to find their own success in future, and is attained by investing in people, innovation, customer needs and systems. There are important questions to consider here: what kind of impact leaders want to have on others; who should receive more or less of the impact; and how long the impact should last.

Galford and Maruca (2006) argue that leadership legacy must not be equated with, or related to, vision, mission and strategy. They observe that vision, mission and strategy have their roots in the organization. On the other hand, legacy is grounded in the individual. It is not all about what people think about the leaders after they leave. It is rather the values and ideals they leave behind. It is important to note that leadership legacy seems to have a strong association with leadership purpose that has been considered to be fundamental to leadership development and effectiveness (George and Sims 2007; George 2003). If the leaders have a sense of purpose and they want to achieve a goal in their leadership, they find congruence between their purpose, motivations, needs of followers and expectations of their organizations (George 2004). The 'understanding of purpose' is analogous to 'leadership legacy', which implies that leaders with a sense of purpose want to create a difference in their organizations and in the lives of their followers by creating, living and leaving powerful and positive legacies.

LEGACY LEADERSHIP

While explaining the concept of legacy, Whittington *et al*. (2005) present the model of 'legacy leadership'. They suggest that 'the legacy of the leader's influence is perpetuated through the followers' incorporation of legacy principles into their lives as they become leaders' (Whittington *et al*. 2005: 749). Such leaders who are able to establish positive values and inculcate the 'legacy principles' into followers and organizations are called 'legacy leaders'. The theoretical model of 'legacy leadership' purports that the behaviour of such leaders is consistent with their internal motivation. As a part of their theory, they present three propositions:

> the motives of a legacy leader will influence the leader's choice of methods; the effects of a legacy leader's motives and methods on the followers' changed lives will be mediated by the followers' perceptions of those motives and methods; the impact of legacy leadership will be measured by changes in followers' lives that come to reflect the motives and methods of their leaders.

An example of the successful transmission of a leader's 'legacy principles' into the followers and the organization is the Nelson Mandela Foundation. The Foundation notes (www.nelsonmandela.org) that 'living the legacy of Nelson Mandela means incorporating his values into the work that we do. And that doesn't only refer to content; it refers to how we work. There has to be a high degree of professionalism, passion and commitment to push the boundaries of change. There has to be openness and transparency. And above all, there has to be the belief that no one person or organisation has all the answers.'

Mr Mandela left a strong impact on his followers, and the organization he established. He had qualities of 'legacy leadership' which Whittington *et al*. (2005) describe as: worthy of imitation, boldness amid opposition, pure motive, influence without asserting authority, affectionate and emotional, vulnerable and transparent, authentic and sincere, active, not passive, follower-centred and not self-centred.

METHODOLOGY

This paper reports on part of a study on leadership development in construction professionals in Singapore. It is based on interviews with 10 leaders in the Singapore construction industry. These leaders include past and present presidents of various professional organizations and trade associations, and chief executive officers (CEO) and directors of architectural, engineering and construction (AEC) firms in Singapore.

The questions asked during the interviews related to: (1) the interviewees' leadership philosophy; (2) the influence of significant individuals and events on the leadership development of the interviewees; (3) key turning points in their leadership development; (4) the personal and professional challenges they have faced; (5) what they want to achieve as leaders; and (6) the legacy the interviewees hope to leave behind as leaders. This paper reports on the findings from the last two questions covered in the interviews.

PURPOSE AND LEGACY: INTERVIEW RESPONSES

All the interviewees described their leadership purpose, what they wanted to achieve and the legacy they would like to leave behind. The discussion may be considered under the following themes:

- Developing the leader's followers and finding a successor
- Bringing about the positive changes the leaders desire to see in their organizations
- Bringing about the changes they would like to see in the construction industry in Singapore
- Leaving a legacy of the leader

DEVELOPING THE FOLLOWERS AND FINDING A SUCCESSOR

When the interviewees were asked what they wanted to achieve from the leadership roles they were playing, their responses related mostly to what they perceived as the purpose of their leadership roles. Most of the leaders wanted to develop their followers to be better professionals. For example, one of them, the managing director of a contracting firm, said:

> I want my staff to pick up knowledge of the field and to see the big picture. If they are able to see the big picture, it will be better for them as well as for the organization. I lecture my staff every day and try to get them to take a helicopter view. I challenge them most of the time and encourage them to think.

Another leader, the managing partner of a quantity surveying consultancy firm, highlighted the need for customer care in the construction industry and stated his desire for his followers to be sensitive to the needs of the clients they serve; this had brought benefits to the firm. He noted:

> I want to have a few more like me. I want my employees to have a caring attitude. We get jobs not because we are the best quantity surveying firm in town. It’s because we care for people and our clients. I think it’s a matter of trust that we have built up over the years. It keeps bringing us jobs.

Whereas all the leaders interviewed were concerned about mentoring their followers, a few specifically expressed their intention and active effort to find suitable successors to take over the reins of the organization from them. One of them said:

> I would like my employees to go further in their jobs. I hope to mentor my juniors and wish that that the organization has a succession plan for others to take over my position. My current emphasis is on mentoring and skill development of those I lead. And I want to train the first liners and second liners in my organization to take over the leadership role in the future.

CHANGES IN THE ORGANIZATIONS

The leaders interviewed expressed their desire to bring about certain changes into their organizations. Describing their aspirations for the future of their organizations, some leaders said that they wanted to bring more professionalism into their organizations so that they can contribute more to society. A CEO of an engineering design consultancy firm noted that:

> I want it to be a very professional firm. That is whatever we do; we have to do it very professionally. My engineers understand it well. It’s tough but I want to have a clear conscience. To me, safety comes first. My clients would know that we do it professionally. We are willing to help the client but we are ready to listen to a better way. We can learn from contractors as well as suppliers. That’s a good way of learning in this competitive environment.

The managing director of a contracting company emphasized that his employees were under heavy work pressure with short deadlines, and that he wanted them to have more time to produce better output. He noted:

> I wish people are given more time to do their jobs better. There is mostly no quality of work and that is the saddest thing we face in this industry. Clients think of a project for years but they want to finish it in a day. In Singapore, there is a site meeting every week … sometimes twice a week. And this is ridiculous. Due to these deadlines and short schedules, we are taxed. I wish we get more time to accomplish quality jobs.

CHANGES IN THE CONSTRUCTION INDUSTRY

The interviewees also expressed their desire for major changes in the construction industry. Most of the leaders interviewed highlighted: the need for more professionalism in the industry; a change in the traditional conservative mindset of the industry; the need for the industry to consider adopting manufacturing processes in its operations; and the need for innovation in construction methods.

Several of the interviewees highlighted the need for professionalism in the industry as a whole. The general manager of a contracting firm also observed:

> There is an urgent need to bring about more professionalism in the industry. There is a lack of principles and professionalism in our sector. Its not only me, everyone in the industry must become a professional. And that means the pursuit of a fair and equitable outcome from the project. Most stakeholders believe that all others can make money but not the contractor. We receive the blow every time and there is little consideration in the industry. In my opinion, every player must become the professional. It can change but needs hard work. In the past, there was a healthy relationship between the designer and the contractor. But it’s not the case anymore. I hope it will change in our industry.

The president of a professional organization expressed the same concern. In his view, the construction industry was moving in a positive direction yet a lot more still needed to be done. He noted:

> I would emphasize more professionalism in the construction industry. We all have to play our roles well in our own capacities. The client must pay well, the designer must design well, and the contractor must build well. This way, people can save their costs and would not need to cut the corners. I believe the industry is improving and it’s getting better though. Yet a lot of improvement is required while some is still going on. I also think that the government plays a very important role in bringing the industry to a better position.

A senior executive in an architects’ firm expressed a desire for more effective integration of the contributions of the participants in the construction process, saying:

> I believe that there is lot of opportunity and scope for bringing synergy among various professions in the industry, and contractors. I believe that the contractors, like an architect and engineer, should also be mandated by an Act which means that you become a registered contractor. At the moment, as a contractor, your primary responsibility is the contractual responsibility. Your statutory responsibility is up to the point where you

> have built the building in accordance with the approved drawings, from the structural point of view. But you have got no other statutory liability. And in order to level up the whole profession, you really have to have some responsibility beyond that point. And only when you understand that you need to take some liability beyond that will you be prepared to change your mindset towards bringing in more professionalism into your business.

A vice president of a developer's firm put stress on innovation in the construction process and improved safety for the construction workers. He observed:

> The construction industry should adopt manufacturing processes to some degree. We need to learn from the manufacturing industry and take 30% of our construction value into the manufacturing process. We need to reduce the value of onsite manufacturing. This will improve productivity and raise the level of professionalism such that construction workers can work in premises with a roof over their heads. Everyone has a roof over his head; why not the poor construction worker? Let us do something to bring more safe and secure working conditions to the construction workers.

LEAVING A LEADERSHIP LEGACY

Some of the interviewees had not previously thought about the kind of legacies they would like to leave behind. However, many were sure about what they wanted to leave behind. The subjects of these legacies varied. Some of the leaders interviewed mentioned how they wanted to be remembered after they left the company. Most of the responses affirmed the loyalty of the leaders to their professions. A CEO of an engineering design firm said:

> For my own company, I would like to be remembered as a practical engineer. Someone who can work well with all parties involved in the project. I would like to be remembered as someone who has a heart for people and someone who can make a difference in their lives.

Similar sentiments were shared by another executive from an architectural design firm, who noted:

> I just want to be known as a good and fair architect. We are very few from [this minority group] holding key positions in architects firms in Singapore. And I wish to leave a good impression on others. Also, I want to be a good mentor, a good listener.

One director in a firm of architects was of the view that leaving individual legacies in professional corporate firms was not that easy because of the lean hierarchy. However, he emphasized the need for the establishment of systems within the firms to ensure their sustainability. He explained:

> In a practice where we have six directors, who are all very mature and level headed, I do not think we can leave our own legacies in the firm. But what we can leave behind is a structure of the organization, capable staff, and our design capability. After learning from experience and from challenges, we want to put a system in place so that we do not repeat the mistakes. However, I would like to be remembered that I left the firm in good shape.

Another executive from a developer's company put forward a vision of the desirable features of the properties his firm was developing. He reflected:

> We started with laying bricks to build small houses in Singapore. For almost 20 years, we did the same thing and laid bricks. However, the last eight years have been different. We have reached a stage where people know that our product quality is good. I hope that in next 10 years, people say that our properties are efficient to maintain and economical to operate, energy efficient, and sustainable.

The CEO of a contracting firm wanted to take more of a teaching and coaching position and transfer knowledge and skills to his followers. He also advocated the importance of market dynamics and hoped that his staff would learn these from him:

> My aim is to develop knowledgeable staff and those who can see the big picture. I want to impart to them the market intelligence that is the key to success in today's market.

These legacy statements show that the leaders in the construction industry try to relate their legacy to their professions. Although they have reached the level in their firms where they undertake more managerial duties, they still consider themselves, and think, as civil engineers, architects or quantity surveyors, and want to be remembered as that as well.

DISCUSSION

The findings of this study are in line with the conclusions reached by Nash and Stevenson (2004) in their study of successful executives and professionals. They identified four components of enduring success: happiness (feelings of pleasure or contentment about one's life); achievement (accomplishments that compare favourably against similar goals others have strived for); significance (the sense that one has made a positive impact on people one cares about); and legacy (a way to establish one's values or accomplishments so as to help others to find success in future). The leaders interviewed in this study were all happy about what they were doing, and they had realized significant accomplishments in their professional lives. More importantly, they were all committed to making a positive impact on their colleagues, followers and organizations. It was clear that they were living their values and accomplishing their leadership purpose. It was also evident that the leaders interviewed were focused to live the legacies they wanted to leave behind.

The interviewees expressed their desire to develop their followers and prepare the young professionals under their wings to take up leadership roles in the future. Most of them were actively developing their followers to have the same values and motivations which had helped them (the interviewees) to become leaders and to realize many achievements. Those who were a few years away from retirement were looking for suitable successors to whom they could pass on their responsibilities and legacies. The younger ones were trying to create and live their legacies, and were finding congruence between their passions and organizational values. The interviewees also showed their concern for the sustainability and future health and success of their organizations. They wanted to leave their organizations in a strong structural and financial shape, with enviable achievements, organizations which also had strong foundations and good future prospects.

The leaders interviewed also wanted to see significant changes in the way the construction industry in Singapore operates. A common aspiration of the interviewees was a desire for a high level of professionalism in the industry. They wished to see changes in the practices, relationships and the overall culture of the construction industry in Singapore, especially its adversarial nature. Many authors elsewhere have noted that the construction industries in their countries remain conventional in their culture, and in their operations and, business strategies (see, for example, Koskela and Vrijhoef 2001). Rameezdeen (2007) asserts that the construction industry in the UK has suffered from a poor reputation among other industries. In some countries, construction is known for a high level of corruption (see, for example, Transparency International, 2006) in addition to its lack of professionalism (see, for example, Mezher and Tawil 1998). This image of the construction industry in those countries has made it unpopular to young and bright talent as a field in which to pursue their careers (Rameezdeen 2007). Thus, whereas the adversarial attitude, lack of professionalism and poor social image of the construction industry are not limited to Singapore, the response of the interviewees indicated that there is a strong desire for change among the industry's leaders in Singapore. This bodes well for the future of the construction industry in the country.

Another area which some of the leaders interviewed highlighted as needing change was that of innovation in the technologies adopted. A specific suggestion was that more of the activities on the construction site should be moved into manufacturing. Gaining more value from innovation through manufacturing would increase both productivity and safety on site. This issue has been mentioned in other studies in Singapore (see, for example, Construction 21 Steering Committee 1999), and there have been programmes to promote innovation in the industry since the mid-1980s, including policy guidance, financial incentives, awareness creation and other forms of promotion but it is evident from the interviews that there is still a long way to go. In this regard, Singapore's construction industry seems to lag behind those of some countries as some recent works show that the pace of efforts to industrialize the construction process has increased, and much progress has been made (Winch 2003; Monjo-Carrio *et al*. 2007). Thus, much more is yet to be done in the area in Singapore and the leaders expressed a desire to see progress in it.

IMPLICATIONS FOR LEADERS

There are many lessons that can be learnt from the discussion on 'leadership legacy' in this paper. Galford and Maruca (2006) note that some leaders never give a thought to their aspired leadership legacy because they are too busy in their jobs. However, it is never too late to leave a legacy or, at least, to think about it. Once the leader knows the legacy the leader would like to leave behind, it is easier to feel the worth of leadership and put in the effort to achieve the desired legacy. Brooks *et al*. (2004) observe that a leadership legacy is not something that just happens all at once. A legacy is built up moment by moment, in small activities and interactions. As mentioned above, true leaders do not only create their legacies but actually live them. A strong belief in living one's legacy can uplift the followers' spirits and inspire them to perform better. Therefore, leaders, at all stages of their careers, should give some thought to the legacy they would like to leave behind.

All leaders (and especially those who are near to retirement) should start thinking about the legacy they want to leave behind for their followers, organizations and more specifically their successors. Such contemplation of their legacies is likely to improve their performance in their positions as they would have a clearer idea of what they want to leave behind for their successors (Freeman 2004). They should also reflect upon the real legacies they have created so far during their careers, and the impact these legacies have made. If leaders articulate and communicate their legacies, that can help others to recognize the importance of those legacies, and to determine how they can keep the legacies alive. Such messages can also help the younger leaders or leaders-to-be in the organizations to start thinking about their own legacies and the impact they would like to make on their colleagues and their organizations.

Thinking about leadership legacy should be a catalyst for action and a lens through which the young leaders can see their future. They can assess their own motives and values and try to establish their consistency with organizational goals and their followers' expectations. Thinking about one's legacy also leads to a greater sense of purpose, and decisions that go beyond daily routine tasks (Maruca 2007). Thinking about what they want to leave behind and be remembered for, young leaders can take the opportunity to find a suitable environment where they can realize their dreams. George (2004) argues that doing this may take experience in several organizations before one can find the right place for creating and living one's legacy.

Thinking about leadership legacy also makes the leaders think more about what they really want to change, what difference they aspire to make, and what service they can render to society. Once they are true to what they want to achieve from their leadership and clear about what they want to leave behind, they gradually become more self-aware and self-disciplined or simply put, authentic leaders (Luthans and Avolio 2003; George and Sims 2007). Understanding their leadership legacy will inspire the young leaders to work towards their goals.

CONCLUSIONS

The leaders of the construction industry in Singapore who were interviewed for this study showed commitment to the development of their followers, and to leaving their companies in good shape after they retire. They want to leave legacies in the form of knowledgeable followers who can take the leadership role in the future. They also want to be remembered as fair and practical professionals who contributed positively towards the growth of their company and betterment of the construction industry. They also expressed their aspiration for bringing more professionalism, and a culture of healthy relationships into the construction industry. Thus, the leaders of the Singapore construction industry who were interviewed in this study seem to be in agreement with George and Sims who noted that 'the only thing you take with you is what you leave behind'(2007: 203). Good leaders are critical to the long-term well-being of an industry as their legacies shape the culture of the industry and the way it operates into the future. This puts the need for leadership development into relief.

STANDARDIZATION AND PREASSEMBLY: A DRIVER FOR PREDICTABILITY AND EFFICIENCY IN CONSTRUCTION

Wilfred M. Matipa[1] and John C. Fausset[2]

[1]*University of Central Lancashire, Faculty of Science and Technology, Department of Built Environment, Preston, Lancashire PR1 2HE, UK*
[2]*Telford Hart Associates, 71 Highgate, Kendal LA9 4ED, UK*

A construction project will only be regarded as successful if the product is delivered on the predicted date, at the required price and of the requested quality. A successful project therefore passes approval upon the professionals and craftsmen who completed the project. All too frequently though, projects are proving incapable of accomplishing these objectives. The unrelenting excuses presented for the persistent disappointments have ultimately portrayed the construction industry as being unreliable and ineffective. One construction process which periodically re-emerges is again receiving commendation from many quarters. Standardization and preassembly in the form of 'off-site manufacturing' (OSM) are seen to be a principle factor for improving construction in the 21st century. These concepts form the basis of the research, which proposes to evidence whether standardization and preassembly could drive overall product predictability and efficiency in construction. Based on primary data collected from the North West of England, the research shows that predictability and efficiency in the construction industry are achievable if standardization and preassembly are central to the construction process, and could contribute significantly to the desired level of value for money to the clientele sector of the industry.

Keywords: efficiency, off-site manufacturing, predictability, value for money.

INTRODUCTION

Standardization can be defined as extensive use of processes or procedures, products or components, in which there is regularity and repetition (Gibb 2001b). It can also be described as the optimum exploitation of standard components and designs (Groves 1998). Standardization of components is prerequisite in the manufacturing industries and if savings on assembly costs and predictability of product are to be realized, components must be completely and consistently interchangeable (Sparksman *et al.* 1999). Market forces are forcing contractors to reconsider their approach to satisfying customers' requirements; so are government policies and regulations that are promoting sustainable construction (Richards 2003). Traditional styles of construction such as bricks and mortar are being replaced with a wider application of industrialized building systems (Constructing Excellence 2004). Cycles of success and failures over the years have driven innovative methods in construction (Waskett 2001; Barker

[1] wmmatipa@uclan.ac.uk

2003). Most recent efforts consider that ‘standardization and preassembly’ have been drivers of predictability and efficiency in construction (Egan 1998). This research set out to establish the construction industry’s awareness of standardization and preassembly, generically called ‘off-site manufacturing’ (OSM), and the levels of acceptance for OSM in the North West of England. The paper assesses ‘whether standardization and preassembly could be a driver for predictability and efficiency in construction’. Using primary data on current trends on off-site manufacturing collected from the North West of England, the paper proves the argument that OSM could drive predictability and efficiency in construction.

STANDARDIZATION AND PREASSEMBLY

There is a relationship between standardization and preassembly in that they all tend to extensively use processes or procedures, products or components, in which there is regularity and repetition, hence requiring the organization and completion of a substantial proportion of a project’s final assembly work before installation in its final position (Gibb 2001a, c). Off-site manufacturing (OSM), however, is an all-inclusive process which incorporates prefabrication and preassembly. The process involves the design and manufacture of units or modules, usually remote from the work site, and their installations form the permanent works at the work site (Gibb 2001a; Sterling 2005). Following the Second World War, a series of initiatives enabled the UK construction industry to increase housing completions from just over 50 000 per annum in 1945 to a peak of over 400 000 per annum in 1968/9 (Barker 2003). However, as Uff (1997) conveys, for the next three decades the industry succumbed to perpetual problems and successive failures. Reports released in 2003 observed that annual completions had fallen below 140 000, a figure which the Housing Forum (2002) considered to be insufficient to satisfy new requirements, let alone replace the ageing housing stock. The importance of the construction industry to the UK economy is emphasized (Bourn 2001); hence there tends to be a cost–efficiency relationship between the unit cost of manufacturing an item and the number of times the unit is repeated (Gibb 1999). Volume and uniform production flows are fundamental to reduce the costs connected to product design, development and factory overheads (Davis Langdon and Everest 2004). Presently the minimum production runs for modular housing units are around 30 to 40 units (*ibid.*). However for significant economies of scale, orders around 150 units are required.

Preassembly in the UK construction industry

Whenever there is a shortage of labour or materials, innovative methods of construction materialize; conversely when supplies of labour and materials conform to demand, a reversion to traditional masonry construction ensues (Ross 2002).

Key drivers for OSM include but are not limited to:

- generic demand for better products from the marketplace (Ross 2002; Housing Forum 2002);
- the ‘perpetually cyclonic’ twin pressures of a reducing skills base and an ever increasing housing demand;
- government action in terms of planning guidelines, revised Building Regulations and a move towards more sustainable building techniques have combined to drive the UK house building industry into a renewed search for innovative processes and procedures, capable of achieving rapid delivery

(Parliamentary Office of Science and Technology (POST), 2004; Sterling 2005).

It is envisaged that some of the benefits of OSM could be, but not are limited to: reduced on-site time; greater cost predictability; reduced downstream costs; improved the technical performance of the final product through dependable and reliable quality and thereby reduced defects and the amounts of rework; a reduction in waste; improved project safety and health; use of new and sustainable materials, which are designed to improved and specific technical and functional standards (Gibb 2001a; Gibb 2000; Gann 2003; Sparkman *et al.* 1999). In order to increase construction efficiency, reduce overruns and improve overall quality of constructed facilities, it is vital to use faster and more efficient construction procedures such as OSM (Delves *et al.* 2001; Gibb 2001a). Cost savings could also be realized – reduced site logistics and 'site set-up' costs, rather than in the individual costs of the prefabricated units (*ibid*.). Broyd (2001) claims that prefabrication alongside site modelling tend to improve the health and safety of the workplace because factory-based manufacturing has more rigorous safety procedures. There are several obstacles preventing the uptake of OSM: the costs of setting up a construction factory and training the workforce; companies' investments in factories are not guaranteed a constant supply of projects, because it is difficult to predict the market dynamics; and there is a the preconceived idea that OSM is 5% to 12.5% more expensive than traditional construction processes.

RESEARCH METHOD

The selection of the appropriate research method was determined by the accessibility to primary data (Fellows and Liu 2003). A questionnaire survey was adopted as a primary data collection tool because of: (1) limited time; (2) reduced costs; (3) improved practicality; and (4) increased level of reliability and validity of the research data. Primary data were essential for testing the hypothesis (H_a) that 'standardization and preassembly could be a driver for efficiency and predictability in construction'; challenging 'null' hypothesis (H_o) that 'standardization and preassembly cannot be a driver for efficiency and predictability in construction'. For this research, a qualitative approach was presumed enough for the research problem at hand.

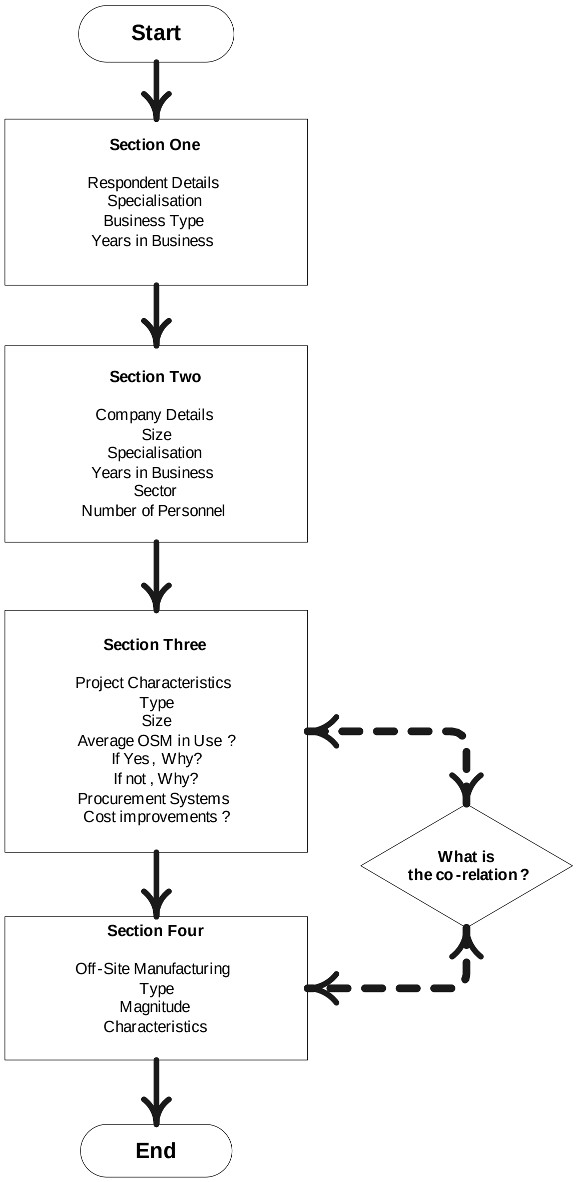

Figure 1: Questionnaire sequence model

The questionnaire for this research programme

The questionnaire had four sections, as shown in Figure 1. Section one covered personal and company details; this facilitated categorization of both the respondents and their companies. Sequentially the data were linked to section two which comprised company characteristics such as size and industrial sector. Before respondents were sent questionnaires, it was important to create a sample of the population. The principal objective of sampling is to provide a practical means of collecting and processing data representing the population under study. Any subset of observations from a population can be characterized as a sample (Witte and Witte 1998). The survey represented several sectors of the construction industry including architects, civil engineers, cost consultants, designers, housing associations, housing developers, main contractors, OSM manufacturers, quantity surveyors, structural engineers, subcontractors and town/city councils. Ninety companies from the North West of England had been sampled, using a simple fish-bow technique. Table 1 shows a breakdown of the questionnaires administered and the type of responses obtained.

The primary data collection exercise yielded a 66% response rate; out of a total number of 90 questionnaires administered, 59 were positive responses. Respondents could be further broken down into main contractors at 47%; private housing sector at 27%; education at 17%; civil engineering at13.6%; social housing and hotels 12%; industrial construction at 10%; retail at 5%, and health at 3% However, this is to be expected because OSM largely affects firms that actively implement construction such as contractors. There was no response from the architectural sub-sector; hence their view of this subject is not omitted for the sake of it, but rather, for the lack of response.

DATA PRESENTATION AND ANALYSIS

The presentation of research data and subsequent analysis follows the questioning format as modelled on the questionnaire sequence in Figure 1. This system has been adopted so as to improve the readability and comprehensibility of the research.

Incorporating standardization, preassembly, off-site manufacturing

The objective of this question was to determine whether any specific sector of the industry has accepted OSM procedures more actively than others. In the survey 70% of the responding companies claim to have used OSM in their projects, 31% responded negatively. Councils and housing associations are the only sector to display less use of OSM than recognition. The benefits derivable through the regular use and the economy of scale cannot be determined from this question alone; correlation between several of the following questions was required. Additional data suggested that OSM is becoming established across the industry and especially so in the main contractor and housing sector. This means that improvements and innovations in construction procedures have not only made the incorporation of the OSM elements easier, but the components are far more readily available.

Principal method of OSM used

The objective of this question was to ascertain the frequency of OSM used and if the implementation was restricted to particular sectors of the industry. The two most popular forms of OSM systems are framing at 20% and structurally insulated panels at 16.6%, which conforms to generic individual sectors. Respondents also indicated that the levels of acceptance for the various OSM systems were comprehensive across the industry sectors with the exception of bathroom and kitchen pods; because typical industrial units do not require large numbers of toilets or kitchens, these elements are usually bespoke. Key factors cited included: improved cost control (12%); improved speed of construction (41%); introducing innovative systems (8%); previous experience of OSM (1%). It was also envisaged that procurement systems as well as financial mechanisms could influence the use of OSM; hence there was a section on the questionnaire covering generic procurement systems, and financial mechanisms for projects.

Assessment of procurement systems for projects that incorporate OSM

The conclusions to be drawn from this question were expected to display parallel correlation between private and public-driven procurement systems. It was observed that housing (public or private) predominantly uses traditional procurement processes, still displaying the fragmented and individualist nature of this sector of the industry as reported by Egan (1998). A possible rationale could be that clients in the housing sector control the entire project from the design and development process through to completion, employing the individual professionals for the separate tasks as and when they are required. Conversely, the larger projects, education, health, hotel and retail sectors, request the supply chain to be moderated and place the responsibility (risk) upon the contractor to complete the entire construction; which is predominantly design and build, and its variants such as private finance initiative, partnerships and so forth.

Assessment of financial mechanisms for projects that incorporate OSM

It was important to extract the difference between public funded projects and private financed ones so as to establish the influence funding could have on OSM. Privately funded projects accounted for 45.8% of the total, which included private housing, civil engineering, retail and industrial projects. The eight publicly funded projects, in education, health and social housing signified 13.6%, i.e. the deployment of OSM was higher in privately financed projects than in the public sector. However, that is to be expected because the private sector is profit driven, hence any system that could enhance that tends to be of use. Depending on the design, the total value of OSM elements as a percentage of the overall contract value was estimated at below 20%. The highest volume of OSM elements used in the survey were framing systems and structurally insulated panels, representing 37% of the total. The elements in the structure of buildings that these two elements supplement or replace are the ‘internal walls’. These elements were revealed in the Building Cost Information Service (BCIS) survey (2004) to make up approximately 18% of the project total costs. Therefore, it is considered it would be difficult for most projects to achieve above the 20% boundary limit.

Assessment of predictability and efficiency for projects that incorporate OSM

Sinclair (1992) defines ‘predictability’ as, ‘happening as expected’ or ‘happening or turning out in the way that might have been expected or predicted’ and ‘efficiency’ is identified as, ‘competent, having the ability to do something well or achieve a desired result without wasted energy or effort’. When applied to OSM ‘predictability’ is referred to as completing the project at the desired cost and ‘efficiency’ is realizing maximum employment of the resources, labour and material, reducing both project duration and waste. Using a quantitative ordinal data scale (Fellows and Liu 2003) respondents were asked to rate predictability and efficiency of projects that incorporate OSM. The rating to the responses ranks the dataset, in terms of being larger/smaller, the same, greater/lesser, assigning an order (rating) for the choices (Holt 1998). Processing research data using this format is beneficial for observing correlation between sub-sets or testing the hypothesis (*ibid.*). Five responses were obtained: (1) ‘significantly increases’ project predictability; (2) ‘slightly increases’ project predictability; (3) ‘no discernible difference’ to project predictability; (4) ‘slightly reduces’ project predictability; (5) ‘significantly’ reduces project predictability. To evaluate the appropriateness of OSM it was prudent to monitor changes that could result from deploying OSM on projects using the BCIS (2005) survey of construction projects completed between 1998 and 2002, which indicated that: (1) 60% of projects overran by a mean of 16% on project duration; and (2) 53% displayed a mean discrepancy of 20% on project cost overrun.

The findings of secondary data compilation revealed the mean of the OSM case studies to be overall 6 1 percents on total project/budget cost. The ‘initial costs’ of OSM projects over a similar sized traditionally constructed building were 4% above traditional costs; over the project period, the median was a 22% reduction in project duration, and the mean at 17% decrease in project duration. Producing OSM projects consistently create such savings: projects achieving a 15% (16% – 61%) improvement on project cost predictability is 'significant'. Similarly if OSM projects consistently produce a 20% (+20% to 17%) improvement in project duration, they must also be considered 'significant'. Table 1 summarizes the ratings of various facets of the questionnaire by respondents. The table shows a matrix of how respondents rated various aspects of OSM under key sub-headings such as project predictability, project quality, project health and safety, project efficiency, project duration, project costs and environmental impact. It is from these ratings that data were obtainable to test the research hypothesis. Additionally, the qualitative findings from the survey demonstrated that 59% of the respondents thought incorporating OSM improves the project quality by some; while 53% of the respondents believe OSM improves project health and safety; and 65% of the respondents believe OSM improves the environmental impact of construction. Before testing the hypothesis, it was prudent to evaluate the correlation of sections of the questionnaire. Two pairs of questions were provided: question 13 reflected on project predictability; question 16 was concerned with project efficiency question; question 17 project duration and question 18 considered project costs. The intent was to present data that qualify OSM as offering predictability and efficiency in construction.

Using correlation tests it was possible to determine whether two variable sets of data (predictability and efficiency) are related. This entailed identifying a tendency for pairs of observations to occupy similar relative positions in their respective distributions. Additionally before correlation can be detected, the trends or observations require the same distribution of numbers, i.e. from highest to lowest, or as in this instance, a rating system of most acceptable to least acceptable answer (Witte and Witte 1997). There are three forms of relationship: 'positive relationship': the pairs of observations display a predisposition to occupy similar relative positions; 'negative relationships': occupy dissimilar or opposing positions in their respective distributions; 'no relationship': occurs when there is neither positive nor negative similarity. Once a relationship has been established, it can be interpreted for predictive purposes by means of either a 'scatter plot chart', or a measure known as a correlation coefficient.

Table 1: Summary of ratings from respondents

Compilation of the ratings	**Predictability**	**Project quality**	**Health and safety**	**Project efficiency**	**Project duration**	**Project costs**	**Environment**	**Median of the responses to questions**
Rating 'No. 1'	19	27	25	24	30	21	27	24.7
Rating 'No. 2'	21	8	27	23	19	15	23	19.4
Rating 'No. 3'	17	18	6	10	8	16	6	11.6
Rating 'No. 4'	2	6	1	1	1	5	3	2.7
Rating 'No. 5'	0	0	0	1	1	2	0	0.6
Grand total	**59**	**59**	**59**	**59**	**59**	**59**	**59**	

The Pearson correlation coefficient, ***r*****,** is a number between minus one (–1) and one (1) which defines the relationship between pairs of quantitative variables (numbered observations) (Witte and Witte 1997). The sign of *r* indicates the type of linear relationship, whether positive or negative (*ibid.*) and the value of *r* without regard to sign, indicates the strength of the linear relationship (*ibid.*). A strong relationship between the variables is indicated by *r* being as near as possible to either (–1) or (1), i.e. variables computing a correlation coefficient of (–0.7) have a stronger (negative) correlation than variables with coefficient (0.65) (positive).

The *r* value of the regression line is (Microsoft Office Excel 2003):

$$r = \frac{n(\Sigma XY) - (\Sigma X)(\Sigma Y)}{\sqrt{[n\Sigma X^2 - (\Sigma X)^2][n\Sigma Y^2 - (\Sigma Y)^2]}}$$

The primary data from the survey could be classified as qualitative (Witte and Witte, 1997), even though the presentation is in numerical format such as percentage or correlations. Table 2 maps the coefficients for the data variables. Project predictability's lowest coefficient is with project quality, 0.71, a reasonable correlation; however its strongest coefficient is with project cost, 0.95. The correlation coefficient and therefore association between the datasets are both strong. Project efficiency's lowest coefficient is with project quality 0.67, neither strong nor weak. Conversely, its strongest relationship is with project duration 0.95, a strong association and correlation coefficient. With confirmation of the strong association between the datasets, it became prudent to test the hypothesis that 'standardization and preassembly is a driver for efficiency and predictability in construction'. The chi-square statistical test uses the concept of proof by contradiction; it uses the ordinal level data to test the frequencies. By comparing the actual or observed frequencies of the variables against frequencies without any form of relationship it creates the 'null hypothesis test' (Ott 1998).

Table 2: Pearson correlation coefficient, *r*, for data variables

Pearson correlation coefficient	**Predictability**	**Project quality**	**Health and safety**	**Project efficiency**	**Project duration**	**Project costs**	**Environment**
Predictability		0.7094	0.8545	0.9190	0.8190	0.9530	0.8290
Project quality	0.7094		0.5481	0.6662	0.7746	0.8758	0.6511
Health and safety	0.8545	0.5481		0.9833	0.9302	0.8456	0.9838
Project efficiency	0.9190	0.6662	0.9833		0.9562	0.9225	0.9768
Project duration	0.8190	0.7746	0.9302	0.9562		0.9099	0.9727
Project costs	0.9530	0.8758	0.8456	0.9225	0.9099		0.8743
Environment	0.8290	0.6511	0.9838	0.9768	0.9727	0.8743	

The null hypothesis is denoted by H_o; and the 'research hypothesis' (also called the alternative hypothesis) is denoted H_a. The hypothesis H_a for the paper is: 'standardization and preassembly is a driver for efficiency and predictability in construction'. The opposing null hypothesis H_o is: 'standardization and preassembly is not a driver for efficiency and predictability in construction'. Using Table 2, a yardstick against which to measure the table's chi-square value can be derived, and it is possible to assess whether or not it is significant: the probability of getting a chi-square value of a minimum given size even if the variables are not related to the larger population from which our sample was drawn (Naoum 1998; Witte and Witte 1997), that is, how much larger than 0 (the absolute chi square value of the null hypothesis). Table 2's chi-square value must be established before we can confidently reject the null hypothesis. The probability sought depends in part on the degrees of freedom of the table from which our chi-square value is derived, which, mechanically is a table's degrees of freedom (df) expressed as: df = (r–1)(c–1). The datasets for the questions were placed into the table, presenting the following statements: 'chi-square = 45.95'; '*p* is less than or equal to 0.01', which translates to 10% level of confidence. Therefore because the distribution is significant, the null hypothesis H_o can be rejected. The hypothesis H_a is true. 'Standardization and preassembly is a driver for predictability and efficiency construction.' It is important to note that owing to lack of space, it is not possible to include the theory of chi-square testing in this paper.

CONCLUSIONS

The research shows that even though there are modest improvements in the deployment of OSM, more needs to be done if the construction industry is to continue improving efficiency during the production phase of its products; more so presently due to the buoyancy of the industry. It can also be observed that crucial project success/failure factors such as cost, time, health and safety, the environment and quality can impact on each other positively or otherwise; hence any technique that could improve any of the factors is worth pursuing. It is important to note that value for money can be achieved not only by using OSM in isolation, but from using other methods. Further research in the views of architects on this subject would be valuable to OSM.

INTERFACE PROBLEMS WITH VOLUMETRIC PREFABRICATION

Ali Danby[1] and Noel Painting[2]

[1]Unite Modular Solutions Ltd, Brunel Way, Stroudwater Business Park, Stonehouse, Gloucestershire GL10 3SX, UK
[2]School of the Environment, Construction Research Team, University of Brighton, Cockcroft Building, Lewes Road, Brighton BN2 4GJ, UK

Modern methods of construction can assist the construction industry to achieve higher levels of production and a higher quality of product. They are being promoted by the UK government and are seen by some as a panacea to the ills of the construction industry. Prefabrication does however need to be integrated with more traditional methods of construction and this interface is often problematic. The aim of this work is to identify these interfaces and to facilitate an understanding of how problems arise. The research included interviews with team members from a key prefabrication provider and selective questionnaires from contractors managing (and not managing) projects using elements of prefabrication. A lack of understanding between prefabrication specialists and those providing more traditionally built infrastructure was found to create problematic working relationships and good communication was found to be a key factor in successful projects. The various types of interface are mapped and then set against the parties involved and their timing within the project.

Keywords: communication, interfaces, prefabrication.

INTRODUCTION

This aim of this research is to model the characteristics of interface problems between volumetric prefabrication and traditional construction. The research comprises case studies, interviews and questionnaires leading to the identification of a timeline of common interface problems. The research was carried out in the UK and its validity must be considered within the emerging prefabrication market.

Modern methods of construction (MMC) is a term used to describe technical improvements in prefabrication, encompassing a range of on- and off-site construction methods (Parliamentary Office of Science and Technology 2003). It is moreover a term used by the Housing Corporation to embrace a variety of approaches including off-site manufacturing (OSM). Falling under this heading are volumetric construction, panellized construction, hybrid systems, sub-assemblies and components (BRE 2003).

The current severe skills shortage coupled with the short timescale demanded by clients means that demand for new construction is unlikely to be met by conventional construction techniques. It would seem that the market for prefabricated accommodation could increase dramatically over the coming years if manufacturers are able to overcome the barriers (McAllister *et al*. 2000; ODPM 2006).

[2] n.j.painting@brighton.ac.uk

The Egan Report, *Rethinking construction* (Egan 1998) provided impetus for the UK construction industry to consider the way in which it operated and specifically the opportunities that existed for improving the process and delivery of a higher value product. This raised the level of interest in prefabrication techniques and studies are underway to assess its potential.

IDENTIFICATION OF INTERFACES

To develop an understanding of interfaces between volumetric prefabrication and traditional construction a series of interviews were arranged. The bulk of interviews were with a selected modular prefabrication company. Interviewees chosen had a range of roles and responsibilities within the same company and were found to see the interfaces differently. Their roles can be categorized as: project management, construction management, manufacturing management, marketing and promotion and logistics.

A common list of interfaces was first established from initial pilot interviews. This list of interfaces was then given to each respondent with space for other interfaces to be added.

Table 1: List of common interfaces

Number	Process	Number	Process
1	Acoustic testing	34	Modular specifications
2	Ancillaries	35	Module tolerances
3	Arrival of modules on site	36	Offer to supply
4	Authority to manufacture	37	Operations and maintenance manual
5	Bathroom pods delivery and installation	38	Outline general arrangement drawings
6	Budgetary quotation	39	Planning applications
7	Communication	40	Pre-delivery checks
8	Defect report completion on installed modules	41	Pre-start meetings
9	Demand schedule/call offs	42	Preliminary demand schedule
10	Design/project meetings	43	Progress meetings
11	Detailed architect module layout drawings	44	Project management involvement
12	Door deliveries and installation on and off site	45	Remedials
13	Electrics installation	46	Roof structure details
14	Engineering change notes	47	Scheme elevations
15	Erection schedule	48	Scheme plans
16	Final handover	49	Shipping call-offs
17	Final health and safety file	50	Shroud
18	Finished modules on site	51	Site levels surveys
19	Fire stopping	52	Site managers
20	Fixings schedule	53	Site requisitions
21	Floor layouts	54	Site returns
22	Foundation details	55	Standard reference drawings
23	Frozen general arrangement drawings	56	Technical queries
24	Frozen quotation	57	Testing
25	Getting hold of materials	58	The crane
26	Handover documents to re-programme doors	59	The team
27	HSB drawings	60	Timing and programming
28	Initial health and safety file	61	Transport
29	Initial inquiry	62	Variations to the contract
30	Installation	63	Weather proofing

31	Lifting equipment	64	Weekly delivery report
32	Management of lifting frames	65	Window delivery & installn. on & off site
33	Manufacturing supply risks	66	Window drawings and schedules

These added interfaces were included in the subsequent list of interfaces for later interviewees. The list given in Table 1 shows the final list of common interfaces.

These interfaces were mapped against the different respondents and it was noted whether the interfaces were internal to the organization or whether they were interfaces with external organizations (but within the project organization). The interviews demonstrated that there is limited overlapping of common interfaces between the four specialisms taking part in the interview process. This seeming lack of common understanding between the various disciplines is in itself significant.

COMMUNICATION INTERFACES ESTABLISHED FROM INTERVIEWS

Communication interface problems were frequently mentioned in the interviews – with the source being interference in the communication process. This was identified by Dainty *et al.* (2006) and shown within the linear process diagram shown here as Figure 1.

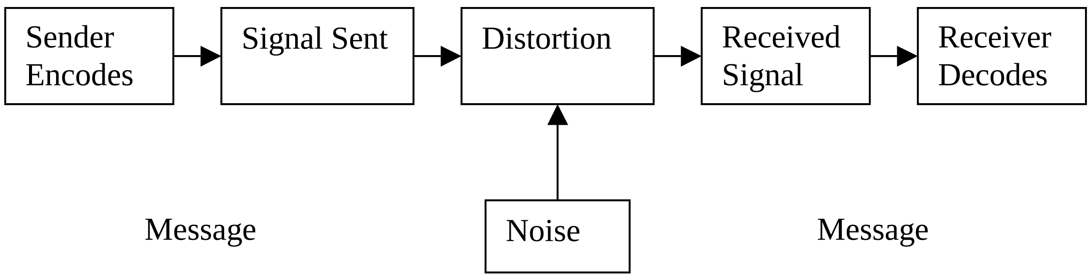

Figure 1: A model of the communication process (Dainty *et al*. 2006)

If a message, at the start of the process, is distorted due to noise (i.e. a distraction) the received signal is decoded so arrives as something different from the message sent at the start of the process.

Dainty *et al*. (2006) identified that effective communication is the key to achieving coordinated results, managing change, motivating employees and understanding the needs of the workforce. Thus improved communication is as vital to the prefabrication sector as it is in the industry as a whole.

Table 2 shows the interview responses to each individual interface both internally and externally highlighting the problems from each area from the modular supplier.

This chart shows all responses from the in-depth interviews for all interface issues both communicational and physical; as can be seen from the chart there are a wide range of interfaces for which a frequent breakdown has been established. The chart shows that there are many internal interface issues, which may highlight that the interviewees are concerned with their internal environment.

Those shaded more lightly show the links between the interfaces and external parties; those shaded darker indicate that the interface occurs within the internal environment of the business. Using the example of acoustic testing the client, principal contractor and acoustic testers are all involved within the process.

The information gathered from the interviews and questionnaires was used to establish a set of interface issues relating to the timing, communication, organizational structure, the internal and external environment and parties involved within the prefabrication process as a whole.

Table 2: Mapping interface versus respondents internal/external view

Interface problems identified involving interaction with external parties

Weekly delivery report	33	38	22			
Window delivery and installation on and off site		39		12		19 Window fitters& suppliers
Window drawings and schedules	34	40		13		20Window suppliers
Number of ‘external interfaces’ in which problem has been encountered	34 (52%)	40 (60%)	22 (33%)	13 (20%)	7 (11%)	20 (30%)

The percentages indicate the frequency of engagement in the problematic interfaces. The principal contractor is therefore involved with 60% of the problematic interfaces, the client with 52% the installer with 33%, other contractors such as window and transport suppliers with 30%, the architect 20% and finally the structural engineer with 11%.

Based on the findings from the interviews a questionnaire was then devised to issue to selected commercial contractors and house developers in order to gain an insight into whether the prefabricator’s perception of problems correlated with those of contractors managing the construction project. Fifteen questionnaires were circulated to selected commercial contractors and house developers of which eight responses were returned.

Open-ended and closed questions were used and a series of rating scales provided to determine frequency and severity of interface problems.

The open-ended questions enabled more qualitative responses to be provided by the contractors: ‘offsite production took the burden of repetitive works off the critical path’ and ‘the system was relatively costly, but the speed helped to reduce prelims and allowed other trades to commence early in dry conditions’.

Some negative aspects established from the respondents were that ‘it is difficult for trades up to DPC if they have not had previous experience with areas such as accuracy of bases, design detailing also needs considerable special attention, long lead in times for prefabricated components and designs have to be done a long way in advance with some designs completed late causing complications to the construction’. From this it is clear that design is (potentially) a key negative factor with the use of prefabrication. The need for early design input and for knowledge and expertise of designing for prefabrication is essential. Attitudes of respondents were however generally positive with few negative points.

Answers to the questionnaire were formatted within a matrix to include the frequency rating of the problematic interface and the severity rating of the specific interface. This matrix (Table 3) shows the frequency and severity rating of the respondent’s experiences with the interfaces. There are many overlapping interfaces where more than one respondent answered the same frequency or severity rating. From this it is clear that there are few very high frequency ratings and very few high severity ratings, suggesting that prefabrication is viewed positively by the responding contractors.

Table 3: Frequency and severity ratings of interface problems

Ref	Interface	Problem frequency rating				Severity rating				IF PARTICULAR PROBLEM OCCURS PLEASE STATE HERE
		1	**2**	**3**	**4**	**1**	**2**	**3**	**4**	
1	Arrival of prefabricated modules on site	2	1 3			1 2		3		
2	Quotations from the prefabrication company	1	2 3			1	2	3		
3	Poor communication	1	2	3		1	2		3	
4	Design/project meetings			1 2 3				1 2 3		Difficult when prefabrication company is far away
5	Detailed architect module layout drawings		2 3	1			2	1 3		Designers need specialist knowledge
6	Deliveries of prefabricated components to site		2 3	1			1 2	3		Some upper floor panels arrived before ground floor
7	Erection schedule		1 2 3			1	2 3			
8	Final handover of prefabricated components		1	23			1	2 3		Clear scope of works required, who provides what
9	Health and safety files for the prefabricated components	1 3	2			1	2 3			
10	Movement of finished prefabricated components on site		2 3				2	3		
11	Fire stopping between prefabricated components and traditional construction			1 2 3			1 3	2		Careful attention/detailing required
12	Fixings schedules for the prefabricated components	1	3	2		1		2 3		Normally clear and concise
13	General arrangement drawings from the prefabrication company	1	2 3			1	2 3			Normally clear and concise
14	Handover documents for the prefabricated components	3	1 2				1 2	3		More difficult if other parties become inv
15	Installation of prefabricated components	1 3	2			1 3	2			
16	Lifting equipment for the prefabricated components	1 3		2		1	3	2		Quite easy
17	Modular specifications	1 3	2			1	2	3		
18	Tolerances for the prefabricated components	3	2	1		3	2	1		Can be very difficult
19	Offer to supply form the prefabricated company	3	2				2 3			
20	Operations and maintenance manuals for the prefabricated components	1	2 3			1 3	2			
21	Planning applications for the prefabricated components	1 3	2			1 3	2			No great problems but restrictions on design freedom
22	Involvement from the prefabrication company	1	2 3			1	2	3		
23	Remedials on the prefabricated components	1	2	3		1	2 3			
24	Reference drawings for the prefabricated components	1 3	2			1	2	3		
25	Testing of the prefabricated components	1	2	3		1	2	3		
26	Technical queries for the prefabricated components		2 3	1			2 3	1		Designers need to fully understand the system
27	The crane usage for the prefabricated components	1 3	2			1 3	2			
28	Timing and programming for the prefabricated components	1	2 3			1	2	3		
29	Transport for the prefabricated components	1 3	2			1 3	2			
30	Supply risks of the prefabricated components	1 3	2			1 3	2			
31	Variations to the contract from the prefabricated components	3	1 2			1 3	2			
32	Weather proofing of the prefabricated components	3	1 2			1 3	2			

Table 4 gives a summary of these findings in terms of the frequency they occur, their severity, and the number of contractors who identified each level.

T**able 4:** Frequency and severity rating

	Problematic frequency				Severity rating			
	1	**2**	**3**	**4**	**1**	**2**	**3**	**4**

Total answers (1 + 2 + 3 + 4 = 100%)	35%	**47%**	18%	0%	34%	**40%**	25%	1%
1 Respondent	46%	34%	53%	0%	44%	53%	61%	100%
2 Respondents	54%	59%	12%	0%	56%	47%	26%	0%
3 Respondents	0%	7%	35%	0%	0%	0%	*13%*	0%
Total respondents (1 + 2 + 3 + 4 = 100%)	100%	100%	100%	0%	100%	100%	100%	100%

A problematic frequency and severity rating of 2 was the most popular choice followed in popularity by rating of 1, which means that the frequency and severity is low or infrequent for the majority of interface problems. A rating of 4 is not identified for any respondent in terms of frequency and only 1% for severity rating.

The findings from the questionnaires show that there clearly are problematic interfaces between modular and traditional construction although these interfaces carry different weightings of severity and frequency. The most frequent score was 2 which represents ‘occasional frequency’ and ‘medium severity’ ratings. These ratings are relatively low which suggests that problems are manageable and could with care be reduced to have less impact on the project.

CONCLUSIONS

This paper set out to investigate how modern methods of construction (MMC) interface with the traditional aspect of construction. The aim was ‘to model the characteristics of interface problems between volumetric and traditional construction’.

From the interviews the following key issues were identified:

- types of problematic interface;
- lack communication within prefabrication companies concerning interfaces; and
- internal and external organizational interface problems for the prefabrication company.

From the questionnaires key points established included: severity scales for each interface problem; generally positive views on working with prefabrication except where lack of experience; the importance of design detailing and advance detailing and lead-in times for the prefabricated components.

The results from these questionnaires and interviews enabled the development of an interface model incorporating parties affected, frequency of occurrence and severity involved.

This will facilitate development of a potential solution to avoid problematic interfaces occurring. It is intended that a process time mapping model be developed in order to incorporate aspects of timing, parties, predecessors to each interface and finally the severity ratings as calculated from the questionnaires. There is great scope for further research in this field. It is hoped that this research project can be continued to enable the participation of a wider sample of prefabrication companies and contractors using this model as a basic framework.

EVALUATING THE IMPACT OF MULTI-SKILLING ON UK'S CONSTRUCTION AND BUILDING SERVICES SECTOR

O A K'Akumu,[1] A Blyth and B Jones

Property and Construction, University of Westminster, School of Architecture and the Built Environment (SABE), 35 Marylebone Road, London NW1 5LS, UK

Evidence seems to suggest that multi-skilling is a tentative redress for ameliorating skills crisis in a construction and building services industry. A 43-year time series data on 23 manpower attributes were evaluated as part of a research effort. The developed linear regression models show that the concept of multi-skilling obeys the 'law of diminishing returns'. That is, a weak relation was found between construction output and three or more combination of manpower attributes. An optimization model is prescribed for traditional trades**.**

Keywords: multi-skilling, law of diminishing returns, manpower attributes, optimization model.

INTRODUCTION

The decline in the number of entrant trainees, low trainee and employee retention, and increasing demand for construction products and services are today considered the greatest challenges facing sustainable construction in the UK (Olomolaiye *et al*. 2005; Ejohwomu *et al.* 2006a; *Construction News* 2006). Simply put, the UK's construction sector is skills proficiency deficient. The implication of which is a threat to global competitiveness, reliance on informal labour market and client dissatisfaction (Ejohwomu *et al*. 2006b; Leitch 2006). Thus, it should be safe to argue that the skills crisis within the construction sector is somewhat peculiar to service industrialized nations such as the UK and US, and not naturally endowed transition economies like India and China – an argument that is complimentary of an earlier investigation (Carley *et al*. 2003).

To this end, skills deficiency redress strategies in the UK have been focused on trainee management strategies; investment in people initiative; the new deal employment scheme; greater use of prefabrication; and the push for a demand led framework (Dainty *et al*. 2005; Olomolaiye *et al*. 2005). Comparatively, construction firms in the US particularly, in addition to the aforementioned redress strategies, have been exploring the concept of multi-skilling as an alternative workforce strategy for the skills crisis. This is a situation where workers breadth of skills crosses a number trades (Carley *et al*. 2003).

With emphasis on multi-skilling, prior research in non-construction industries shows significant benefits can be gained from utilizing a multi-skilled workforce. That is, there is a significant correlation between adopting the concept of multi-skilling and

[1] o.kakumu@wmin.ac.uk

proficiency in skills supply strategy (Alster 1989; Denton 1992); by training workers in more than one job, a workforce is more likely to support labour-saving technical progress (Carmichael and Macleod 1993). Also, more construction-focused studies by Burleson (1997, 1998) argue that the benefits of multi-skilling includes a potential 5–20% reduction in construction costs, a 35% reduction in required workforce and a 45% increase in average employment duration.

Regardless of some of its drawbacks: trainee capability and resistance to change (Park 1996; IRS Employment Review 1996), anecdotal evidence purports that the concept of multi-skilling is a tentative redress for the UK’s skills proficiency deficit. Therefore, whilst taking onboard the consequences of varying organizational practices (Xiao and Proverbs 2003), the objective of this paper therefore is to evaluate the impact (if any) of adopting the concept of multi-skilling as an alternative redress for ameliorating the skills deficit in the UK’s construction and building services sector.

UNDERSTANDING THE FUNCTIONAL CONCEPT OF MULTISKILLING

As a prelude to understanding the functional application of the concept of multi-skilling, this section of the paper will be discussing known construction and known construction multi-skilled modelling frameworks.

Non-construction specific multi-skilling models

In an investigative study of the dimensions of multi-skilling (with particular emphasis on audiology), Johnson (1999) has argued that there are three central multi-skilling models, which are appropriate to the practice of audiology: subordinate, collateral and collateral-subordinate multi-skilling.

A subordinate model

This involves the health professional performing varieties of non-professional tasks at non-professional level of practice. For example, subordinate multi-skilling is used to train the audiology professional to perform non-clinical tasks. This is particularly beneficial to a situation where the gap lies in the educational audiologist not having readily available support personnel.

A collateral model

In a collateral multi-skiling model, professionals from other disciplines are up-skilled through cross training to perform non professional works. For example, nurses can be trained to perform pure-tone air-conduction hearing screening.

A collateral-subordinate model

In this model, support personnel of other professions are up-skilled through cross training to perform the duties of a non professional in a different section. However, regardless of the distinct peculiarity of each of the aforementioned multi-skilling model, it is commonplace in the literature that the concept of multi-skilling can best function where manpower gap(s) exist. But the flexibility/application of these models to a construction specific sector remains unascertained.

Construction-specific multi-skilling models

In an exploratory effort to quantify, at project level, the potential benefits of utilizing a multi-skilled workforce, Burleson *et al.* (1998) derived four multi-skilling modelling strategies: dual, four, four skills-helpers and theoretical maximum labour strategies.

A dual skill labour strategy
Burleson *et al*. (1998) argued that the dual skill labour strategy was developed as a direct extension of the traditional wave theory of project scheduling. That is, as a schedule is developed, the primary objective of a working gang will be to achieve maximum productivity whilst performing tasks – a pattern that is consistently employed whilst dealing with all allocated tasks (Coombes 1990). Drawing on this theory, it can be argued that the dual-skill concept identifies craft combinations with complimentary workloads, thus ensuring employees enjoy a prolonged employment duration by being dual-skilled.

A four skill labour strategy
A four skill strategic model is a multi-skilling framework for minimizing sets of general craft classifications. In order words, if the skills requirement for executing a particular project from its conception to completion phase is classified into four general groups, for instance, its multi-skilling factor would then be centred on four different combinations. For example, in the development of the CII model plant project, Burleson *et al*. (1998) derived these four skill craft groupings: civil/structural workers, general support workers, mechanical workers and electrical workers – a grouping that is specific to the CII model plant project.

A four skill-helpers labour strategy
This is a modification of the four skills labour strategy. However, in this case, each original craft group consists of workers from three skill levels: novice/helper, journeyman, and foreman. Although, the underlying concept of the four skill-helpers labour strategy is somewhat a direct translation of a collateral-subordinate multi-skilling model. Burleson *et al*. (1998) has argued that the theoretical basis of this strategy is dependent on factor flexibility across the project.

A theoretical maximum labour strategy
This multi-skilling model assumes that the ‘construction worker’ consists of just one craft classification system. Theoretically, all construction workers are fully multi-skilled and flexible – thus, they can be moved across any project task. In order words, functionally, a theoretical maximum labour strategy identifies a maximum to the benefits of multi-skilled craft utilization (Burleson *et al*. 1998).

PRESENTATION AND ANALYSIS OF DATA

The study data – a 43-year time series, which is secondary – was harnessed following a literature review and questionnaire survey (semi-structured) of, the supply and demand for construction and building services skills in the Black Country (Olomolaiye *et al*. 2005; Ejohwomu *et al*. 2006b). Hence, it would be pertinent to note that the rationale for investigating this secondary information stems largely from the paucity of construction firms that completely imbibes the concept of multi-skilling. However, the suitability of the data used rests in its wholeness, that is, the annual construction statistics report (primary source of the secondary data) reliably compiles indexed information on the goings-on of the construction and building services sector.

Reliability of data

Drawing on the arguments for and against the reliability of the existing construction and building services statistics (Pearce 2003; Briscoe 2006), emphasis was placed on addressing the problems of data inconsistencies, i.e. ensuring consistency of constructs through ‘re-assignment’. In addition, data conversion software was employed during data computation to eliminate typographical and duplication errors.

Missing data
With the aid of SPSS, all missing data were coded using numerical values. Although this value simply tells the computer that there is no recorded value for a participant for a certain variable; in this study, missing values were computed using averages to particularly enhance any continuity of trend (Field 2000).

CORRELATION

Following the explorative data analysis, a measure of the linear relationship of the participating variables became imperative for robust modelling.

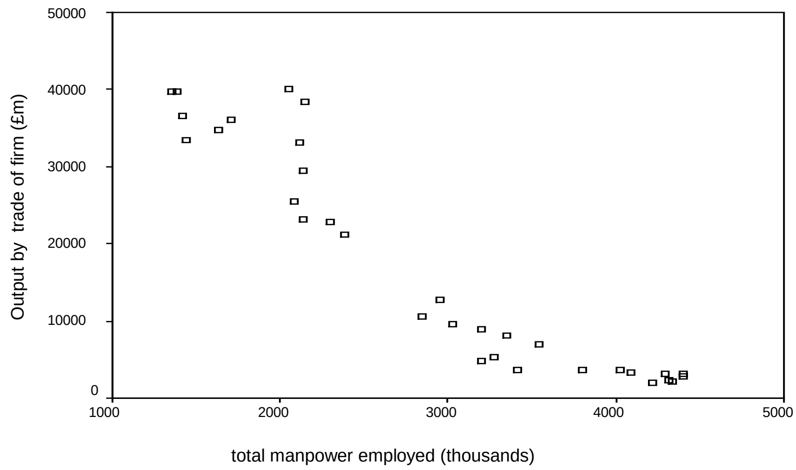

Figure 1: Scatter plot – output against TMPE

Figure 1 is a scatter plot of aggregate output and participating aggregate manpower variables. A scatter plot tells us the nature of the relationship, if any, what type of relationship it is and whether any cases are markedly different (outliers) from the others? Overall, the resulting scatter plot (Figure 1) suggests a negative linear relationship persists, that is, as output increases aggregate manpower decreases. Also, there are no obvious outliers in that most points seem to fall within the vicinity of other points. Note that a scatter plot of aggregate output against disaggregated manpower (22 independent variables) showed semblance characteristics. See Appendix 1 for 3D scatter plot of traditional and non-traditional manpower variables.

Pearson’s Correlation Coefficient (PCC)
On completing the preliminary glance at the data, correlation was conducted in SPSS using Pearson’s Correlation Coefficient (PCC). The decision to perform the PCC was informed by the nature of data (parametric) being investigated.

		Total manpowe employed Thousan operatives trade of	total value work
Total employed - operatives by trade firm	Pearson	1	-.938**
	Sig. (2-	.	.000
	N	32	32
total value of work	Pearson	-.938**	1
	Sig. (2-	.000	.
	N	32	32

**. Correlation is significant at the 0.01 level (2-

Figure 2: Correlations

Figure 2 provides a correlation for output and manpower variables. Underneath each correlation coefficient, both the significance value of the correlation and the sample size (N) on which it is based are displayed. In Figure 2, aggregate output and aggregate manpower are negatively correlated with a Pearson's Coefficient of r = -0.938 and there is a less than 0.001 probability that a correlation coefficient this big would have occurred by chance. The significance value suggests that the probability of this correlation being a 'fluke' is very low. Hence, the confidence that the relationship between manpower and output is genuine; but the correlation matrix for output and disaggregated manpower revealed an averagely high Pearson's Correlation, r. The implication of which is difficulty in fitting the data to a linear regression model given likely possibilities of multicollinearity. Therefore, as precautionary measure factor analysis, which is a data reduction technique was implored as a cushion for multicollinearity (Dunteman 1989).

EXPLORATORY MODELS

Following the successful disaggregating and identification of all underlying variables and in line with the concept of multi-skilling, eleven exploratory models were developed based on Equation 1, which is a multiple regression equation

$$Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \ldots\ldots\ldots\ldots\ldots + \beta_nX_n \qquad (1)$$

Where, Y = dependent variable; β_0, the intercept (constant) and $X_{1\text{-}n}$, independent variables. In other words, functionally, the dependent variable Y is the value of work done (construction output). While the independent variables from which the conceptual framework used in evaluating the concept of multi-skilling was derived (see appendix 2) are: general builders; building and civil engineering contractors; civil engineering; demolition; reinforced concrete specialist; roofers; asphalt and tar sprayers; scaffolding specialist; insulating specialist; plumbing; heating and ventilation; plastering; joiners and carpenters; flooring contractors; floor and wall tiling specialist; suspended ceiling specialist; painting; glazier; plant hirers; electrical contractors; constructional engineers; and miscellaneous.

However, it would be pertinent to note that some of the predictors in these exploratory models are accepted based on past research findings (Burleson 1997; Carley *et al.* 2003); while others were based on substantive theoretical inferences. Table 1 is a summary of the developed exploratory models showing the values of r, r^2, Durbin-Watson, p-value and full regression equations. See Appendix 2 for fuller details on the adopted skills combination framework

Table 1: Summary of developed exploratory models

Predator Variables	R	R^2	P-value	D-Watson	Model
1) Un-factored TT	0.998	0.995	0.0001	1.227	Y=1165.938 + (10.23Heating&Venti) + 14.52Joiners&Carpenters
2) Factored TT	0.963	0.928	0.0001	0.208	Y=22819.731 + (12944.45 TT)
3) 2 Step Multiskill A	0.997	0.993	0.0001	1.704	Y=747.550 + (15.66 Heating & Venti)
4) 2 Step Multiskill B	0.972	0.946	0.0001	0.169	Y=3548.792 + (40.068 Joiners &Carpenters)
5) 2 Step Multiskill C	0.925	0.857	0.0001	0.062	Y=3264.533 + (28.447 Painting)
6) 2 Step Multiskill D	0.998	0.995	0.0001	1.727	Y=1165.938 + (10.23Heating &Venti) + (14.52 Joiners&Carpenter)
7) 3 Step Multiskill A	0.997	0.993	0.0001	1.704	Y=747.550 + (15.663 Heating & Venti)
8) 3 Step Multiskill B	0.995	0.990	0.0001	0.562	Y=-5360.506 + (31.47Joiner&Carpenter) + (31.44Elec Contr) + (8.77Roofers)
9) 4 Step Multiskill A	0.998	0.995	0.0001	1.227	Y=1165.938 + (10.23 Heating& Venti) + (14.52Joiner&Carpenter)
10) 4 Step Multiskill B	0.972	0.946	0.0001	0.169	Y=3548.792 + (40.07 Joiner&Carpenter)
11) Factor TT & N_TT	0.999	0.999	0.0001	0.967	Y=22819.73 + (12944.45 TT) + (3571.94 N_TT)

* TT = Traditional Trades; N_TT = None Traditional Trades

As shown in Table 1, the eleventh model with predictor variables *factored TT and N_TT* explained the most variance in *output* (R^2 = 0.999), simply because all of the 23 manpower variables were considered. However, in reality, it would be rarity for a tradesman to be skilled in all 23 trades.

Model number five with predictor variables *painting* and *plasterers* explained the least variance in *output* (R^2 = 0.857), a finding that can be attributed to considerable poor mix of skills. Also, models one, six and nine, regardless of their different combinations of predictor variables, explained precisely the same amount of variance in *output* (R^2 = 0.995), which is a clear indication that given the ideal mixes of skills, the concept of multi-skilling can only be beneficial.

However, the overall implication of these finding is that, the concept of multi-skilling obeys the economic theory of diminishing returns. That is, as we add more units of a variable input (for example, labour) to fixed amount of construction output, the change in variance explained will first rise and then fall. Therefore, based on these analyses, the optimum number of manpower attributes is two, a finding that is complementary of the results of an earlier investigation by Gomar *et al*. (2002), wherein further research involving optimization models indicates that there is almost no marginal benefit to being semi-skilled (or greater) beyond three combinations of manpower attributes. Furthermore, the negative coefficient derived in model number eight is a clear indication that the wrong combination of skills can result to negative productivity. Note that the decision to fit the models on a linear regression was informed by the nature of variable relationship (see Figures 1 and 2). In addition to the 11 models being statistically valid (by referring to the R – squares and p-values only), conclusively, emphasis will be placed on model number 6 because it is arguably the most efficient and/or economical, as suggested by its Durbin-Watson value of 1.727.

CONCLUSIONS

The UK construction and building services sector is skills proficiency deficient. The implication of which is the threat to global competition, reliance on informal labour markets and client dissatisfaction. However, drawing on existing gaps – skills crisis – a labour utilization strategy (multi-skilling) was considered as tentative redress for efficiency in skills supply proficiency and sustainability. To this end, this paper's finding showed that multi-skilling is beneficial to the UK construction sector provided the appropriate combination of skills is used. An optimization model for implementing the concept of multi-skilling thus prescribed - Y=1165.938 + (10.23Heating &Ventilation) + (14.52 Joiners and Carpentry).

INVESTIGATING THE MAIN CAUSES OF VARIATION IN CONSTRUCTION PROJECTS IN DUBAI

Mohammad A Salama,[1] Paul D Gardiner and Habib A Malikappurayil

Management, Heriot Watt University, Riccarton, Edinburgh, EH14 4AS, UK

The construction industry in UAE in general and Dubai in particular has been witnessing an unprecedented boom. However, despite the readiness of financial resources as well as the active participation of multinational construction companies, the construction projects suffer from considerable variations in time and cost. The study aims at investigating the main attributes of the construction industry in Dubai in an attempt to identify the key factors that cause variations. The research comprised a set of semi-structured interviews to identify the factors followed by a questionnaire to investigate the probability of occurrence and the impact of the main factors on time and cost. The study shows that the prevalent intervention of the clients in the decision making process throughout the project lifecycle coupled with a tendency to expedite projects are the primary causes for variations in time and cost. In addition, the results reflect the gap between supply and demand in the construction sector due to the rapid growth fuelled by the needs of the fast growing economy in UAE. The study concludes with recommendations to create more awareness among stakeholders, and especially clients, of the importance of the initiation and planning phases of the project to hedge against future variations.

Keywords: construction, cost, Dubai, time, variation, client.

THE CONSTRUCTION INDUSTRY IN UAE

In UAE, the construction industry contributes almost 7.5% of non-oil GDP besides being a vital source of employment. In the first quarter of 2004, almost 6000 construction companies were registered; 2119 buildings were completed including 1,436 villas and residential complexes, 393 multi-storey commercial buildings and 290 industrial, entertainment and service buildings (Belaid and Bader 2005). With prestigious projects like Burj Al Arab (the world's tallest hotel), Ibn Batutta Mall and the Mall of the Emirates (the largest shopping centre outside North America), Dubai has succeeded in capturing the interest and attention of both construction specialists and investors in the global market. Even ordinary people strolling the streets of Dubai will assure that property prices in Dubai is guaranteed to appreciate in the range of 15–25% per annum, hence rendering the property developing firms' shares amongst the best performers in the Dubai stock exchange market. In a different context, tourists come just to cast their eyes on these landmarks. To add to the list of major upcoming mega construction projects in Dubai there are: the Palm islands (Jumeirah Palm, Deira Palm and Jebel Ali Palm), World Island, Burj Dubai (which will be the tallest tower in the world upon completion) and, finally, Dubai land, which is said to be another Disneyland but will be twice the size of it.

[1] m.a.salama@hw.ac.uk

According to a study by EFG-Hermes, an Egyptian investment bank with offices in Dubai, the real estate and construction sectors have become the centrepiece of Dubai's economy. Hanware (2005) estimated that at least $50 billion of residential projects will be built in the next four years, including at least 85,000 new homes.

In 2003, the construction industry employed 111,700 employees, which is 15% of the total employees in UAE with a soaring trend to meet the demand due to the increasing volume of construction. During the period 2000–2003, the number of employees in the construction industry in Dubai increased by 33%. Moreover, after allowing expatriates to own property in Dubai in 2002, the freehold market and the property market have witnessed a remarkable growth that has contributed to the expansion of the construction industry. The number of freehold properties is expected to double by 2009 (ASTECO 2005).

Dubai has 30,000 of the world's total 125,000 construction cranes and, as of April 2006, US$300bn worth of projects is ongoing in UAE (Gulf news 2006). Despite having such a high statistic in terms of the number of construction projects, plant and machinery, it is surprising to note that around 90–95% of construction projects witness an overrun in terms of time and money. For example, the Mall of the Emirates, a 223,000 square metre shopping centre was tendered for an amount of approximately AED 600 million and scheduled for 18 months. The final figures soared up to AED 850 million upon completion, i.e. around 38.5% increase in cost. The Dubai Police headquarters building, which is a landmark in Dubai, was tendered for a value and duration of AED 115 million and 18 months respectively. The figures at completion are 26 months and AED 147 million, which is 28% over budget and 44% over scheduled duration. The same project attracted 180 variation claims, out of which about 165 were approved.

The study aims at investigating the main factors that lead to time and cost variation in the construction industry in Dubai despite several mitigating factors that suggest the availability of both knowledge and skills: readiness of resources and active participation of multinational construction firms.

RESEARCH METHODOLOGY

The study starts with a review of the factors stated in the relevant literature both in the global construction market and in the Middle East in particular.

The research design comprised a set of seven semi-structured interviews in which experts were asked to identify the factors they perceived as the most important drivers for variation. The output of the interviews was consolidated into a questionnaire that was sent to a sample of 55 project managers out of which 23 responded, representing a response rate of 42%. The data collected are discussed in the analysis section.

The study concludes with recommendations for the Dubai construction industry based on the research findings.

Literature review

Time and cost overruns are significantly a lose-lose situation for all the stakeholders involved in the project (Eden *et al*. 2005). The increase in cost of materials due to inflation, inaccurate material estimating and the degree of project complexity results in cost overruns. Whereas, in the case of delays, amongst the important factors are design changes, poor labour productivity, inadequate planning and resource shortage (Arian and Pheng 2005). Failure to apply adequate or appropriate project management tools and techniques result in overruns, which in turn lead to rework due to the absence of quality tools and techniques essential for performance improvement (Love *et al*. 2000).

Al Momani (1996) investigated the causes of delay on 130 public projects in Jordan. The results indicate that the main causes of delay in the construction of public projects relate to project designers, user changes, weather, site conditions, late deliveries and economic conditions. Assaf (1987) investigated the main causes of delays in large building projects and their relative importance and main causes of delay that exist in Saudi Arabian construction projects. This study classified the factors according to key stakeholders' perspective: the contractors, consultants and owners. The contractors' factors included design change, preparation and approval of drawings, subcontractors' progress and payment by owners. The consultants' factors included cash problems during construction, relationships and slow decision making by owner. The owners' factors included design error, labour shortage and inadequate labour skill.

Koushki and Kartam (2004) investigated the impact of construction materials on time and cost of construction projects in Kuwait: 450 residential projects were studied. The research delved into various sub-factors that are the drivers for cost overrun due to materials. The factors included selection, availability, late delivery and price inflation during the construction. They concluded that one fourth of the projects were delayed due to late material delivery, where as price inflations accounted for project cost overrun in approximately 13% of projects.

Koushki *et al*. (2005) investigated the delays and cost increases in construction projects in Kuwait. The study stated that the three main causes of time-delays included changing orders, owners' financial constraints and owners' lack of experience in the construction business. Regarding cost overruns, the three main causes were identified as contractor-related problems, material-related problems and, once again, owners' financial constraints. The minimization of time delays and cost overruns in private residential projects would require the availability of adequate funds, allocation of sufficient time and money at the design phase, and selection of a competent consultant and a reliable contractor to carry out the work.

Salama *et al*. (2005) studied the relationship between macroeconomic factors like GDP, exchange rate, interest rate and the cost of construction in Egypt. The study emphasized the impact of the macroeconomic factors on project costs especially in periods of economic turbulence. However, these factors are not considered to be embraced in the cost estimating process explicitly.

Eden *et al*. (2005) mentioned that public projects are more prone to have massive overruns compared to other construction projects and referred to some examples: Denver Airport (cost overrun of 200%), the Danish kroner Oresund Bridge (68%) and the Scottish Parliament, which witnessed a tenfold increase in the budgeted figures.

However, other construction projects are also prone to overruns attributing these problems to factors such as poor project management practice, government polices, economic factors, and natural environmental issues (Frimpong and Oluwoye 2002).

Eden *et al.* (2000) and Ciccarelli (2004) mentioned that a major factor during the execution phase is the intervention of the client to change the scope hence altering the project's time schedule and cost. Hatush *et al*. (2005) stated that clients change the scope and requirements quite frequently without a proper recognition of the consequences thus resulting in project overrun. The study recommended freezing the design philosophies also suggested that changes should be allowed only under controlled circumstances.

Data collection

To identify the main factors that cause delay and cost overrun, semi-structured interviews were conducted with seven experts. As Dubai has a diversified and multicultural population with nearly 88% foreign population (ASTECO 2005), a diversified sample of different nationals was selected for the interview sample. The sample included representatives of the three main categories, namely the client, the consultant and the contractor with a minimum 15 years of experience in construction and an average of 25 years of experience for the whole sample. Also the sample has an average of 10 years of experience in UAE construction market covering a wide range of projects including residential, commercial and industrial buildings with values ranging from $10m–170m mostly delivered by multinational construction companies. The interviews identified 23 factors as shown in Table 1.

A questionnaire comprising these factors was sent to a sample of 55 project managers from different nationalities with an average experience of 10 years in the construction industry asking them to classify the impact of each factor on time and cost overrun as well as the probability of occurrence for each factor. The questionnaire offered two categories: low and high. In addition, the respondents had the null option if the factor under investigation had zero probability or no impact. However, this option was not chosen by any respondent. Also respondents were offered to add any factor that was not included in the questionnaire if needed.

The results based on 23 respondents were then segregated into three frequency tables for each factor. These are represented by three sets of graphs (probability, impact on time and impact on cost) as shown in Figures 1, 2 and 3. For example, Figure 1 shows the frequency and category of each factor. Factors that are perceived as of high probability of occurrence and meanwhile of high impact on time or cost will be discussed further.

Table 1: Factors leading to variation in time and cost

Factor Number	Factor Description	Factor Number	Factor description
1	Design changes	13	No proper supervision of works executing
2	Inadequate knowledge for requirements	14	Insufficient machineries
3	Inaccurate budgeting and estimating	15	Clients being developers and investors
4	No proper surveying of existing conditions	16	Fast track projects
5	Client procured materials	17	Giving relationship preference over the authority of the consultant
6	Delay in providing information	18	Insufficient time given to consultants for a complete design
7	Structural design problems discovered in the execution phase	19	The requirements are not well defined and explained for the design
8	Delay in approvals of materials	20	Scarcity of specialised subcontractor due to the high volume of construction
9	Delay in approvals of subcontractors	21	Coordination problem as more participants involved
10	Slow progress with respect to the schedule	22	Contractor evaluation not proper with respect to the construction volume
11	Inadequate skills	23	Client dominated market
12	Misinterpretation of scope		

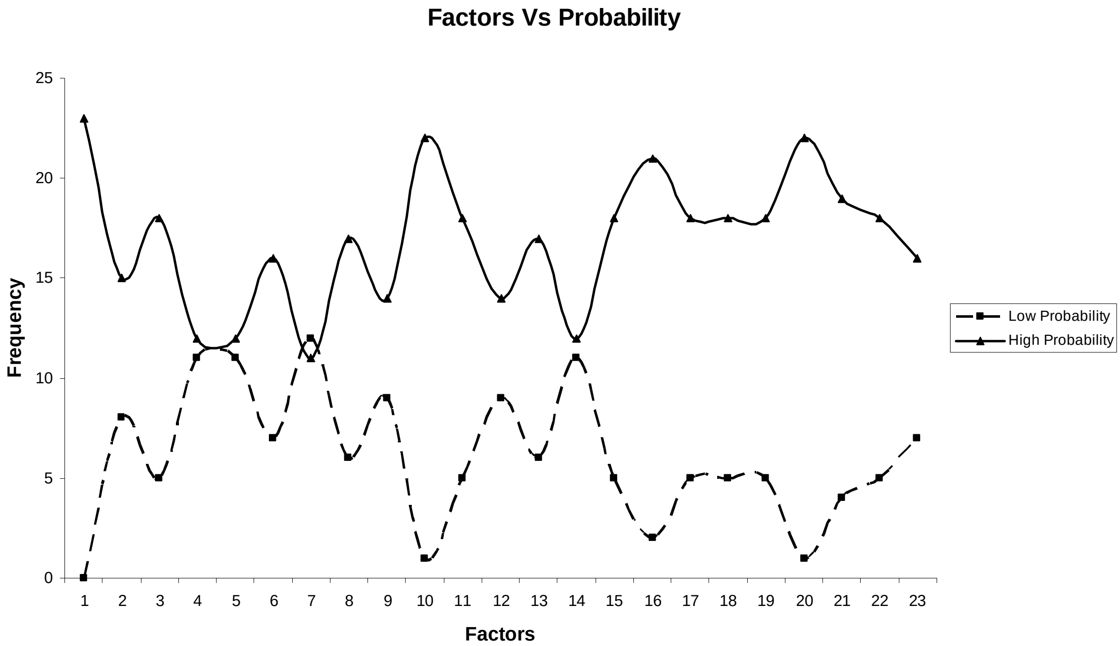

Figure 1: Factors vs. probability

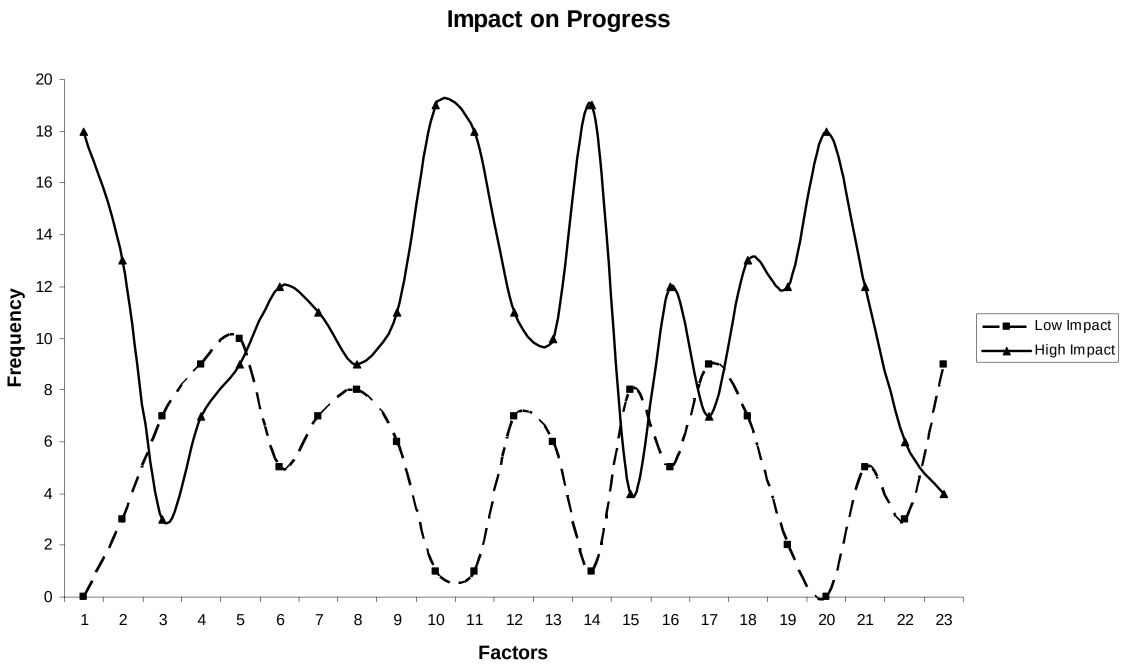

Figure 2: Impact on progress

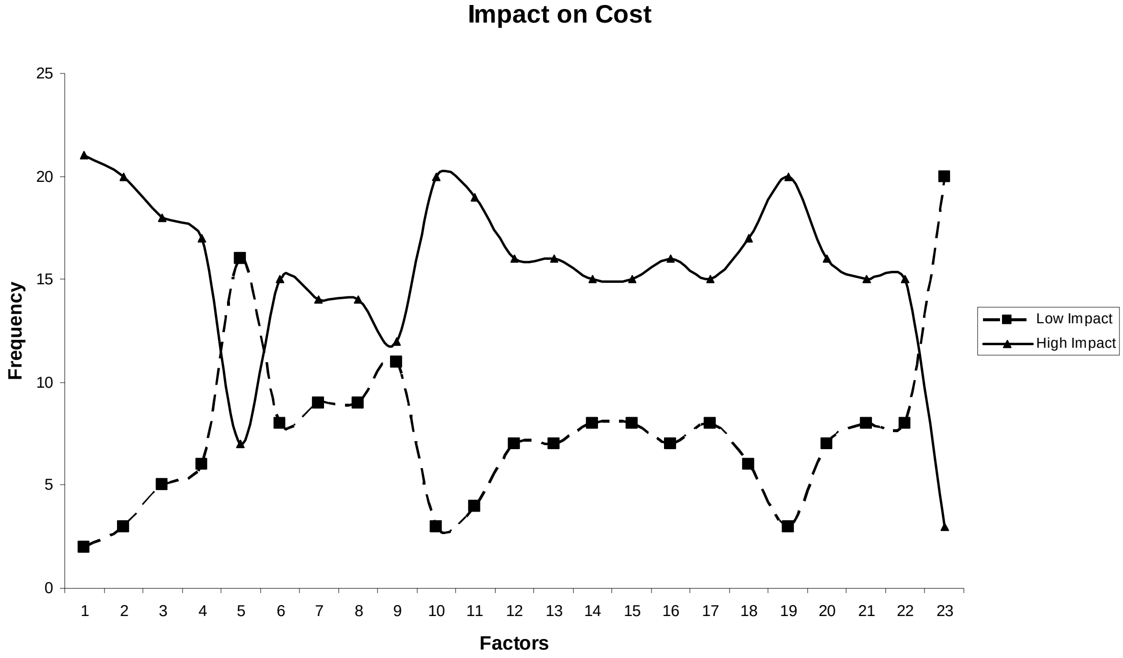

Figure 3: Impact on cost

Discussion

The results show that factors 1, 10, 16, 19 and 20 are most likely to occur. Four of these factors are interrelated. Fast track projects (16) are mostly associated with imprecision of scope (19) and design changes (1) that would slow the progress (10). Factor (20), the scarcity of specialized subcontractors, is an interesting finding that reflects a gap between the demand and supply in the construction sector in UAE in general and Dubai in particular. This gap is also manifested in factors 11, 13 and 14 reflecting the shortage in skills, and machinery.

Despite the readiness of resources, the hyper rate of development in the UAE and its implication on the construction sector has enhanced the tendency towards fast track projects. However, the industry lacks skills and machinery as the supply cannot keep up with the fast moving demand thus rendering fast track projects a risky endeavour.

The type of client has an impact on the construction industry as illustrated in factors 15 and 23. Being mostly developers and big investors, clients seek to cut costs and time simultaneously. With an annual appreciation of 15–25% in the price of property in Dubai, the rush to enter the lucrative business is another factor that widens the gap between the supply and demand in the construction market. The clients' propensity to rush the project phases is manifested in factor 18 which, when coupled with factors 2 and 4, reflects a lack of knowledge. This results in inaccurate estimates and design problems as stated in factors 3 and 7. The identified factors can be classified into three main categories:

1. Factors that occur during the initiation and planning phase – mainly to do with a lack of clear definition of the project scope, leading to changes in the execution phase resulting in variations in time and costs.
2. Factors that stem from the clients' lack of regard to the importance of each project phase. Mostly clients' market driven attitude pushes them to expedite project phases either by using a fast track approach or by squeezing the time

allocated for the initiation and planning phase as mentioned above. Clients' intervention is one of the major factors that leads to variation as previously identified in the literature review section. Clients insist on playing a leading role in the approval of design, subcontractor selection, materials and changes despite hiring a qualified project management firm thus causing delays in approvals and in many cases influences the quality of the decision made. In making decisions for the construction projects, investors in UAE often have other considerations that are not always aligned with the project management professional's approach and what is widely known as best practice. Practitioners in Dubai, for instance, report a considerable number of cases whereby the client requests additional floors to a building after the construction has started or a review of the whole design to add flats to each floor to increase profits.

3. There are external factors that inflict on the construction industry and lead to unfavourable consequences at least in the short term (manifested in a shortage of skills and machinery in general and specialised subcontractors in particular). The rapidly growing economy of the UAE is associated with a fast moving mechanism of decision making that relentlessly reviews the rules and regulations to cater for the needs of the fast growing economy. Such changes may cause a gap between the demand and supply in the construction industry (at least in the short term) as was the case when Dubai allowed expatriates to own property and moreover to boost up the property market: property owners in Dubai are allowed permanent residence in the country. The price of property in Dubai soared attracting more investors to enter the lucrative property market (ASTECO 2005). On the other hand, the fast growth of the economy is attracting expatriates from various countries in all sectors. The constantly increasing numbers of expatriates moving to Dubai maintain the demand side in the property market and keep property prices on the rise despite the construction boom. It is suggested in this paper that these conditions will prevail in the short term.

On the other hand, the results suggest that there is a lag in supply manifested by a shortage in skills, subcontractors and machinery and is identified as an important cause of the variations in projects as shown in Figures 2 and 3. These figures illustrate the impact of the different factors on time and cost respectively. The findings mostly agree with the literature emphasising the importance of the initiation and the planning phases where proactive measures can be factored in at an early stage to hedge against cost and time variations in the later stages.

The results show that clients' intervention leading to delays in approvals or drifting key decisions in favour of agendas foreign to the project and alien to the norms and best practice has unfavourable consequences on time and cost alike.

RECOMMENDATIONS

In January 2007, the financial market in Dubai made an effort to create awareness among investors to conduct adequate research before embarking on risky endeavours that jeopardise the whole stock market. The discussion above suggests the need for a similar campaign targeting the clients in the construction industry by communicating the importance of the planning phase whereby a clear scope should be identified and agreed upon by stakeholders. Also there should be a mechanism for decision making that, besides being flexible to absorb the market changes should be based on set standards and a clear definition of roles and responsibilities. This would regulate the clients' intervention and act as a safeguard against decisions that yield unfavourable ramifications. Together with an effective configuration management system from the outset, the consequences of the inevitable changes could be managed proactively.

CONCLUSIONS

The study explores the main attributes of the construction industry in Dubai in an attempt to identify the key factors that cause variations in time and cost. The results indicate that poor planning manifested in the ambiguous scope definition leads to considerable changes in the execution phase. This, together with the clients' disorganized intervention imposing decisions in such a manner that contradicts what is widely known as best practice, is among the most significant causes of variation. The results also show that there is a lack of skills and, in some cases, projects suffer shortages in machinery, which suggests a gap between the demand and supply due to the continuing growth in economy. The study draws attention to the need for effective measures to create awareness of the importance of the initiation and planning phases with emphasis on the clarity of scope and the set up of an effective configuration management system. Furthermore, the study recommends the establishment of an efficient mechanism that regulates the decision making process to hedge against any hasty decisions made by clients at the project level in response to the dynamic business environment in Dubai.

Limitations and further direction

The sample size in this study is relatively small; therefore, a further detailed study pursuing a larger sample is being undertaken. The future study will investigate the sub sectors of the construction industry in UAE, mainly the public and private sectors separately and in more depth with emphasis on the effect of delays and cost overruns on customer's satisfaction and the quantified impact on the construction industry in aggregate.

RISK MANAGEMENT AND ANALYSIS TOOLS FOR CONSTRUCTION SITES

Ai Lin Evelyn Teo[1]

Department of Building, National University of Singapore, Singapore 117566

Most of the monitoring tools for managing site safety used by local construction industry do not allow for the different risk levels inherent in the factors contributing to accidents on sites. These tools also do not reveal whether such deficits are critical or non-critical in warranting immediate attention. This study postulates the hypothesis that "unless the critical factors are identified and managed, a site with a high Construction Safety Index Rating may not be safe." Survey questionnaires were conducted to gather information on the construction firms in Singapore to ascertain their opinions on the factors affecting site safety. The respondents were asked to rate the degree of each factor according to the likelihood and severity of accidents into these categories: (a) 'frequent-likely', (b) 'occasional-maybe', (c) 'remote-unlikely', and (1) 'major-fatal', (2) 'moderate-permanent disability', (3) 'minor-temporary disability' respectively. Based on the research findings, the key components influencing the occurrence of accidents in relation to their likelihood and severity are determined. A model was then developed to assist the management to better manage site safety; highlighting unsafe practices basing on the likelihood and severity of accidents. This proposed model is useful as it can help the management to prioritise so that accidents can be eliminated – especially the major-fatal ones whereby precious lives can be saved.

Keywords: accidents, construction safety index, risk management, risk matrix, safety.

INTRODUCTION

In the past, there was reluctance by owners to become involved in matters related to construction safety for fear of incurring added liability exposure (Sikes *et al*. 2000). Similarly, Singapore owners also adopt the same attitude of not getting involved in safety matters for the same reason (Teo *et al*. 2004). However, since the enactment of the new Workplace Safety and Health Act (WSHA 2006), more local owners have expanded their role to proactively promote safety, as contractors are no longer solely responsible for safety; the new Act has emphasized that all stakeholders have a role to play, including owners, for construction safety. Research by Levitt and Samelson (1987) demonstrated that reducing the frequency and severity of construction injuries is the only sure way of reducing their potential liability for worker injuries. Thus, Owners must come to realize that the costs of injuries are ultimately reflected in the costs of their construction projects (Gambatese 2000).

According to Huang and Hinze (2006), the involvement of owners has been regarded as an essential requirement for the zero injuries objective and they stressed the importance of the owner's influence on construction safety. It is shown that their impact on project construction safety is significant; it was found that an important

[1] bdgteoal@nus.edu.sg

prerequisite attributed to excellent safety performance was the involvement of the owner in financially supporting the contractor's safety program as well as in the day-to-day project safety activities (Hinze 2001). In the construction accident causation model developed by Suraji *et al*. (2001), construction accidents are caused by inappropriate responses to certain constraints that emerge during the development of the project scope, in an untimely manner. According to Huang and Hinze (2006), two of the three of the owner's involvement roles are to communicate (set safety expectations) and participate (play a part in safety programme, safety observations, safety inspections, safety enforcement, and job-safety analysis).

The key to preventing accidents is through effective identification and control of risk (Peckitt and Coppin 2005). This requires performance feedback via a structured auditable assessment process. Most of the monitoring tools for managing site safety used by local construction industry do not allow for the different risk levels inherent in the factors contributing to accidents on sites. These tools also do not reveal whether such deficits are critical or non-critical in warranting immediate attention (Teo and Ling 2006).

According to Abednego and Ogunlana (2006), a good governance concept is developed to evaluate the performance by: (a) making the right decision at the right time, which is a form of active participation; (b) taking responsive, concrete action within a reasonable time framework; and (c) continuous control and monitoring, in order to achieve the goal and to prevent the risk from occurring.

As indicated by Ward *et al*. (1991), the best strategy to prevent/minimize consequences are (1) risks must be properly identified, understood and evaluated; and (2) risk should be allocated to the party with the best capability to control the events that might trigger its occurrence, in timely manner. To sustain the consequences of the risk or to prevent the risk from occurring, it depends on the best capability to control the risk. The implemented risk management strategy dealt with the consequences of the risk by problem-solving and preventive approach. Incapability to control risk properly will be reflected in absence of good safety governance thus resulting in an unsatisfactory safety performance (Flanagan and Norman 1993).

This research is conducted to ascertain the likelihood and severity of construction accidents and utilizing the findings as the foundation to develop the concept of good safety governance by providing the priorities list for immediate actions. The theoretical relationship used in this research can be summarized in Figure 1. Following the theoretical framework in Figure 1, the research is conducted to investigate the different perceptions of proper risk management. In effect, the study utilizes this knowledge to develop the good safety governance concept as a guideline for proper risk management in construction projects.

The aim of this research is to *develop an integrated safety assessment system* (ISAS) – risk management and analysis tool, by adding on to the existing tested and validated 3P + I framework (Teo *et al*. 2004) with the following proposed features:

- The proposed system is capable of prioritizing the non-compliance in the order of likelihood and severity of accidents based on their risk level.
- The proposed system can provide the identified 'consequences of non-compliance' and 'list of recommendations' for better monitoring and management of risks.

- The proposed system can identify the risk associated with the non-compliant factors and highlight the cost implication and legal implication for not complying.

Figure 1: Proposed theoretical framework

In short, the proposed *integrated safety assessment system* (ISAS) would develop a theory to contribute additional knowledge to the existing tested and validated 3P + I framework by revealing whether such deficits are critical or non-critical in warranting immediate attention and also by highlighting the consequences for failure to act (refer to Figure 2). Moreover, the proposed system can also highlight the safety measures to be undertaken by owners for (1) providing and maintaining a safe work environment; and (2) ensuring people are not exposed to hazards arising from the workplace or areas under the employer's control. This study is important because it is stipulated by the new WSHA that owners are required to take responsibility of safety standards and outcomes.

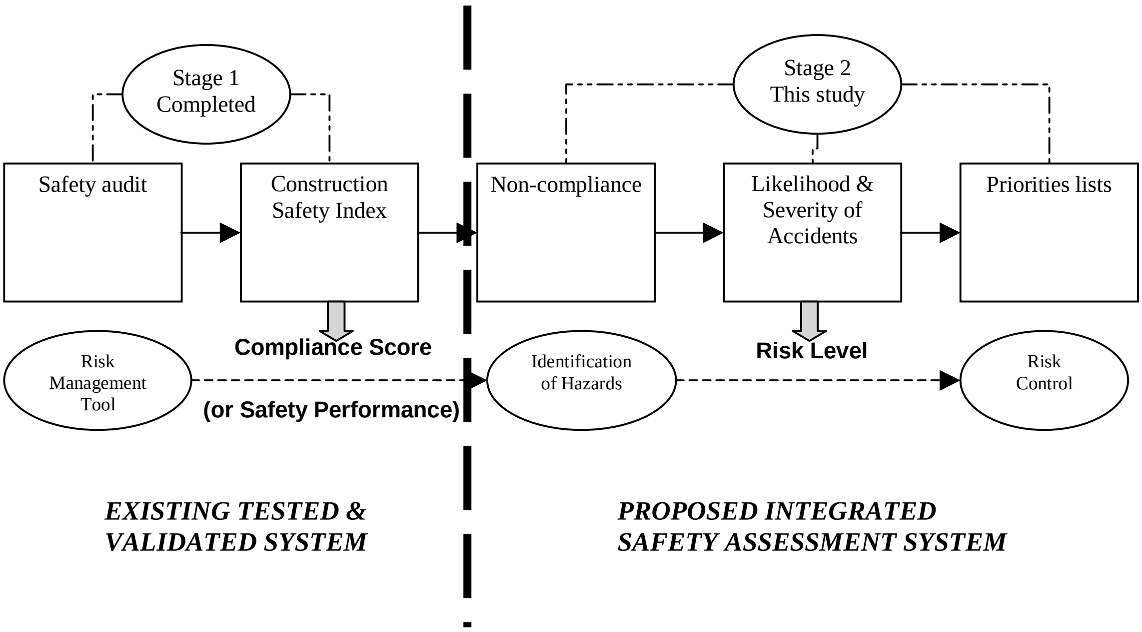

Figure 2: Stages of research

RISK ASSESSMENT AND MANAGEMENT

The safety management system (SMS) was introduced by the Singapore Ministry of Manpower (MOM) to formalize the management of site safety so that contractors are required to implement SMS to improve safety levels on site. However, effectiveness of SMS varies between sites. In response to the need of a tool to assess the effectiveness of a SMS, the 3P + I framework was developed (Teo *et al*. 2004). Based on this 3P + I framework, a Construction Safety Index (CSI), which objectively shows the safety level of the construction site (classified under four main categories namely Policy, Personnel, Process and Incentives), can be calculated (Teo *et al*. 2004). With the enactment of the WSHA in March 2006, the new Occupational Safety and Health (OSH) framework emphasizes the significance of good OSH management systems, particularly the need for comprehensive risk assessments, targeting at reducing risk at its source, with better defined liability regime. Owners, among other stakeholders under the new liability regime, have to take reasonably practicable measures to protect people affected. Moreover, companies will be required under the WSH (Risk Management) Regulations (which came into force on 1 September 2006) to conduct comprehensive risk assessments, take active steps to eliminate or minimise the identified risk and disseminate information to employees and others; as well as to comply with the Regulations, Codes of Practice and industry practices. Therefore, inserting Risk Management Regulations into the existing tested and validated 3P+I framework is vital.

One can attempt to eliminate risks, if risks are known. Nevertheless, it is impossible to eliminate all risks; some can only be reduced. When many risks exist at once or when resources are limited, the problem is knowing what risks to deal with first. This requires setting priorities (Brauer 1994) and there are several methods for doing this, such as applying quantitative or qualitative methods.

In accordance with MOM's Guidelines on Risk Assessment (MOM 2005), risk is made up of two components; namely (a) **likelihood of the occurrence** of the accident/incident or ill health taking into account the existing risk controls; and (b) the **expected severity** of a possible accident / incident or ill health originating from an identified hazard. According to Clemens and Simmons (1998), a common definition of risk for safety infers a quantitative concept; risk is the product of frequency (likelihood) and severity (consequences) of potential losses. Frequency is the probability of occurrence of an event, whereas severity is potential loss when an event occurs.

Risk assessment is an integral part of risk management, according to MOM (2005), risk assessment is a process of (a) identifying and analysing safety and health hazards associated with work; (b) assessing the risks involved and (c) prioritizing measures to control the hazards and reduce the risks. Risk assessment provides qualitative and quantitative data to decision-makers for later use in risk control. Risk assessment in the construction industry can be performed by identifying any hazardous activities or practices and evaluating the danger level (Clemens and Simmons 1998). The risk assessment matrix method is one of the commonly used methods and it is based on the risk plane concept. This is qualitative risk analysis that uses expert opinions to evaluate the probability and consequence of an event's occurrence. The risk matrix provides detailed classifications for likelihood and severity. There are several versions of risk matrix depending on the numbers of level to categorize likelihood and severity. It can be a '5 x 5', '4 x 5' or '3 x 3' risk matrix. The goal of risk management is to reduce uncertainty in describing factors that contribute to accidents, injuries and death. The aim of this research is to develop a risk management and analysis tool for helping the owners in revealing what factors contribute to accidents and injuries for administering the risk assessment and management process.

RESEARCH METHODOLOGY

This study's survey questionnaire adopted MOM's definitions. The method of collecting primary data is through a postal questionnaire targeted at the authority, the contractors and the safety consultants. The objective of the survey is to identify the significant factors in influencing site accidents from the existing tested and validated 3P+I framework with reference to MOM's definitions. The likelihood of occurrence of accident or incident can be categorised into **Remote**, **Occasional** and **Frequent** as shown in Table 1.

Table 1: Classification of likelihood of accidents used in the questionnaire

Likelihood	Description	Importance ranking in questionnaire	
Remote	Not likely to occur	Unlikely	1
Occasional	Possible or known to occur	Maybe	2
Frequent	Common or repeating occurrence	Likely	3

Similarly, the expected severity of accident or incident can be further classified into **Minor, Moderate** and **Major** to be used in the questionnaire. For the purpose of the survey in this study, modifications were made to the descriptions of moderate and major severity to make them more applicable for the study. For moderate severity, *temporary disability* was introduced to the description while for major severity; permanent *disability* was added to give better meaning to it. The modifications are illustrated in *italics* in Table 2.

Table 2: Modifications to the description of accidents' severity used in the questionnaire

Severity	Description by MOM	Modifications made to questionnaire	Importance ranking in questionnaire
Minor	No injury, injury or ill-health requiring first aid treatment only	*No injury, injury or ill-health requiring first aid treatment only	1
Moderate	Injury requiring medical treatment or ill-health leading to disability	Injury requiring medical treatment or ill-health leading to *temporary* disability	2
Major	Fatal, serious injury or life-threatening occupational disease	Fatal, serious injury *leading to permanent disability* or life-threatening occupational disease	3

* No changes were made in the survey questionnaire

The main objective of conducting surveys with the professionals is to obtain practical insights of the industry's perceptions of the risks associated with safety issues on construction sites, as opposed to theoretical studies. This will aid the development of a heuristic model to classify the factors from the existing tested and validated 3P+I framework into different risk levels. The purpose of this proposed system is to provide management with the tool that they could make use of to supplement the CSI to prioritise their attention on the significant factors influencing safety on construction sites.

The postal questionnaire comprises two main sections. The first section contains the demographic questions for the purpose of data classifications. Section two lists 114 factors extracted from the existing tested and validated 3P+I framework that could have an impact on site safety levels. The factors are divided into four categories and the number of factors contained within each category is depicted in Table 3.

Table 3: Summary of factors contained in questionnaire

Category	Number of factors
Incentive	4
Policy	13
Process	75
Personnel	22
Total	114

The respondents were asked to rate these factors according to the likelihood of accident occurrence (likely (3), maybe (2) and unlikely (1)) and the expected severity of accidents (major (3), moderate (2) and minor (1)] in their absence or non-compliance. The quantitative data collected from the survey would reveal the significant factors to be incorporated into the proposed model to allow management to exercise greater control in minimising accidents on sites.

The population for the study was 1919 contracting firms registered with Building and Construction Authority (BCA 2005). Given the size of the population, sampling was necessary for B1–C3 contractors. No sampling was necessary for the authority, the safety auditors and A1 and A2 contractors as their population sizes were small. Systematic sampling was conducted for B1, B2, C1 and C2 contractors. As the population for C3 contractors was large, simple random sampling was carried out to select 46 samples from the population of 1305 (refer to Table 4).

A total of 300 questionnaires were sent out to the respondents through mail. A cover letter explaining the purpose of the research was enclosed. To encourage response, anonymity was assured as the respondents were not required to state their name. Also, a copy of the research findings would be offered to all companies who had responded to the survey. In addition, follow-up calls were made to individual firms three weeks after the questionnaires were posted to encourage them to respond to this study.

DATA ANALYSIS

Parametric t tests and factor analysis were employed to analyse the quantitative data from the survey. The central limit theorem requires a minimum of 30 samples (n=30) for data analysis in order to achieve a normal distribution. Parametric t tests are used in the data analysis since it is assumed that the sampled data from the population follows a normal distribution. Fifty usable responses (n=50) were used for the data analysis; therefore, the distribution is assumed to be normal and a one sample t test could be applied using the Statistical Package for Social Sciences (SPSS).

The one sample t test compares the mean score of a sample with a hypothetical mean with the level of significance set at 5% ($\alpha = 0.05$). μ is fixed at 1 for ***Likelihood of Accident*** because by the definition in the rating scale lesser and/or equal to 1 is ‘accident not likely to occur’. The test hypothesis is highlighted as H_0: $\mu \leq 1$ and H_1: $\mu > 1$.

The two sample t test compares the mean score of a sample with a hypothetical mean with the level of significance set at 5% ($\alpha = 0.05$). As for ***Severity of Accident***, μ is fixed at 1 because by the definition in the rating scale equal to 1 is ‘no injury or minor injury which does not lead to disability'. The test hypothesis is highlighted as H_0: $\mu = 1$ and H_1: $\mu \neq 1$.

If the p-value is smaller than the significance level, the null hypothesis is rejected and the test result is termed significant. This implies that the variable plays a very important role in influencing safety.

RESULTS

A total of 55 professionals responded to the survey. After checking through the completed questionnaires, 50 were found to be suitable for data analysis. This yielded a response rate of 16.67%. The distribution of the questionnaires sent and the response rate for the individual categories are highlighted in Table 4.

Table 4: Population and sampling method employed in the study and the response rate

Categories	Population	Sample	Sampling method	Response Rate (%)
Authority	1	1	No sampling	0 (0.00)
*Safety auditors**	22	22	No sampling	9 (3.00)
*Contractors Grade***				
A1	33	33	No sampling	16 (5.33)
A2	22	22	No sampling	2 (0.67)
B1	50	40	Every 5^{th} on the list was excluded	5 (1.67)
B2	102	51	Every odd number on the list	6 (2.00)
C1	200	40	Every 5^{th} on the list	3 (1.00)
C2	184	45	Every 4^{th} on the list	3 (1.00)
C3	1305	46	Random sampling	6 (2.00)
	1919	**300**		**50 (16.67)**

* MOM list of approved Safety Auditors (2005) & ** BCA Contractors Registry (2005)

Of the 50 respondents, 9 were safety auditors and 41 were contractors. Generally, the respondents' average working experience in the construction industry is 14.2 years. In addition, 64% of the respondents had 10 or more years of working experience. It is expected that a certain level of accuracy in the data collected is assured.

The 114 factors were input into the SPSS software and a one sample t test was conducted to sieve off the insignificant factors. Of the 114 factors, 24 were found to be insignificant in causing site accidents (Appendix 1 of research report – see: http://courses.nus.edu.sg/course/bdgteoal/RiskManagmentTool/discuss.htm). The remaining 90 significant factors are also reflected in Appendix 1. The mean scores for the factors ranged from the 2.167 to 2.776. This suggested that they played a very important role in influencing the likelihood of accidents on construction sites.

A statistical t test of the mean was also conducted for the category concerning the severity of accidents. Of the 114 factors, 37 were found to be insignificant in so far as severity of accidents was concerned (Appendix 2 of the research report – see http://courses.nus.edu.sg/course/bdgteoal/RiskManagmentTool/appendix_2.htm). Appendix 2 also lists down the distribution of the remaining 77 significant factors. The mean scores for the significant factors ranged from the 2.191 to 2.854. This implied that if accidents involving the factors were to occur; the nature of the accidents would be severe.

The mean rating for each of the factors used in the survey were calculated using the following formula.

Mean = $\sum Y_i RAR_i / N$

Where Y = i^{th} observation

AR = Associated rating (1 or 2 or 3) and N = Total number of observations (n = 50).

As a result, a mean rating for each factor under both Likelihood of accident and Severity of accident was obtained. Applying the risk matrix assessment concept, together with the mean rating obtained from the survey; a risk management and analysis tool can be developed riding on the existing tested and validated 3P + I framework.

PROPOSED RISK MANAGEMENT AND ANALYSIS TOOL – ISAS

The findings of the survey were used to derive the risk matrix assessment system. With the severity and likelihood being established, the risk level can be determined by using the following '3 X 3' matrix. The risk level may be classified as low, medium or high and as shown in Table 5.

Table 5: '3 x 3' risk matrix

		Likelihood		
		Remote = 1	Occasional = 2	Frequent = 3
Severity	Major = 3	3 Medium Risk	6 High Risk	9 High Risk
	Moderate = 2	2 Low Risk	4 Medium Risk	6 High Risk
	Minor = 1	1 Low Risk	2 Low Risk	3 Medium Risk

Before a risk assessment model (refer to Figure 3) can be constructed, a Risk Definition Range is required. Risk Definition Range is referring to the range of value in which the risk level is determined. In order to define a range value for all the risk levels, the '3 x 3' matrix (refer to Table 5) shall be expanded into a '5 x 5' matrix (refer to Table 6) because the risk level of every non-compliant factors in this study is not an integer but any value between 1 to 9. For example, if the risk level is found to be 5.2, it will pose a problem of classification if the '3 x 3' matrix (refer to Table 5) is used. Thus, it is necessary to classify Risk Level using a range of number. Henceforth, the risk level may be classified as Low, Medium or High if the risk level is between '$1 \leq R \leq 2.5$'; '$2.5 < R \leq 5$'; and '$5 < R \leq 9$' respectively. In this way, the expanded '5 x 5' matrix (refer to Table 6) can help to draw a better distinction between High, Medium and Low Risk.

Table 6: '5 x 5' risk matrix

	1 Remote	**1.5 Rare**	**2 Occasional**	**2.5 Likely**	**3 Frequent**
3 Major	3 Medium Risk	4.5 Medium Risk	6 High Risk	7.5 High Risk	9 High Risk
2.5 Severe	2.5 Low Risk	3.75 Medium Risk	5 High Risk	6.25 High Risk	7.5 High Risk
2 Moderate	2 Low Risk	3 Medium Risk	4 Medium Risk	5 High Risk	6 High Risk
1.5 Insignificant	1.5 Low Risk	2.25 Low Risk	3 Medium Risk	3.75 Medium Risk	4.5 Medium Risk
1 Minor	1 Low Risk	1.5 Low Risk	2 Low Risk	2.5 Low Risk	3 Medium Risk

Figure 3 depicts the risk assessment module of the proposed ISAS, and the last step for risk assessment is Risk Control. The proposed ISAS (refer to Figure 4) identifies the consequences (highlights what kinds of hazards would result and what penalties would be imposed for non-compliance) and provides recommendations (refer to Table 7) for controlling risk. Expert knowledge was embedded in the proposed ISAS to assist owners in decision making when assessing risk. The proposed ISAS also provides site safety performance reports. It highlights results of all the findings of safety on sites in various formats (construction safety index report, risk evaluation report, and action plans report (consequences and recommendations)). The owners can used these reports for submission to the authority.

Table 7: Risk action

Risk level	Acceptability	Recommended action
Low Risk	Acceptable	No additional risk control measures may be needed. However, frequent review may be needed to ensure that the risk level assigned is accurate and does not increase over time.
Medium Risk	Moderate Acceptable	A careful evaluation of the hazards should be carried out to ensure that the risk level is reduced to as low as is practicable within a defined time period. Interim risk control measures, such as administrative controls, may be implemented. Management attention is required.
High Risk	Not acceptable	High Risk level must be reduced to at least Medium Risk before work commences. There should not be any interim risk control measures and risk control measures should not be overly dependent on personal protective equipment or appliances. If need be, the hazard should be eliminated before work commences. Immediate management intervention is required before work commences.

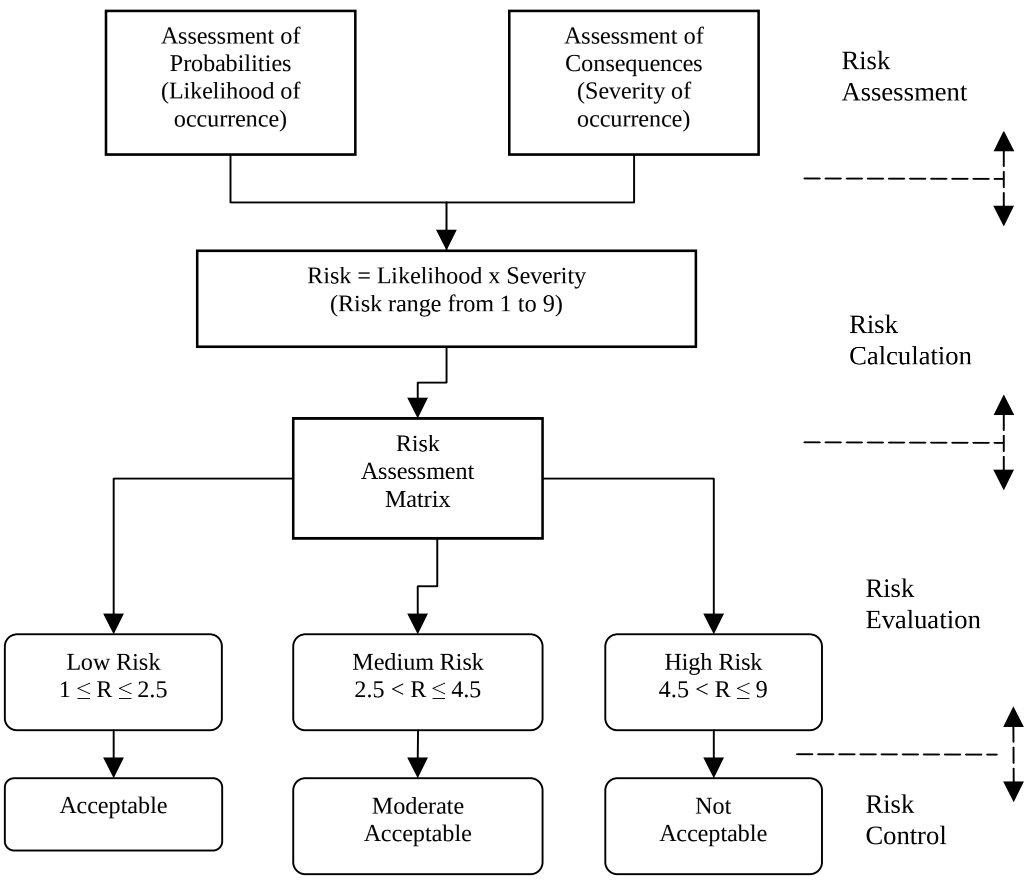

Figure 3: Proposed risk assessment model – a module of ISAS

CONCLUSION

This research has developed a theory to contribute additional knowledge to the existing tested and validated 3P + I framework by revealing whether such deficits are critical or non-critical in warranting immediate attention and also by highlighting the consequences for failure to act. Moreover, the proposed system can also highlight the safety measures to be undertaken by owners in order for them to provide and maintain a safe work environment. As it is stipulated by the new WSHA that the owners are required to take responsibility of safety standards and outcomes; the proposed risk management and analysis tool (ISAS) will be a practical tool for the owners (also can be used by other stakeholders) to conduct the risk assessment on construction sites.

The key feature of the proposed ISAS is its ability to assess risk using the risk matrix concept. The practical use of this proposed ISAS is that it provides guidelines on reasonably practicable measures for assessing and controlling risk. It adopts the enforcement strategy by using the intelligence-led monitoring approach that focuses on improving OSH performances and not simply meant for identification of non-compliance. This approach is shifting from reaction to prevention so as to enhance the risk assessment and management for construction safety. This proposed model is useful as it can help management to prioritise so that accidents can be eliminated, especially fatal ones so that precious lives can be saved.

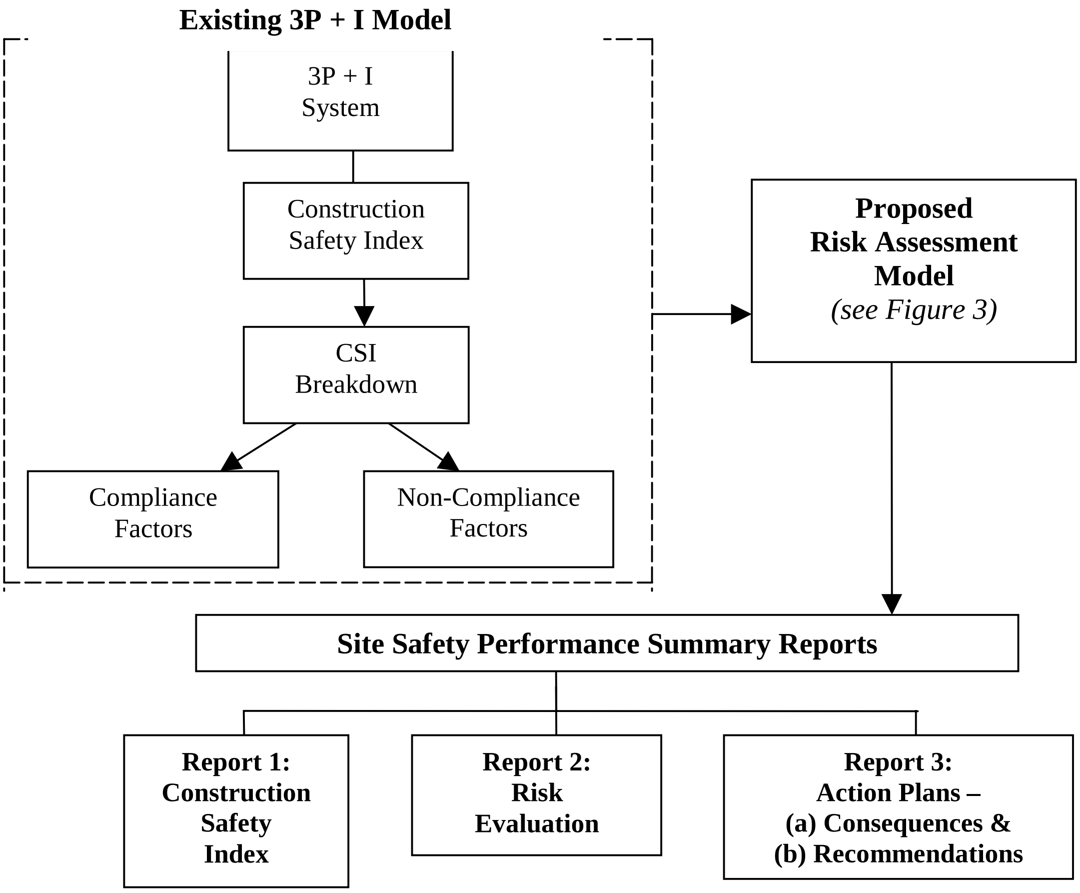

Figure 4: Proposed risk management & analysis tool – Integrated Safety Assessment System (ISAS)

ACKNOWLEDGEMENTS

The author gratefully acknowledges the National University of Singapore (R296-000-094-112) for providing funding for this research project. Ng and Pham's participation in various parts of the research project are also gratefully acknowledged.

PROJECT MANAGER PERFORMANCE

Motiar Rahman,[1] Christopher Miller,[2] Gary Packham,[2] Nabil Sawakhroon[3] and Ji Meng[1]

An array of skills and attributes are necessary in order to responsibly carry out the duties of project managers (PMs), in delivering successful projects. The purpose of this paper is to identify and assess various necessary skills and attributes of PMs for project success. Results from statistical analyses of 155 questionnaire responses from China, Oman and the UK are presented. Despite the evident differences of perceptions among respondents on the relative priorities of various items, it was observed that a balanced set of various skills is essential for PMs, with leadership abilities for teamworking and meeting the project objectives. Although the skills related to "education" appear to be less important than some other skills, results indicate that there is no alternative of formal training and education. Respondents also consider that an attitude for attaining a satisfactory level of customer satisfaction and approach to teamworking are among the two most important attributes of PMs that lead to project success, along with the ability to complete the project on time, within budget and to an acceptable quality. The overall results indicate the readiness of the respondents in these three countries to consider some 'non-traditional' skills and attributes that PMs should possess to deliver successful projects.

Keywords: China, leadership, Oman, project manager, skills, United Kingdom.

INTRODUCTION

The success of construction projects depends on a multitude of factors, including human-related factors, project-related factors, project procedures, project management actions and the external environment (Chan *et al*. 2004). Arguably, project managers (PMs) play the central role, directly or indirectly, in addressing such diverse – both seen and unforeseen – issues for delivering a successful project. The PM, as either a company or an individual (Wang and Huang 2006), is responsible for managing a project to deliver it in the agreed schedule, to the correct technical specification (defined to meet user requirements) and within the approved budget and other specified criteria, i.e. key performance indicators (BoK 2000). The PM is also responsible for leading the whole project team, including establishing a direction, aligning people, and motivating and inspiring (PMBOK 2004). Therefore, the PM should not only be able to successfully carry out the works in terms of technical ability, such as those relating to time, quality and cost, but also be able to effectively mobilize coordinating, motivating and collaborating efforts in terms of relational harmony, such as approach to teamworking. Understandably, the PMs need to have an array of skills and attributes in order to carry out their responsibilities soundly, as well as to deliver projects successfully.

[1] mrahman@glam.ac.uk

There is a trend of inter-changeably using the terms PM, project management and leadership (Turner 2006). This is perhaps due to the (1) emergence of various collaborative working arrangements (CWAs) in construction based on teamworking concept, where the management of relationships and other soft issues among different contracting parties are considered critical and (2) consequent changes in the role of PMs in delivering their project management activities. Kolltveit *et al*. (2007) reveal that today the leadership perspective of project management is the dominant one, while earlier the task perspective was the most emphasized. Other researchers advocate that leadership is critical for the performance of the project team (Weinkauf and Hoegl 2002; Callanan 2004; Natal *et al*. 2004; Wing 2005). A leader must acknowledge, embrace and manage (or deliver) aspects to yield positive results from teamwork (PMI 2006). An adjusted set of skills for PM appears to be necessary to address such a changed environment. Hence, the importance of this exploratory study for identifying and prioritizing various skills and attributes of PM, with an appreciation of the changes in the role of PMs, and before suggesting a general guideline for PMs to meet the challenges in their changed/new roles.

Relevant previous studies include: (1) identification of different factors hindering the performance of construction PMs (Powl and Skitmore 2005); and (2) investigations into the relationships between roles, skills and professions of project managers (Wilkinson and Palmer 2006). None of these studies considered the changed roles of PMs in CWAs. The present study delves somewhat deeper into specific aspects, in that it is attempting to address the changed roles of PMs in CWAs and assessing various skills and attributes of PM, for their prioritization. The overall research project has been approached through the multiple methods of literature review (stage one), questionnaire survey (stage two), and interviewing industry experts (stage three). In stage two of this study, the questionnaire survey was carefully designed to meet the objectives of prioritizing (1) various necessary skills or qualifications, and (2) attributes or approaches of PM, that contribute to project success or failure, especially with an appreciation of present trend of CWAs in construction. This paper presents the interim outcomes of the study and reports the perceptions of 155 respondents (see Table 1) from China, Oman and the UK. Space limitations only permit the presentation of key extracts of the results.

QUESTIONNAIRE SURVEY

The questionnaire was developed in the UK, on the basis of a wider literature review, and to meet the above objectives. Individual items of the questionnaire were sourced from 11 better practices for improvement of leadership as suggested by Behn (2004); 15 factors hindering the performance of construction PMs as reported by Powl and Skitmore (2005); various roles, skills and professions investigated through 14 questions by Wilkinson and Palmer (2006); and 111 potential facilitating and deterring factors for various CWAs reported by Rahman *et al*. (2007). The individual factors were selected and tuned to suit the specific purposes of the present study, namely their prioritization, including allowing evaluation of generic or traditional skills and attributes in the changed environment, and assessing the importance of other factors to address the changed environment. The questionnaire was then (1) pilot tested by two practitioners from Oman, two practitioners from the UK and one academic from the UK with extensive knowledge in Chinese construction industry, and (2) improved based on the opinions received from these experts. The questionnaire included two specific sections requesting the respondents to express their perceived importance on a scale from 1–10 (varying from lowest to highest) on: 32 skills or qualifications and 28 attributes or approaches of PM, which contribute to project success or failure in general (see Appendix). Two MSc students were engaged to carry out the survey: one in China and the other one in Oman and the UK. Literature suggests that the practice of modern project management and CWAs in China are relatively new (Wang and Huang 2006). The practice of the former is not new in Oman, but traditional procurement systems are still dominant (Sawakhroon 2006). On the other hand, the both are well practised and documented in the UK. It was therefore expected that the questionnaire survey in these three different countries would yield an interesting comparison. In particular, this will help collect more 'problems' and their potential solutions, allowing the proposed general guidelines useful.

As shown in Table 1, 155 responses were received, with an average total experience of 11.4 years. At the time of the survey, 53 respondents were holding the senior level position, whereas other 69 and 33 respondents were holding mid-level and junior level positions respectively, showing a balance between the number of respondents, to some extent. However, the number of respondents from China (85) was more than the total of those from Oman (33) and the UK (37). Also, respondents from China have relatively less total experience (7.5 years) compared to those from Oman (18.8 years) and the UK (13.9 years).

Table 1: Questionnaire distribution and respondent profile

Items		**China**	**Oman**	**UK**	**Total**
Questionnaire distributed:		300	80	160	540
Responses received:	Contractor	14	24	33	71

	Junior	22		11	33
Total experience:	Average in years	7.5	18.8	13.9	11.4
	Range (years)	2–35	5–42	1–45	1–45
Experience at present level:	Average in years	5.05	10.39	5.69	6.34
	Range (years)	1–20	1–25	1–23	1–25

For the purposes of this paper, the mean scores of different groups of respondents (based on country and also the whole sample as total) on individual factors were ranked and compared. Statistical t-tests of the mean at significance level 0.05 were undertaken to establish whether each factor is significantly important. ANOVA was carried out at 95% confidence level to determine whether the three groups of respondents had different perceptions on the relative importance of various factors. Factor Analysis was carried out to narrow down the long list of factors into a smaller number of representative components. For the purpose of this exercise, the Principal

Component method of extraction was applied, coupled with Varimax with Kaiser Normalization method of rotation. Eigenvalues for the extracted components of ≥ 1.0 were considered, and "factor loadings" of ≥ 0.40 were considered to contribute to different components. However, for the purposes of brevity, t-test results of only the total sample are shown in Table 2. In addition, only the key extracts of the results are summarized here, in order to meet the space limitations.

RESULTS

Comparison of means: necessary skills/qualifications of PM

Table 2 shows the perceptions of respondents on 32 factors that express various skills/qualifications necessary for PM to carry out different duties and responsibilities, along with significance obtained from one sample t-test for the total sample, and the ANOVA results for the groups of three countries.

Table 2: Comparison of means and ANOVA results of various skills/qualifications of PM

Notes: *Please see Appendix for detail description of the factors.
Rank: 'e' signifies equal rank and the next rank(s) is/are omitted, except the lowest rank where the previous rank(s) is/are omitted.

It is seen that “ability to effectively direct, manage and motivate the project team” (f02, score 8.07) is the most important skill of PM. This perhaps point to the fact that PMs must have a balanced set of various skills, instead of being ‘champion’ in any specific skill. However, this is followed by “leadership” (rank 2, score 7.91), “ability to meet project targets and objectives” (rank 3, score 7.90), “ability to effectively apply standard project management tools/ approaches” (rank 4, score 7.87) and “preparing and maintaining the project execution plan” (rank 5, score 7.77). “Build and maintain effective means of communications” is the 6th most important skill, whereas “experience” (f11) and “managing the project for the required deliverables” (f19) share the equal rank of 7. It is observed that factors ranking from 2 to 7 do not show any specific trend. Although very important, they simply show the level of their individual importance when compared with other factors. However, the top-ranked factor appears to have fed from all these skills, since these skills are essential “to effectively direct, manage and motivate the project team”.

The relative importance of some other factors are, in terms of ability of PM, on “proactive decision making” (f14, rank 9), “clear communications” (f13, rank 10), “defining and clarifying project objectives” (f20, rank 12), “tailoring expert knowledge” (f04, rank 13), “developing and implementing detailed stage/ milestone plan” (f03, rank 16), “quality management” (f06, rank 18e), and “proactive risk management” f26, rank 27). Relatively less importance on skills related to managing “quality” and “risk management” may taken to be interpreted as such skills are supposedly covered in “proactive decision making”, “clear communications” and “tailoring expert knowledge”.

“Knowledge” (f12, f32) of a PM is more important (ranks 11 and 14) than “personal attitude and motivation” (f10, rank 17), “professional ethics” (f29, rank 20), “technical competency” (f30, rank 21) and “legal awareness” (f16, rank 23). On the other hand, “financial awareness” (f17, rank 18) is more important than “influencing budget” (f31, rank 25e), whereas contextual “training” (f09, rank 22) is more important than any formal “education” (ranks 28–32). “Level of education: masters and above” (f08) is seen to be the least important factor with the score of 6.16, which is more than the average (i.e. 5.50) of the measuring scale (i.e. 1–10), implying a general importance of all the 32 factors. This is confirmed by the one-sample t test: all the factors expressing various skills/ qualifications of PM are significant, both in the total sample and in the groups of three countries, except the five education related factors in the UK group (f07, f08, f25, f27 and f28). General importance of all the factors may be taken to imply the respondents’ readiness of practising all the skills of PM identified in this study, including those are non-traditional. Although ranks of individual factors within different groups are different, ANOVA results show that respondents from three countries have similar perceptions on 24 factors. However, they significantly disagree on the relative importance of eight factors (f05, f06, f07, f08, f10, f21, f22, f25). There might be a number of reasons for such disagreements.

For example, the ranks of the factor relating to “effective means of communications” (f05) in the groups of the UK (rank 1e) and Oman (rank 2) are close, but their scores are considerably different (UK 8.43, Oman 7.79). On the other hand, the score of this factor in the group of China is sufficiently close (7.44) to that of Oman, but with a rank of 10. This led to the rank of 6 in the total sample with a score of 7.75. This might be due to the reason that respondents from China have less total experience in construction, than those from the UK and Oman. Moreover, the practice of project management in China is relatively new (Wang and Huang 2006), so is the use of teamworking-based approach in construction (Ji 2006). Therefore, they are yet to appreciate the appropriate importance of "effective communications" (f05). On the other hand, respondents from Oman have considerably high total experience (18.8 years, see Table 1), as well as rich in international construction experience (Sawakhroon 2006). Respondents from the UK have sufficiently high total experience (13.9 years), with a culture of teamworking-based approach in construction. Such background of the respondents from Oman and the UK might have led to highly appreciate the importance of "effective communications", which is different with those from China.

Comparison of means: factors/attributes related to PM for project success

It was seen that completing the project on time (ff01), with satisfactory customer satisfaction (ff04) and within budget (ff02) are the top-most three factors related to PM for project success. PM's approach to teamworking (ff13, rank 4) and motivate the project team (ff17, rank 7) is very important. So is to ensure acceptable quality (ff03, rank 5) and approach to quality management (ff05, rank 6). Respondents consider that PM's ability to influence top management (ff18, rank 8) is more important than relationship with top management (ff24, rank 14), building relationship within the project team (ff19, rank 21), as well as relationships with other parties (ff25, rank 23). Approach to coordination (ff21, rank 10) is more important than leading the whole project team (ff23, rank 13), risk management (ff10, rank 15), open communication (ff16, rank 17e), conflict management (ff12, rank 25e) and change management (ff22, rank 25e).

Moreover, professional ethics (ff14, rank 11) is more important than innovative ideas (ff16, rank 16), service of the same PM during the entire project period (ff15, rank 19e), mentoring junior officials (ff27, rank 22) and delegate authority (ff08, rank 24). Respondents do not appear to enthusiastically recommend non-contractual relationships (ff20, rank 27), and 'fit for purpose' (instead of written specifications) (ff28, rank 28) is seen to be the least important factor, showing the preference of the respondents on the written contracts, instead of unwritten commitment or transactions. However, the score of this least important factor is 6.91, which is higher than the average of the measuring scale (i.e. 5.50). This implies a general importance of all the factors, with some factors more important than some others. This is confirmed by the one-sample t test. The significance levels obtained from the t-test of all the factors are less than 0.05, both in the total sample and in the groups of three countries, indicating that all the factors/attributes related to PM for project success are significantly important. However, general importance of all the factors may imply readiness of respondents' from the three countries of practicing all the skills of PM identified in this study, including the non-traditional ones. It may also be taken to apply a gradual or step-wise focus of implementing different factors or attributes, according to their priority of relative importance.

On the other hand, the ranks of individual factors in the three groups of respondents are mostly different. ANOVA results show that respondents from three countries significantly agree on the relative importance of 14 factors only, and disagree on other 14 factors. This may be due to the diverse origin, practice and overall experience in construction of the respondents. Space restrictions do not permit a detail discussion, which is expected to be presented in a follow-up paper, if suitable.

Factor analysis: necessary skills/qualifications of PM

Table 3 shows the summary of the outcomes from "factor analysis" for necessary skills/ qualification of PM. Explaining over 62% of the total variations, seven components were extracted from this exercise: (1) ensuring project execution and meeting the objectives; (2) proactive decision making appreciating underlying environment; (3) adequate knowledge and experience for leadership; (4) effective use of standard project management tools; (5) appropriate education and training; (6) professional development and proactive risk management; and (7) technical competency and ability to influence budget. Ten factors are seen to contribute to more than one component, with some factors contributing equally or almost equally to two components. For example, factor f32 contributes to components 1 and 2 with equal factor loadings of 0.47, whereas factor f10 contributes to components 4 and 2 with factor loadings of 0.45 and 0.44 respectively. Such 'primary' and 'secondary' contributions loosely inter-relate all the components, either directly or indirectly, suggesting the requirement for a balanced set of skills for PM, except component 5. None of the factors of component 5 contribute to any other components, suggesting unique importance of 'education and training'.

Table 3: Factor analysis outcomes of necessary skills/qualifications of PM

Components	Primary factors*	Secondary factors*	Eigen-values	% of Var. explained (cumulative)
1: Ensuring project execution and meeting the objectives	f18, f19, f20, f22, f23, f24, f32	f17, f21	3.97	12.4 (12.4)
2: Proactive decision making appreciating underlying environment	f14, f15, f16, f17, f21	f10, f13, f20, f32	3.39	10.6 (23.0)
3: Adequate knowledge and experience for leadership	f02, f11, f12, f13	f05, f14, f24	3.17	9.91 (32.91)
4: Effective use of standard project management tools	f01, f03, f04, f05, f06, f10		3.07	9.6 (42. 51)
5: Appropriate education and training	f07, f08, f09, f25		2.44	7.62 (50.13)
6: Professional development and proactive risk management	f26, f27, f28, f29		2.33	7.27 (57.4)
7: Technical competency and ability to influence budget	f30, f31	f28	1.78	5.57 (62.97)

Notes: Rotation converged in 15 iterations. Kaiser-Meyer-Olkin Measure of Sampling Adequacy was 0.835. Bartlett's Test of Sphericity: Approx. Chi-Square 2225, df 496, $p<0.000$. *See Appendix

Factor analysis: factors/attributes related to PM for project success

Six components emerged, and together they account for over 63% of the total explained variations. Those are: (1) structured collaboration and relationship management; (2) leadership, teamworking and issue resolution; (3) effective project control – budget, time and quality; (4) management of project risks, utilities and deliverables; (5) continuity of service and mentoring; and (6) customer satisfaction. All the components are seen to feed from the factors that contribute to more than one component, and, as such, eight factors are seen to contribute to two components. Several factors are seen to contribute almost equally to two components, e.g. the factor 'approach to fit for purpose' (ff28) is seen to contribute to components 1 and 5 with factor loadings of 0.54 and 0.58 respectively. Thus, all the components are interrelated with 'primary' and 'secondary' contributions, either directly or indirectly, although nomenclature of different components (as above) is based on their 'primary' contributing factors only.

FUTURE WORK

The paper presents the interim outcomes from the preliminary observation of the research process. The next stage of this research agenda is to conduct an interview-based survey. This is planned to collect expert opinion in an attempt to explore the various (1) reasons of the commonalities and disagreements between the three countries as seen above, and (2) potential means of generalizing the diverse opinion, including the necessity of any tailor-made activities, in order to devise a general guideline for PMs. It is expected that the latter investigations will allow far more detailed comparisons of country specific differences of opinions and their commonalities as well.

CONCLUSIONS

Project Managers (PMs) need to deal with a range of issues for successful delivery of construction projects. PMs therefore need to equip themselves with an appropriate set of various skills and/ or attributes, not only to successfully carry out their works in terms of technical ability, such as those relating to time, quality and cost; but also to effectively mobilize coordinating, motivating and collaborating efforts in terms of relational harmony, such as approach to teamworking. However, some of the skills and/or attributes may be more useful than some others. This is important, especially due to the changing roles of PMs affecting from the emergence of various collaborative working arrangements in construction. As such, various skills and attributes were identified in this exploratory study, in order to ascertain their relative importance and to offer any incentive in designing appropriate strategies for PMs in delivering their duties soundly. Results led to the following observations:

- All the 32 necessary skills/qualifications identified in the study were found to be significant. In addition, respondents from three countries significantly agreed on the relative importance of most of the listed skills/qualifications.
- All the 28 factors/attributes related to PM for project success were found to be significant. However, the three groups of respondents significantly agreed on the relative importance of 14 factors and disagreed on the other 14 factors.
- It was found that a balanced set of various skills and attributes is essential for PMs, with leadership abilities for teamworking and meeting the project objectives in terms of time, cost and quality.
- The priority of a few non-traditional approaches was also noticed, including ensuring customer satisfaction.
- The general importance of all the items relating to various skills and attributes of PM for project success was interpreted to imply a gradual or step-wise implementation, according to their relative importance, and to reflect the readiness of the respondents to practice some non-traditional approach, e.g. customer satisfaction.
- The factor analysis exercise extracted seven and six components for (1) necessary skills/qualifications of PM and (2) various factors/attributes of PM for project success, respectively.
- On the whole, results from factor analysis suggest the need for consolidated but interrelated approaches, both for various necessary skills, factors/attributes of PM for project success, with unique importance of formal training and institutional education.

The paper presents the preliminary observations only. Further investigations are expected to allow more detailed comparisons among different countries.

APPENDIX

Necessary skills/qualifications of project manager (PM) in general

(f01) Ability to effectively apply standard project management tools/approaches to the specific requirements of the project. (f02) Ability to effectively direct, manage and motivate the project team. (f03) Ability to effectively develop and implement detailed stage/milestone plan. (f04) Ability to effectively tailor expert knowledge to meet specific circumstances. (f05) Build and maintain effective means of communications with other parties involved in the project as required. (f06) Ability to apply quality management principles and processes. (f07) Level of education: undergraduate. (f08) Level of education: Masters and above. (f09) Level of training received.(f10) Personal attitude and motivation. (f11) Experience gathered. (f12) Knowledge acquired. (f13) Ability to communicate clearly. (f14) Ability to make decisions proactively. (f15) Negotiation skills. (f16) Legal awareness. (f17) Financial awareness. (f18) Leadership. (f19) Managing the project for the required deliverables. (f20) Ability to define and clarify project objectives. (f21) Management of resources, including their procurement and/ or mobilization. (f22) Preparing and maintaining the project execution plan. (f23) Ability in identifying and obtaining any support and advice required for managing, planning and controlling the project. (f24) Ability to meet project targets and objectives. (f25) Educational background in project management. (f26) Ability in managing dynamic/proactive risk management strategies. (f27) Educational background in civil engineering. (f28) Educational background in other disciplines (e.g. building services, quantity surveying, etc.). (f29) Professional ethics. (f30) Technical competency. (f31) Ability to influence budget. (f32) Good overall knowledge.

Factors/attributes related to PM for project success in general

(ff01) To complete the project on time. (ff02) To complete the project within budget. (ff03) To ensure acceptable quality. (ff04) To attain satisfactory level of customer satisfaction. (ff05) Approach to quality management. (ff06) Designing and applying an appropriate execution plan for the project. (ff07) Production of the required deliverables of the project. (ff08) Approach to delegate authority. (ff09) Planning and monitoring of all utilities of the project. (ff10) Approach to risk management and/ or sharing, including any contingency plans. (ff11) Ensure project progress and usage of resources, including any corrective action where necessary. (ff12) Approach to conflict management and/ or issue resolution. (ff13) Approach to team working. (ff14) Professional ethics. (ff15) Service of the same PM during the entire project period. (ff16) Approach to open communication within the project team, up to a certain level. (ff17) Ability to motivate project team. (ff18) Ability to influence top management. (ff19) Approach to building relationship within the project team. (ff20) Approach to non-contractual relationships. (ff21) Approach to coordination. (ff22) Approach to change management. (ff23) Approach/ attitude in leading the whole project team. (ff24) Relationship with top management. (ff25) Relationships with other parties. ff26) Approach to innovative ideas. (ff27) Approach to mentoring junior officials, e.g. through on-the-job training. (ff28) Approach to 'fit for purpose', instead of written specifications.

PERFORMANCE IMPROVEMENT THROUGH PLANNING OF CONSTRUCTION OPERATIONS

John C. Hildreth,[1] Michael C. Vorster[1] and Hank Adams[2]

[1]*Charles E. Via, Jr. Dept. of Civil and Environmental Engineering, Virginia Polytechnic Institute and State University, 200 Patton Hall, Blacksburg, VA 24061-0105, USA*
[2]*Kiewit Constructors, Inc., 470 Chestnut Ridge Road, 2nd Fl. Woodcliff, NJ 07677, USA*

Construction operations can be categorized as either routine and repetitive or unique and complex. Routine and repetitive construction operations can be improved through traditional field operations analysis techniques, while unique and complex operations can be improved through reactively analysing and proactively planning similar operations. The intent of planning is to assemble the information and knowledge necessary to successfully execute the work. Plans are developed under the general headings of safety, quality, and operational performance. A laboratory exercise was developed to demonstrate the effectiveness of reactively analysing and proactively planning operations. Construction duration was reduced by approximately 40% and significant improvements were reported in material handling, understanding of responsibilities and work flow efficiency.

Keywords: construction planning, construction process, education, planning, site operations.

INTRODUCTION

Construction operations can be classified as either “routine and repetitive” or “unique and complex.” The methods and techniques used to understand and improve operational performance are different for each classification. Traditional techniques of field operations analysis are applied to improve routine and repetitive operations. Unique and complex operations do not present the opportunity to analyse previous performance. Such operations can be improved through a reactive analysis of a similar operation to develop an understanding and then drawing upon this knowledge to proactively plan the upcoming operation.

The traditional methods for improving routine and repetitive operations are well documented in the literature. To gain an understanding of planning for unique and complex operations, the proactive planning methods of a successful heavy civil contractor have been studied and are presented under the general headings of safety, quality, and operations planning.

Methods for operations analysis and improvement are an integral portion of a construction engineering and management education program. The Construction Performance Improvements courses at Virginia Tech have been restructured to include a specific laboratory exercise aimed at demonstrating the benefits of detailed operations pre-planning for unique and complex construction operations.

[1] hildreth@vt.edu

OPERATIONS IMPROVEMENT TECHNIQUES

Techniques for improving construction operations are applied either during or prior to construction. Field operations analysis techniques are applied to ongoing operations to record data, analyse performance, identify problems and devise solutions (Oglesby *et al*. 1989). Prior to operational performance, a proactive planning process may be employed to gather information, develop an operations pre-plan and disseminate the information to the involved parties.

Repetitive operations analysis

Routine and repetitive construction operations are those comprised of cycles that can be optimized through traditional productivity analysis and improvement techniques. The techniques applied have developed over time, but are fundamentally based on time studies performed to record the time required to complete various tasks comprising repetitive construction cycles (Oglesby *et al*. 1989).

Field operations analysis was originally performed by observers using stopwatches and manually recording data. Oglesby *et al*. (1989) noted several limitations to the technique including difficulties in determining exact start/stop points in a cycle, difficulties in observing multiple cycle components, and data being subject to the physical limitations and biases of the observer.

Time-lapse photography improved field operations analysis by providing all the information that makes such studies beneficial. Oglesby *et al*. (1989) noted that time-lapse photography is able to record the interrelationships between observed resources and provides an easy to understand permanent record. Sprinkle (1972) investigated its use and found a single camera is able to replace multiple observers and the resulting data can be repeatedly reviewed without doubt regarding is accuracy.

Video recordings replaced time-lapse photography due to the advantage of instant replay, continuous recordings, and less expensive and more reliable equipment (Oglesby *et al*. 1989). Video recording has been used to document the construction of entire projects (Everett et al. 1998) and in field operations analysis (Bjornsson and Sagert 1994). While an improvement over photographic methods, the primary disadvantage of real-time recordings is the time required to review the data. Digital video has helped to overcome this shortfall and with the aid of software can be viewed at speeds up to 32 times real time. In practice, it has been found that speeds greater than four times real time result in discontinuous or “jumpy” videos.

Observational techniques that rely on visual data are subject to two principle limitations: data is limited to that within the field of view of the observer or camera and the analyst must make instantaneous decisions regarding the start/stop of tasks based on visual information. On-board instrumentation systems have been employed to overcome these limitations (Hildreth *et al*. 2005; Kannan and Vorster 2000). Sensor data is recorded and analysed through automated techniques to identify the timing of key points in a production cycle.

While each of the analysis techniques presented has been successfully employed, each is predicated on the availability of repetitive cyclical field operations for observation and analysis. Ongoing operations are analysed and improvements identified are implemented on the studied operation and subsequent operations.

Unique operations analysis
Unique and complex operations are, by definition, operations that have not been performed previously and do not present an opportunity for analysis and improvement through traditional techniques. The operation life cycle shown in Figure 1 can be applied to understand performance and identify potential improvements.

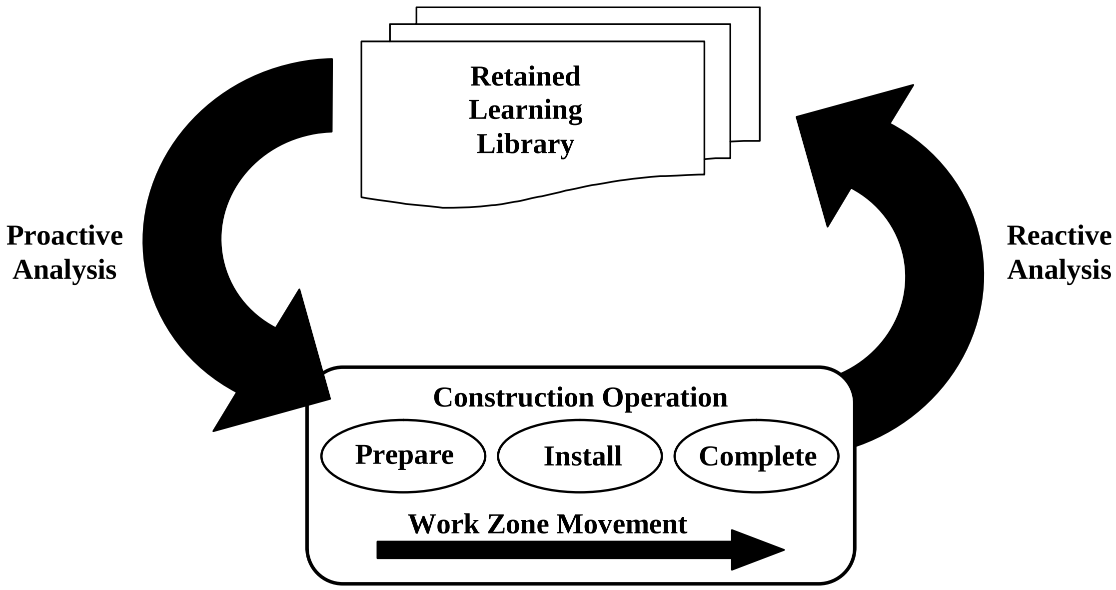

Figure 1: Operation life cycle (Casten 2007)

Reactive analysis of a completed operation is an opportunity to analyse performance and learn how to plan and improve similar operations. Analysis begins with the steps required to perform the operation. Steps are categorized as either value adding or non-value adding, where value adding steps are those that directly contribute to the completion of the work (Casten 2007). Non-value adding steps may be those that contribute to performance, but not completion, or those steps that are unnecessary. Analysis of value adding steps is an opportunity to understand and improve the workflow, while analysis of non-value adding steps is an opportunity to improve operational support and eliminate waste. An analysis of wastes identified in the performance allows delay-free construction time to be estimated and waste free performance to be envisioned. Opportunities for improvement can be identified through a reactive analysis such that behaviours and habits can be better understood and accommodated.

The lessons learned through reactive analysis should be documented and archived in a retained learning library that can be used when proactively planning similar operations (Casten 2007). Proactive planning involves analysing an operation, planning its performance, preparing for performance, and disseminating the information. Analysis includes defining and quantifying specific tasks required for completing the overall scope of the operation. Materials from the retained learning library may be used in developing an initial workflow scheme. Operational planning is the assignment of responsibility, means and methods, physical space, and time of performance to each task. Preparing to perform an operation may include developing work zone drawings, physical or computer models, procuring the necessary inputs, completing prerequisite work, or making special site preparations. The final stage of a proactive analysis is to disseminate the information to the work crew. This can be achieved through structured meetings to discuss the operation and documentation of the proactive planning process.

EXAMPLE OF PRACTICE

A heavy civil contractor that works globally dedicates a large amount of resources to pre-planning operations and attributes much of the company success to its ability to execute the plans. The intent of pre-planning operations is to assemble in a single document the information and in one person the knowledge required to successfully execute the work in the field. The person is a field engineer that develops the plan under the guidance and assistance of field supervision personnel. Once the plan is approved, the engineer assumes responsibility to direct and supervise execution in the field. The engineer returns to a planning responsibility once the operation is complete.

Formal planning documents principally contain information pertaining to safety, quality, and operations. They are developed and disseminated throughout the organization for discussion and approval. The document is scored for completeness in terms of safety, quality, contingency planning, operations planning, and plans and specifications. Approval comes via the physical signatures of vice-presidents, project managers, safety coordinators, quality coordinators, foremen and each crew member engaged in the operation.

Operations planning
The planning of operations gives consideration to what work is required to perform a specific operation and how it can be best performed. This approach differs from project planning, in which consideration is given to what work the project requires and when activities can be performed.

The operations plan provides general information regarding the work to be performed and specific information pertaining to each step required to complete the operation. The general information includes a description of the work, resource requirements, sequence of work, and budget and target production values in terms of manhours per unit. Sketches, project drawings, catalogue cut sheets, etc. that are applicable are attached. Sketches of the site are used to depict the flow of materials and changes to the site as work progresses.

Safety planning
The safety plan is based on the step-by-step outline of the operation. Principal job hazards are identified along with considerations for the safety of the public in the vicinity of the work. Personal protection equipment requirements are itemized and access/egress points used during the operation are described. Each step in the operation is analysed to identify the associated hazards and preventive actions that are to be taken to avoid the hazard. Care is taken to consider all aspects of the step being performed so that a complete listing of hazards and preventive actions is developed. The personnel responsible for each step is listed and approves the hazard analysis of each step. The plan includes material specifications listing relevant data such as dimensions and weights. Equipment specifications are also included to provide size, type dimensions and lifting capacity. The complete safety plan is reviewed with the crew members and each member signs-off on the plan.

Quality planning

The quality plan is based on the quality requirements identified for each step in the operation. Quality requirements for each step are analysed to identify critical items, actions to get the work built properly, tolerances on each item, and the responsible personnel. There are often multiple critical items for each quality requirement. When possible, checklists are developed to allow for uniform and non-arbitrary quality evaluations in the field. The completed quality plan is reviewed with the crew members and each member signs-off on the plan.

LABORATORY EXERCISE

A portion of the Construction Performance Improvement course at Virginia Tech was designed to provide for learning from the operations life cycle by constructing bridge replicas using K'NEX Real Bridge Building Kits. Students working in groups were tasked with constructing the Tower Bridge with only five minutes to plan their operations. Following construction, a Reactive Analysis and an After Action Review were performed. Plans for the Astoria-Megler Bridge were then provided and students were provided one week to develop a detailed Work Plan. A Before Action Review to discuss, review and communicate the work plan was held after two days and construction was performed one week later. A Reactive Analysis and After Action Review were again performed for the Astoria-Megler Bridge construction.

RESULTS

Results of the exercise indicate that significant improvements can be realized through operations analysis and planning. All groups reported improvements in material handling, understanding of responsibilities and workflow efficiency. While the complexity and number of components were similar for both bridges, the time required for construction was reduced by approximately 40%. The analysis and review reports detail the impressive work performed by the students. The results presented pertain to one group, but the results and examples are representative of the quality of work produced by all groups.

With little time to plan operations, construction of the Tower Bridge required 54 minutes. The Reactive Analysis focused on the non-value added activities and concluded that they accounted for approximately 50% of the time. Non-value added activities were defined as those in which bridge parts were not being assembled. These activities included transporting materials, studying construction drawings, and organizing materials.

The Tower Bridge After Action Review report focused on opportunities for improvement in material handling, communication and coordination, and work group management. It was noted that material organization and handling could be improved through knowledge of the parts required to construct the components assigned to each group member. Communicating responsibilities prior to construction and tracking the completion of components was suggested to avoid duplication of work and allow members to quickly shift focus to their next assigned task. During construction, members focused on the bridge foundations, as these components required completion first. It was noted that improvements in the overall construction process could be realized by focusing members on the components requiring the greatest time to construct. Additionally, it was suggested that the work site be organized to allow connecting components to be constructed in adjacent locations.

Work plan

The Work Plan produced for the Astoria-Megler Bridge focused on assigning responsibility for work components and the tasks required for their assembly to group members. Material lists were compiled for each component to aid material handling and a flow diagram was developed to communicate the work plan.

Eleven bridge components were defined based on the estimated assembly time for each and time at which completion was required. Forty tasks are required to construct the bridge and the tasks for each component were identified. Figure 2 depicts the breakdown of bridge components and assembly tasks.

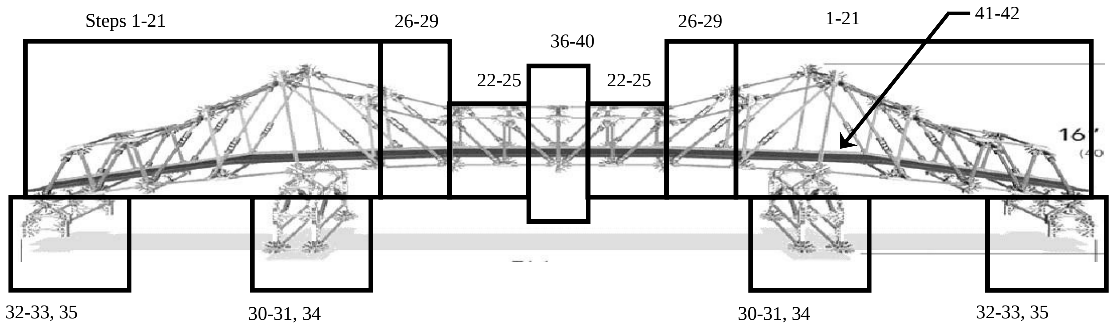

Figure 2: Bridge components and assembly responsibility

The work flow diagram is presented as Figure 3 and indicates the sequence in which assembly of components was planned. Responsibility for components was assigned to individual group members, with all members working towards and responsible for final bridge assembly.

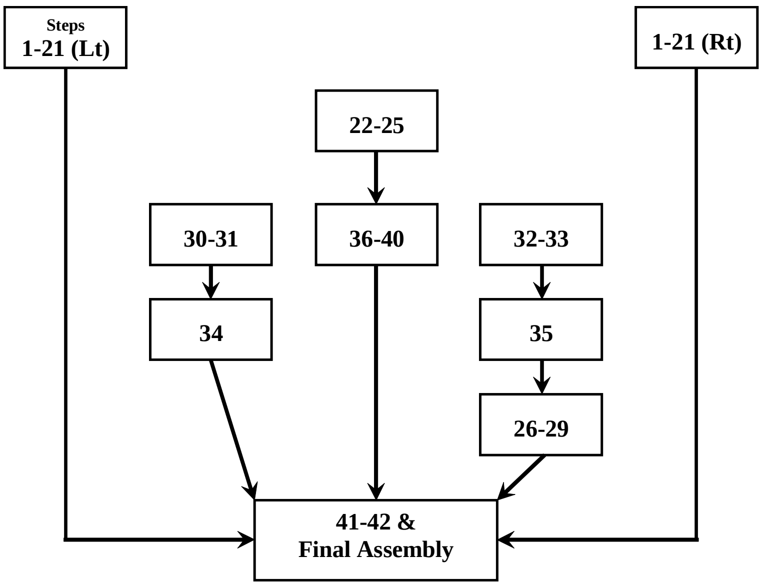

Figure 3: Work flow diagram

Material lists were compiled and provided to each group member. The lists indicate the number and type of materials required for assembly during each task. Materials were organized into separate containers for each component or sub-component. The construction sequence for each group member was included with the material list.

Figure 4: Typical material breakdown by group member

With planning completed at a great level of detail, a construction schedule was able to be developed to indicate the timing and sequence of 23 work activities. The duration of activities was estimated in minutes. Based on this schedule, the bridge was scheduled to be completed in 24 minutes. The actual time required to construct the Astoria-Megler Bridge was less than 26 minutes, which is less than half of the time required to construct the Tower Bridge.

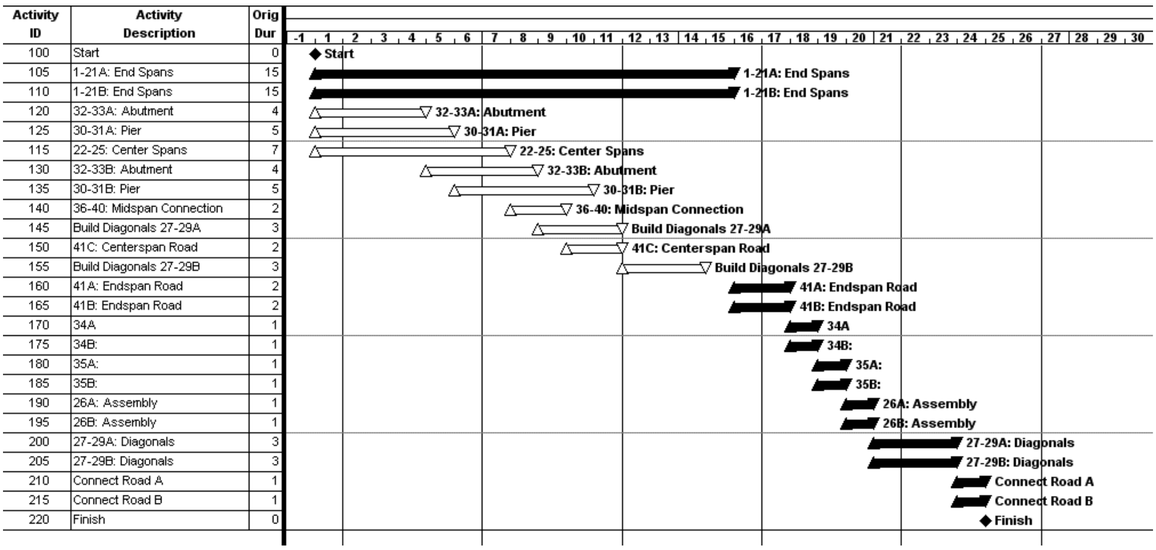

Figure 5: Construction schedule (note: durations in minutes)

CONCLUSIONS

Routine and repetitive construction operations can be improved through traditional field operations analysis techniques, while unique and complex operations can be improved through proactively planning based on reactive analysis of similar operations. Reactive analysis is an opportunity to analyse performance and learn how to plan and improve similar operations. Proactive planning involves analysing an operation, planning its performance, preparing for performance, and disseminating the information.

In practice, the intent of pre-planning operations is to assemble in a single document the information and in one person the knowledge required to successfully execute the work in the field. Success has been achieved engineers planning operations in terms of performance, quality, and safety then managing execution of the plan in the field. Support for the plan is gained by communicating with those directly performing the work.

The effectiveness of this approach for planning and improving unique and complex operations has been demonstrated through a laboratory exercise incorporated into the Construction Performance Improvement course at Virginia Tech. Reactive analysis of one operation led to detailed planning and responsibility assignment for a similar subsequent operation. Construction duration was reduced by approximately 40% and significant improvements were reported in material handling, understanding of responsibilities and work flow efficiency.

APPLYING AN EXPERIMENTAL APPROACH TO COMPARING CONTRACTORS' BIDDING BEHAVIOUR IN DIFFERENT COMPETITIVE ENVIRONMENTS

Bee-Lan Oo,[1] Derek Drew and Hing-Po Lo[2]

[2]*Department of Management Sciences, Hong Kong City University, Hong Kong*

In developing research methods for comparing contractors' bidding behaviour in different competitive environments, the central task is achieving reliable comparisons. In this paper discussion is concentrated on the designed bidding experiment that aimed to examine, in terms of decision to bid and mark-up decision, the extent to which individual Hong Kong and Singapore contractors are influenced, to varying degrees, by (1) market conditions, (2) number of bidders, (3) project type and (4) project size. This approach allows for a greater control over the manipulation of the bidding variables than would have been gained using real data, and in doing so make possible more direct comparisons between the two competitive environments (i.e. Hong Kong and Singapore). The research to date reveals that the experimental approach is well accepted by the Hong Kong and Singapore contractors in which useful data were obtained for subsequent analysis.

Keywords: bidding, experiment, research methods.

INTRODUCTION

The competitive environment is not static, nor the competition. Organizational theorist emphasizes that business organizations must adapt to their environment if they are to remain viable (Duncan 1972). With no exception of the construction firms, the behaviour of construction firms is strongly influenced by the environment within which they operate (Hillebrandt *et al*. 1995). The competitive environment within which contractors compete is seen by Newcombe (1990) as consisting of the (i) general environmental factors of politics and law, economics, sociology and technology and (ii) competitive environmental factors of finance, plant, labour, management, suppliers, subcontractors, consultants and clients. In addition, there are many bidding factors affecting contractors' bidding behaviour in terms of decision to bid and mark-up decision (Ahmad and Minkarah 1988; Odosute and Fellows 1992; Shash 1993). It follows that contractor's bidding decisions are dependent on individual firm-specific characteristics (e.g. competitive strategy, capability of management etc.) as evidenced in these studies where there are differences in ranking of factors that contractors consider when making decision in bidding competition.

To compete successfully, contractors not only need to have an understanding of the make up of different competitive environments within each country but also of contractors' competitive behaviour within those environments. The overall aim of this research project is to compare the bidding behaviour of contractors operating within

[1] beelan.oo@polyu.edu.hk

two different competitive environments (i.e. Hong Kong and Singapore). Within the context of four important bidding variables, i.e. market conditions, number of bidders, project type and project size (Skitmore 1989), the bidding experiment designed for data collection purposes is the focus of this paper.

Hong Kong (HK) and Singapore are chosen mainly on the basis of high *comparability* between the competitive environments in construction of these two city states (Oo and Drew 2005). Also, the designed bidding experiment is based on the conventional public sector building projects in HK and Singapore since they are *representative* and made up approximately 50% of the total construction demand in both industries (Oo and Drew 2005). In this way, reliable comparisons are promising in this research project by taking into account the two desired key elements of an international comparison study, i.e. comparability and representativity (Meikle 1990).

EXPERIMENTS IN CONSTRUCTION BIDDING RESEARCH

Fellows and Liu (2003: 84) define experiment as "an activity or *process*, a combination of activities, which produces *events*, possible outcomes". The basic intent of experimental research design is to allow researcher to control the research situation (or controlling for all other factors that might influence the outcome), so that one or more variables can be manipulated in order to test a hypothesis (Zikmund 2003). Research methods of experimental nature are not new in construction research. In particular, for studies of comparative nature such as comparing cost performance (Xiao and Proverbs 2002) and comparing price, methods and productivity (Edkins and Winch 1999; Proverbs *et al*. 1999) where the participants were required to response based on hypothetical projects, thus allowing the authors to control the research situation.

Experimental research in construction bidding may be traced as early as 1970. For example, Hackemer (1970) examined the effect of variability of estimate, number of competitors and mark-up on bidding strategy by asking five competitors to bid for 200 contracts. The bidding experiment, what the author refers to as 'simulation', has produced some 200,000 bids via application of different variability factors of estimate. Dyer *et al*. (1989), on the other hand, compared the naive and experienced bidders in the construction contract bidding in a laboratory experiment setting. This laboratory experiment does provide reasonable results as evidenced in their follow-up study via interviews and past bid data (Dyer and Kagel 1996). More recently, Drew and Skitmore (2006) used a bidding experiment to test the applicability of Vickery's revenue equivalence theory in construction bidding. Despite small sample size in this study with only six participants, appropriate procedures were used for selecting participants to enhance reliability and to keep their interest in the experiment that required them to bid for hypothetical projects over ten rounds.

Based on the classification framework suggested by Bowen (1978), the previous work using bidding experiments, variously termed as bidding games or simulations, in construction bidding research can be classified into one of three purposes: (i) learning (e.g. Harris and McCaffer 1989); (ii) teaching (e.g. Nassar 2003); and (iii) research (e.g. Hackemer 1970; Han and Diekmann 2001; Drew and Skitmore 2006). Although these previous work do have the potential to generate the data needed for this research, so many other issues would need to be considered. For example, the data from 'teaching' and 'learning' game formats are generally the products of specified lesson in the games and highly depend on the course of play, which cannot be specified in advance. In the last case, the research game is used as an empirical tool for investigating decision-making that allows controlled hypothesis testing. Han and Diekmann (2001) studied the contractors' risk attitude in the selection of international construction projects using a research game. Based on similar rationale, it was therefore decided to develop a controlled experimental design research game, i.e. a bidding experiment that specifically focuses on testing the effect of principal variables of interest on contractors' bidding behaviour.

The designed bidding experiment presented here was developed from a laboratory experiment on auction theory by Dyer (1987). It is worth noting that experiments have been remarkably successful in terms of extending the theoretical framework of auction theory. Kagel and Levin (2002) have devoted a whole volume to the experimental research in auction theory. It is argued that experimental approach is feasible to reveal some of the salient aspects of the complexities involved in construction bidding that would have been revealed using past-pooled bids or other forms of research design.

BIDDING EXPERIMENT METHOD

The 'after-only' quasi-experimental design (Zikmund 2003) is chosen for the bidding experiment. It involves an exposure of a group to an intervention followed by a measurement to determine the effect of the exposure. Although the quasi-experimental design does not qualify as true experimental design in a formal scientific sense due to its inadequacy to address potential threats to validity of an experiment (Creswell 2003), it is acceptable in construction management research due to impracticality of true experimental design (Fellows and Liu 2003). They go on to point out that it is neither practical nor possible to set up an experiment that is an exact replica of the commercial construction industry given that there are numerous independent variables on most occasions. For instance, Shash (1993) identified 55 factors affecting contractors' decision to bid. Thus, the usual approach is to adopt quasi-experimental design in which main independent variables, except the one of interest, are held approximately constant and the consequences for the major dependent variable are measured.

With respect to the four principal variables of interest, i.e. (1) market conditions, (2) number of bidders, (3) project type and (4) project size, the designed bidding experiment permits the following that justified its application:

- A direct comparison of contractors' bidding behaviour in terms of decision to bid and mark-up decision between the two city states.
- Generation of adequate sample that covers the region of interest of the principal variables (e.g. data sample for number of bidders scenarios ranging from 4 to 30), given that it is difficult to access real past bid data for projects of different type and size along with different market conditions and number of bidders.
- Examination of the effect of changing number of bidders on contractors' bidding decisions, as decision to bid and mark-up decision for several possible number of bidders scenarios are unobtainable in 'real world', where contractors only submit one-off bid in bidding for a project.
- Heterogeneous approach to modelling contractors' bidding decisions since a reasonable size dataset is obtained from each participant in the experiment.

The participants

Given that the focus here is on public sector contracting, the centralized contractors' registry systems maintained by the local government agencies were used as a basis in the selection of participants. All the (i) Group C contractors listed on the Hong Kong Environment, Transport and Works Bureau's (ETWB) List of Approved Contractors for Public Works (2005), and (ii) Groups A1, A2 and B1 general building contractors listed in the Singapore Building Construction Authority's (BCA) Contractors Registry (2005) were contacted for the research purposes. A review on past tender reports revealed that these groups of contractors are the 'active' market players in public sector general building contracting.

The procedures

The participants were invited to participate via email in the bidding experiment by (i) acting as senior managers of their construction firms; and (ii) bidding for 20 hypothetical projects. These were arranged in two rounds according to two extreme market conditions scenarios. The use of hypothetical projects removes the need to identify matching projects from HK and Singapore, and thus enhance the comparability of data collected. Project information from past tender reports by the local government agencies was used to give a broad but carefully worded description of the hypothetical projects in attempt to enhance representativity of data collected. The experiment requires the participants to draw upon their previous experience in deciding (i) which jobs to bid for and (ii) what mark-up should they apply to the job if they decided to bid.

Participants were informed that their ultimate aim is to survive and prosper in which lowest bidder will win the job. This was done to reflect the local industry norm that lowest bidder tends to win a job (Construction 21 Steering Committee 1999, Construction Industry Review Committee 2001). In attempt to establish a strong basis of comparison of results, a repeated-measures design was adopt for the experimental procedures in which the same 20 hypothetical projects were used in both rounds of the experiment. The sequence of the 20 projects, however, was randomly revised in the second round in order to avoid contamination of responses.

Manipulations of the principal variables of interest

The manipulations of the four principal variables of interest, in terms of values or levels that they assumed, are based on literature and previous empirical findings. Thorpe and McCaffer (1991) take the view that market conditions as an all embracing subjective terms which on a macro-(industry)level includes such factors: the total construction order for all work; the total orders for each market sector; projected future orders; current and projected governmental policy and legislation; construction price levels; cost of capital. On a micro-(company) level, it includes an assessment of contractors' local, national and international opportunities; competitor activity; volume of on-going work; and order books. Ngai *et al*. (2002) agreed that there is no definitive measure of market conditions in construction that exists in literature, with various variables employed including the ratio of tender price index to construction cost index, number of bids received for particular projects, and rate of change of a particular price index (e.g. tender price index). Prevailing market conditions oscillate between periods of economic boom and recession. It was therefore decided to set the two extreme market conditions scenarios as: (i) boom times with low need for work, and (ii) recession times with high need for work. This setting is closest in spirit to the work by de Neufville *et al*. (1977) in what they refer to as 'good' and 'bad' years where prevailing market conditions is seen as the proxy variable for the contractors' need for work. Participants were informed that all hypothetical projects could be completed within the stated boom and recession periods since larger project may extend over one or more phases of business cycle and contractors do anticipate likely future in their bidding decisions.

There are eight number of bidders scenarios (ranging from 4 to 30) for every hypothetical project with the *estimated* number of competing bidders, *N*, increasing in the levels of 4, 6, 8, 10, 14, 18, 24 and 30. This range of the number of bidders is determined based on recorded number of bidders per contract for HK and Singapore public sector general building contracts (Fu 2003; Oo and Drew 2005). The participants were asked to bid up to the bidding scenarios of *N* bidders that they wish to bid. This enables a close examination of bidding patterns when there is less number of bidders, and reduces the repetitive nature of the experiment since divergence in bidding decisions is expected to be less noticeable if there are too many bidders (Wilson *et al*. 1987). Also, the term 'estimated' was used because contractors are unlikely to have the exact number of competing bidders when submitting a bid.

The 20 hypothetical projects are of conventional type, i.e. new construction or rehabilitation works that involve buildings of usual design, and do not require any unusual construction technologies. This was done to control the effect of project type on contractors' bidding decisions since both the project type and complexity, to some degree, determines the potential group of competing bidders.

In terms of project size, the predetermined range of project size is based the participants' tendering limits set by the local government agencies for the perspective HK and Singapore participants. All the 20 projects selected are of size ranging from HK$ 50 to S$ 150 million (or S$ 10 to 30 million based on a conversion rate of S$ 1 to HK$ 5) in order to establish a competitive ground if the HK Group C, and Singapore Groups A1, A2 and B1 contractors are to compete.

So as the same project list can be used for these two city states to form a strong basis for comparisons, ten conventional projects that satisfied the selection criteria were selected from the past tender reports published by the HK and Singapore local government agencies, respectively. Project information of the selected projects was used to form a realistic baseline data for the construction of hypothetical project list used in the experiment. It should be noted that the wording of project description was changed as necessary to reflect the local bidding practices, for example, the term 'conversion and extension' and 'addition and alteration' were referred to upgrading and maintenance work in HK and Singapore, respectively. Also, the corresponding awarded contract values or lowest bid prices of the selected projects were used to compute the cost estimates for the hypothetical projects with necessary adjustments and updated to a common base date using published tender price indices.

To facilitate the participants' decision making, the cost estimate was (i) expressed in million of dollars, e.g. 55 million (instead of actual dollars) in respective local currencies, and (ii) defined in the experiment instrumentation as an 'unbiased estimate' of the net construction cost (i.e. contractors' in-house estimate) that includes the project preliminaries and site overheads, but without any adjustments for items such as general overheads, risk margins, competition, finance and profits.

The instruments

The instruments for the bidding experiment consist of a leaflet and two sets of bid response forms. As an alternative of a cover letter, an eye-catching colour-printed leaflet with a brief summary of this experimental research was first sent to the participants in seeking their voluntary participation in the experiment. This was done to seize their attention so as to increase the response rate. Indeed, the two-round nature of the bidding experiment had placed significant hurdles in recruiting participants.

Each participant were required to complete two sets of bid response form, each of different bidding (market conditions) scenarios. The bid response form consists of two parts, i.e. a single page of written instructions was presented in the first part, comprising assumptions, definitions and steps required to complete the bid response form, and the 20 hypothetical projects were listed in the second part of the bid response form. A copy of the bid response form is available from the author.

Controlling the extraneous variables

Apart from the information of the four principal variables, the participants were also given information on cost estimate, project duration, location, client and contract type to facilitate their decision making. Given that it is impractical for not including any extraneous variables in the experiment, a *constancy of conditions* was established in controlling these extraneous variables (Venkatesan and Holloway 1971 cited in Zikmund 2003). The basic intent of this procedure is to ensure that all the participants were exposed to situations that are exactly alike except for the differing conditions of the independent variables.

Threats to validity of the experiment

Experiments are judged by two measures: (i) internal validity – indicates whether the independent variable(s) was the sole cause of changes in dependent variable(s); and (ii) external validity – indicates the extent to which the results of the experiment are applicable in a real world situation, and whether the results can be generalized to the population it is meant to represent (Campbell and Stanley 1963). Table 1 summarizes the various measures designed to overcome the identified threats (Creswell 2002) to both internal and external validities of the bidding experiment.

Table 1: Adopted measures to overcome the threats to internal and external validities of the bidding experiment

Threats	Definition	Adopted measures
Internal validity		
• History effect	A specific event in the external environment occurring between 1st and 2nd measurements that is beyond the control of experimenter	A short interval was allowed between the repeated measurements, i.e. three weeks between the 1st and 2nd rounds of experiment
• Maturation effect	An effect caused by changes in experimental participants over time; it is a function of time rather than response to a specific event	Same as above
• Testing effect	An effect that occurred if identical instrument is used more than once	The sequence of the 20 projects was randomly revised in the second round of the experiment to avoid contamination of responses
• Instrumentation effect	An effect caused by a change in the wording, or other changes in procedures to measure the	A pilot test on the instruments used for the bidding experiment was

	dependent variable	carried out prior to data collection
• Selection effect	A sample bias or sample selection error	The selection of participants for the bidding experiment was based on the tendering limits set by the local government agencies
• Mortality effect	Sample attrition that occurs when participants drop-out during the experiment for any number of reasons (e.g. time, interest and money)	All the perspective contractors were contacted since it is very likely that some participants will drop-out after first round of the experiment. This was done to increase the number of complete response sets from the two rounds of the experiment
External validity		
• Interaction of selection and treatment	Inability to generalize beyond the groups in the experiment	The feasible measure to overcome this particular threat is to repeat the experiment with different samples, e.g. HK Group B contractors. If, however, the replication with this group of contractor gives rise to different results, it does not mean that the experimental procedure is flawed. Rather, it enables the experimenter to specify the limits of generalization and the groups of contractors to whom the results *do* and *do not* apply
• Interaction of setting and treatment	Inability to generalize from the setting where the experiment occurred to another setting	Similar to the above, replication is the possible strategy to draw the limits of generalization by conducting the experiment in different context, say, for private sector contracting along with different settings for the four independent variables
• Interaction of history and treatment	Inability to generalize findings to past and future situations	Likewise, replication is the possible strategy to draw the limits of generalization by conducting the experiment in different periods of time

Experiment limitations

Setting up a bidding experiment that is an exact replica of the commercial construction industry is extremely difficult, if not impossible. Given that there are so many possible factors affecting bidding decisions, the focus has therefore been on those key factors that comprise market conditions, number of bidders, project type and size. Other factors in the experiment including project duration, location, type of client and contract type have been held constant in establishing a setting that the subjects are familiar with, thus allowing their experience to manifest itself effectively.

The experiment, however, does not consider the direct effect of bidding decisions on future event since the 20 hypothetical projects were released at once. No feedback information were given to the subjects at the end of each round of the experiment as the two rounds of experiment are treated as independent study, based on different market conditions scenarios. It is felt that inclusion of 20 projects is necessary to generate a reasonable data set and to reflect that contractors are selective in their bidding decisions as bid enquiries are received continuously. Also, the participants tend to be more risk seeking in an experimental setting, although it is believed that industry practitioners who are willing to spend times on non-rewarding academic studies (in this case, two rounds of experiment) will respond genuinely since many stated they would do so.

CONCLUSIONS

In contrast to most published construction bidding work based on past-pooled bids, the research to date reveals that the experimental approach for data collection is well-accepted by the Hong Kong and Singapore contractors. In fact, the analysis undertaken at the time of writing shows that useful data were obtained for statistical modelling of the effect of (1) market conditions, (2) number of bidders, (3) project type and (4) project size on HK and Singapore contractors' bidding decision to bid and mark-up decision.

Replication of the bidding experiment method is feasible to reveal further some of the salient aspects of the complexities involved in construction bidding. For example, it is possible, through scenario building, to study the extent to which the (i) likelihood of claim back options, (ii) likelihood of follow-on project, and (iii) likelihood of post-tender negotiation would affect contractors' bidding behaviour. Data difficulties are anticipated in providing an insight on these phenomena, whereas other forms of research design appear to be inefficient or difficult to give an interpretation.

MEASURING COMPETITIVENESS IN THE CONSTRUCTION SECTOR – A NEW PERSPECTIVE

Roger Flanagan, Carol Jewell[1] and Weisheng Lu

School of Construction Management and Engineering, University of Reading, UK

There is no widely accepted definition of competitiveness and its measurement is complex, but measuring competitiveness remains an important goal for firms, industry and nations. This research sought to establish a method for measuring competitiveness that took account of the different perspectives of the stakeholders in the industry: clients, investors, design and construction enterprises, employees and society. Over 300 factors of competitiveness were identified through workshops, a Delphi study, interviews and a literature review. A framework was devised – the construction competitiveness hexagon (CCH) – for use at a national, industry and company level. The construction competitiveness toolbox (CCT) was produced: software that allows competitiveness to be measured using predetermined or customized factors relevant to the user(s). The main finding was not the competitiveness scores themselves from each of the three countries in the study but an understanding of the effect of different stakeholders' perspectives. Identifying, weighting and understanding the interdependency between the factors is crucial for the measurement of competitiveness.

Keywords: competitiveness, measurement, productivity.

INTRODUCTION

Globalization has created an interconnected and interdependent world. It converts the world into a complex and multi-faceted dynamic place with competition, trade, financial deregulation, growth of exports and imports and so on. Mobility of capital and an information and communications revolution has brought about time–space compression overcoming national boundaries. The effects can be seen in the UK construction sector with the rapid growth in imported construction components and materials, and the increase in UK companies, particularly design consultants, working overseas. To survive economically in this global marketplace, both companies and nations must be competitive, hence the importance of understanding the factors influencing competitive and comparative advantage.

OBJECTIVE

The objective of this paper is to give a new perspective on construction competitiveness by considering how construction competitiveness can be measured. It considers the development of a construction competitiveness toolbox that is computer aided and driven by organizations who want to measure some aspect of competitiveness.

[1] c.a.jewell@reading.ac.uk

THE CONCEPT OF COMPETITIVENESS

Competitiveness is high on the agenda for firms, industries and nations, but it is not well understood and has no common definition or metrics. There are many definitions:

> Competitiveness refers to a country's ability to create, produce, distribute and/or service products in international trade while earning rising returns on its resources. (Scott and Lodge 1985)
>
> Competitiveness is the degree to which a country can, under free and fair market conditions, produce goods and services which meet the tests of international markets while simultaneously maintaining and expanding the real incomes of its people over the longer term. (OECD 1997)
>
> Competitiveness is the ability of a country to create added-value and thus increase national wealth by managing assets and processes, attractiveness and aggressiveness, by integrating these relationships into an economic and social model. (International Institute for Management Development 1996)
>
> Competitiveness is about creating high skills, high productivity and therefore a high usage economy. (HMSO 1994)
>
> Competitiveness is the capacity of businesses, industries, regions, nations or supranational associations exposed, and remaining exposed, to international competition to secure a relatively high return on the factors of production and relatively high employment levels on a sustainable basis. (European Commission 1994)

The range of definitions indicates the complexity of the concept; there is no one definition accepted by all. The lack of consensus is due to diversity caused by different perspectives. The definitions tell us about the meaning of competitiveness and the factors involved, but they do not address the fundamental issue of how to measure competitiveness.

Competitiveness is not a zero-sum game. One country does not improve its competitiveness at the expense of other countries. The competitiveness of a national construction sector relates to the productivity, the intellectual capital, the core competencies, and the entrepreneurship and influence of a nation.

SUMMARIZING COMPETITIVENESS

Besides the various definitions, a number of other interesting characteristics are useful for gaining insights into the concept. They are:

Multi-defined: There is no general, generic definition of competitiveness and hence the term is subject to misinterpretation and consequent confusion (Porter 1990; Boltho 1996; Chaharbaghi and Feurer 1994; Lall 2001; Cho and Moon 2000).

Multi-measured: There is no single, generic measurement of competitiveness. Instead measurements vary with the definitions (Chaharbaghi and Feurer 1994; Buckley *et al*. 1988). More importantly, there is no standardized approach about how to measure the factors of competitiveness.

Multi-layered: Competitiveness may be applied to the national, industry and company levels (Momaya 2004; Lall 2001; Nelson 1992).

Dependent/Interdependent: Competitiveness depends on the values and the focus of the stakeholders of the entity under investigation (Momaya and Selby 1998; Chaharbaghi and Feurer 1994), and it will be influenced by a number of endogenous and exogenous factors.

Relative: Measurement of competitiveness needs to be looked at in a relative sense, either against some maximum ideal level, or against the peers in the sector (Chaharbaghi and Feurer 1994; Lall 2001).

Dynamic: The factors that influence competitiveness change with time and context, for example as a national economy moves from a less, to a more developed stage (Momaya 2004; Cho and Moon 2000).

Process: Competitiveness involves assets (human, financial and physical), processes and performance, where processes turn assets into performance (Buckley *et al*. 1988; Crouch and Ritchie 1999).

To summarize, the objective of competitiveness of nations centres on human development, growth and improved quality of life, while firm competitiveness is based more upon profitability, productivity and other business factors. Nations continually attempt to make cross-country comparisons. However, their competitiveness depends upon micro and macro economic factors in which a nation's firms compete.

Firm competitiveness is related to market performance, with productivity and the exploitation of knowledge capital being keys to success. The objective of firm competitiveness, after having secured survival, is the creation of profits and new growth options that create value and returns for shareholders. Hence, competitiveness is associated with achieving an objective. Competitiveness is not an end, but a means to an end (Buckley *et al*. 1988).

CONSTRUCTION SECTOR COMPETITIVENESS

Research on competitiveness conducted at Reading put forward a broad definition for competitiveness in the construction sector as the extent to which a business sector:

1. satisfies the needs of customers from the appropriate combination of the product–service characteristics such as price, quality, speed of delivery, certainty, innovation and reliability;
2. satisfies the needs of its constituents (stakeholders), for example, enterprises and workers in terms of wages, safe workplace, training, steady employment and pleasant work environment with career development;
3. offers attractive profits and return on investment, the potential for growth, with acceptable levels of risk;
4. satisfies the needs of society to be a responsible corporate citizen and to meet the needs of society in terms of pollution, energy conservation, sustainability and safe systems of working.

This definition differs from many others by recognizing the different stakeholders in the industry and their range of perspectives. Time is an important determinant in competitiveness. Most debates focus on past performance and assume that future performance will replicate the past. They adopt a longitudinal approach with a latitudinal measurement. A longitudinal approach is one that considers sustained competitiveness over time with all the stakeholders being satisfied.

FACTORS OF COMPETITIVENESS

Productivity is not the only factor of competitiveness. 'Productivity depends on the value of goods and services produced per unit of the nation's human, capital and natural resources, measured by the prices they can command in open markets and the efficiency with which they can be produced' (Porter 2002: 55). Productivity is about getting the best value from all inputs across the whole value chain. There needs to be sustained improvement in management, products and processes in component and materials manufacturing, design management and processes, site production and assembly.

Many factors make up competitiveness; each may be weighted differently when compiling an overall competitiveness 'score'. The following company competitiveness factors were identified from a literature review:

Price	**Productivity**
Intellectual property/competencies	Quality of management (profitability, seamless project delivery, speed of reaction)
Reputation for performance, reliability, and quality	Culture (underlying beliefs and behavioural manifestations)
Location and geographic representation	Size of turnover/strength of balance sheet
Availability of and access to resources – human, capital and natural	Innovation, research and development

Factors of national competitiveness are different (World Economic Forum 2002), they provide the framework in which a company operates:

Economic performance	**Business efficiency**	**Government efficiency**
Domestic economy	Productivity	Public finance
International trade	Labour market	Fiscal policy
International investment	Finance	Institutional framework
Employment	Management practices	Business legislation
Prices	Impact of globalization	Education
Infrastructure		
Basic infrastructure	Scientific infrastructure	Health and environment
Technological	Infrastructure	Value system

The list is not exhaustive, but it does provide a framework from which to base a measurement system for competitiveness.

MEASURING COMPETITIVENESS

Construction competitiveness cannot be measured by treating the construction sector as one industry. The sector can be classified into three distinct sub-categories because of the different mix of skills, capital and finance, and technology:

1. Manufacture and assembly of plant, equipment, components and raw materials – requires high capital and technology input. They can be manufactured anywhere and exported, as long as they are price competitive and meet the required codes and standards appropriate for the domestic market, and have the facility to support ongoing maintenance.

2. Professional design and consultancy services – mainly dependent on knowledge and intellectual capital and can take place in any country and be exported. The professional services are primarily dictated by the design codes, business and professional registration requirements and the cultural dimension of that country.
3. Site assembly/production carried out by contractors and specialist contractors – heavily dependent on organization and labour skills, plant, equipment and technology, use local labour (with culture and education and training variables), and experience local conditions (climate and geology variables). They frequently require companies to have a local presence or local partner.

Within the above groups, there are sub-groups. For example, housing contractors have very different organizational and business characteristics from those of civil engineering contractors. Housing contractors either work in social housing or they build speculatively for sale; they are focused upon the needs of the individual customer. They have a land bank which may stretch many years into the future; frequently this means large amounts of capital is locked up in land. The civil engineering contractor is generally dependent upon public sector organizations for workload. Projects involve using a lot of plant and equipment, and ensuring a project is cash positive as quickly as possible, using the client's money to fund the construction phase.

Therefore, when measuring the competitiveness of the firm, there must be an understanding of the different sets of factors of competitiveness of the business being considered. It is tempting to use the same factors throughout the sector, but these will not reveal the special characteristics of a country or a company.

THE READING RESEARCH

A research project (2004–06) undertaken by Reading University 'Measuring construction competitiveness in selected countries', funded by the EPSRC with matching industrial funding, considered construction industry competitiveness in the UK, Sweden and Finland. There was collaboration with the USA, Japan and Australia.

A four-step approach was used:

1. Undertake a literature review and consider the theoretical underpinning of competitiveness.
2. Identify the factors of construction competitiveness through workshops, Delphi study, focus groups and questionnaires.
3. Develop a model for construction.
4. Develop a tool for measuring competitiveness to be used at national, industry and firm level. The tool must be simple, adaptive, encourage lateral thinking, and be easy to operate for it to be used by the industrial community.

Step 1
A comprehensive literature review was conducted to understand the concept of competitiveness, the theoretical underpinnings, and its implications on the exploration of competitiveness factors. The literature review revealed extensive publications on competitiveness. None of the models was found to be a perfect match

for construction, but Porter's Diamond was considered to be the best fit and the most appropriate for adaptation; it proved to be the most robust and cross-disciplinary. As the starting point for developing a framework for the mapping of explanatory factors, it is important to consider the conclusions drawn by Ofori (2003). He suggests that 'in developing a model for analysing international construction, it would be relevant to consider the four determinants in Porter's diamond, as well as culture and institutional arrangements and government's influence. Chance would be an exogenous variable and there should also be an international dimension. Thus, each company's or industry's competitiveness would be depicted by a series of linked (national) diamonds' (Ofori 2003: 389). Interestingly, the construction industry was not the focus of any of the frameworks explaining competitiveness as discussed above, and thus it is likely that some special characteristics relevant to construction have not been taken into account.

Step 2

Over 300 factors of competitiveness were identified by the industry in all three countries. These factors were combined together on what was agreed to be a suitable level for a study on an industry level, ignoring the most detailed factors. Having eliminated the superfluous factors, a list of 158 factors remained. The different countries in the research focused on different priorities as being the most important factors. Finland regarded information and communication technology as being the key factor, whereas Sweden ranked this in the top 10 and the UK in the top 50. Sweden ranked the role of trade unions in negotiations as being in the top category, whereas Finland ranked it in the top 10 and the UK only in the top 100. The respondents in the sample were selected from different stakeholders, such as clients, government bodies, trade unions, design consultants, contractors and the supply chain. In every case, safety and human resource issues ranked very highly in the factors of competitiveness.

Step 3

A construction competitiveness hexagon was developed based on Porter's Diamond. Adaptations were made to the Diamond: Related and supporting industries was left out (due to the multi sub-group nature of the construction sector), Context for firm strategy and rivalry was split into Firm strategies, management and organization and Industry characteristics; Government was moved from being an exogenous determinant to being part of the hexagon, and Factor conditions were split into Human resources and Factor conditions. These changes were based on the literature (Cho 1994; Lall 2001; Stopford and Strange 1991; van den Bosch and de Man 1994) and data from interviews and workshops in Finland, Sweden and the UK. Figure 1 shows the construction competitiveness hexagon, its six faces and culture and chance which impact on all these.

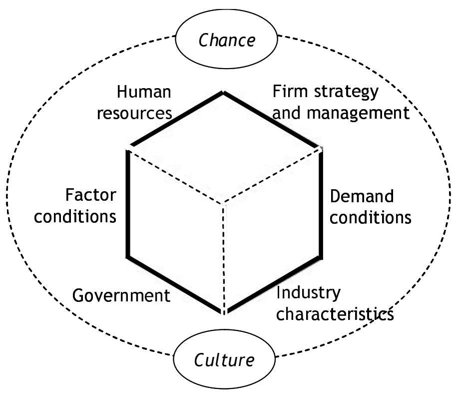

Figure 1: The construction competitiveness hexagon

For simplicity, the hexagon can be considered as a cube; on each face of the cube there are factors that influence performance and competitiveness. For example under 'Firm strategies and management', the following factors were identified from the data; the list is not exhaustive, it is intended to illustrate the principles involved:

Corporate
- Risk management
- Business ethics
- Environmental awareness
- Change management
- Attitudes and priorities towards new technology
- Labour/capital balance
- Level of R&D investment

Project
- Ability to create financial solutions for clients and projects
- Ability to give financial guarantees to clients
- Lean production in construction
- Production process
- Standardization of the production process (design, materials and work methods)
- Health and safety
- Conflict in contracts
- Use of IT in design and production

Various approaches to measurement were considered, including the analytical hierarchical process (AHP) and analytical network process (ANP) and Bayesian networks, which let us understand an event by gathering qualitative and quantitative data on its causal factors and mapping the relations between them. Until recently, there was neither the theoretical framework, nor the means to analyse such 'messy' statistical integration problems. Modelling the causal factors determining construction industry competitiveness presents enormous methodological challenges. For some factors (e.g. productivity), statistically valid quantitative data from industry and government sources are available. For others (e.g. human resource performance), it was necessary to draw on primary or secondary sourced qualitative data (principally expert opinion). For many factors questionable or sparse quantitative data were integrated with expert opinion.

Step 4

A construction competitiveness toolbox (CCT) was devised based upon the competitiveness hexagon providing the user with a number of ways of looking at the factors of competitiveness and the measurement. The CCT can be used at the national level to compare countries, or by companies to assess their competitiveness. The toolbox is sufficiently flexible for a company to allow competitiveness factors that are important to each firm to be considered in a methodical way. This is done through the toolbox's six matrices, under the headings used in the construction competitiveness hexagon.

The first step is the selection of the factors of competitiveness which can either be from a predefined list or a company can produce a unique list of factors. The CCT can be used at all levels of the business, from top management to a project team. From a long list generated by the selection system, the top factors are entered into the appropriate matrix in the program.

A weighted evaluation matrix allows the user to rank the factors against each other, with a weighting that is based upon subjective judgement. There is no hard science to the measurement, it is opinion based. The result of determining the importance of each factor relevant to another factor becomes the raw score in the matrix on a scale 1–100 – see Figure 2. The scoring is attempting to prioritize each of the factors by using a raw score; the next step is to look at the performance of each of those factors.

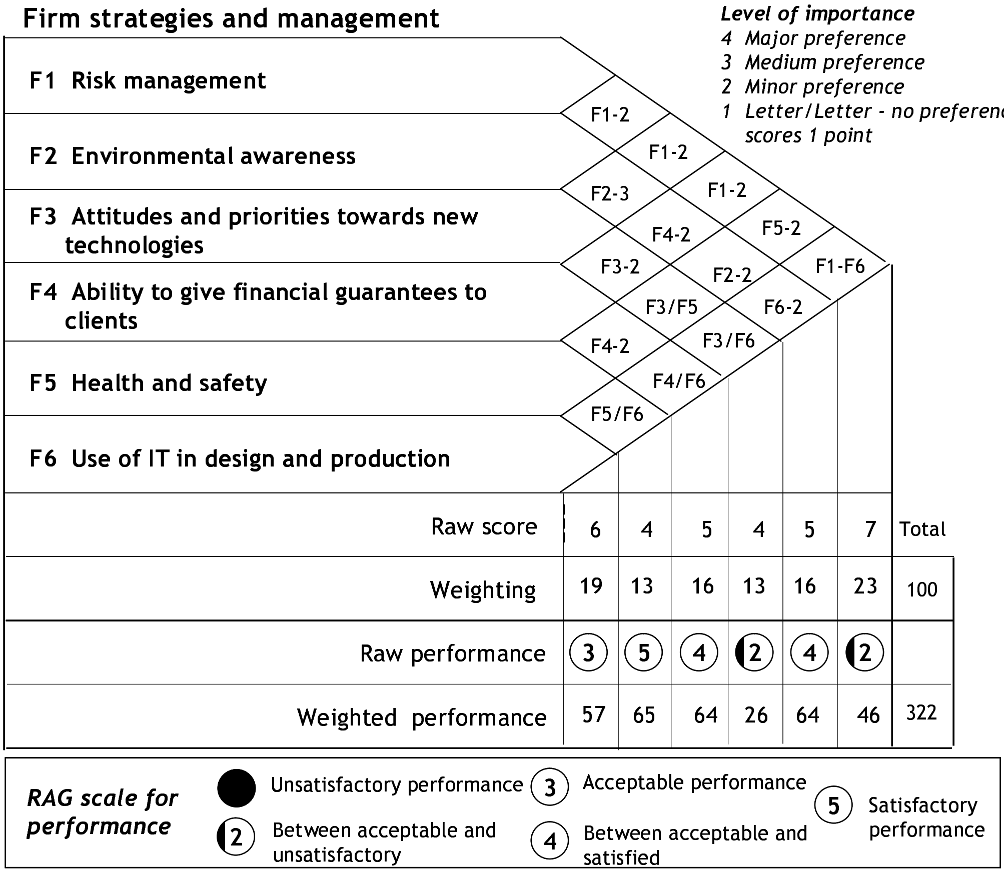

Figure 2: The weighted evaluation matrix used for the relative importance of factors within the firm strategies and management determinant

A five-point scale is used, based on the RAG (red–amber–green) scale ranging from unsatisfactory to satisfactory – see Figure 2. The selected top factors are generated in the left hand side of the matrix. These are compared to each other, by the group using a preference scoring system. For example, comparing the importance of F1 (Risk management) to F2 (Environmental awareness) F1 is moderately preferred to F2. In the same way, a comparison between F2 and F3 (Attitudes and priorities towards new technologies) results in a moderate to strong preference for F2.

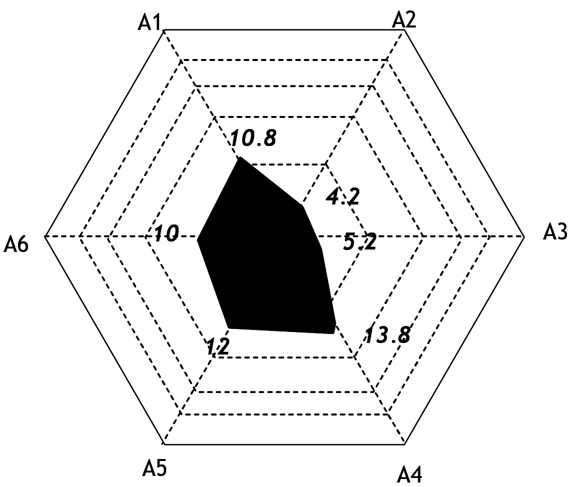

Figure 3: The hexagon produced from the weighted evaluation matrix for each determinant, giving the total competitiveness score

Once the matrix has been completed the program automatically produces the raw scores and importance levels. The next step is to assess the performance of each of the factors at a company/project level, allowing the program to calculate the weighted performance.

The program then calculates the competitiveness score and produces a ‘spider’ diagram, shown on the left hand side of the screen shot in Figure 3. This not only allows the results to be graphically seen, but also allows comparisons to be made if the process is undertaken by different people or at different times. The figures on the right hand side are further graphic representations of the results.

SUMMARY OF CCT

The flexibility of the CCT is important with the changing environment of construction and global business. The impact of factors of competitiveness will change over time and is relevant to geography. For example the factors chosen by a project team for an office development in Manchester will be very different from those selected for a multi-million pound hotel complex in Dubai.

Company strategies change over time and the CCT can reflect this, allowing different sets of factors to be used at different times. The graphical nature of the output is easy to understand and does not require the user to have a great deal of computer expertise. The hexagon output allows easy comparisons to be made of ‘results’ from different time periods or, if appropriate, from an analysis of competitors.

CONCLUSION

Competitiveness is a complex issue; it is much more straightforward to measure the factors of competitiveness at the firm level rather than at industry or national level. While there was general agreement across the UK, Swedish and Finnish construction sectors on the factors of competitiveness, views on the measurement of the factors varied according to the level of importance each country placed on them. It was evident that a computer-assisted toolbox was required to provide both a structure and a range of alternatives that could be used at the three levels – national, industry and firm.

The CCT toolbox developed allows the user to recognize the interdependency between the factors of competitiveness and customize the choice of factors according to the business, the market or a project strategy. Its flexibility allows it to be used in all spheres of construction. The toolbox is at its early stages of development, ongoing research and dissemination will help to refine and improve it to meet the needs of its users. It has been tested and validated in practice with consistent and reliable results.

The CCT is a practical tool emanating from academic research thus bridging the gap between theory and practice.

ECONOMICS OF INCORPORATING EARTHQUAKE RESISTANT PROPERTIES INTO RESIDENTIAL BUILDING DEVELOPMENT IN JORDAN

Ghaleb J. Sweis,[1] Rateb J. Sweis,[2] Anis S. Shatnawi[1] and Nazzal S. Amouti[1]

[1]*Civil Engineering Dept, University of Jordan, Amman, Jordan*
[2]*Amman Arab University, Amman, Jordan*

Due to the rapid urban development process in the last two decades, Jordan's vulnerability to earthquakes has increased. This research assessed the direct cost of structural mitigation and expected damage to a typical five-storey apartment building in case of an earthquake in Jordan. Cost estimates for the typical reinforced concrete building were calculated before and after applying the 2005 Jordanian Seismic Design Code. In addition, the Turkish Damage Probability Matrices were adopted to assess the magnitude of earthquake damage. The cost of incorporating earthquake resistance against collapse and subsequent loss of life was estimated at 1.63% of the capital cost of building. This is likely to prove of significant financial benefit, making the actual incorporation of earthquake vulnerability reduction strategies into public policy a sound decision.

Keywords: construction design, cost-benefit, earthquakes, Jordan, structural mitigation.

INTRODUCTION

Disasters, whether natural or man-made, have serious long-term negative impacts on the development of a community. A relatively small, single investment in disaster preparedness or mitigation can greatly reduce the recurrent losses of capital items and production caused by disasters. However, in any development program there will be competition for resources and priorities need to be set. Of particular interest here are the techniques and methods by which decision-makers compare development alternatives. There are ranges of models, which represent the ways in which comparisons are made in development decision-making. Politicians rarely view mitigation with much favour. Short-term considerations tend to dominate and mitigation often has little mass-appeal in electoral terms. For many populations, the main concern is with day-to-day survival and this is inevitably reflected in the political arena. In many countries, disasters occur rather infrequently, and it is perhaps understandable that some politicians and government officials usually discount the possibility of having to justify a lack of expenditure on mitigation. In addition, if a disaster does occur, there is always the perceived benefit of "putting on a show" of large-scale relief, however ineffective it may be (Dowrick 1987).

Mitigation within the framework of sustainability involves long-term planning of multiple objectives. It aims to improve the living conditions of the poor and to safeguard the environment, while meeting needs of current and future generations. Approaches to sustainable mitigation of natural disaster acknowledge that natural

[1] gsweis@ju.edu.jo

processes and human activities interrelate to produce disasters and that most of the issues and solutions are therefore also interrelated. Therefore, a solution to one problem can meet more than one goal or need (Sirleaf 1993).

The country of Jordan recently experienced a boom in the construction sector as a result of rapid population growth as well as regional political developments. The construction processes of many residential apartment and office buildings are applied with little attention to ethical standards and comprehensive national design codes and practices. Consequently, populations are exposed to ‘unsafe conditions’ in which a fragile physical environment and local economy unite with the overall shortcomings of a vulnerable society to prevent disaster mitigation and preparedness.

This research aims at raising the question about Jordan’s increased vulnerability to earthquakes and moving further towards the goal of developing means to deal with this phenomenon. Namely, determination of the direct cost of structural mitigation, damage to a typical building in case of an earthquake, and how many earthquake-incurred damages can be avoided per unit time.

LITERATURE REVIEW

UNDP- DHA (1994) suggests that there are two main aspects to this relationship between development and vulnerability to disaster: a positive one and a negative one. According to this analysis, which is also supported by Sirleaf (1993), the relationship between community development and vulnerability to disasters can be summarized under four headings (see Figure 1).

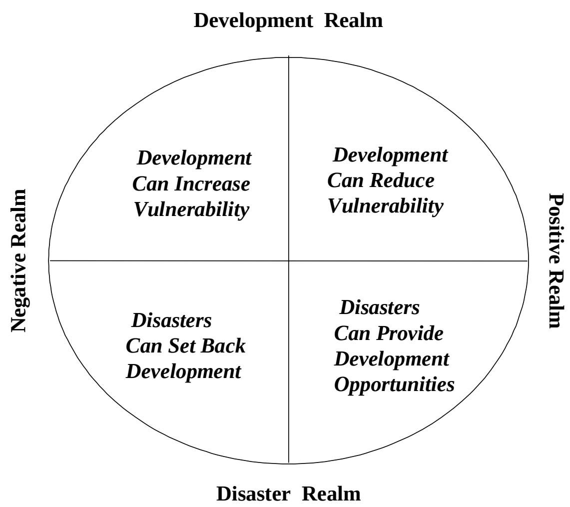

Figure 1: The relationship between development and vulnerability to disasters (UNDP-DHA 1994)

According to Ozwedem and Barkat (2000) in their article entitled “After the Marmara earthquake: lessons for avoiding short cuts to disaster”, the context of the close-woven relationship between disasters and a society’s social, economic, political and physical vulnerabilities has been explored by Quarantelli (1978), Davis (1978, 1986), Anderson and Woodrow (1989) and Blaikie *et al*. (1994). They all agree that a disaster occurs when its two main components, hazard and vulnerability, coincide in time and place.

Based on this argument, Blaikie *et al*. (1994) proposed the concept of a pressure and release model for disasters, which presents the progression of vulnerability from root causes to unsafe conditions. Development requires institutional and structural transformations of societies to speed up economic growth, reduce levels of inequality, and eradicate absolute poverty. Over time, the effects of disasters can seriously degrade a country's long-term potential for sustained development and cause governments to substantially modify their economic development priorities and programs.

In conjunction with the preceding argument, a number of mitigation strategies in parallel can be employed to ensure urban safety against disaster. Strategies can include structural measures and non-structural measures. Structural measures would reduce the impact of disasters and non-structural measures would enhance the management skills and improve capacities of the community, local self-governments, urban bodies and the State authorities to prepare, prevent and respond effectively to disasters. Non-structural measures include vulnerability mapping, risk assessment analysis, hazard zoning, inventory of resources to meet the emergency, knowledge networking of best practices etc.

RESEARCH METHOD

This research proposes a framework for developing a methodology to assess the benefits of direct cost of mitigation and damage to a typical five-storey building in Amman, Jordan. The focus of this research will be on structural measures to reduce the impact of disaster. Cost estimates will be made using the Construction Specification Institute's Master Format. Namely, the specification writing standard for most commercial building design and construction projects in North America and is currently adopted by many firms in Jordan.

Building on the findings of Yucemen (2005) stating that, due to the uncertainties involved, the damage that may occur during future earthquakes in Jordan has to be treated in a probabilistic manner, Damage Probability Matrices (DPM) are constructed from observational and estimated data. A DPM expresses what will happen to buildings, designed according to some particular set of requirements, during earthquakes of various intensities. It is necessary to obtain the DPMs that are applicable for the seismic zone in which Amman city is located. Since it was not possible to obtain these DPMs directly for Jordan, other sources of information have to be used. For this purpose, the research utilizes the DPMs developed for the four different seismic zones of Turkey by using both empirical results and subjective judgment of experts (Yucemen 2005).

DETERMINATION OF DIRECT COST OF MITIGATION

The vast majority of Jordan's urban population today lives in five-storey apartment blocks constructed of reinforced concrete similar to the one considered in this research. The research utilizes a design strategy that applies the 2005 Jordanian Seismic Design Code for Buildings to a typical five-storey reinforced concrete building. The structural system of the building for both vertical and lateral load systems consists of a dual system in both directions. The system considers ordinary shear wall elements coupled with ordinary reinforced concrete moment-resisting frame elements. Both elements are designed and detailed according to ACI-318 standard, release 2002.

The new Code is intended to provide designers with the required provisions for the "performance-based" seismic analysis and design of new structures. It is important to understand that seismic codes result in earthquake resistant buildings rather than earthquake-proof buildings. Their purpose is to protect life safety by preventing building collapse and allowing for safe evacuation. The contents and interiors of buildings, even those of well-designed buildings, may receive extensive damages and critical functions of a building may cease. Also, structural damage may occur from major earthquake ground-shaking. Structures built according to the new Jordanian Code for Earthquake-Resistant Buildings should:

1. Prevent frequent structural and non-structural damage in frequent minor ground shaking.
2. Prevent structural damage and minimize non-structural damage in occasional moderate ground shaking.
3. Avoid collapse or serious damage in rare major ground shaking.

Generally, structures that are designed and constructed in conformance with the code requirements are expected to encounter earthquake related structural damage (Al-Nimry and Kahhaleh 2005).

For the typical five-storey building in Amman, Jordan, the cost of incorporating earthquake resistance against collapse and subsequent loss of life is estimated at 1.63% of the capital cost of building (see Table 1). This finding supports a study conducted by the Building Seismic Safety Council (BSSC) in 1985 where they contracted seventeen design firms from nine US cities to perform two designs for each of several typical building types, first using the existing local code and then using the seismic provisions. They found the average increase in total costs to be 0.7% for low-rise residential buildings, 3.3% for high-rise residential buildings, 1.3% for office buildings, 0.5% for industrial buildings, and 1.7% for commercial buildings. Cities with previous seismic design provisions in their codes averaged much smaller cost increases (0.9%) than did cities with no seismic codes at all (Building Seismic Safety Council 1985.)

DETERMINATION OF DAMAGE TO THE BUILDING

In the context of this analysis, the severity of earthquake is expressed in terms of peak ground acceleration (PGA). The damage to the building from earthquakes of different PGAs is then to be estimated based on fragility curves. The fragility curves of a particular building provide the probability of exceeding different levels of damage (e.g. slight, moderate, major, collapse) as a function of the level of shaking. Fragility curves can be determined either empirically using damage data from past earthquakes or by numerical analysis.

Unfortunately, at this time, for the country of Jordan, no fragility curves for a representative structure are available. The computation of earthquake damage requires information on future earthquake hazard and expected earthquake damage on engineering structures, which are not readily available in Jordan.

Table 1: Direct cost estimates for the sample five-storey building in Amman, Jordan

Div. No.	Proposed Area = (2140 M2)	Typical Design			Seismic Design		
	Description	**Rate/M2 $**	**Amount $**	**%**	**Rate/M2 $**	**Amount $**	**%**

15	Mechanical Works	42.37	90,678	12.45%	42.37	90,678	12.24%
16	Electrical Works	28.25	60,452	8.30%	28.25	60,452	8.16%
	Sub-Total	340.40	728,446	100%	346.05	740,537	100.00%

This research utilizes the DPM's developed for Turkey's four different seismic zones. There are five levels of damage states. The damage ratio (DR) is defined as the ratio of the cost of repairing the earthquake damage to the replacement cost of the building. For mathematical simplicity, it is convenient to use a single DR for each damage state (DS). This single DR is called the central damage ratio (CDR) (see Table 2).

Table 2: Damage probability matrix (Yucemen 2005)

Damage State (DS)	Damage Ratio (DR) %	Central Damage Ratio (CDR) %

None	0–1	0
Light	1–10	5
Moderate	10–50	30
Heavy	50–90	70
Collapse	90–100	100

ANALYSIS OF THE ECONOMICS OF SEISMIC MITIGATION

Is it worth it? This is the primary question about seismic mitigation to reduce expected damages and casualties from future earthquakes. Decision-making about the prospective seismic mitigation in new apartment buildings in Jordan may be difficult due to lack of estimates of the benefits (i.e. avoided future damages, losses and casualties). In many cases, life safety (avoiding casualties) is the principal motivation for implementing seismic mitigation, while in some instances property protection or continued functionality of important services may be the driving economic force.

The research will employ estimates of the benefits by answering the following question: is it cost effective to incorporate earthquake resistance in residential building in Amman, Jordan?

After some reflection on the above question, one could reasonably contend that incorporating earthquake resistance in residential buildings leads to an incremental increase in investment costs. Benefits are in term of reduced chance of future damages and causalities.

Additional assumptions needed during the analysis of the situation include:

- Since it was not possible to obtain DPMs directly for Jordan, other sources of information have to be used. For this purpose, the DPMs developed for the four different seismic zones of Turkey by using both empirical results and subjective judgment of experts.
- A building useful life (N) of 50 years with repeatability and the Discount Rate (i) of the Federal Emergency Management Agency (FEMA) of 7% will be used (FEMA 1997).
- In the event of a severe earthquake, cost of fatalities will not be considered, only the direct cost of the physical damage to the building.

Selecting the dollar as the common unit of measure. The annual cost of incorporating earthquake resistant (A) can be calculated:

(A) = P (A/P, i%, N)

Where P is the additional cost of $ 12091.00 associated with incorporating earthquake resistance (see Table 1) and (A/P, i%, N) is the capital recovery factor where i=7% and N= 50 years.

From the above equation, A = $877.00/year

Table 3 depicts the expected damage cost in (US$) of not incorporating earthquake resistant. The ratio of the cost of expected damage to the annual cost of incorporating earthquake resistant reveals the number of years in which an earthquake related structural damages can be avoided. In the event of minor ground shaking, if incorporating earthquake resistant will result in at least one earthquake –incurred damages being avoided during the next [$37000.00/($877.00/year)] = 42 years, then the mitigation is cost effective. Although in the short term, it can be contended that mitigation leads to increased cost, the benefits of increased personal safety and mitigation of possible damage costs in the long-run more than offset the apparent short-term cost savings.

Table 3: Cost of damage/damage probability matrix

Damage State (DS)	Damage Ratio (DR) %	Central damage ratio (CDR) %	Cost of expected damage (in thousands of dollars)
None	0–1	0	0
Light	1–10	5	37
Moderate	10–50	30	222
Heavy	50–90	70	518
Collapse	90–100	100	741

Furthermore, the benefits are underestimated because they do not account for the benefits of reducing fatalities, injuries, fire potential or economic losses. This research provides valuable analytic support to the claim that incorporating earthquake resistance in residential buildings is cost-effective, even in the event of minor ground shaking.

CONCLUSIONS AND FURTHER RESEARCH

Horrific images of recent disasters demonstrate the importance of shifting from post-disaster emergency actions to pre-disaster mitigation. To reduce population’s vulnerability to earthquakes, Jordan needs to examine its strengths and weaknesses, build on the strengths, and systematically take actions, which can reduce or eliminate the weaknesses.

Earthquake damage can range from minor damage to non-structural elements, which often does not exceed 2% of the value of the building, to more major damage of structural elements, which will require the relocation of the occupants while repairs are carried out. In the extreme, the total loss of the building, leading to its demolition, may occur. Damage can therefore range from less than 2% to more than 100%. Considering consequential losses, the cost of including earthquake-resistant features into a building’s design (usually less than 2% of the initial construction costs) is therefore likely to prove of significant financial benefit.

Adding to these benefits is the logical connection between adopting mitigation measures in advance and the claims costs from insurance should an earthquake occur. Balamar (2001) and Gulan (2001) highlighted this importance by citing previous experience with earthquakes in Turkey.

Ensuring the preservation of life is equally important to the occupants of the building. It is not usual to place a financial value on the "peace of mind" of the occupants, nor on the personal and financial losses incurred from injury or loss of life. However, this is an important consideration to the macro-economic framework of a country. The prevention of dislocation to businesses and individuals will impact on the time taken for the country’s economy to return to normal.

Subcontracting is the most prevailing means employed by a general contractor to execute a project. For a general contractor, how to select a set of good subcontractors to complete all the construction activities is one of the crucial strategic decisions in business administration. This study is to develop an objective system to help the general contractor select qualified subcontractors, which is crucial to a project success. The factors to select the subcontractors are investigated by questionnaires and interviews. Furthermore, by means of both Analytic Hierarchical Process (AHP) and Fuzzy Multiple Criteria Decision Making method, a quantitative selection system, which includes the evaluation factors and weights, is developed for the general contractor to select his subcontractors objectively.

Keywords: subcontractors selection, AHP, Fuzzy MCDM.

INTRODUCTION

The construction industry is the one that brings about the development of other industries and is always regarded as the “locomotive industry”. Further analysis shows that the parties involved in construction projects are architecture firms, engineering consultant companies, insurance companies, real estate owners (the government or the private enterprises), law firms, the stakeholders from real estate industry and banking industry, and so on. Among them, the parties with a direct relationship to a construction project are real estate owners, designers’ sectors (architectural companies, engineering consultant companies), general contractors, and subcontractors. The cost during the construction stage occupies over 90% of the total cost of a construction project and the general contractor is always fully responsible for the overall performance at the construction stage.

With the trend of specialization, general contractors have switched from the traditional emphasis on substantial construction technology to the management-based model. The main roles managed by the general contractor are the different kinds of subcontractors (or the collaborating business firms or small contractors, which are generally divided into four kinds: material suppliers, manpower subcontractors, manpower-and-material subcontractors, and mechanical work subcontractors) engaged in specialized production. Hence, the construction skills of subcontractors and the extent of their cooperation with the general contractor are directly and significantly correlated to the

[1] cnhuang@mail.knu.edu.tw

performance of a construction project in terms of quality, production rate, cost and safety. In other words, the means to strengthen the connection between two production units, the general contractor and the subcontractors, is a significant step towards improving the project quality and construction productivity.

In the entire construction process, a close relationship has to be maintained between the general contractor and the subcontractors. Such a business relationship starts from the selection of the right subcontractors, extends at the stage of construction and inspection and then the performance evaluation of subcontractors, and ends at the guarantee period. Whether qualified subcontractors are chosen by the general contractor at the selection stage of construction projects will impose critical effects on the incentive schedule and the quality of a project. Having made preliminary interviews with several contractors and gathered some information from them, the study finds that although general contractors have certain procedures of selecting subcontractors, uncertainties or the lack of objectivity exist in the evaluation criteria, making the general contractors too much dependent upon (such as quotations of business firms) or neglect certain indicators (such as quality control ability), and consequently leading to a conflicting collaboration, or even resulting in the failure of the project. In view of this, the study carries two purposes:

1. To understand the transaction process and problems between the general contractor and the subcontractors, particularly concerning the selection of subcontractors.
2. To analyse the general contractor's selection factors of subcontractors, and establish the objective indicators.

ESTABLISHMENT OF SELECTION MODEL IN THE CONSTRUCTION INDUSTRY

Through literature reviews and information extracted from business firms, this study collates the general contractors' selection factors of the subcontractors and the hierarchal relationship among these factors. The hierarchal relationship among different factors is acquired after revision is made by two experts. The relationship is further used as the basis for the formulation of questionnaires. The establishment process of the hierarchal relationship and the analytic results are explained as follows.

Establishment of the hierarchal structure and the nature of the attributes

Many factors were found to influence the general contractors' selection of the subcontractors. Having interviewed the experts and the managers with working experience in the construction industry for more than 10 years, the researchers summarize the information from 5 perspectives: quality control, economic perspective, technology perspective, collaboration level and progress control. These 5 perspectives can further be divided into 14 items. The relationship between each perspective and the items are shown in Figure 1.

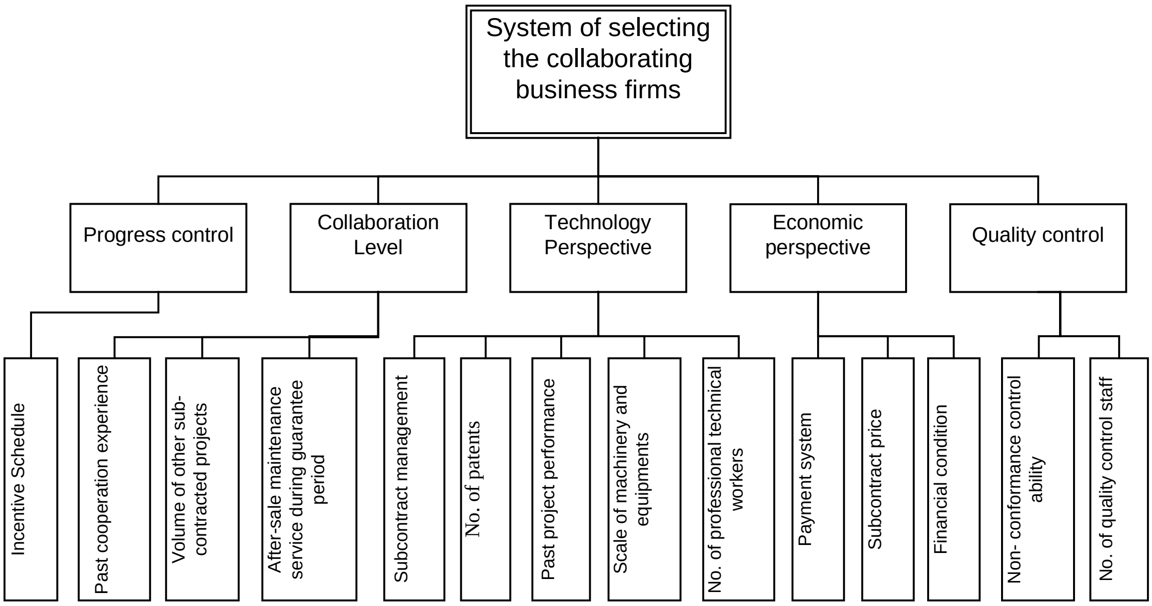

Figure 1: Structure of the selection system of subcontractors

Quality control perspective

As more attention has been placed on the engineering quality in Taiwan, general contractors have thus been receiving greater pressure of quality from the real estate owners. Therefore, during the selection of subcontractors, more and more general contractors lay particular concerns on the quality control ability. General contractors evaluate the quality control ability of a subcontractor from two aspects:(1) number of quality control staff; and (2) non-conformance control ability.

Economic and financial conditions

To both the general contractor and the subcontractors, making profit is the first priority of the purposes of operation. Therefore, both parties care much about the economic indices of their companies' operation. When a general contractor is selecting the subcontractors, there are three indices most commonly mentioned:(1) financial condition; (2) proposed prices by subcontractors; and (3) payment system.

Technology perspective

In the five evaluation perspectives, what technology perspective represents is the ability performing professional skills of a business firm. Since technology-ability of a business firm is usually associated with the technical workers and the resource allocation ability, the evaluation items of this perspective include five items:(1) number of professional technical workers; (2) scale of machinery and equipments; (3) actual project performance; (4) number of patents; and (5) number of times of subcontracting the projects.

Collaboration level

In most of the interviews, a majority of the targeted general contractors mentioned a rather obscure but important evaluation items of the subcontractors: "collaboration level". Furthermore, this study attempts to divide the collaboration level into three parts: (1) after-sale maintenance service during the guarantee period; (2) volume of other subcontracted projects; and (3) past cooperation experience.

Progress control

Progress control is a very important perspective in the project control. Its main evaluation item is the subcontractor's ability of the incentive schedule of a project. In the study, this item is assumed/found to be a positive qualitative index.

Determining the evaluation criteria weights

Since the evaluation criteria of the general contractors' selection of subcontractors have diverse levels of significance and meanings, it is not suitable to assume that each evaluation criterion is of equal importance. Many methods were employed to determine the level of significance of the effects on the project performance, such as the eigenvector method, weighted least square method, entropy method etc. (Hwang and Yoon 1981). To select the subcontractors for a general contractor is a complex and wide-ranging problem, so this problem requires the most inclusive and flexible method. The AHP developed by Saaty (1980) is a very powerful tool to assist users to carry decision making with multiple criteria and has successfully been applied to many related cases in the construction industry (McIntyre and Parfitt 1998; Fong and Choi 2000; Al-Harbi 2001; Cheung *et al*. 2001; Mahdi *et al*. 2002; Al Khalil 2002; Cheung *et al*. 2002). However, during the operation of implementing the AHP method, it is easier for evaluators to make decision on "item A is much more important than item B" than "the ratio of level of significance between item A and item B is seven". Hence, Buckley (1985) updated Saaty's AHP to the condition where the evaluators are allowed to employ fuzzy ratios in place of exact ratios to solve the problem of difficult decisions for evaluators. Therefore, in this study, we employ Buckley's method, FAHP, to fuzzify hierarchical analysis by allowing fuzzy numbers for the pairwise comparisons, and figure out the fuzzy weights of the investigated factors.

Fuzzy Analytic Hierarchy Process (FAHP)

The procedure for determining the evaluation criteria weights by FAHP can be summarized as follows:

Step 1: construct pairwise comparison matrices among all the elements/criteria in the dimensions of the hierarchy system. Assign linguistic terms to the pairwise comparisons by asking which is the more important of each two elements/criteria, such as

$$\tilde{A} = \begin{bmatrix} 1 & \tilde{a}_{12} & \cdots & \tilde{a}_{1n} \\ \tilde{a}_{21} & 1 & \cdots & \tilde{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{a}_{n1} & \tilde{a}_{n2} & \cdots & 1 \end{bmatrix} = \begin{bmatrix} 1 & \tilde{a}_{12} & \cdots & \tilde{a}_{1n} \\ 1/\tilde{a}_{12} & 1 & \cdots & \tilde{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 1/\tilde{a}_{1n} & 1/\tilde{a}_{2n} & \cdots & 1 \end{bmatrix} \quad (1)$$

where

$$\tilde{a}_{ij} = \begin{cases} \tilde{1},\tilde{3},\tilde{5},\tilde{7},\tilde{9}, & \textit{criterion i is relative } \text{importance } \textit{to criterion } j \\ 1, & i = j \\ \tilde{1}^{-1},\tilde{3}^{-1},\tilde{5}^{-1},\tilde{7}^{-1},\tilde{9}^{-1}, & \textit{criterion i is relative less } \text{importance } \textit{to criterion } j \end{cases}$$

Step 2: to use geometric mean technique to define the fuzzy geometric mean and fuzzy weights of each criterion by Buckley (1985) as follows:

$$\tilde{r}_i = (\tilde{a}_{i1} \otimes \cdots \otimes \tilde{a}_{in})^{1/n}, \quad \tilde{w}_i = \tilde{r}_i \otimes (\tilde{r}_1 \oplus \cdots \oplus \tilde{r}_n)^{-1} \quad (2)$$

where $\tilde{a}_{in}$ is fuzzy comparison value of criterion *i* to criterion *n*, thus, $\tilde{r}_i$ is geometric mean of fuzzy comparison value of criterion *i* to each criterion , $\tilde{w}_i$ is the fuzzy weight of the i^{th} criterion, can be indicated by a triangular fuzzy number, $\tilde{w}_i = (Lw_i, Mw_i, Uw_i)$. Here Lw_i, Mw_i and Uw_i stand for the lower, middle and upper values of the fuzzy weight of the i^{th} criterion.

Table 1: Membership function of linguistic scale

Fuzzy number	Linguistic scales	Scale of fuzzy number
$\tilde{1}$	Equally important (Eq)	(1,1,3)
$\tilde{3}$	Weakly important (Wk)	(1,3,5)
$\tilde{5}$	Essentially important (Es)	(3,5,7)
$\tilde{7}$	Very strongly important (Vs)	(5,7,9)
$\tilde{9}$	Absolutely important (Ab)	(7,9,9)

Note: this is synthesized the linguistic scales defined by Chiou and Tzeng (2001) and fuzzy number scale used in Mon *et al*. (1994).

Fuzzy Multiple Criteria Decision-Making (FMCDM)

Bellman and Zadeh (1970) were the first to probe into the DM problem under a fuzzy environment, and they heralded the initiation of FMCDM. This analysis method has been widely used to deal with DM problems involving multiple criteria evaluation/selection of alternatives. The practical applications reported in the literatures are: weapon system evaluating (Mon *et al*. 1994); technology transfer strategy selection in biotechnology (Chang and Chen 1994); optimization of the design process of truck components (Altrock and Krause 1994); energy supply mix decisions (Tzeng *et al*. 1994); urban transportation investment alternatives selection (Teng and Tzeng 1996); tourist risk evaluation (Tsaur *et al*. 1997); electronic marketing strategies evaluation in the information service industry (Tang *et al*. 1999); restaurant location selection (Tzeng *et al*. 2002), and performance evaluation of distribution centres in logistics (Chen 2002). These studies showed advantages in handling unquantifiable/qualitative criteria, and obtained quite reliable results. This study uses the method proposed by Bellman and Zadeh with the FMCDM theory to evaluate the subcontractors and rank the priority for them accordingly. The following will be the method and procedures of the FMCDM theory.

Alternatives measurement

The measurement of linguistic variables was applied to demonstrate the criteria performance (effect-values) by expressions such as "very good", "good", "fair", "poor" and "very poor". The evaluators were asked to conduct their subjective judgments, and then each linguistic variable can be formulated by a triangular fuzzy number within the scale range of 0–100, as shown in Figure 2. In addition, the evaluators can subjectively assign their personal range of the linguistic variable that can indicate the membership functions of the expression values of each evaluator. Take $\tilde{E}_{ij}^k$ to indicate the fuzzy performance value of evaluator *k* towards subcontractor *i* under criterion *j*, and all of the evaluation criteria will be indicated by $\tilde{E}_{ij}^k = (LE_{ij}^k, ME_{ij}^k, UE_{ij}^k)$. Since the perception of each evaluator varies according to the evaluator's experience and knowledge, and the definitions of the linguistic variables vary as well, this study uses the notion of average value to integrate the fuzzy judgment values of *m* evaluators, that is,

$$\tilde{E}_{ij} = (1/m) \otimes (\tilde{E}_{ij}^{1} \oplus \tilde{E}_{ij}^{2} \oplus \cdots \oplus \tilde{E}_{ij}^{m}) \qquad (3)$$

The sign $\otimes$ denotes fuzzy multiplication, the sign $\oplus$ denotes fuzzy addition, $\tilde{E}_{ij}$ shows the average fuzzy number of the judgment of the decision-makers, which can be displayed by a triangular fuzzy number as $\tilde{E}_{ij} = (LE_{ij}, ME_{ij}, UE_{ij})$. The end-point values LE_{ij}, ME_{ij}, and UE_{ij} can be solved by the method put forward by Buckley (1985),

$$LE_{ij} = \left(\sum_{k=1}^{m} LE_{ij}^{k}\right) \Big/ m; \quad ME_{ij} = \left(\sum_{k=1}^{m} ME_{ij}^{k}\right) \Big/ m; \quad UE_{ij} = \left(\sum_{k=1}^{m} UE_{ij}^{k}\right) \Big/ m \qquad (4)$$

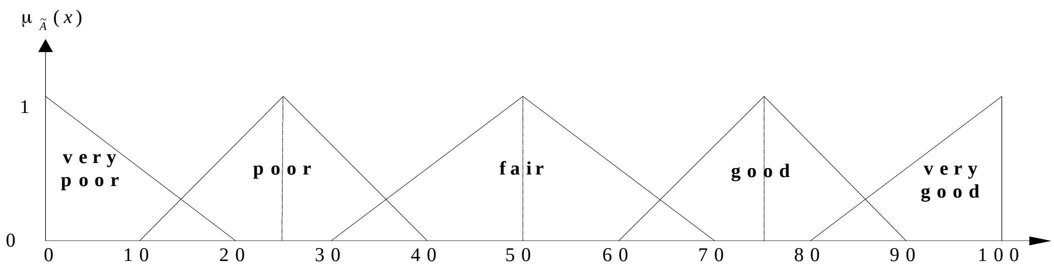

Figure 2: Example of membership function of linguistic variables for measuring the performance value of subcontractors

Fuzzy synthetic decision

According to the each criterion weight $\tilde{w}_j$ derived by FAHP, the criteria weight vector $\tilde{\boldsymbol{w}} = (\tilde{w}_1, \ldots, \tilde{w}_j, \ldots, \tilde{w}_n)^t$ can be obtained, whereas the fuzzy performance matrix $\tilde{\boldsymbol{E}}$ of each of the subcontractors can also be obtained from the fuzzy performance value of each subcontractor under n criteria, that is, $\tilde{\boldsymbol{E}} = (\tilde{E}_{ij})$. From the criteria weight vector $\tilde{\boldsymbol{w}}$ and fuzzy performance matrix $\tilde{\boldsymbol{E}}$, the final fuzzy synthetic decision can be conducted, and the derived result will be the fuzzy synthetic decision matrix $\tilde{\boldsymbol{R}}$, that is,

$$\tilde{\boldsymbol{R}} = \tilde{\boldsymbol{E}} \circ \tilde{\boldsymbol{w}} \qquad (5)$$

The sign "o" indicates the calculation of the fuzzy numbers, including fuzzy addition and fuzzy multiplication. Since the calculation of fuzzy multiplication is rather complex, it is usually denoted by the approximate multiplied result of the fuzzy multiplication, and the approximate fuzzy number $\tilde{R}_i$, of the fuzzy synthetic decision of each alternative can be shown as $\tilde{R}_i = (LR_i, MR_i, UR_i)$, where LR_i, MR_i and UR_i are the lower, middle and upper synthetic performance values of the alternative i, that is:

$$LR_i = \sum_{j=1}^{n} LE_{ij} \times Lw_j; \; MR_i = \sum_{j=1}^{n} ME_{ij} \times Mw_j; \; UR_i = \sum_{j=1}^{n} UE_{ij} \times Uw_j \qquad (6)$$

Ranking the fuzzy number

The result of the fuzzy synthetic decision reached by each subcontractor is a fuzzy number. Therefore, it is necessary that a non-fuzzy ranking method for fuzzy numbers be employed for comparison of each subcontractor. In other words, the procedure of defuzzification is to locate the Best Non-fuzzy Performance value (BNP). Methods of such defuzzified fuzzy ranking generally include mean of maximal (MOM), centre of area (COA), and α-cut (Teng and Tzeng 1996). To utilize the COA method to find out the BNP is a simple and practical method, and there is no need to bring in the preferences of any evaluators, so it is used in this study. The *BNP* value of the fuzzy number $\tilde{R}_i$ can be found by the following equation:

$$BNP_i = [(UR_i - LR_i) + (MR_i - LR_i)]/3 + LR_i, \quad \forall\, i \tag{7}$$

According to the value of the derived *BNP* for each of the subcontractors, the ranking of the subcontractors can then proceed.

CASE STUDY ANALYSIS

Background of the case

A case study was conducted to select a subcontractor for a traditional painting project of a newly constructed office building. The total amount of the entire construction project is $360 million, and the painting project is about $24 million. There are five business firms being considered by the general contractor.

The weights of selection criteria

Since the selection of professional subcontractors involves many professional assessments and has significant effects on overall performance of a project to the general contractors, this study conducted a questionnaire survey on the worksite supervisors and project managers who have practical experience and professional decision-making authority, as well as the professional person-in-charge of a company for acquiring their opinions on the selection of qualified subcontractors. From the survey, the three decision-makers' weights, shown in Table 2, towards the five perspectives and fourteen selection criteria were developed. The results and analysis of the weights of different selection criteria are presented as follows:

Comparison of weights on the five perspectives

From the analysis on the ranking of the weights (as the level of significance) of five perspectives during a general contractor's selection of the subcontractor, i.e. technology, quality, collaboration level, progress and economical level, it was found that the most important one should be the technological execution ability, which is followed by quality control, but the difference of their weights is not too significant (0.302 and 0.295). It implies that the general contractors highest concern is whether the project item subcontracted to the subcontractor can be completed corresponding to the specified quality standards to avoid the penalty charged by the project owner. According to the results of weights analysis, the more surprising result is that the weight of economic conditions is rather low (0.044). This result seems to be tremendously different from the instinct perception that general contractors take the lowest price as the main subcontracting means.

Comparison of weights on the selection criteria

Regarding the quality control perspective, the concerns that the investigated general contractor laid on the non-conformance control ability are far more than the number of quality control staff. It implies that the substantial quality control result is more appropriate than the number of quality control staff. For the economic perspective, the financial condition and the payment system are not at all the concerned items to the general contractor in the case study since their proportions are below 1% (weights being 0.006 and 0.009 respectively). As to the technology perspective, past project performance (0.161) is more significant compared to other items. It represents the past experience accumulated by the subcontractor, which of course gains a certain degree of attention from a general contractor. Besides, although the general contractor puts less concerns on the subcontract management than the past project performance by

10% (0.06), it is ranked as the second significant item on the perspective of technology execution ability. It refers that the general contractor puts more concerns on the problems of subcontract managements than the number of technical workers and the scales of machinery. For the perspectives of collaboration level and progress control, the higher weights of past cooperation experience and promptness in completion (0.14 and 0.156 respectively) also show that the interviewed general contractors are more concerned on the project management process and the execution results. It should also be the main reason for the general contractor to bear the responsibility for the ultimate result of the overall project performance.

Table 2: Table of average weights of the evaluation perspectives and criteria

Evaluation perspectives	Weights	Evaluation criteria	Weights
Quality control	0.295	No. of quality control staff (C1)	0.052
		Non-conformance control ability (C2)	0.243
Economic	0.044	Financial condition (C3)	0.006
		Subcontract price (C4)	0.029
		Payment system (C5)	0.009
Technology	0.302	No. of professional technical workers (C6)	0.031
		Scale of machinery & equipments (C7)	0.017
		Past project performance (C8)	0.161
		No. of patents (C9)	0.033
		Subcontract management (C10)	0.060
Collaboration level	0.203	After-sale maintenance service during guarantee period (C11)	0.037
		Volume of other subcontracted projects (C12)	0.027
		Past cooperation experience (C13)	0.140
Progress control	0.156	Promptness in completion (C14)	0.156

Evaluation results of each subcontractor to be selected

This paper uses the method of average value to integrate different decision-makers' fuzzy judgment value towards the same selection criterion. It also refers to the employment of fuzzy addition and fuzzy multiplication to figure out the average fuzzy values of the performance values given by each decision-maker to each evaluation item of each investigated business firm (Table 3).

From the weights acquired from the calculation by FAHP (Table 2) and the performance value of each evaluation criterion given by the decision-maker (Table 3), it can be induced that the final fuzzy synthetic decision of each investigated subcontractor is R_i. Based on the fuzzy decision result, and by using the COA, the study explores the best non-fuzzy performance value (BNP_i), which is taken as the ranking of the five investigated business firms. The ranking results are displayed in Table 3.

Table 3: Average fuzzy performance values and ranking results of each subcontractor

Evaluation Criterion	Business Firm 1	Business Firm 2	Business Firm 3	Business Firm 4	Business Firm 5
C1	(50.0,68.3,76.7)	(50.0,68.3,76.7)	(68.3,81.7,90.0)	(65.0,80.0,90.0)	(55.0,70.0,80.0)

CONCLUSIONS AND SUGGESTIONS

Since most general contractors encounter the problems of unclear standards and insufficient information, it is difficult for them to figure out the qualified subcontractors for their projects. To solve this problem, the study underwent literature reviews, analysis on the accumulated information, interviews with experts, application of FAHP and analysis of cases, and finally developed a set of rather objective standards of selecting subcontractors. Meanwhile, the following conclusions and suggestions are made:

1. There is a clear hierarchal relationship among the factors of the general contractors' selection of subcontractors. It is really workable to implement the fuzzy analytic hierarchy process (FAHP) to establish the selection standards, and employ the fuzzy multiple criteria decision-making (FMCDM) to quantify the selection item that could not be measured in quantitative. This paper provides a workable research direction.

2. The study develops the weights of the five perspectives for the general contractor's selection of subcontractors. The ranking of these five perspectives are: (1) technology execution ability of subcontractor, being 30.2%; (2) quality control ability, being 29.5%; (3) collaboration level, being 20.3%; (4) progress control ability, being 15.6%; and (5) economic and financial conditions, being 4.4%.

3. The study is a preliminary study. As limited by time, it can only adopt the opinions of three decision-makers, so the representative of the acquired results still needs to be strengthened. Besides, the study needs subsequent expansion of the selection of samples and the strengthening of the verification of actual examples.

AN OPTION-BASED DYNAMIC OPTIMIZATION MODEL TO EVALUATE ADR INVESTMENTS IN AEC CONSTRUCTION PROJECTS

Carol Menassa[1] and Feniosky Peña Mora

Civil and Environmental Engineering Department, University of Illinois at Urbana-Champaign, 205 North Mathews Avenue, Urbana, IL 61801, USA

Managing claims and mitigating their adverse impact on a construction project is a major concern for AEC industry participants. Alternative dispute resolution (ADR) techniques can be implemented to achieve reasonable settlement of claims, and avoid their escalation to disputes that require protracted litigation for final determination of merit. These ADR techniques require allocation of resources internally within the corporation and externally in the form of third party assisted ADR. Managerial decisions regarding the size, timing and required expenses for these resources need to be economically justified. A cost–benefit analysis of ADR investments is developed using dynamic optimization, which allows for the division of ADR investments into two parts: immediate and subsequent ADR investment decisions made during the construction phase of the project. In the model, having the option to invest in a given ADR process to resolve claims in a project is seen as being analogous to having 'real options' on capital investment projects. The simulation of the model results in an ADR investment profile that depicts the ADR expenditure trend throughout the project life cycle based on the owner's perception of the uncertainty associated with the occurrence of the claim and the effectiveness of the chosen ADR process.

Keywords: claims, cost–benefit analysis, real options investment in alternative dispute resolution, risk and uncertainty.

INTRODUCTION

The construction industry in the US spends an estimated amount of $13–26 billion on change orders and claims (Hanna and Gunduz 2004) per year. These figures are relatively high when compared to the total share of the construction industry to the US gross domestic product (GDP) which reached 1.14 trillion or 9% of the GDP in 2005 (AGC 2006). According to Associated General Contractors (AGC) CEO Stephen Sandherr, 'every dollar added to construction adds $2 to the GDP' (AGC 2003). Thus, every dollar spent on change orders and claims will have an impact on the construction industry's role as a major contributor to the economy.

Change orders and claims occur on a regular basis when the contractor believes that he is entitled to additional compensation and/or an extension of time beyond what was originally agreed upon in the contract documents (Fenn *et al*. 1998; Adrian 1988). When the owner of the construction project determines that the claim is baseless and refuses to compensate the contractor either partially or in full, the claim escalates to a dispute. At this phase the owner and the contractor, either willingly or because they are forced to by the contract, engage in an alternative dispute resolution (ADR) process in

[1] menassa2@uiuc.edu

an attempt to resolve the claims at the project level, and preserve an amicable working environment to ensure that the project is completed as initially planned in terms of schedule, budget and quality.

In this context, alternative dispute resolution is a catchall term that describes a number of methods used to resolve disputes out of court, including negotiation, standing neutral advisors and arbitration (Caltrans 2000; USACE 1989). A common denominator of all ADR methods is that they are faster, less formalistic and often less adversarial than a court trial. However, most of these techniques require the allocation of resources by all parties involved in the project to analyse claims and determine their validity, or with external input when claims can only be resolved through third party assistance. Given that most construction projects operate on tight budgets, managerial decisions regarding the size, organization, timing and amount of expenditure required to implement a given ADR in the project need to be economically justified. In other words, every dollar invested in a given ADR process needs to be outweighed by the perceived benefits for it to be worthwhile. These perceived benefits include settling the claim at lower values than what was originally claimed by the contractor. When the difference between the original amount claimed and the actual amount of settlement (what was actually paid to the contractor) is positive, and exceeds the amount invested in the ADR, then the investment is worthwhile.

However, the severity, time of occurrence and amount of change orders and claims in construction projects are directly related to certain project characteristics such as the type of project and the contractual arrangement between the participants, which makes it hard to predict the amount and time of occurrence of these claims during the planning phase of the project when decisions regarding the type and amount of investment in ADR need to be made. Added to this, there is the difficulty in estimating the effectiveness of the ADR in resolving these claims. The difficulty in estimating the expected cash flows from a given ADR investment implies that the application of the traditional net present value technique to value these investments will not reflect the actual value of these investments nor provide the owner with the flexibility of timing these investments based on how claims escalate during construction.

In order to overcome the project and ADR uncertainties, and estimate the cost–benefit trade-offs of any ADR investment decision, the owner of a construction project needs a decision-making tool that provides flexibility as to how much needs to be expended and the optimal timing of these investments. In order to develop such a framework, this research investigated the possibility of using option valuation techniques to value ADR investment decisions in construction projects. In particular, the dynamic optimization technique presented by Majd and Pindyck (1987) is adapted to model ADR investments, and evaluate optimal investment decisions related to the timing and the amount of expenditure. The model developed illustrates that when parameters of valuation are optimally chosen then such a framework can assist in guiding ADR investment decisions throughout the project construction phase by providing the owner with an ADR investment profile that spans the construction phase of the project.

CHARACTERISTICS OF ADR INVESTMENTS IN CONSTRUCTION PROJECTS

Change orders and claims occur on a regular basis in most architecture, engineering and construction projects. They are usually initiated by the contractor due to delays on the part of the owner (for example, in providing the contract drawings); performing work not within the scope of the original tender documents; performing work which, though included in the contract documents, is more difficult than that described in the contract documents or is undertaken under different circumstances (for example, the contractor expected to have a clear site but arrived to find a number of other trade contractors working on the site); the owner requesting additional work or deleting work from the work described in the original tender documents (Adrian 1988). In each of these and other circumstances, the contractor believes that his claim has merit and entitles him to additional payment and/or an extension of time. When the owner of the construction project determines that the claim is baseless and refuses to compensate the contractor either partially or in full, the claim escalates to a dispute. At this point the owner and the contractor, either willingly or because they are forced to by the contract, engage in an ADR process in an attempt to resolve claims at the project level, and preserve an amicable working environment to ensure that the project is completed as initially planned in terms of schedule, budget and quality. A number of methods that can be specifically adapted to the different phases of a construction project are shown in Figure 1 (Peña Mora *et al*. 2003; AGC 2000). The owner of a construction project might choose to implement different ADR processes to address the different levels of claim severity as part of a dispute resolution framework. For example, California Department of Transportation (Caltrans) dispute resolution process involves partnering on construction projects with bid estimates exceeding $25 million. This is coupled with negotiation at the initial stages of the claim followed by dispute review board hearings (standing neutral) if the project has not been completed, and arbitration if the contractor files the claim after the project has been completed and turned over to Caltrans (Caltrans 2000).

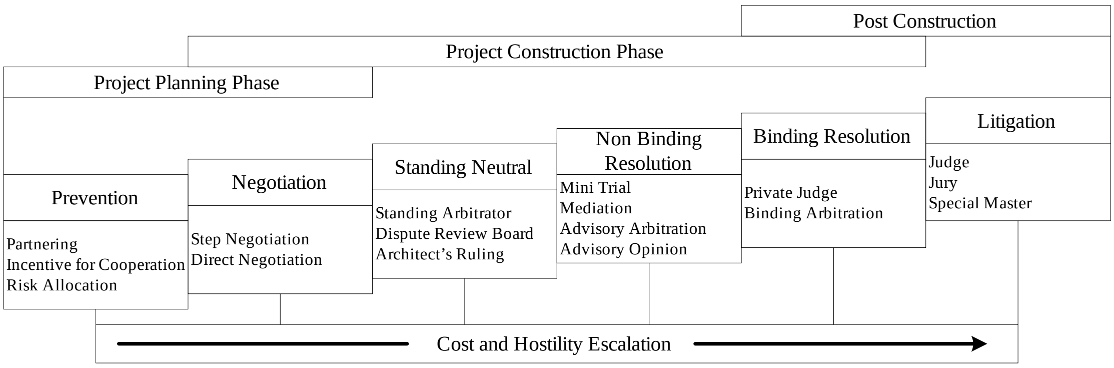

Figure 1: Steps in the construction dispute resolution (adapted from Peña Mora *et al*. 2003 and AGC 2000)

As is the case in any investment opportunity, the perceived benefits (e.g. estimated savings in the project due to claim avoidance and mitigation) from any ADR implementation must outweigh its costs for the investment to be worthwhile. These perceived benefits can be calculated as the difference between the original amount of the claim as indicated in the contractor's notice of claim and the actual amount of settlement achieved after ADR implementation. For example, suppose the contractor files a claim whose amount is $100 000 due to unforeseen site conditions that required the contractor to change the type of foundation for a building project, and the owner rejects this claim because of a contract clause requiring the contractor to inspect the site to determine its condition prior to initiation of construction. If the owner and contractor reach an impasse and cannot resolve this claim through negotiation, they might decide to attempt to resolve this claim by seeking the advice of a third party neutral arbitrator. This arbitrator will review the position of each party, and try to mediate a settlement based on the entitlement of each party. If this arbitrator determines that the contractor is entitled to $70 000 instead of the originally claimed $100 000, then the net saving to the project budget from implementing this ADR is $30 000. Now if the arbitrator's fees exceed this amount, then the investment in the ADR needs to be rejected. However, if the arbitrator's fees are lower than $30 000, then it might be optimal to consider investing in this ADR. Valuation tools like the net present value can be used to perform this analysis when explicit assumptions regarding the expected cash flows (cost of ADR and perceived savings in project) can be determined with certainty during the planning phase of the project. More specifically, in order to properly evaluate ADR investments using the net present value technique the cash flows related to the amount claimed, amount settled and ADR cost need to be estimated with certainty for the analysis to yield acceptable results.

However, ADR investment decisions are often made within the context of three main characteristics, namely: irreversibility, uncertainty and timing. These characteristics are typical of any capital investment project (Dixit and Pindyck 1994). Once the means of ADR is chosen and implementation initiated at the start of construction, any costs incurred become sunk costs that cannot be recovered by the owner in case the chosen method of ADR proves ineffective in addressing claims occurring in the project. Also, the occurrence of conflicts and claims can only be determined with certainty once the project is underway, which creates difficulty in estimating the expected cash flows from an ADR implementation. The cash flows from any ADR investment in a construction project, and the related sources of uncertainty, are shown in Figure 2.

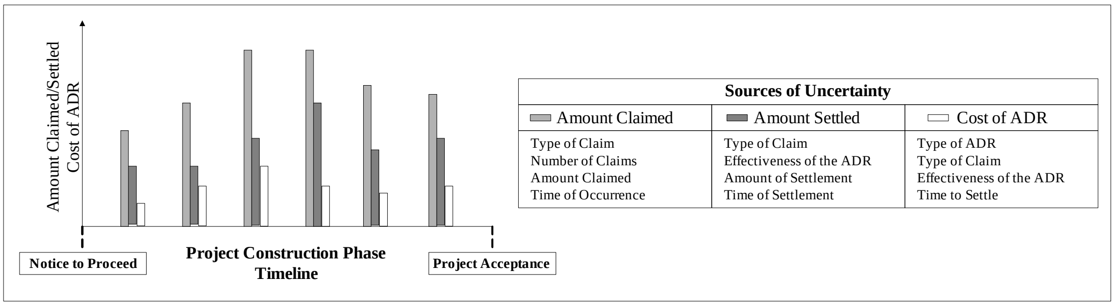

Figure 2: Sources of uncertainty for ADR investment cash flows

Finally, the project owner, who does not know whether a given ADR will be needed to resolve claims that might arise in the project due to certain project indicators, will consider a full investment in the ADR at the beginning of the project a risky undertaking. The variation in the investment decision based on the perceived level of uncertainty is shown in Figure 3.

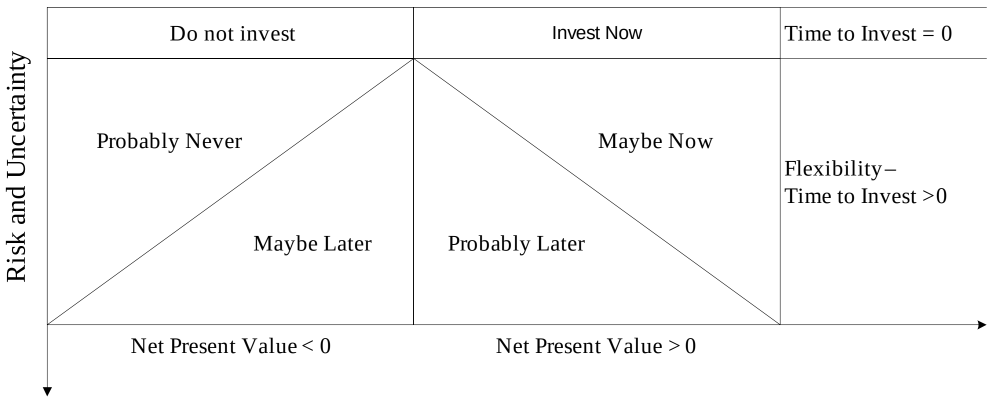

Figure 3: ADR investment space (adapted from Luehrman 1998)

FINANCIAL AND REAL OPTIONS

Options on traded assets like stocks, foreign currencies and commodities give the holder the right to buy (call options) or sell (put options) these assets at a fixed price (referred to as the exercise price) on or before expiration date (Hull 2000). European options can only be exercised on the expiration date, while American options can be exercised any time before expiration. The owner of the option has the right but not the obligation to pay the total sunk cost or exercise price in return for the stock. Options offer the investor the flexibility to postpone investment decisions until information about future market conditions become available; thus, buying/selling occurs only if market conditions are favourable and positive payoffs are realized. This 'caps' the losses down to zero (no negative payoffs) when market conditions are not favourable (Fichman and Tiwana 2005).

The modern theory of option pricing dates to 1973 when Black and Scholes presented a formula for valuing call options as a function of the price of the underlying common stock *S*, the exercise price *X*, uncertainty σ, risk free interest rate *r*, and time until expiration *T*. The basic assumption underlying this solution is that the change in the stock price follows a geometric Brownian motion, a special case of the stochastic generalized Wiener process, of the form $dS/S = \mu dt + \sigma dz$ (Wilmott *et al*. 2005; Hull 1999; Trigeorgis 1996; Dixit and Pindyck 1994). The parameter μ represents the instantaneous growth rate in the price of the stock over time, σ the associated proportional standard deviation parameter, and *dz* is the increment of the standard Wiener process that is normally distributed with a mean of 0 and a variance that increases linearly with the time interval *dt*. The main idea behind this assumption is that the stock price change has a deterministic component μdt that depends on the average rate of return expected by investors from the given stock, and a stochastic component σdz that depends on the volatility or the standard deviation of the returns associated with the market conditions.

An important application of this option pricing theory comes in the form of real options, or the ability to evaluate investments in capital (that is, non-financial) projects by drawing analogies from financial market options (Boute 2004; Trigeorgis 1993). Real options give the capital investor the flexibility to defer, expand, stage or abandon the investment at any time during the project life cycle in response to changes in the future circumstances of the project. This flexibility adds more value to the investment opportunity because the investor has the opportunity to strategically make expenditures in the project depending on the market conditions (Boute 2004; Trigeorgis 1996; Nichols 1994; Sick 1989). For example, a planned investment to acquire a cement factory is analogous to a call option on the stock with the underlying asset being the price of the cement or the expected future demand for the cement in the market. If the same investor realizes that the demand for cement will drop he might decide to dispose of the project for a salvage value, which is again analogous to exercising a put option (Fichman and Tiwana 2005; Luehrman 1995).

REAL OPTIONS WHEN THERE IS 'TIME TO BUILD'

In 1987, Majd and Pindyck presented a model to evaluate investments in a factory construction project where there is 'time to build'. Time to build refers to the case when investment decisions can be made sequentially In the factory example, Majd and Pindyck (1987) present a model that provides the owner of the factory with the flexibility to adjust the rate at which construction proceeds, and in this case capital expenditures, based on the arrival of new information. This model assumes that construction (investment) can be stopped and restarted at no extra cost. The basic assumption in the model is that the owner of the factory has the right but not the obligation to pay the total construction cost in return for the completed project. As in the case of stocks, the value of the factory V is assumed to follow the standard Weiner process $dV = \alpha V dt + \sigma V dz$ where α is the expected growth rate, and σ is the uncertainty associated with the value of the completed project. At any given time during the construction period, the total remaining construction cost K ($K \leq K_0$) is assumed to be spent optimally over the construction period at a predetermined maximum rate k per unit of time. This expenditure occurs only if the value of the completed project V at that given instance of time is greater than the optimal investment value $V^*(K)$ which depends on the initial value of the investment K_0, the risk free interest rate r, the opportunity cost of capital δ, and the uncertainty in the value of the complete project σ. Thus, $V^*(K)$ is determined to be as follows:

$$V^* = \frac{\beta}{\beta - 1} K_0 \tag{1}$$

where:

$$\beta = \frac{1}{2} + \frac{(r-\delta)}{\sigma^2} + \left[\left(\frac{(r-\delta)}{\sigma^2} - \frac{1}{2} \right)^2 + \frac{2r}{\sigma^2} \right]^{1/2} \tag{2}$$

This implies that the total remaining construction cost K at any time t varies as follows:

$$dK = -kdt \text{ when } V^*(K) \geq V \tag{3}$$

$$\text{and } dK = 0 \text{ otherwise} \tag{4}$$

Espinoza and Luccioni (2005) presented an approximate solution to this investment problem based on the closed form solution for perpetual American call options proposed by Samuelson (1965). If r is the risk free discount rate; $\delta = \mu - \alpha$ $(\mu > \alpha)$ is the opportunity cost; μ is the market risk adjusted expected rate of return from owning the project, then:

$$K_0 = (1 - e^{-rT})\, k/r \tag{5}$$

where K_0 is the present value of the remaining investment cost if this investment is assumed to be made continuously over the time period $T=K/k$ (time until project is completed) at a constant rate k.

The value of the investment $C(V)$ which represents the net payoffs from investing at any given time is given as:

$$C(V) = V_0 - K_0 \text{ when } V \geq V^*(K) \tag{6}$$

$$\text{and } C(V) = \frac{V^* - K_0}{(V^*)^\beta} V_0^\beta \text{ otherwise} \tag{7}$$

where V_0 is the present value of the completed project that is expected to grow at a rate α and can be estimated by discounting at the discount rate μ as follows:

$$V_0 = Ve^{(\alpha-\mu)T} = Ve^{-\delta T} \tag{8}$$

The results of this proposed approximation are successfully compared to the results obtained using the numerical analysis technique proposed by Majd and Pindyck (1987).

ADR INVESTMENTS AS REAL OPTIONS

This research focuses on analysing ADR investments in construction projects as real options. Holding an option to invest in a given ADR at the beginning of the project without committing all the resources gives the project owner the flexibility to 'call' on a specific ADR depending on the type of claims occurring in the project. For example, an owner might retain the services of a mediator during the project planning phase, and ask him to intervene only when a conflict escalates rapidly to a claim that requires third party intervention for resolution. At the same time, the owner has the flexibility to 'put' on or discard a specific ADR, and lose the initial investment if this ADR proves to be ineffective in handling the claims occurring in the project. For example, an owner might decide to forgo the services of a standing arbitrator with strong legal background if the claims filed by the contractor are related to design and construction issues. This is because even though the contract governs the relationship between the owner and the contractor, it might be necessary to resolve claims due to design and construction problems through a construction-experienced, neutral third party.

Based on the above discussion, it becomes evident that there are a lot of uncertainties surrounding the ADR investment that need to be taken into account by the owner prior to making any decision regarding which type of ADR to implement and the optimal timing of any ADR investment expenditure. That is why proper evaluation of cost–benefit trade-offs of ADR investments necessitates categorizing and understanding the sources of ADR investment risks to be able to make guided investment decisions. Two main sources of ADR investment risks have been identified by this research, namely: project-specific and ADR-specific risks that are summarized in Table 1 below.

Table 1: Sources of ADR investment risks

Project-specific risks	ADR-specific risks
1. Key project characteristics	1. Effectiveness of ADR
2. Type of claim	2. Demand for the ADR
3. Number of claims	3. Total cost of the ADR implementation
4. Time of occurrence of the claim	4. Time to settle
5. Amount claimed	5. Amount settled per each claim

Project specific risks refer to uncertainties inherent in the construction project itself. These uncertainties are directly related to the key project characteristics which include both project organizational issues like structure, process and people, as well as internal and external uncertainties (Peña Mora *et al*. 2003). For example a design-build (structure) highway project may have proper information-sharing and communication channels put in place but experiences delays (process) due to unrealistic expectations on the part of the owner and negligence on part of the contractor (people). This same project might also experience design errors and construction challenges (internal uncertainty), as well as social, environmental and political risks (external uncertainty) depending on the location where it is to be constructed. Once construction is initiated, these project characteristics have a direct effect on the types of claim (for example differing site conditions claim, design errors, material shortage, etc.), the time of occurrence of the claim (for example during the early phases, middle or last stages of construction or even after the project is turned over to the owner), and finally the amount of the claim in terms of time and money which will have a direct impact on the project schedule and budget, respectively. On the other hand, the ADR-specific risks are related to the ADR chosen and its effectiveness in addressing the claims in the project in terms of minimizing the amount claimed and time to settlement, and maximizing the expected cost savings for a given claim (difference between amount claimed and amount settled). These cost savings must outweigh the required ADR expenditure for the investment to be worthwhile.

Thus, the value of the option and decision to invest in ADR depend on several parameters, including the expected direct cost of the investment in the ADR, the initial value of the anticipated cost savings in the project, the magnitude of the up and down moves in these cost savings during the project construction phase, and the probability that these cost savings will increase/decrease in the coming periods. Also, the perception of risk is more pronounced owing the fact that, depending on the type of ADR chosen, resolution of the claims and disputes takes time during which the value of the cost savings in the project may change significantly because delaying resolution of a given claim may impact on other activities in the project and give rise to additional claims. The adoption of an ADR technique in the project is often voluntary and the time of its implementation does not follow a preset schedule but rather depends on the time of claim occurrence in the project. That is why the implementation of the ADR technique in the project can be viewed as a perpetual American call option, where the owner has the right but not the obligation to pay the total sunk cost of the ADR in return for the estimated cost savings in the project.

ADR INVESTMENT MODEL

A model to determine the optimal time to invest a certain amount *I* in ADR in return for an expected savings in the project *S* is developed using system dynamics. In this model the expected amount of the cost savings in the project *S* is analogous to the gross project value *V* for the factory project analysed by Majd and Pindyck (1987) as presented in a previous section. If the expected amount of savings due to a given ADR implementation up till time *t* during the construction phase of the project is denoted by *S(t),* then in a small time interval *dt*, this expected amount saved changes from *S(t)* to $S(t+dt) = S(t) + dS$. The formula for the change in the cumulative amount claimed is taken to be similar to the generalized Wiener process assumed for the change in gross project value, $\frac{dV}{V}$, in capital investment projects. The rate of change in the cumulative amount saved, $\frac{dS}{S}$, is therefore broken down into two main parts. One is predictable, deterministic and anticipated change similar to change in the value of a certain amount of money invested in a bank account at the risk free rate. It gives a contribution of:

$$\frac{dS_1}{S} = \mu dt \tag{9}$$

where μ = average rate of growth of the cumulative amount saved.

In this model μ is assumed to be a constant that depends on the project organization issues (structure, people and process). This implies that each type of project has a unique μ.

The second contribution to the rate of change in the cumulative amount saved, $\frac{dS}{S}$, is the random change in response to the internal and external uncertainties associated with the project. This contribution is represented by:

$$\frac{dS_2}{S} = \sigma dz \tag{10}$$

where:

σ = standard deviation (volatility) of the change in the cumulative amount S;

dz = Wiener process with the following properties: *dz* is a random variable drawn from a normal distribution, the mean of *dz* is zero, and the variance of *dz* is *dt.*

Adding together both the deterministic (Equation 9) and random contributions (Equation 10) to the change in the cumulative amount saved, we obtain the following stochastic differential equation:

$$\frac{dS}{S} = \frac{dS_1}{S} + \frac{dS_2}{S} = \mu dt + \sigma dz \tag{11}$$

The decision rules affecting the level of ADR investment at any given time during the project life cycle incorporate both the project-specific and ADR-specific risks. To develop the ADR investment model, decision rules that determine the behaviour of the system and how the investment decision changes with time due to additional information obtained about the claim situation in the project were first determined. These rules compel the owner of the construction project to either invest or forgo/defer investment in a given ADR. The decision rules used in the model correspond to the factory project decision rules stipulated in Equations 3 to 5 above. The model assumes that at a given time *t*, the current value of the cost savings *S* in the project is known. This value is unknown for subsequent periods of time; however, it is assumed to evolve according to the standard Weiner process; refer to Equations 9 to 11 above. This assumption will be further validated in the ongoing research. In this model, ADR investment expenditure is assumed to have two main characteristics:

1. Any investment expenditure is irreversible. This means that any ADR costs incurred in the project are sunk costs that cannot be recovered in case ADR fails to achieve the desired results in terms of effectively resolving the claims and realizing the perceived cost savings.
2. The ADR investment can be delayed until more information about the project claim conditions becomes available to the owner once construction is underway. This information includes the number of claims occurring in the project, the amount claimed per claim, and the probability of effectively settling these claims given the actual project conditions and relationship between the owner and the contractor. This information will allow the owner to more realistically assess the resources required to settle these claims during construction and avoid their escalation to post-construction disputes.

Table 2 below summarizes the different parameters/variables used to develop the model based on the analogy with the construction project model and Figure 4 shows the schematic model.

Table 2: Notations and assumptions

Construction project model (Majd and Pindyck 1987)		**ADR investment model**	
V:	Value of the completed construction project	**S:**	Expected cost savings in project
V*:	Optimal investment value of the completed project as a function of the remaining investment cost	**S*:**	Optimal investment value of the expected cost savings in the project as a function of the remaining ADR investment cost
K:	Total construction cost spend at a maximum rate *k*	**I:**	Total desired ADR investment spend at a maximum rate *i*
r:	Risk free interest rate	**r:**	Risk free interest rate
σ:	Instantaneous deviation of project value	**σ:**	Uncertainty surrounding the expected cost savings in project
δ:	Opportunity cost	**δ:**	Opportunity cost of not having the option to invest in ADR
C(V):	Option value of the completed project	**F(S):**	Option value of the ADR investment

The uncertainty value σ and opportunity cost δ represent the uncertainties resulting from both the project-specific and ADR-specific risks. The values of these parameters as stipulated in the model depend on the owner's perception of the level of risk associated with the project and ADR process itself. The variation in the values of σ is shown in Table 3 below. These expected values of σ need to be verified by analysing historical data related to claims occurring in different types of projects.

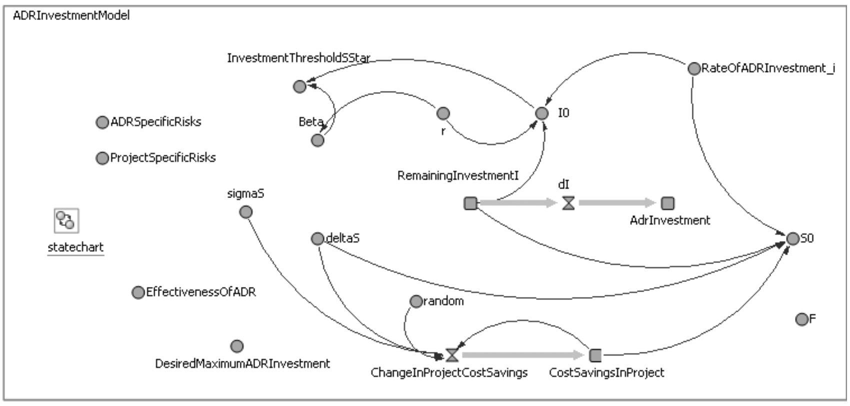

Figure 4: ADR investment model

The opportunity cost δ varies with the effectiveness of the ADR as shown in Figure 5. This figure shows that the effectiveness of the ADR is in turn a function of the ratio of the desired maximum investment of the ADR to the expected cost savings in the project.

Table 3: Values of σ based on perceived level of risk

		Project-specific risks		
		High	**Medium**	**Low**
ADR -specific risks	**High**	75%	60%	50%
	Medium	60%	50%	40%
	Low	50%	40%	25%

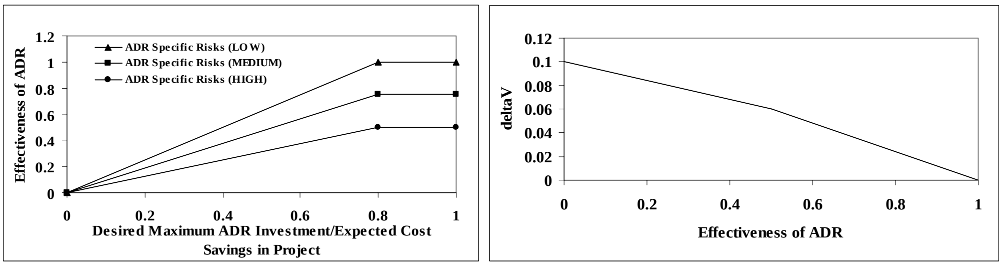

Figure 5: Variation in ADR effectiveness and δ

In running the model, the user can input the expected cost savings in the project, the desired maximum ADR investment, the desired maximum rate of ADR investment, as well as the project-specific and ADR-specific risks. The model simulation will result in variation in the expected cost savings during the life of the project, the proposed ADR investment profile and the investment value. Figure 6 shows an example of the model input and simulation. In this example, the owner estimates the expected cost savings in the project due to a given ADR process to be $1 000 000. The desired maximum investment in the ADR is set to $500 000 to be spent at a maximum rate of $40 000 per year over a period of 10 years. The owner perceives the project-specific risks to be medium while the ADR-specific risks are set to high. The simulation of the model under these input parameters indicates that the investment value is always positive, and thus investment in the ADR proceeds at a constant rate of $40 000 per year as seen in the ADR investment profile graph in Figure 6.

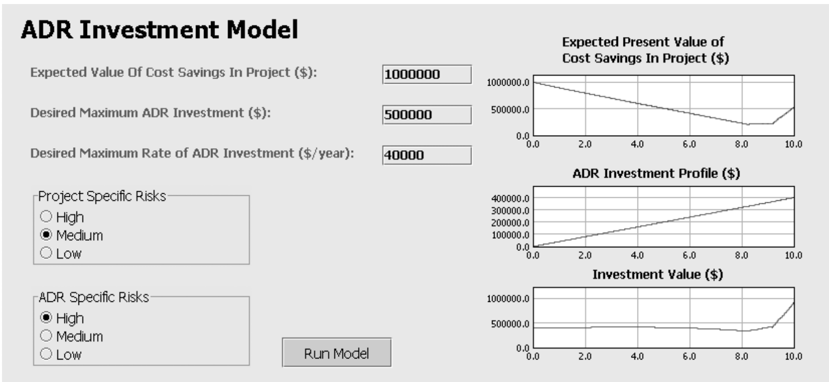

Figure 6: ADR investment model simulation window

CONCLUSION

This paper investigated the application of real option valuation when there is time to build to evaluate ADR investments in construction projects. A system dynamics model is presented that takes into account the uncertainties surrounding the ADR investment cash flows; as well as the project-specific and ADR-specific risks. It is perceived that such a model will guide ADR investment decisions regarding the amount and timing of such investments.

The future research will focus on developing the presented model to take into account different levels of any dispute resolution process. Also, extensive research and data analysis are currently underway to determine estimates for the parameters of the model. Finally, the model shall be validated through application to a real construction project and comparing real time data to those obtained from the model.

CONSTRUCTION PROJECT CLAIMS AND CONFLICT IN SINGAPORE

Ajibade Ayodeji Aibinu[1]

Faculty of Architecture, Building & Planning Old Commerce Building, Room 402 The University of Melbourne, Victoria 3010 Australia

Resolving a construction contractor's claims is a complex and difficult process. It could generate conflict and, ultimately, costly dispute resolution during the construction process. This study explores the extent to which nine potential issues of disagreement were responsible for conflict when resolving claims on 41 construction projects in Singapore. It also investigates the overall frequency and severity of disagreements on each project, how most disagreements were terminated and the impact on the contractors' attitudinal propensities and relationship with the employer. The results shows that in about 68% of the projects, the EoT claims requested by the contractors was more than 10% of the original contract duration while in 40% of the projects the additional cost requested by the contractors was more than 15% of the original contract sum. In more than half of the projects (56.09%), the contractors were awarded more than 60% of the amount of EoT claims requested while more than 60% of the additional cost claims requested were awarded to the contractors in less than half of the projects (41.46%). Disagreements arose more frequently on the quantum of the contractor's entitlements. This was followed by criticality of delay, responsibility for delay, whether work giving rise to claims was required by the contract or was extra work, type and amount of information used in substantiating claims, whether or not the contractor actually incurred added cost, contract interpretation, concurrency of delays and methodology/technique used in substantiating and assessing claims. One-sample t test analyses suggest that, overall, disagreements were very frequent and moderately severe on the projects. Analysis further revealed that in 41.5% of the projects, disagreements were mostly resolved by mutual consent, while in 43.9% the contractors compromised their position so as not to engage in formal dispute. The employer's position was imposed on the contractor in 14.6% of the projects. One-sample t test analyses further suggest that on projects where most of the conflicts were terminated by mutually agreed upon solution, working relationship was moderately affected. Negative attitudinal propensities such as the contractor's potential to reject the outcome and potential to dispute were also moderate. Whereas projects where most of the conflicts were terminated by the contractors' compromise or by the employers' imposition of a decision on the contractors, relationships were moderately affected. However, the contractors indicated a very high level of negative attitudinal propensities. Among other things, the findings suggest that when parties focus on finding a mutually acceptable solution to claims – rather than a one-sided compromise or forceful imposition of a decision – disagreements may have a moderate impact on a contractor's negative attitudinal propensities and thereby overall performance of the project and the construction industry at large.

Keywords: claims, conflict, contract administration, cost, time.

INTRODUCTION

Claims and conflicts are major sources of inefficiency in the delivery of construction projects (Latham 1994). In the United Kingdom, contractors' claims for extension of time (EoT) and loss and expenses claims are the second and fourth most frequent subjects of litigation between the main contractors and employers (Russel 2001). The problem of claims, conflict and dispute has also been reported in other countries (Jergeas and Hartman 1994 – Canada; Uher 1994 – Australia; Barrie and Paulson 1992 – USA). Wong, (2005) reported that contractors' claims for variation and project delays are the first and second most frequently disputed issues in Singapore. Reaching reasonable settlement of claims in an effective, economical and timely manner is difficult (Barrie and Paulson 1992).

One of the reasons is that substantiating and assessing construction claims are complex and subjective, involving numerous assumptions (Perlman 1984). Claims also involve strong underlying conflict of interest between the employer (building owner or the client), contractor and the person certifying the claims. Thus, claims could generate conflict and dispute that may be costly and time-consuming (Diekman *et al*. 1994). Robinson *et al*. (1996) observed some increasing trend of contentious behaviour in Singapore and Malaysia construction industry.

The aim of this study was explore the levels of claims on some construction projects in Singapore, assess the extent to which nine potential issues were responsible for conflict in the handling of claims and, in that regard, assess the intensity of conflict generated, the mode by which the conflicts were terminated during negotiation, and the impact of the conflicts on relationship between the parties involved and on the contractors' attitudinal propensities. The results provide useful information to construction industry stakeholders on claims and conflict climate in the Singapore construction sector. Useful information is provided for reducing potential for contract dispute and breakdown of working relationship when resolving claims. The results are of international application in that construction sector in most countries are faced with similar problems.

PROJECT CLAIMS AND CONFLICT

For the purpose of this study, a claim refers to any application by the main contractor to the engineer (or architect) pursuant to any relevant clause of the contract – for any additional payment, extension of time and or damages for any alleged breach of duty by the employer (client) and the engineer (or architect) (Kumaraswamy and Yogeswaran 1998). The process for administering claims may be accompanied by conflict in the form of disagreements with claims certifier's decision, hostility and negative attitudinal propensities of the parties involved (March and Simon 1958; Pondy 1967).The reason is that resolving claims involves questions that potentially have commercial implication for employer and the contractor. The questions include (Perlman 1984): should the construction period be extended because of the claim event and, if so, should the contractor be paid for additional cost? And if an extension of time is inappropriate, should the contractor be required to pay liquidated damages?

When attempting to address these questions, conflict may escalate and grow in intensity. Intensity is an important conflict characteristic (Bercovitch and Langley 1993). According to Yiu and Cheung (2005), when tension level reaches a threshold in construction conflict, the conflict level would be high even if the tension level subsides and the conflict may not return to the original level. Thus, conflict intensity may influence negative attitudinal propensities of parties involved. Negative attitude may be in the form of the potential to reject the outcome and formally dispute claims. Conflicts may also damage the working relationship between the parties. In this study, conflict intensity is measured by two items: frequency and severity of disagreements during the process for administering claims (Diekman *et al*. 1994; Bercovitch and Langley 1993; Kressel and Pruitt 1989).

CONFLICT ISSUES IN THE HANDLING OF CLAIMS

In process for administering claims, the claims certifier is expected to form a view on the validity of the contractor's claims and make recommendation on the quantum of the contractor's entitlements. To enable the claims certifier to form his/her view, the following questions of facts that are potential causes of disagreements are typically addressed (Perlman 1984):

1. Whether or not the works giving rise to claims is required by the contract or is extra work
2. Whether the delay is due to the contractor's inefficiency or the employer's or his/her representative's actions (hereafter referred to as *Responsibility for delays*)
3. Whether the delay is on the critical path (hereafter referred to as *Criticality of delays*)
4. Whether the employer-related delay is concurrent with another contractor-related delay (hereafter referred to as *Concurrency of delay*)
5. Whether or not the contractor actually incurred added costs.

There use of different approach to claims substantiation and assessment may also constitute an area of disagreements (Zack 2002). There are different methodologies that may be used for substantiating extension of time (EoT) claims by the contractor, upon which the claims certifier then assesses the claims, also using one or more of the varieties of methods. The use of different information and methodology by the contractor and claims certifier to substantiate and assess claims respectively would produce different results and conclusion (Kumarswamy and Yogeswaran 2003; Zack 2002) and thereby high potential for conflict and dispute. Where claims involve issues of facts, making a fair and reasonable decision would depend on the type and quality of information available (Jergeas 2001). Reaching a decision on claims would also depend on the interpretation of contract provisions relating to EoT and additional cost claims. Sometimes, contract terms are ambiguous and incomplete and may be a subject of heated argument (Spittler and Jentzen 1992). Thus, the following are other potential issues that could generate disagreements:

6. The type and amount of information used in substantiating claims
7. The methodology and technique used in substantiating and assessing claim
8. The quantum of contractor's entitlements
9. Contract interpretation.

There may be three modes by which parties could terminate conflict during negotiation of claims, namely forcing a decision on the contractor, mutual agreement between the parties and a compromising mode where one or both parties compromise their initial position (McDuff and Ray 2002). Terminating conflict by mutual agreement is collaborative and may yield an outcome that accommodates the interest of the contractor and the employer. Thus, it may lessen negative attitudinal propensities and reduce damage to parties' relationship. Compromise may de-escalate conflict but may lead to dissatisfaction and negative attitudinal propensities especially where a contractor compromises because of fear of damage to its reputation and potential loss of future jobs from other clients. Forcing a decision on the contractor may lead to further escalation of conflict, damage the contractor's relationship with the employer and/or may generate negative attitudinal propensities.

DATA AND METHODOLOGY

Data was obtained through a questionnaire survey of main contractors' contracts managers and quantity surveyors in Singapore who have experience with handling of claims. The respondents were employees of selected sample of construction firms operating in Singapore. The firms were selected from the contractor's registry of the Singapore Building and Construction Authority (BCA). The BCA is an authoritative source documenting the names and addresses of construction contractors serving the procurement needs of government departments, statutory bodies and other public sector organizations in Singapore. Two hundred contractors belonging to the grades A1, A2 and B1 under the Construction WorkHead CW01 – General Building and Construction WorkHead CW02 – Civil Engineering categories were selected for the data collection. The grades A1, A2 and B1 are classified based on the tendering limit as follows: A1 – unlimited, A2 – 65 million dollars and B1 – 30 million dollars respectively. Thus, contractors in categories A1, A2 and B1 are big players with technical and management expertise.

The respondents were asked to base responses on their experience, attitudes and attitudinal propensities in the process for administering claims on a project of their choice. The questions were designed to measure the level of claims requested and level of claims allowed. Other items were measured on a Likert-type scale ranging from 1 to 7. The frequency to which each of the nine issueswere responsible for disagreements was measured on response options ranging from 1 representing "least often" to 7 representing "most often". The overall frequency of conflict was measured with response options 1 representing "rarely" to 7 representing "very frequent". Severity of conflict was measured with response options ranging from 1 representing "minimal" to 7 representing "very severe". The respondents were also asked to indicate how most of the conflicts were terminated by selecting from among three options: (1) "Most of the solutions were mutually agreed upon"; (2) "Most of the decisions were imposed on us (the contractor)"; (3) "In most cases, we (the contractor) compromised our position so as to reach a solution and not engage in dispute".

Two attitudinal propensities of the contractor were also measured as follows: the potential to reject the final outcome and the potential to dispute were measured by response options 1 representing "low" to 7 representing "high". The extent of damage to working relationship with the employer was also measured on scale 1 representing "low" to 7 representing "high". The data obtained from the questionnaire were analysed. The results are presented next.

DATA ANALYSIS AND RESULTS

Responses to the survey

Of the 200 contractors contacted, 41 responded – representing a response rate of 20.5%. A total of 32% were foreign construction firms operating in Singapore while 68% were local firms. However, the 41 respondents from the 41 firms were Chinese, except one who was German. In addition, 41.5% were contract managers while another 41.5% were quantity surveyors. A total of 17% were either project managers or site managers. A total of 70% of them had over 11 years' experience in construction while 65.85% have been involved in over 11 projects in the past. Further, 63% of the projects upon which the responses were based are building projects while 37% are civil engineering projects. A total of 51.2% were procured by the public sector clients while 48.8% were procured by private clients. In terms of the conditions of contract used, 51.2% of the projects made use of the Public Sector Standard Conditions of Contract (PSSCOC) while 48.8% were procured with the Singapore Institute of Architect Conditions Contract (SIA).A substantial number of the projects (43.9%) are above 65 million dollars in value.

Level of claims requested by the contractors

Table 1 shows the levels of extension of time (EoT) and additional cost claims requested by the contractors. In 68.2% of the projects, the EoT claims requested were more than 10% of the original contract duration while in about 40% of the projects the additional cost requested by the contractors was more than 15% of the original contract sum.

Table 1: Extension of time (EoT) and additional cost claims requested by the contractors

% of contract duration	EoT claims requested			Additional cost claims requested		
	Frequency	**%**	**Cumulative percentage of projects**	**Frequency**	**%**	**Cumulative percentage of projects**
40% and above	4	9.75	9.75	3	7.32	7.32
30% and up to 39.99%	1	2.44	12.19	3	7.32	14.64
20% and up to 29.99%	7	17.07	29.26	2	4.87	19.51
15% and up to 19.99%	5	12.20	41.46	3	7.32	26.83
10% and up to 14.99%	11	26.83	68.29	5	12.20	39.03
5% and up to 9.99%	3	7.32	75.61	13	31.71	70.74
0.1% and up to 4.99%	10	24.39	100	12	29.26	100
Total	41	100		41	100	

Level of claims awarded/granted by the employers

Table 2 shows the percentage of the EoT and addition cost claims requested by the contractors which were awarded by the employers. In about 56% of the projects, the EoT claims awarded were above 60% of the amount requested while in the remaining 44%, the EoT awarded were less than 45% of the amount requested. More than 60% of the additional cost claims requested were granted in 41.46% of the projects while less than 60% of amount requested were granted in about 58.54% of the projects. The outlook is that in more than half of the projects surveyed, the contractors were awarded more than 60% of the amount of EoT claims requested while more than 60% of the additional cost claims requested were awarded to the contractors in less than half of the projects (41.46%). Success rate for EoT surpass that of additional cost claims. During the questionnaire interview, some of the respondents pointed out that in many cases they were awarded EoT but were asked to abandon their request for additional cost claims.

Table 2: Extension of time (EoT) and additional cost claims awarded by the employer

% of amount requested	EoT claims awarded			Additional cost claims awarded		
	Frequency	%	Cumulative percentage of projects	Frequency	%	Cumulative percentage of projects
90% and up to 100%	12	29.26	29.26	4	9.75	9.75
75% and up to 89.99%	9	21.96	51.22	6	14.64	24.39
60% and up to 74.99%	2	4.87	***56.09***	7	17.07	***41.46***
45% and up to 59.99%	6	14.64	70.73	6	14.64	56.10
30% and up to 44.99%	1	2.44	73.17	1	2.44	58.54
15% and up to 29.99%	2	4.87	78.04	8	19.50	78.04
0.1% and up to 14.99%	9	21.96	100	9	21.96	100
Total	41	100		41	100	

During the interview, all the respondents except one reported that when cost claims are granted, the same amount certified were paid by the employer. In the defiant case, the respondents reported that the employer refused to pay despite the fact that the cost claims were certified. At the time of the interview, the case was still under negotiation. However, the respondent indicated that if negotiation fails, the case would be pursued with formal dispute resolution because of the commercial implications of the amount involved. The analyses of the level of claims requested and awarded (Tables 1 and 2) are based on the information obtained on projects selected by the respondents. It is possible that respondents selected projects with larger claims, so the analyses presented may be an incomplete picture of the overall claims level in

Singapore. However, given that the respondents are personnel of big players in the Singapore industry, the result is indicative of claims levels in Singapore and, of more importance to this study, it is reflective of the claims level on the projects surveyed.

Conflict issues

The mean of the scores assigned by the respondents to each of the nine conflict issues was estimated and ranked. The results (Table 3) show that quantum of claims is the most frequent issue responsible for disagreements (1^{st}). This is not surprising when one considers the fact that construction contracts are commercial transactions and parties would desire to maximize returns. The question of criticality of delay is the next most frequent issue of disagreements (2^{nd}). In a delays claims process, a contractor's entitlement to EoT would depend on the question of whether the delay event is on the critical path and whether it contributes to the overall project delays. The question of criticality could be an area of argument especially where the construction programme is not progressively and consistently updated and monitored. Following disagreements on criticality of delays, disagreement regarding responsibility for the event causing the claims ranked third (3^{rd}). This is not surprising because when claims events occur, liability for the event is typically allocated to the party responsible for the event. Given the complex nature of construction activities, interdependency of roles and responsibilities and the high conflict of interest among the parties in a construction contract, arguments relating to responsibility for claims events are likely to be an area of frequent disagreements.

Table 3: Mean score and ranking of conflict issues

Issue	Mean Score	Rank
The quantum of contractor's entitlements	5.41	1
Criticality of delays	5.24	2
Responsibility for delays	4.73	3
Whether or the not the works giving rise to claims was required by the contract	4.71	4
The type and amount of information used in substantiating claims	4.59	5
Whether or not the contractor actually incurred added cost	4.46	6
Contract interpretation	4.27	7
Concurrency of delays	4.20	8
The methodology and technique used in substantiating and assessing claims	3.90	9

Disagreements on whether the works giving rise to the claims was required by the contract ranked next (4^{th}) to disagreement on responsibility for delay. This is also an important aspect of claims process, which is needed to determine the validity of contractor's claims and the quantum of the entitlements. This frequency may depend on the level of completeness of contract documents prior to the execution of contract agreement. Disagreements on type and amount of information ranked fifth (5^{th}). This was followed by disagreement on whether or not additional cost was incurred (6^{th}), issues of contract interpretation (7^{th}) and concurrency of delays (8^{th}). The problem with methodology/approach used in calculating claims ranked lowest (9^{th}).

Intensity of conflict

A one-sample t test was conducted to determine the overall intensity of conflict (measured by the overall frequency of disagreements and the severity of the disagreements). The t test was conducted to ascertain whether the mean score of the two items were significantly different from 4 (midpoint representing "moderately frequent" and "moderately severe" on the Likert scale of 1 to 7). The results (Table 4) show that the mean frequency of disagreements (4.68) is significantly different from 4 (p = 0.006). However, the mean severity of the disagreements (4.02) is not significantly different from 4 (p = 0.920). The results suggest that the disagreements were very frequent but were moderately severe.

Table 4: Results of one-sample t test for intensity of conflict (test value = 4)

Items	Mean	t value	Sig. (2-tailed)
Frequency of disagreement	4.6829	2.901	p = 0.006
Severity of disagreement	4.0244	0.101	p = 0.920

Termination of conflict

Data on how conflicts were terminated was analysed. Table 5 shows that in 41.5% of the projects conflicts were terminated by a mutually agreed upon solution during negotiation, while in 43.9% of the cases the contractor compromised its position so as not to engage in dispute and to protect its reputation. Most of the decisions on claims were forced on the contractor in 14.6% of the projects.

Table 5: Termination of conflict

Mode of termination of conflict	Number of cases	% of total
Most of the solutions were mutually agreed upon	17	41.5
In most cases the contractor compromised its position so as to reach a solution and not engage in dispute.	18	43.9
Most of the decisions were imposed (forced) on the contractor	6	14.6

The result suggests that in most of the projects, conflicts were terminated in two dominant modes namely: compromise by the contractors and mutual agreement between the parties. The dominance of the comprising mode (43.9%) may be due to the size of the Singapore construction market and cultural influences (Chinese culture). Chinese culture and traditional values tend to prefer to avoid conflict in the belief that maintaining relationship is necessary for sustaining good will and ensuring future cooperation (Cheung and Chuah 1999) and for securing future work.

Effect of disagreements on relationship and contractors' attitudinal propensities

It was expected that the impact of the disagreements on working relationships, the contractor's potential to reject the outcome of claims and contractor's potential to dispute the outcome of the claims would vary across the three modes of conflict termination (see Table 5). A t test was conducted to check if the mean scores of each of these items were significantly different from the midpoint of 4. The results (Table 6) show that where conflict was terminated by mutual solution and mutual agreement, the impact of the conflicts on parties relationship was moderate (mean 3.41, p = 0.116). Negative attitudinal propensities were also moderate (for potential to reject the outcome, the mean = 3.88, p = 0.811; for potential to dispute the mean = 3.71 with a p value of 0.569).

Table 6: Results of one-sample t test for the impact of disagreements on parties' relationship and contractors' attitudinal propensities (test value = 4)

Conflict termination mode	**Impact of disagreement on working relationship**	**Contractor's potential to reject decision**	**Contractor's potential to dispute**
By mutual agreement (n = 17)	Mean score = 3.41 t value = -1.661 p = 0.116	Mean score = 3.88 t value = - 0.243 p = 0.811	Mean score = 3.71 t value = - 0.582 p = 0.569
By contractor's compromise (n= 6)	Mean score = 4.50 t value = 1.40 p = 0.177	Mean score = 5.05 t value = 3.12 p = 0.006	Mean score = 5.05 t value = 2.491 p = 0.023
Solution imposed on the contractor (n= 18)	Mean score = 4.83 t value = 1.38 p = 0.177	Mean score = 5.50 t value = 4.39 p = 0.007	Mean score = 4.67 t value = 1.195 p = 0.286

Where most of the conflicts were terminated by contractors' compromise, the impact on contractors' relationship with the employers was also moderate but they indicated a very high negative attitudinal propensities (for potential to reject the outcome the mean = 5.05, with a p value of 0.006; and for potential to dispute the mean = 5.05 with p = 0.023). Where a solution was imposed on the contractor, the impact on the relationship was moderate whereas the contractors indicated a very high potential to reject the outcome (mean = 5.50, p = 0.007) but moderate potential to dispute (mean = 4.67, p = 0.286).

CONCLUSION

This study has explored the nature of claims and conflict in Singapore. It has shown that success rate for EoT claims surpass that of additional cost claims. Most often, the first three issues responsible for disagreements include quantum of claims, questions of criticality of delay and responsibility for the event causing the claims. The three issues reflect the general believe that stakeholders in the construction industry are self-interested and seek to maximize their gain. It also reflects the problematic complexity of construction projects and interdependency of construction activities and their influence on conflict. These characteristics are justifiable given that construction is a commercial transaction among economically dependent organizations. Nevertheless, when conflict arises, their impact on negative attitudinal propensities of parties involved may be reduced by finding a settlement that is mutually acceptable and focuses on the needs of all parties involved – rather than imposing or forcing a decision on a party or by compromise of one party. Attempting to impose or force a decision on a party is a win/loose approach, one sided, adversarial, threatening and aggressive in nature. It may generate costly contract disputes. Although Chinese culture and traditional values mean that conflict is sometimes avoided in the belief that maintaining good relationships is necessary for sustaining good will, ensuring future cooperation (Cheung and Chuah 1999) and for securing future work, the results of this study suggests that the compromise mode for terminating conflicts may be counterproductive. Compromising by making concessions for the sake of reputation or a relationship is one sided. It is a win/lose situation that makes the compromising party ignore its won needs in order to meet the needs of the other party. The compromising party may suffer losses and become dissatisfied. This may generate a very high propensity for negative attitude and may encourage adversarial culture in future contract relationships. Mutual settlement focuses on parties' respect for one another's interests. It leads to a win/win solution and could lead to a long-lasting relationship on the project. These conclusions provide vital information for stakeholders in Singapore construction sector where withdrawing/avoiding and the compromise style of conflict handling is dominant. The findings are also applicable to other countries.

ALTERNATIVE DISPUTE RESOLUTION: SUGGESTIONS FOR APPLICATION IN THE TURKISH CONSTRUCTION INDUSTRY

Deniz Ilter[1], Attila Dikbas[1] and Mel Lees[2]

Dispute is a common occurrence in the construction industry, and litigation, the formal way of settling disputes, is time-consuming and expensive besides several other drawbacks. This has led the authorities and the industry to seek and establish non-judicial dispute settlement methods in quest for more cost-effective and swifter solutions that prevent deterioration of business relations between the parties. Such alternatives to litigation are generically called alternative dispute resolution (ADR) methods. The ADR approach has been widely adopted by the EU, and considering Turkey's EU accession process as well as the need for low-cost and non-bureaucratic methods of dispute resolution, a genuine need exists to identify the legislative and the institutional pre-requisites for adoption and practise of ADR methods in the Turkish construction industry. Based on the conceptual framework proposed by Esman, the fundamental criteria are developed and formulated for the institutionalization of ADR in the Turkish construction industry in accordance with EU directives. This study aims to be a timely contribution to the process of the establishment of ADR in the Turkish construction industry, and the fundamental criteria set forth in this study are contemplated to serve as basis for an implementation model to be developed in subsequent studies.

Keywords: alternative dispute resolution, institutional development, Turkish construction industry.

INTRODUCTION

Disputes, as Cheung *et al*. (2002) suggest, are frequently the rule rather than exception in the construction industry and they arise for a number of reasons. The quality of materials, standard of workmanship, contractor delays, applications for extensions of time not being granted, variations, cost overruns and the meaning of contractual terms can be the subject of expensive claims and turn into disputes that threaten the success of the project (Adriaanse 2005). This poses a serious risk to a construction project for all parties if the disputes are not resolved before going to court, as litigation is a long, expensive and acrimonious process. In order to avoid litigation in dispute resolution, a range of 'alternative dispute resolution' (ADR) methods are widely used in the construction industry and have become an important issue of construction research and literature in the last decades.

ADR is a non-adversarial technique that is aimed at resolving disputes without resorting to the traditional forms of either litigation or arbitration (Ashworth 2005: 53). It is defined in the European Commission's Green Paper (2002: 6) as "out-of-

[1] artande@itu.edu.tr

court dispute resolution processes conducted by a neutral third party excluding arbitration". The most widely used ADR methods are mediation, conciliation, adjudication and dispute review boards/panels. The discussion on arbitration in the literature seems to result in defining arbitration not as an ADR method but a quasi-judicial procedure because of its features that are closer to (or worse than) litigation in terms of duration, cost and the level of bureaucracy (EC Green Paper 2002: 6; Adriaanse 2005: 347; Carmichael 2002: 265). The European Commission's Green Paper also suggests that expert opinion process should not be considered as a dispute resolution method as it is a procedure involving recourse to an expert in support, usually in litigation or arbitration. In this paper, the definition by the European Commission's Green Paper is followed and Alternative Dispute Resolution methods are referred to by the acronym "ADR", following the already widespread practice.

Rubin and Quintas (2003) suggest that the salient characteristics of ADR make it an attractive option for settling the complex and time-sensitive disputes that often arise during the course of construction projects. Beside being a faster, less bureaucratic and more cost-effective process that does not require the use of attorneys to present claims, the real-time approach to disputes can prevent deterioration of business relations. In addition, the consideration of disputes by knowledgeable industry professionals can achieve more equitable results based on the realities of the construction process instead of applying the strict letter-of-the-law removed from its relevant context.

The negative perceptions of the use of ADR in the construction industry have been analysed by Brooker and Lavers (1997) on the basis of an extensive survey in the UK construction industry, which identified the following most frequently stated negative attitudes to ADR: (i) proposing ADR to the other side is a sign of weakness; (ii) ADR reveals one's position to the other side; (iii) ADR before discovery of documents could result in a settlement being entered into when one should have gone for something better; (iv) ADR can be used to delay payment; and (v) ADR is non-binding and therefore too weak to be effective (for non-binding methods of ADR). Despite these negative perceptions, Broker and Lavers (1997) conclude that the widespread dissatisfaction with its long-established 'rivals' speaks in favour of ADR. Many respondents who had never used ADR expressed an interest in doing so and ADR was perceived as enjoying real advantages over litigation and arbitration, in terms of reduction of damaging confrontation, reduced cost and time, and the expectation of flexibility and a good settlement rate.

ADR is widely used in many countries' construction industries and is spreading fast globally (Cheung 2006). However, although the benefits of ADR are widely appreciated, as Cheung (2006) suggests, the adoption and implementation of such new methods is obstructed by the relevant laws, regulations and the absence of adequate institutions. Therefore, resolute government policies for both the adaptation of the legislation and the institutional development are required for viable implementation.

In tune with the initiatives by the EU agencies to establish and promote the ADR methods, this paper develops a set of fundamental criteria for the institutional framework to adopt ADR in the Turkish construction industry, based on an assessment of the current problems of the industry associated with dispute resolution and an outlook of the related legislation.

A REGULATORY FRAMEWORK FOR ADR

A regulatory framework with two aspects is needed for the implementation of ADR. First, despite its informal structure, the proper functioning of ADR depends on a sound relationship between legislation and ADR. The ADR mechanisms are legally empowered when they or their outcomes are recognized by law. The second aspect is the planning and the creation of an institutional framework for implementation, governing the policies and the rules associated with ADR. Buyck (1991) offers a definition for institutional development as the creation or reinforcement of the capacity to generate, allocate and use human and financial resources effectively to attain development objectives, public or private. It includes the building, strengthening, retrenchment or liquidation of institutions in the pursuit of institutional, sectoral or government-wide realization. From the perspective of developing countries, such as Turkey, institutional development is seen as more essential for the development of construction industries (McDermott and Quinn 1995). Kaming *et al*. (1994) describes institutional development as one of the key strategies in identifying the common problems of the construction industries in developing countries and strategic responses thereto. Being a candidate state, Turkey is following EU doctrine in the institutional development process of ADR and also good practices in the member states.

Development of ADR regulations within the EU

In the last decade, ADR has become an established part of the dispute resolution in construction and in general commercial dispute resolution in the UK, following its birth and rapid growth in the United States. Compared to other member states, the UK is the first in the EU to institutionalize ADR with respect to both enactment of regulations and the wide acceptance in practice (Cairns 2005). Nesic (2002) explains, in her discussion of the status of ADR in UK, that the construction industry in the UK is the largest single user of ADR (mediation), followed by other industries. The greatest determining factor in the successful deployment of ADR in the UK has been the robust government policies and regulations that promote ADR, such as the Housing Grants, Construction and Regeneration Act in1996 (which imposed the statutory adjudication for the resolution of construction disputes), the Woolf Reforms in Civil Procedure Rules in1998 (which promote the use of ADR before commencing proceedings) and the ADR Pledge in 2001 committing all UK Government Departments and agencies to settle disputes by ADR. These regulations resulted in a substantial reduction in domestic arbitration and litigation, where the number of new proceedings issued in the Technology and Construction Court in 2004 dropped to 390, which is only 22% of the 1778 new proceedings in 1995 (Gaitskell 2005). In the same period, an increase is observed in the number of commercial and non-commercial ADR providers, who are an indispensable part of the system.

Following the rapid development of ADR in the UK, the EU also declared the deployment of ADR as a “political priority”. In April 2002, the European Commission prepared a consultation report, the Green Paper on Alternative Dispute Resolution in Civil and Commercial Law due to the increasing attention on and diversity of ADR practices in the member states.

Green Paper on ADR in civil and commercial law

The objective of the Green Paper was to initiate a broad-based consultation on the salient features of the ADR processes. This would allow the determination of the approach to be taken by the Commission in promoting ADR and the determination of European Community-wide rules, which will constitute a common base for the institutions that have been deployed and those that will be deployed in future. In this context, the Commission stated the role of ADR as offering an alternative to the problems associated with litigation, emphasizing the growing number of the cross-border disputes that bring forth the problem of the conflict of national laws and jurisdiction. In addition, it invited the member states to encourage the bodies responsible for out-of-court settlement to operate in a way that provides adequate procedural guarantees for the parties concerned. Academic studies are also encouraged as an important help for the public authorities in their task of monitoring and/or developing ADR. The paper was in the form of discussion topics raising a series of questions concerning the possible regulations about ADR processes. The responses were received from the governments of member states and also third countries, ADR providers, structures for training and information in ADR, academic circles, judges, bar associations, commercial companies and professional federations which helped the Commission to define the general lines of the policies and its role as the promoter of legislative and operational initiatives. This consultation resulted in the Proposal for a Directive in October 2004.

Proposal for a directive on certain aspects of the ADR process of mediation in civil and commercial matters

On 22 October 2004, the European Commission published a Proposal for a Directive seeking to facilitate access to dispute resolution by promoting the use of mediation, which is among the widely used methods of ADR. The Proposed Directive defines mediation in Article 2 as a process where two or more parties to a dispute are assisted by a third party to reach an agreement on the settlement of their dispute, regardless of whether the process is initiated by the parties, suggested or ordered by a court or prescribed by the law. As a result of the consultation made in Green Paper, the Directive comprises the base rules to be adopted by the member states for the implementation of mediation concerning the referral to mediation, ensuring the quality of mediation, the enforcement of the settlement agreements and suspension of limitation periods. In the explanatory memorandum 1.1.3 of the Directive, the Commission stresses the untapped potential that mediation holds as a dispute resolution method and as a means of providing access to justice for individuals and businesses as a quicker, simpler and more cost-efficient way to solve disputes. It also allows for taking into account a wider range of interests of the parties, with a greater chance of reaching an agreement which will be voluntarily respected, and which preserves an amicable and sustainable relationship between them. When agreed, the Directive will apply to all civil and commercial matters and to cross-border disputes, making provision that member states will bring into force laws, regulations and administrative provisions necessary to comply with the Directive by 1 September 2007. As a candidate state, Turkey also has to follow and adopt the EU Acquis in order to progress in the Accession Negotiations.

ADOPTION OF THE EU ACQUIS IN ADR

In July 1959, Turkey made its first application to join the then recently established European Economic Community. The ensuing negotiations resulted in the signature of the agreement creating an association between the Republic of Turkey and the European Economic Community (the "Ankara Agreement") on 12 September 1963. This agreement aimed at securing Turkey's full membership in the EEC through the establishment in three phases of a customs union that would serve as an instrument to bring about integration between the EEC and Turkey. On 1 January 1996, the Customs Union came into effect and shortly after, at the Helsinki European Council held on 10–11 December 1999, Turkey was officially recognized as a candidate state on an equal footing with the other candidate states. At the end of 2004, the Accession Negotiations between the EU and Turkey were formally started, initiating a formalized process whereby Turkey will be required to complete the adoption of the EU Acquis. Turkey administers its adoption of the EU Acquis according to a "National Programme", furnishing a road map for adaptation of the legislation and the institutional development for implementation. The adaptation of legislation for ADR is beyond the scope of this paper; however, the current Turkish legislation regarding ADR is overviewed below for the judiciary linkages of the institutional development process.

Adaptation of the legislation for ADR

In Turkish law, there is no specific act pertaining to ADR in the existing legislation. However, there are provisions of ADR in some acts and draft acts. Within the National Programme, an ADR act is being prepared by the Ministry of Justice.

Advocateship Act

There are two acts in the current legislation that include provisions on ADR in Turkish Law, one being the Code of Criminal Procedure that is out of the scope of this paper and the other statutory provision that supports ADR is in the Advocateship Act. The Article 35/A of the Advocateship Act suggests that if a client demands mediation, the attorney may invite the other party to mediation. If the parties reach an agreement at the end of mediation, the act provides that the parties and the attorneys will execute a written agreement disposing of the dispute, which is enforceable in the same manner as any other final judgment (Ozbek 2005).

The Draft Civil Procedural Code

The draft code adopts a structure that enables and encourages the out of court dispute mechanisms. Although there are no specific provisions for ADR in the context of court proceedings, the second part of Article 145 gives the judge the duty of encouraging the parties for negotiation or mediation in the pre-investigation stage. If the judge is convinced that the parties may reach a settlement, or on the demand of the parties, he can postpone the hearing to another date in order to enable the parties to resolve their dispute by negotiation or mediation. The Explanatory Memorandum of the Draft Civil Procedural Code recommends the promulgation of a separate act to be drafted for the regulation of ADR in the legislation concordant to the legislation of the Member States of EU.

The Draft Non-contentious Judiciary and Alternative Dispute Resolution Act

As a part of the Judiciary Reform, the Ministry of Justice is planning to prepare this act for the adoption of ADR methods in Turkish law as a means to resolve disputes effectively, fast and with a minimum cost, covering provisions pertaining to both the ADR in the context of court proceedings and the regulations for conventional ADR.

The Draft Code of the Foundation, Duties and Authorities of Mediation Boards

This draft code suggests the settling of private law disputes between administrative authorities and private parties by ADR before commencing proceedings. In this draft code, reference has been made to Recommendation (2001)9 of the Council of Europe Committee of Ministers on alternatives to litigation between administrative authorities and private parties.

These developments in Turkey are closely observed by the European Commission. In addition to Accession Negotiations, assessment reports are prepared by the experts of the European Commission for monitoring both the adaptation of the legislation and the institutional development process. The Directorate General for Justice and Home Affairs and the Directorate General for Enlargement of the European Commission have made annual visits and prepared three assessment reports on Turkey's progress in the adoption of the EU Acquis in legislation. In their last advisory visit in 2005, the experts reported that the draft acts pertaining to ADR are being prepared and that their progress should be monitored closely. The experts recommended the adaptation of legislation should be completed and the institutes and/or boards be structured not only for resolving disputes between the parties but also constituting the benchmark criteria in their field of study (The Functioning of the Judicial System in the Republic of Turkey: 44).

The deployment of ADR is an important target in Turkey's State Strategy and Action Plan for 2007–2013 Judiciary Report (2006: 60). According to the report, ADR mechanisms such as negotiation, mediation, dispute resolution boards and ombudsmen that enable resolving disputes without going through a long judicial process with high costs should be adopted in order to reduce the disputes waiting for proceedings. To realize this objective, it is reported that the necessary councils for mediation and dispute review boards specialized in sectors base should be constituted.

ADR in Turkish construction industry

The implementation of ADR can be realized more successfully if planned on a sectoral base, since this gives the opportunity to constitute the institutional development according to the technical, economic, social and cultural aspects of a sector in order to meet its special needs.

Although there are some ADR mechanisms defined for some other fields, there are no institutions established for the resolution of disputes with ADR in Turkish construction industry. The one exception is the High Technical Board, which acts only as an advisory board to give expert opinion on the disputes in public works, only to the public authorities on their request. The High Technical Board was founded within the Ministry of Public Works and Settlement with the mission of preparing the standard contract types, specifications and price analysis for public works and providing expert opinion on the draft codes, statutes, regulations as well as the disputes in public works. The referral to High Technical Board before litigation is not obligatory for the parties and only public authorities can refer a dispute to the Board. Contractors and other parties do not have this right by law. The decisions taken by the Board are not recognized by law and, therefore, public authorities often hesitate to implement a decision in favour of the other parties and proceed to litigation. In practice when the disputes are referred to litigation after a decision taken by the Board, judges often decide in accordance with the decision of the Board. Similarly, when a dispute is taken to litigation directly, judges often take the dispute to the Board themselves. This mechanism causes a waste of time and other resources in the public works. On the other hand, the members of the Board are designated by the Ministry and these members work as officials of the Ministry, which raises doubts on the impartiality of the decisions taken on the disputes in public works.

Besides lack of adequate mechanisms, the lack of knowledge, experience and trained human resources in the industry concerning ADR results in poor administration of disputes especially in public works and international projects.

PRESENT PROBLEMS OF TURKISH CONSTRUCTION INDUSTRY ASSOCIATED WITH DISPUTE RESOLUTION

The public construction works and international projects are the main are areas prone to problems associated with dispute resolution in Turkish construction industry.

Public construction works

The state is the largest employer and investor in the Turkish construction industry but, at the same time, public construction projects are amongst the worst administered. Construction projects are by nature very prone to disputes. Since a legal and institutional framework does not exist for ADR in public construction projects, disputes normally end up in litigation, which in turn translates into failure in meeting project goals, both with respect to budget and schedule. Projects delayed for decades or left unfinished are very common figures of the Turkish public construction works landscape and no doubt, among other factors, notoriously slow progress of litigation has its share in it. The problems associated with the High Technical Board and the judiciary constitutes barriers that can hinder the progress in a project for a very long time. Because of the lack of specialized courts for construction disputes (such as the Technology and Construction Court in the UK), the disputes are referred to experts, but the judges have difficulty in finding qualified experts which is another reason for dissatisfaction with the judicial system beside the extremely long process.

In a research conducted by Gunay (2001), Turkish contractors were asked about their dispute experiences with the public authorities. The chosen group for the research comprised the members of the Turkish Contractors Association and most of the members reported that they had or still have disputes that lasted for years. The average duration of the disputes mentioned in the research that were resolved by the courts was seven years and the average was five years in the case of arbitration. However, in the same research, it was revealed that in many cases, to avoid a bad reputation, Turkish contractors refrained from taking disputes in public projects to the court and preferred to release their rights in fear of compromising their place in the invitation list to public tenders. These show that the current system of resolving public project disputes may not be equitable for both sides and more importantly causes a waste of the public resources in Turkish construction industry.

The study of Gunay (2001) also reports that the application of legal procedures in order to resolve disputes is less appreciated by the contractors in the presence of alternatives. The contractors considered a resolution method to provide partial acceptance or mutual coverage of expenses much more convenient than going to court. The reasons were explained as the monetary and non-monetary losses due to extremely long legal process, the worry about the impartiality and the qualifications of the court experts, the worry that employer would have a negative attitude for future works and the fact that gains do not compensate the real expenses even if a trial is won at court.

These problems associated with the adversarial methods of dispute resolution reported by the Turkish contractors can be avoided by the implementation of ADR in the public works. As suggested by Rubin and Quintas (2003), the real time approach to disputes in ADR can prevent antagonistic relationships by resolving claims promptly, allowing the work to proceed while claims are being considered. A dispute review board (DRB), for example, is established at the start of a project and is kept informed of the job's progress and of potential areas of dispute. In this way, if a dispute arises, DRB is already conversant with the background facts. This provides a first-hand knowledge on the issues in question and the consideration of disputes by knowledgeable industry professionals familiar with the often complex and technical issues that invariably arise during construction. In most ADR models, parties themselves identify either a person or a panel who will be responsible for examining project claims and to apply their knowledge to reach solutions based on the realities of the construction process either by issuing binding determinations, proposing viable solutions, or facilitating settlement, instead of applying the strict letter-of-the-law removed from its relevant context. On the other hand, Rubin and Quintas (2003) points to the biases, statutory constraints and policy considerations of the public authorities as factors affecting the dispute resolution process in public works and often diminishing some of the advantages that ADR has to offer. Therefore, the challenging next step in mainstreaming the use of ADR is to develop a model addressing the special concerns of public employers as well as the other actors in the industry.

International projects

International projects are another aspect where the institutional development of ADR is needed. In Turkey, expensive public construction projects tendered by a range of public authorities are often financed by international credit agencies that require the use of international standard contract forms with ADR provisions. These projects are usually contracted to multinational construction firms where the public authorities usually find themselves in poor administration of disputes that arise during the project because of their limited knowledge and experience in ADR procedures. On the other hand, Turkish contractors working abroad complain that they have difficulty finding human resources expert in ADR processes. These indicate the need for an institution giving consultancy, professional education and training on ADR in the Turkish construction industry.

THE FUNDAMENTAL CRITERIA SUGGESTED FOR THE INSTITUTIONAL DEVELOPMENT OF ADR IN TURKISH CONSTRUCTION INDUSTRY

The deployment of adequate ADR mechanisms is expected to result in more cost-effective and swifter solutions for disputes in the Turkish construction industry, and to prevent waste of resources, especially in the public works. In order to achieve this, there are legislative and institutional pre-requisites. The legislative prerequisites to put ADR to work in Turkish construction industry are beyond this paper’s purview and may vary, depending on the adopted approach, from promulgating a full-fledged ADR Act, to merely incorporating an ADR clause in the standard form of contracts used in public works. This chapter discusses the institutional pre-requisites.

Considering the problems of Turkish construction industry associated with dispute resolution, the obstacles and insufficiencies of the current mechanism and the requirements of the European Commission, a set of fundamental criteria is suggested for the institutional development of ADR in Turkish construction industry. In formulating these criteria, Esman’s (1972) conceptual framework is used. This framework suggests that the essential elements of institution building are the characteristics of the institute itself, its linkages with its environment and the actual transactions or exchanges that take place between it and its environment (Figure 1).

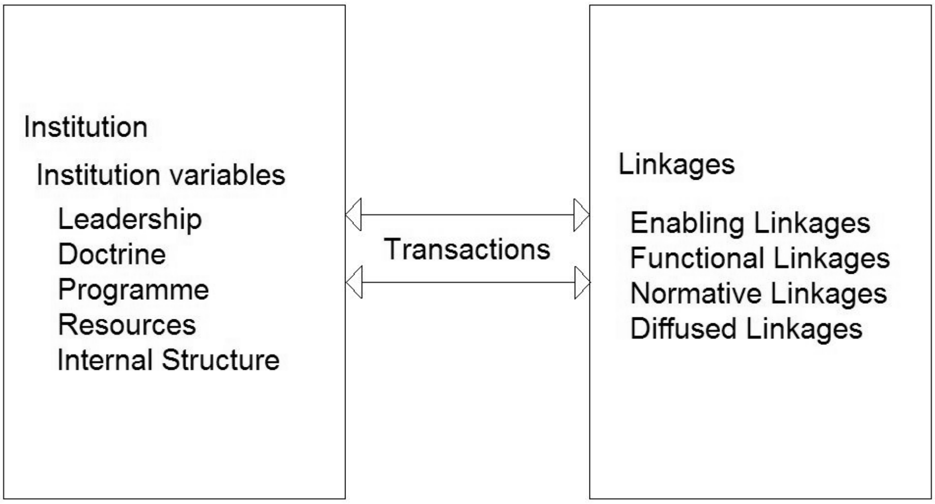

Figure 1: Esman's conceptual framework – 'the institution-building universe'

According to this framework, the major factors affecting the institution are its leadership, the doctrine or style and values that it adopts, the programme of work, the quantity and quality of resources available to it, and the appropriateness of its internal structure to the task and to the culture of the industry. Linkages describe the relationships between the institution and its environment. Enabling linkages establish its legality, purpose and resources, functional linkages establish its collaboration with complementary or competing institutions, which directly help in the achievement of objectives, normative linkages are the lesser relationships with other organizations of some common interest and diffused linkages are the relationships with external people or groups, which lend credibility or acceptability.

Institution

The institution should be specialized in construction ADR and responsible for all activities related to the development and implementation of ADR in Turkish construction industry.

Leadership

The institution should be developed in a way independent of direct government intervention in its internal functioning, autonomous itself or as part of an autonomous body like universities or professional federations.

Doctrine

- The values adopted should be in accordance with the values of European Commission, which are revealed in its Green Paper, The Proposed Directive and the Code of Conduct for Mediators.
- Impartiality: confidence is one of the most important issues in the adoption and the proper functioning of such an institute in the industry especially when dealing with disputes in public projects.
- Research-based: the task of development and the monitoring of ADR in the industry relies on a research based approach as suggested in European Commission's Green Paper.

- International recognition: sustainable development requires the collaboration with similar institutions in other countries.
- Client focused: quality control mechanisms should be constituted concerning the services given.

Programme

- Establishment of the Codes of Conduct for ADR procedures in the Turkish construction industry.
- Determination of referral and settlement processes and preparation of related documents.
- Training of the neutrals.
- Accreditation of the neutrals.
- Promotion of development of ADR in the industry.

Resources

At the initiation stage, the institution should be sponsored by government funds. The functioning should be arranged targeting the creation of own resources.

Internal structure

Task groups should be established for administration, research, training and accreditation.

Enabling linkages: linkages with the government

- Government policies should be constituted for the institutional development of ADR in sectors base.
- Legitimacy and relations with the other government agencies should be stated and specified in regulations.
- Funds should be supplied according to the programme of the Institute.
- Education should be given to relevant professional groups in the judiciary and in related government agencies.

Functional linkages: linkages with the judiciary

- Courts should be given the authority to invite the parties to use ADR in construction disputes.
- It should be ensured that a settlement agreement reached as a result of an ADR process can be confirmed by a court or public authority that renders the agreement enforceable in a similar manner as a court judgment.
- The disclosure of the information or evidence regarding to the course of ADR should not be ordered by the judicial authorities and should be treated as inadmissible.
- The running of limitation periods regarding the dispute that is the subject matter of the ADR process should be suspended during the ADR process.

Normative linkages: linkages with other organizations
The institution should work in collaboration with related EU agencies and other institutions in member states. It should be the member of established networks for international recognition and sustainable development. It should also work in collaboration with the professional associations in Turkish construction industry for the successful institutional development of ADR in the industry.

Diffused linkages: linkages with external groups
The institution should be supported by the prominent people and groups of the industry at the initiation stage.

CONCLUSION

The problem of unfinished public projects, the waste of resources due to poor dispute resolution practices and the need for adequate mechanisms have identified dispute resolution as a key area requiring improvement in Turkish construction industry. Despite the need for more cost-effective and swifter dispute resolution methods especially in the public works and international projects, lack of institutional development has evidently been hindering the acceptance of ADR in the industry. The practices of ADR development in other countries and the debate in the literature show that adequate legislation and institutional development are the pre-requisites for the adoption of such new methods. In the last five years, ADR is announced as a political priority by the European Commission, followed by the presentation of the Green Paper and the Proposal for a Directive and efforts are made by the member states for the adaptation of legislation and the institutional development of ADR in compliance with these reports. Being a candidate state, putting ADR to work is one of Turkey's tasks to be fulfilled in the process of adoption of the EU Acquis; more resolute policies are needed however for timely planning and implementation taking in account its urgency for the Turkish construction industry, especially in public and international projects.

Considering the problems of the Turkish construction industry associated with dispute resolution, the obstacles and insufficiencies posed by the current situation and the requirements of the European Commission as discussed throughout the paper, a set of fundamental criteria is suggested for the institutional development of ADR in the Turkish construction industry, concerning the leadership, doctrine, programme, resources, internal structure and the linkages with the government, the judiciary, other organizations and external groups. Development and implementation of a model as based on the fundamental criteria suggested in this paper is needed for the application and promotion of ADR, and should be tackled in future research as it is deemed to bear actual significance for unfettered development of the Turkish construction industry.

AN EXAMINATION OF THE PERFORMANCE OF STATUTORY ADJUDICATION IN NEW SOUTH WALES AFTER 2000 ADJUDICATION DETERMINATIONS

Michael C. Brand[1] and Thomas E. Uher

Faculty of the Built Environment, The University of New South Wales, Sydney, 2052, Australia

The Building and Construction Industry Security of Payment Act 1999 (NSW) (the NSW Act) is a unique form of statutory regulation for the building and construction industry, which gives virtually all industry participants a statutory right to, and a means of recovering, payments for work done under a construction contract. The research aim is to examine current trends in adjudication applications and determinations under the Act. The data used were those collected by the NSW Department of Commerce as part of a regular reporting regime, which covers the period from 3 March 2003 to 30 June 2006. The research reveals that the adjudication process of payment claim disputes under the NSW Act continues to grow in popularity, and the level of knowledge and awareness of the NSW Act among those working in the construction industry appears to be increasing. Claimants making small payment claims are generally more successful at adjudication than those making large claims. The NSW Act has not yet succeeded in discouraging parties from engaging in the practice of either unduly inflating or undervaluing progress payments. While adjudication provides claimants with a relatively inexpensive means of determining disputes as to payment, further research is needed in order to verify or otherwise the real cost-benefits of the adjudication process in NSW.

Keywords: adjudication, dispute resolution, performance, security of payment.

INTRODUCTION

This paper reports on an ongoing research project being undertaken by the authors into the performance of the Building and Construction Industry Security of Payment Act 1999 (NSW) (hereafter referred to as the 'NSW Act').

The NSW Act commenced in March 2000 and was introduced as part of the New South Wales Government's policy to eradicate the practice of developers and contractors arbitrarily delaying payment to subcontractors and suppliers in the NSW building and construction industry (Iemma 1999). The NSW Act is the first comprehensive legislative scheme to be introduced in Australia to provide, *inter alia*, contractors, subcontractors and building professionals with a statutory right to, and a procedure to recover, progress payments. While it embraces the philosophy of rapid 'statutory adjudication' of payment claim disputes introduced in the UK in the form of the Housing Grants, Construction and Regeneration Act 1996, the NSW Act is substantially different in its structure and operation from its UK counterpart. Similar legislative schemes to that operating in NSW and the UK have since been introduced

[1] michaelb@fbe.unsw.edu.au

in Victoria, Queensland, Western Australia, New Zealand and Singapore, with Malaysia planning to introduce its own legislation in 2007.

'Statutory adjudication' is a process defined in the Act of referring a payment claim dispute to an independent third party known as 'adjudicator'. Whenever a claimant endorses a payment claim as a claim made under the Act, the claimant may elect to have the payment claim adjudicated upon if the respondent withholds payment. The mechanism set out under the Act that leads to an adjudication of a payment claim requires: the claimant to serve a payment claim endorsed under the Act; the respondent to serve a payment schedule indicating the amount of progress payment (if any) that the respondent is prepared to pay and the reasons for withholding payment; the lodgement of an adjudication application by the claimant with an Authorized Nominating Authority (ANA); and the submission of the adjudication response by the respondent within the strict time limits imposed by the Act.

This paper will only be concerned with the NSW Act. As a consequence of a formal review undertaken at the end of the Act's first three years of operation, the Act was significantly amended by the Building and Construction Industry Amendment Act 2002 (NSW) (hereafter referred to as the 'Amendment Act') (Davenport 2003 and 2004). Accordingly, the 'NSW Act' referred to here is the NSW Act as amended.

The aim of the research is to examine the trends in adjudication determinations made under the NSW Act between March 2003 and June 2006. In particular, the paper will attempt to ascertain whether or not the amended Act introduced in March 2003 improved access of claimant organizations to adjudication of payment claims, subcontractors in particular. To that end the trend in the number of adjudication applications and adjudication determinations as well as the rate of success of claimants at adjudications made will be examined. Apart from improving security of payment, the Act also intends to provide a fast and inexpensive mechanism for resolving payment claims disputes. In this regard, this paper will attempt to ascertain a trend in the cost of adjudication.

Given that other Australian jurisdictions have adopted or are about to adopt a similar legislative framework to that in place in NSW, the emerging trends in connection with use of the Act in NSW identified in this research are expected to assist legislators in developing appropriate security of payment schemes or fine tuning those schemes already in use.

SECURITY OF PAYMENT

In the context of this paper, 'security of payment' is a generic term used to describe (NSW Government 1996: 41):

> [T]he entitlement of contractors, subcontractors, consultants or suppliers in the contractual chain to receive payment due under the terms of their contract from the party higher in the chain.

Thus, the security of payment problem refers to (Commonwealth of Australia 2002: 7):

> [The] consistent failure in the building and construction industry to ensure that participants are paid in full and on time for the work they have done, even though they have a contractual right to be paid.

Although the extent of the security of payment problem is unknown, it is generally accepted that it has been an ongoing issue for those who carry out construction work, or supply related goods and services under a construction contract (Commonwealth of Australia 2002).

In sum, the security of payment problem is the result of the practice by principals and contractors in the construction industry of unduly delaying and devaluing progress payments owed to subcontractors for work done under construction contracts. The tactic of principals and contractors in delaying payments or unduly reducing the value of payments is largely designed to enhance their positive cash flow at the expense of subcontractors (Brand and Uher 2004).

The security of payment problem has long been a major source of commercial hardship for those operating in the construction industry, particularly for the many small and often undercapitalized firms, which operate at or near the bottom of the contractual chain (Iemma 1999). It is suggested that, but for the systemically poor payment behaviour of principals and contractors, the problems of commercial hardship and failure among small firms in the construction industry would largely be avoided. Furthermore, one must not overlook the potential for the unnecessary generation of societal problems, such as unemployment and welfare dependence, which often accompanies commercial hardship and failure (Commonwealth of Australia 2002). Thus, any debate concerning security of payment is one that must inevitably deal with the issues of social security.

The next section of the paper describes the research method adopted in this study followed by a synthesis and analysis of the data. Lastly, conclusive remarks are presented.

RESEARCH METHOD

The operation of the security of payment legislation in NSW is facilitated by Authorized Nominating Authorities (ANAs). In total, nine such ANAs are registered in NSW. Their function is to accept adjudication applications, appoint adjudicators and issue upon request an adjudication certificate. Furthermore, each ANA is required by the NSW Department of Commerce (hereafter referred to as the Department) to report regularly on a variety of matters relating to adjudication applications and determinations made in NSW. Reporting is required by the Department with a view of allowing it to ‘better monitor trends in adjudication’ (NSW Department of Commerce, 2004: 6). Data used for this research are the data collected by the Department as part of the aforementioned reporting regime. The data used cover the period from 3 March 2003 (i.e. the date of commencement of the Amendment Act) to 30 June 2006. The data are in the form of tables and figures and are presented in this paper as Tables 1–6 and Figure 1.

Since the data collected by the Department are not aggregated according to the participating ANAs and the type of claimant and respondent firms, the authors were unable to assess the performance of individual ANAs and determine trends in the number of the adjudication applications made by different types of claimant and respondent firms.

The format of the data has ruled out a statistical analysis. Instead the authors attempted to subjectively interpret trends emerging from the data and relate them to the findings derived by the authors in their previous research into the performance of the adjudication process in NSW.

ADJUDICATION APPLICATIONS

As at 30 June 2006, a total of 2698 completed adjudication applications have been lodged with ANAs in NSW.

It is worth noting in Table 1 that since the commencement of the Amendment Act in 2003, the number of adjudication applications increased sharply, and despite a period of levelling off in 2005, the indication is that it continues to rise. The total value claimed under all completed adjudication applications is in the order of AU$1.79 billion (≈ US$1.41 billion). As at 30 June 2006, the highest and lowest claimed amount is AU$93.9 million and AU$224 respectively.

Table 1: Number of adjudication applications

Period	No. of applications
First three years (2000–2002)	116
Year 2003	593
Year 2004	746
Year 2005	734
Year 2006 (up to 30 June 2006)	509

Of the total number of completed adjudication applications lodged with ANAs 74.1% have been determined. At the time of writing, about 2% of all completed adjudication applications were pending determination and about 22% have been 'completed but not determined'. The Department does not explain the status of the remaining less than 2% of adjudication applications lodged.

Adjudication applications that are classified by the Department as 'completed but not determined' are those that are neither determined nor pending determination. This means that while such adjudication applications were made to ANAs, for reasons such as invalidity or withdrawal of applications or settlement of a dispute by the parties, no determinations were made for those applications.

The reasons for, and corresponding distribution of, 'completed but not determined' adjudication applications as at 30 June 2006 are given in Table 2.

Table 2: Reasons for 'completed but not determined' applications

Reasons	Number (% of total)
Withdrawn by claimant	96 (16.0%)
Parties settled and application withdrawn	224 (37.3%)
Invalid application under the NSW Act	271 (45.2%)
ANA/Adjudicator out of time	9 (1.5%)
Total	600 (100%)

Table 2 shows that the rate of withdrawal of adjudication applications once lodged with an ANA is relatively low. However, the Department does not explain the reason for such withdrawals. Table 2 also shows that ANAs appear to be administering adjudication applications promptly and that adjudicators are adhering to the time constraints placed upon them by the NSW Act in accepting adjudication applications and delivering determinations. For clarity, under the NSW Act an adjudicator is required to complete an adjudication determination within 10 business days from accepting nomination, unless the parties agree to grant the adjudicator extra time.

An interesting trend that emerges is that a significant number of disputes as to payment in the 'completed but not determined' category of adjudication applications are settled by the parties after lodgement of an adjudication application but before the application is determined by the adjudicator. Thus, the above data provide *prima facie* evidence that the adjudication process is actively encouraging parties to resolve disputes as to payment between themselves without the need for third party interference. Furthermore, since claimants often use the adjudication process soon after a payment claim dispute arises, it is arguable that the adjudication process is a catalyst for early dispute resolution between parties in the construction industry.

Almost half of all ‘completed but not determined’ applications are invalid under the NSW Act; this equates to about 10% of all completed adjudication applications. While no reasons are given as to why the applications are invalid under the NSW Act, it is likely that their invalidity is related to adjudication applications not meeting the requirements of the NSW Act when closely scrutinized by adjudicators in the course of making an adjudication determination. Brand and Uher (2004) reported a relatively low working knowledge of the NSW Act among particularly smaller subcontracting firms. This may help to explain the reason for invalidity of some adjudication applications. Nevertheless, it is apparent that a large majority of claimants have the requisite working knowledge of the NSW Act and are able to make valid adjudication applications.

Provision of payment schedules

The Department classifies adjudication applications as: (a) ‘standard’; (b) ‘optional with schedule’; and (c) ‘optional without schedule’ (NSW Department of Commerce 2004).

The ‘standard’ application is one where the respondent provides, in response to a payment claim, an initial payment schedule to the claimant in accordance with the Act and the claimant either rejects the scheduled amount or the respondent does not pay the claimant in accordance with the payment schedule on or before the due date for payment. The ‘optional with schedule’ application is one where the respondent fails to provide an initial payment schedule to the claimant in response to a payment claim but does so once the claimant notifies the respondent of its intention to apply for adjudication under s.17(2) of the Act. The ‘optional without schedule’ application is one where the respondent fails to provide an initial payment schedule to the claimant and also fails to provide a payment schedule after the claimant notifies the respondent of its intention to apply for adjudication under s.17(2) of the Act. It should be noted that s.17(2) of the NSW Act requires a claimant to gives a respondent two chances to provide a payment schedule before the claimant is permitted to lodge an adjudication application.

The frequency of submission of payment schedules as at 30 June 2006 under the three abovementioned classifications is given in Table 3.

Table 3: Frequency of submission of payment schedules by classification

Classification	Number (% of total)
Standard	1442 (53.5%)
Optional with payment schedule	217 (8.0%)
Optional without payment schedule	1038 (38.5%)
Unknown status	1 (0.0%)
Total	2698 (100%)

Table 3 shows that in about 60% of cases respondents provide a payment schedule in response to payment claims. Of these respondents about 85% provide an initial payment schedule to a payment claim. The remaining 15% of respondents provide a payment schedule after being notified under s.17(2) of the Act.

Surprisingly, about 40% of respondents do not provide a payment schedule in response to a payment claim. It should be noted that in the absence of a payment schedule, the claimed amount becomes a statutory debt and the respondent is not permitted to lodge an adjudication response to the claimant's adjudication application. A reason reported by the Department (NSW Department of Commerce 2004: 8) for the high proportion of respondents not submitting a payment schedule is that '[respondents] invariably ignore payment claims in order to delay or escape payment'. In consideration of the consequences under the NSW Act for not providing a payment schedule, it is reasonable to conclude that it may also be a result of respondents not understanding the timeframes and procedures set out in the NSW Act with regard to the submission of a payment schedule. However, if this is to be considered a significant reason for the high proportion of respondents that do not provide a payment schedule, then the result is anything but unexpected given that the Act has been in operation for over six years.

ADJUDICATION DETERMINATIONS

The Department reports that as at 30 June 2006, in excess of 2000 adjudication applications of payment claim disputes have been determined in NSW. The total value of determined applications is AU$1.53 billion (≈ US$1.20 billion). During the period, the highest and lowest adjudicated amount is reported as AU$93.9 million and AU$880 respectively.

Since adjudication applications are only concerned with payment claim disputes, it will be of interest to examine in the following sections of this paper the distribution of amounts claimed in payment claims and amounts of such payment claims actually determined by adjudicators.

Payment claims

The distribution of amounts of payment claims sought by claimants in adjudication applications that were determined by adjudicators is shown in Figure 1.

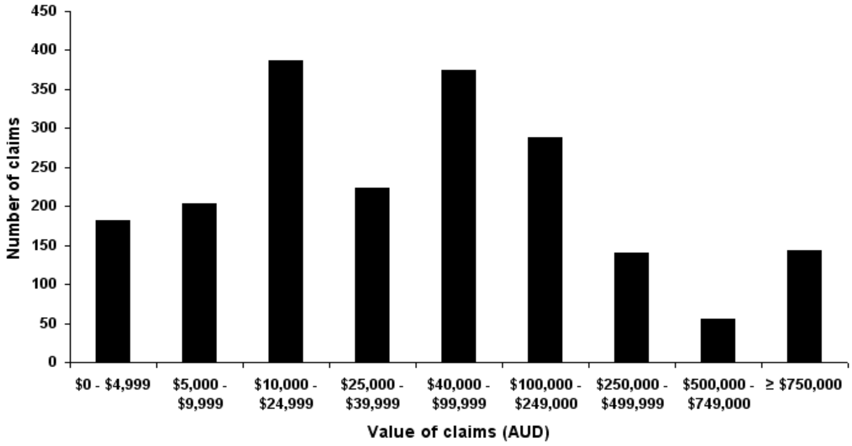

Figure 1: Distribution of amounts of payment claims as at 30 June 2006

Figure 1 shows that about half of all payment claims determined were less than $40 000 in value while about 17% were $250 000 or greater. The most frequently determined payment claims were those of the amount between $10 000–$24 000 and $40 000–$99 000.

However, the Department's data do not identify the type and size of claimants within each range of claims. Brand and Uher (2004) reported that around two-thirds of adjudication applications in NSW are being made by subcontractors. They expected that owing to the smaller size of their contracts, subcontractors' payment claims would be smaller than those made by contractors (Uher and Brand 2005). However, they found that amounts of payment claims made by subcontractors and contractors that proceed to adjudication under the NSW Act are not significantly different from each other. They explained that this is likely due to the fact that contractors' claims against clients are generally made for individual progress payment claims while subcontractors more commonly make claims for the sum of unpaid progress claims.

Level of success of claimants at adjudication

The distribution of outcomes measured as a percentage of claims determined under each adjudication application classification as at 30 June 2006 is shown in Table 4.

Table 4: Distribution of outcomes measured as a percentage of claim determined

Adjudicated amount as % of claimed amount	Standard adjudication	Optional with payment schedule	Optional without payment schedule
100%	317 (28.5%)	80 (44.2%)	461 (67.1%)
80%–99%	238 (21.4%)	35 (19.3%)	103 (15.0%)
60%–79%	110 (9.9%)	17 (9.4%)	33 (4.8%)
40%–59%	112 (10.1%)	10 (5.5%)	11 (1.6%)
20%–39%	105 (9.5%)	9 (5.0%)	14 (2.0%)
1%–19%	85 (7.7%)	10 (5.5%)	12 (1.7%)
0%	144 (13.0)	20 (11.0%)	53 (7.7%)
Total	1111 (100%)	181 (100%)	687 (100%)

A factor to be considered in determining the level of success of claimants at adjudication is the frequency of favourable outcomes measured in terms of the adjudicated amount. Table 4 shows that, on average, claimants were awarded 50% or more of the claimed amount in about 74% of reported adjudication determinations. On average, claimants were awarded the full amount claimed in about 43% of reported adjudication determinations. Only in about 11% of cases were claimants awarded $nil. The data show that claimants achieve the best outcome in adjudication, i.e. they secure the entire claimed amount, when respondents fail to provide a payment schedule. Conversely, claimants' rate of success at adjudication declines sharply when respondents provide a payment schedule.

Trends are also beginning to emerge in relation to the success of claimants at adjudication across a range of payment claim values. Table 5 shows the average claimed, scheduled and adjudicated amount across a range of payment claim values as at 30 June 2006.

Table 5: Average claimed, scheduled and adjudicated amount

Range of claims determined (AU$)	Av. claimed (AU$)	Av. scheduled (AU$) (% of av. claimed)	Av. determined (AU$) (% of av. claimed)
< $5000	$2920	$299 (10.2%)	$2604 (89.2%)
$5000–$9999	$7318	$407 (5.6%)	$6582 (89.9%)
$10 000–$24 999	$16 688	$975 (5.8%)	$13 300 (79.7%)
$25 000–$39 999	$31 968	$2866 (9.0%)	$25 816 (80.8%)
$40 000–$99 999	$63 634	$2545 (4.0%)	$44 714 (70.3%)
$100 000–$249 999	$159 381	$15 557 (9.8%)	$99 446 (62.4%)
$250 000–$499 999	$350 963	$7 323 (2.1%)	$256 112 (73.0%)
$500 000–$749 999	$620 672	$20 407 (3.3%)	$327 014 (52.7%)
≥ $750 000	$9 456 585	$848 247 (9.0%)	$2 291 368 (24.2%)

What emerges from Table 5 is that across the entire range of payment claims determined in adjudication respondents are only prepared to pay up to 10% of the claimed amount. Is it because claimants' payment claims are inflated or exaggerated, or does the above finding indicate that respondents are engaging in gross undervaluation of payment claims? The analysis of data in Table 5 with regard to the amount claimed and the amount adjudicated provides a possible answer.

The data show that the average adjudicated amount is about 70% of the average claimed amount across the whole range of claims determined. This clearly indicates that claimants are successful in adjudication, particularly those making smaller (in $ value terms) payment claims. For example, for payment claims less than $5000 in value claimants recover on average around 89% of the claimed amount. However, the claimants' rate of success in adjudication declines sharply with an increase in the amount of money claimed. For example, the adjudicated amount of large claims over $750 000 in value declines to only 24.2% of the claim.

Although the Department's data do not identify specific reasons for scheduled and adjudicated amounts being less than claimed amounts, the analysis of the data in Table 5 suggests that there can be no doubt that payment claims are inflated, particularly large payment claims.

However, to what extent small payment claims are inflated is unclear. Brand and Uher (2004) reported that although small size subcontractors' working knowledge of the Act and its requirements is only superficial, in making payment claims and in lodging adjudication applications they do not actively seek assistance of lawyers or claim consultants. It may well be that their non-compliance with some of the requirements of the Act, for example, in fully substantiating payment claims, may be the reason for the reduction in the value of small payment claims in adjudication. Whether or not such non-compliance is responsible for the reduction of the entire 11% for payment claims of less than $5000 in value, is again unclear. Considering that respondents generally do not defend small payment claims by employing lawyers or claim consultants in preparing payment schedules and adjudication responses (Uher and Brand 2005), respondents may not regard overvaluation of small payment claims, if any, as a major issue of concern.

Claimants making large payment claims are almost always assisted by lawyers or claim consultants (Brand and Uher 2004), yet such claims result in only 24.2% return to claimants in adjudication (for claims in excess of $750 000). While the presence of such experts in substantiating large payment claims does not rule out the possibility of non-compliance with some of the requirements of the Act, which may be a reason for a reduction in the value of payment claims in adjudication, nevertheless the relatively small return to claimants appears to support the view that large payment claims are inflated.

While the Act has over its first six years of operation in NSW markedly improved security of payment, it has thus far been ineffective in preventing claimants from inflating and respondents from undervaluing payment claims.

COST OF ADJUDICATION

One of the salient objectives of the adjudication process is to provide claimants with a relatively inexpensive method of having disputes as to payment determined by a neutral adjudicator. The distribution of the average total direct fees for all adjudication determinations (i.e. the fees of the ANA and the fees and expenses of the adjudicator) as at 30 June 2006 is given in Table 6.

Table 6: Total direct fees for all adjudication determinations

Range of claims determined (AU$)	**Av. claimed (AU$)**	**Av. total fees (AU$) (% of av. claimed)**
< $5,000	$2920	$544 (18.6%)
$5000–$9999	$7318	$829 (11.3%)
$10 000–$24 999	$16 688	$1497 (9.0%)
$25 000–$39 999	$31 968	$2082 (6.5%)
$40 000–$99 999	$63 634	$2630 (4.1%)
$100 000–$249 999	$159 381	$4391 (2.8%)
$250 000–$499 999	$350 963	$9050 (2.6%)
$500 000–$749 999	$620 672	$6660 (1.1%)
≥ $750 000	$9 456 585	$15 660 (0.2%)

The Department's data do not explain under what circumstances claimants are required to pay adjudication fees. Uher and Brand (2005) reported that when adjudicators award a nil amount of a payment claim, claimants are generally required to pay 100% of the adjudication fee. However, when adjudicators award less than the full amount of payment claim to claimants, the amount of the adjudication fee that claimants are required to pay may vary from nil to less than 100%. This is because under the NSW Act, adjudicators are able, at their discretion, to determine the proportion of the fee each party is required to pay. Some adjudicators require respondents to pay the full amount of the adjudication fee even if claimants are awarded only around 50% of a payment claim. Their argument is that respondents have unreasonably withheld a substantial amount of progress payment and have caused claimants to proceed to adjudication. Some other adjudicators apportion the adjudication fee evenly or unevenly between the parties in line with the adjudicated amount.

While the amounts of total direct fees for adjudication are relatively modest, Table 6 also shows there is an inverse relationship between the amount claimed and the total adjudication fee when expressed as a percentage of the amount claimed. It is interesting to note that although claimants making small payment claims are awarded on average at least 89% of the claimed amount, they may be required to pay the adjudication fee of up to 18.6% of the claimed amount, if they are not totally successful in adjudication. Conversely, the amount of adjudication fee that claimants of large payment claims may be required to pay when not fully successful in adjudication is very small indeed when expressed as a percentage of the claimed amount.

The direct costs of adjudication shown in Table 6 appear modest enough to conclude that adjudication provides claimants with a relatively inexpensive means by which they are able to have disputes as to payment determined by an independent third party. However, while the direct costs of adjudication do not appear to be a problematic issue at this point, meeting the indirect costs of adjudication (i.e. the cost of lawyers' and other consultants' fees) may pose more of a challenge to prospective claimants and respondents. According to Brand and Uher (2004), the cost of preparing adjudication applications and adjudication responses by lawyers and other consultants is significant. They reported that the direct cost to the claimant of preparing a simple payment claim for the amount of $7000 would be around $1000. However, with lawyers involved in preparing an adjudication application for the claimant and an adjudication response for the respondent, the overall cost of adjudication may be as high as $20 000. Thus, it may be said that the intervention of lawyers and other consultants in preparing submissions, particularly in relation to small claims, offsets the NSW Act's objective of providing claimants with a relative inexpensive method of having disputes as to payment determined by a neutral third party. However, if large claims are said to be inflated, and include for example unauthorized variations and delays costs, the presence of lawyers may be necessary to protect respondents from inflated or ambit claims. Legal costs in such circumstances may well be justified. Notwithstanding that such costs may be incurred regardless of the type of dispute resolution process employed, further research is necessary to verify the real cost benefits (if any) of adjudication under the NSW Act.

CONCLUSION

The foregoing discussion on the emerging trends in adjudication in NSW highlights the rapid growth in the number of adjudication applications made under the amended Act. The amended NSW Act has now been in operation over four years and the increasing number of adjudication applications may indicate the growing knowledge and awareness of the NSW Act among the parties working in the construction industry as well as the success of the changes made to the original Act, which, among other things, improved the method of selecting adjudicators and provided for the issue of an adjudication certificate, which when filed in a court, amounted to a judgment for a debt. Of particular interest is the finding that subcontractors, the party at which the Act was primarily targeted, access the Act and its provisions more frequently than contractors.

Claimants' knowledge of the NSW Act appears at present superior to that of respondents. This is evidenced on the one hand by only a small number of invalid adjudication applications lodged by claimants with ANAs and by a relatively low frequency of submission of payment schedules by respondents on the other hand. The fact that the provisions of the Act are initiated by claimants, who have sufficient time to prepare a claim in accordance with the requirements of the Act, may explain why claimants appear to have better understanding of the Act than respondents.

In general, it was found that claimants are highly successful at adjudication measured in terms of the proportion of the claimed amount they are awarded by adjudicators, with claimants making small payment claims being generally more successful than those making large claims. This seems to vindicate the introduction of the Act as a means of improving security of payment, particularly of smaller subcontractors. Moreover, claimants are most successful at adjudication if the respondent does not provide the claimant with a payment schedule. This finding seems to reinforce the previous observation of respondents' poor knowledge of the Act.

The results also show that while claimants attempt to inflate the value of their payment claims particularly of large claims, respondents consistently engage in undervaluing such claims. It seems that the NSW Act is yet to succeed in discouraging the parties from engaging in the practice of either unduly inflating or undervaluing progress payments.

Adjudication fees appear to be modest enough to conclude that adjudication provides claimants with a relatively inexpensive means of determining disputes as to payment by an independent third party. Of greater concern are the indirect costs of adjudication, particularly those related to the cost of lawyers or claims consultants.

Further research is needed in order to verify or otherwise the real cost/benefits of adjudication under the NSW Act.

Overall, the findings of the research show that the changes made to the Act in 2003 have significantly increased the number of adjudication applications made particularly by subcontractors, which is indicative of the growing popularity of the adjudication process in NSW. The findings also suggest that the main aim of the Act to improve security of payment in the NSW construction industry has, to a large extent, been achieved. These findings may assist legislators in other Australian States to develop new legislative schemes or amend existing ones in line with the successful NSW Act.

MISCONCEPTION ABOUT THE USE OF THE STANDARD METHOD OF MEASUREMENT IN DEVELOPING COUNTRIES: A GHANAIAN PERSPECTIVE

Gabriel Nani[1], Anthony Mills[2] and Theophilus Adjei-Kumi[1]

[2]*School of Property Construction and Project Management, RMIT University, Melbourne, Victoria 3000, Australia*

Bills of Quantities are the classical form of financial control used for pricing construction projects throughout much of the developed world. The British-based Standard Method of Measurement (SMM) is widely used throughout Developing countries for generating bill of quantities. However the nature of the construction industry is very different and the SMM is routinely adapted to suit local conditions. This research investigates the typical local conditions that cause departures in the adoption and use of SMM in developing countries. The paper examines some commonly held, but often false assumptions, about how the SMM is applied in developing countries: Ghana. A questionnaire survey approach was used in obtaining information from industry practitioners, while comparisons are made to some developed countries (UK). This has implication for the development of information technology (building information modelling) and international firms that undertake work throughout the world. The paper concludes with the impacts of the departures from the SMM to the international construction community.

Keywords: standardization, measurement, quantity surveying, estimating, information technology, developing countries.

INTRODUCTION

The standard for measurement of construction works is a formal document that sets out the conventions for defining the nature of construction works, how the work is measured or taken-off and quantified (Earley and Gould 2004). This document sets the basis for preparation of bill of quantities which is often used to model cost. The general relevance of SMM is demonstrated by the usefulness of bill of quantities. Ferry *et al*. (1999) noted that Bill of Quantities (BQ) is a total cost model which could be used for various purposes both within the client organization and the contractor's organization. Singh and Banjoko (1990) corroborated this, while researching to produce a 'rational bill' for the civil engineering industry. They discovered that, at the heart of civil engineering measurement projects is financial control, whose satisfactory performance is influenced by how the structure of the construction cost is modelled by the BQ. Other researches confirmed the usefulness of BQ (hence SMM) for cost modelling among other uses such as quality or specification control, and

[1] gabrielnani@yahoo.com

scheduling of activities (Kodikara *et al.* 1993; Law 1994; Nani and Adjei-Kumi 2007).

Standard Method of Measurement (SMM) for works of construction is common with commonwealth nations. In some commonwealth countries, a local SMM is used for measuring works of construction while other countries adopt standard methods from other countries. The most widely adopted standard method of measurement is the British SMMs (Mills *et al.* 2006). About 20% of the total number of countries surveyed in a global survey of SMMs in current use (RICS Construction Faculty 2003), adopted a British standard method of measurement. The rest of the countries (i.e. 80 %) use a form of measurement standard produced locally. Ghana is one of the countries that have adopted the British measurement standards for measuring construction works.

Contrary to the spirit of the British standard methods of measurement, there are some departures from the manner in which they are used in Britain and how they are used in Ghana. The paper investigates the differences in the adoption and use of SMM in UK and in developing countries (using Ghana as a case study). These differences are of relevance to the international community, as international firms doing business in Ghana and other developing countries need to note the local norms and practices of measuring work.

A questionnaire with open-ended and close-ended questions were used to illicit information from quantity surveyors practising in recognized professional quantity surveying firms. The questions require the selection of response from alternatives followed by the respondent's comments. This approach provided the respondent the flexibility to dilate upon their responses and provide further useful information. The respondents were asked to state the differences in the construction industry between Britain (where the SMMs used in Ghana were developed) and Ghana, which have bearing on adoption of SMM. They were further required to point out departures with the application of British SMM in Ghana. They also indicated whether they carry out work for contractors or consultants. This is expected to ensure results represent views from both the consultants' and the contractors' perspectives

The population of quantity surveyors was selected based on their experience with SMMs (they are in constant study and application of SMM). There are fifty seven recognized professional quantity surveying firms in Ghana (Ghana Institution of Surveyors 2006a). Questionnaires were hand-delivered to three randomly selected Quantity Surveyors in each of the 57 firms. Sixty respondents spread over 27 firms returned their questionnaire. This indicates about 35% response rate from Quantity Surveyors spread over 47% of the total number of firms consulted.

In addition 68% of the respondents indicated that they have ever carried out measurement as contractor's quantity surveyor. This indicates that the contractors' perspective is represented in the survey. Other results and comments obtained from the respondents are discussed together with literature review in the ensuing paragraphs.

NATURE AND DIFFERENCES IN THE CONSTRUCTION INDUSTRY IN THE DEVELOPING AND DEVELOPED COUNTRIES

The respondents stated emphasis on project control, standardization construction products and materials, technology and culture as aspects of the construction industry where differences (which affect SMM) exist between developed and developing countries.

52% of the respondents indicated that developing countries emphasize cost control more quality and time control in a project environment. This corroborates Kazi and Charoenngam (1999) observation that the need to control project cost, is paramount to developing countries, since infrastructure development continues to be a priority. They also acknowledged that time and quality control is far less emphasized as compared to cost (Ofori 2000; Shakantu *et al.* 2002). Ogunsemi and Jagboro (2006) also observed that time and cost overruns are rampant in the Nigerian construction industry. They cited Odusami and Olusanya (2000) in a research which showed that projects executed in Lagos Nigeria do overrun their time in excess of 51% of the planed duration. As a result, SMM in a developing country seeks to first address issues of cost as compared to developed countries who pay equal attention to quality and time specifications.

71% of the respondents identified standardization of construction materials and products as poor in Ghana as compared to the UK and other developed countries. As a result, there is influx of materials and products with assorted standards from both internal and external sources. Natural market sizes of some locally produced materials are at variance with what prevails in other developed countries. Most respondents cited the length of timber as example. The maximum continuous length is 4.80 metres, while the British SMM acknowledges a length of 6.00 metres.

About 87% of respondents cited technology levels especially with respect to industrialization of construction process are low in Ghana as compared to other developed countries. They mentioned the presence of craft based large labour force (carrying out work otherwise carried by plants) and few plants on construction sites as evidence. In situ construction is also cited as common compared to pre-cast construction. These influence the practice of the industry, hence any measurement approach adopted for construction works. SMMs in these countries therefore focus on labour intensive and insitu construction rather than the industrialized form of construction.

76% of the respondents stated culture as a major factor that influences the nature and distinguishes construction industries. Cultural differences can be viewed in terms of focus in business. This affects the type of emphasis that is placed on measured construction work. They confirmed that, construction business in Ghana as in most developing countries in Africa is relationship focused unlike most industrialized countries (including UK), where it is deal focused (Langford 2000). This means that business is usually between friends, relatives, and people well known to one another (termed locally as ‘whom you know’). Further comments by respondents explained that, Trust based on relationship between parties has reduced the emphasis placed on highly detailed and accurate measurement of construction work. This has reduced the burden on the quantity surveyor. On the other hand as depicted in the seventh edition of the British standard method of measurement of building works (SMM7), most developed countries emphasize detailed and highly accurate measurement procedures – there may be suspicion of one party taking advantage of the other (Langford 2000). This cultural difference reflects in application of construction contract conditions, hence the rules of SMM. Elimination of cost insignificant items and Simplification of SMM is therefore possible in these developing countries.

COMMONLY HELD BUT OFTEN FALSE ASSUMPTIONS ABOUT THE APPLICATION OF SMM

The function of SMM is to provide the basis for preparing Bill of Quantities which is used to model and control construction cost

Though the SMM is used in preparing Bill of Quantities (BQ) which is used mainly in cost control (Kodikara *et al.* 1993), it also aids specification writing and scheduling of construction activities. 75% of respondents confirmed these other uses for SMM and stated its provision of a ready classification for specification writing and preparation of works programme. Further comments stated that in situations where complete information can not be obtained from available drawings, BQ are consulted for information on specifications and extent of work. The limit of the information obtainable is determined by the SMM used (in this case the SMM is providing specification information). The most commonly omitted specifications in Ghana include painting type and colour scheme, door and window details, fittings and fixtures details, among others. In other instances specifications are incoherent and BQ are consulted for clarification. In the preparation of schedule activities, project managers consult the BQ (though in conjunction with other documents) mainly to determine the extent or volume of work required to be carried out. Their understanding of what the quantities in the BQ mean is based on the SMM used.

The most commonly used standard method of measurement in Ghana is SMM7

69% of respondents in this survey use SMM5 as against 20% for SMM7 and 11% for SMM6 and other methods of measurement. This finding corroborates an earlier finding that SMM5 is used on 65% of the occasions measurement is carried out in Ghana (Nani and Adjei-Kumi 2007). This is contrary to the international surveys (RICS Construction Faculty 2003; Mills *et al.* 2006) that indicate SMM7 is the standard method of measurement for building works used in Ghana. It is in December 2006 that the Ghana Institution of Surveyors (GhIS) declared the compulsory use of SMM7 in Ghana, effective July 1, 2007 (Ghana Institution of Surveyors 2006b). According to respondents, persistent use of SMM5 is due to the fact that most recognized quantity surveying firms in Ghana today were established by principal partners who had their education in the 1970s and 1980s when SMM5 was used in training quantity surveyors. The Ghanaian construction industry also shows characteristics of a craft industry that is better modelled (in terms of quantities and cost) by SMM5 than SMM7. Further, low industrialization of construction, low standardization of construction materials and incomplete documentation at the point of preparing BQ deprive the industry from fully benefiting from the provisions of SMM7.

SMMs are adopted indiscriminately

Most SMMs adopted are not without amendment or abridgement. All respondents who use SMM5 in preparation of bill of quantities and 75% of those who use SMM7 indicated that they modify the measurement rules. This assertion was confirmed by a critical examination of BQs prepared within the respondents firms. The amendments include omission of quantities for cost insignificant items (such as making good concrete work associated with holes, builders work, trimming, labours etc.), aggregation of certain like work items (mullions, transoms, jambs, heads and sills for timber windows and door frames; external and internal finishes when they of the same material etc.), adoption of units contrary to SMM5 (e.g. finishing works in narrow strips, which SMM5 rules requested should be measured linear are measured superficial). These amendments were made possible by the factors discussed as contributing to the nature and differences in the construction industries of developing and developed countries. Low levels of wages for construction workers in Ghana make most labour items in SMM5 insignificant with respect to cost in the Ghanaian context as compared to UK and Australia. For instance an unskilled labourer in Ghana receives an average of Fifty Thousand cedis (¢50,000) per day (equivalent to £2.7), which is less than the hourly rate in the UK.

The adoption of SMM is an agreement between the Contractors and the Quantity Surveyors' professional body

All respondents agreed that SMM5 and other versions of SMM used in Ghana were not selected based on the collective agreement between the Quantity Surveyors professional body and the Contractors association in Ghana. This is contrary to what prevails in the UK, and stated in the preface to SMMs developed in the UK. This appears to be the case with most SMM in various other developing countries as observed in few SMM developed for those countries (Wood and Kenley 1997; N.I.Q.S. 2003; Mills *et al*. 2006). Though, the British SMM was approved by the Ghana government conditions of contract, and most contract conditions in Ghana, the respondents are of the opinion that the contract conditions are imposing the SMM on the contractors. The SMM and its necessary amendments are usually introduced in tender documents by Quantity Surveyors and the contractors are expected to either accept or leave it. The adoption of SMM5 is therefore not an agreement but a unilateral decision by the QS professional body. Though this appears to be a recipe for disputes (with respect to measurement approach), it hardly occurs. The respondents explained this by indicating that most estimators, quantity surveyors and project managers in the Ghanaian construction industry also belong to the GhIS (the Quantity Surveyor's professional body that adopted the SMM). Further, trust developed through working with relations could also be a reason (Langford 2000).

Quantity Surveyors constantly consult the SMM

70% of respondents confirmed the general conception that Quantity Surveyors are in constant touch with SMM. This was however found not to be true as 90% of the respondents use BQ from previous projects to prepare one for new projects rather than prepare them from scratch using an SMM. Consequently, 49% of respondents could not trace their office copies of SMM immediately (though younger Quantity Surveyors were able to retrieve their student copies of SMM7). It was explained that experience has enabled the Quantity Surveyors to carryout their measurement duties in accordance with the SMM and the abridged rules without constantly consulting it. The younger Quantity Surveyors were able to retrieve their copies because they are less experienced, hence consult the SMM more frequently.

Both practice and academia use the same SMM

This assumption was also found to be false during the survey as it was discovered hat that while SMM5 is mostly and still used in practice, the academia began using SMM7 for more than a decade ago. Though students study the principles of measurement, which is mostly the same irrespective of the SMM used; Quantity surveyors who use SMM5 and other methods of measurement indicated that, they re-train new graduates. This enables them to be proficient in the use of SMM5 before they are fully absorbed into the industry. The differences between SMM5 and SMM7 are with the structure of the SMM (i.e. from prose form to tabular form), the use of new classification system (i.e. CAWS or UNICLASS instead of the traditional work sections), and the industrialized building construction approach rather than the traditional labour intensive approach.

IMPLICATIONS FOR INFORMATION TECHNOLOGY

The above discussions suggest a generally flexible and user (regional user) defined method of measurement for the construction industry. The ability of various regional factors such as culture, existing standards, and technology levels to influence the method of measurement of construction works implies software developers must adopt similar flexible approach in order to satisfy clients universally. Building information models (BIM), a recent development in information technology is required to provide 'one-stop' information on all aspects of a project including cost models such as BQ. BIM is defined as a set of interacting policies, processes and technologies producing a methodology to manage the essential building design and project data in digital format through out the building's life-cycle of the project (Pentilä 2006). It may require in-built SMM in order to carry out its cost modelling function such as measurement and compilation of quantities information for a project. Provision must therefore be made for regional customization of the in-built SMM to cater for the factors discussed which may affect the method of measurement. The assumptions about the application of SMM are consequently worthy of note by software developers who work on building information models.

CONCLUSION

The discovery of this survey is relevant to international construction firms that intend to carry out business in Ghana and other developing countries. It is necessary for these firms to understand the cultural technological and other differences that exist between these countries and the developed countries. The differences and the misleading assumptions identified are signals to the international construction community to be cautious, whenever they encounter an SMM or similar document, which is adopted in a country other than its purported country. A complete knowledge of how the SMM is adopted prevents misunderstanding, multiple measurement and payment for work. The finding of this paper gives an insight into some issues, international firms should consider while recovering cost and value for projects in developing countries. Further research is recommended to improve the role of SMM in BIM cost modelling.

THE DIFFERENCE BETWEEN THE BQ AMOUNTS AND THE REMEASURED AMOUNTS ON REMEASUREMENT CONTRACTS IN RENOVATION WORKS OF HOUSING COMPLEXES IN JAPAN

Tetsukazu Akiyama[1]

Department of Architecture, Toyo University, 2100 Kujirai Nakanodai, Kawagoe, Saitama 350-8585, Japan

In renovation work contracts for housing complexes in Japan, a lump-sum fixed price contract is generally adopted, which is not the risk the construction cost change after it contracts. In renovation works, the amount of increase and decrease is generated. It is improper to adopt the lump-sum fixed-price contract; the remeasurement contract is preferable. The aspect of the main analysis is the actual condition of the cost change according to the increase and decrease of the BQ and additional/deleted works, and the attribution analysis. This study analysed progressive consultants who employ remeasurement contracts for renovations of housing complexes to find out the difference between the provisional quantities written in contracts BQ and the remeasured actual quantities written in final documents after the completion of renovation works through 27 renovation projects. It has been understood that the difference of BQ amounts for each project is large, and that the amount of the increase and decrease by additional/deleted works is larger than amount of increase and decrease of BQ. It is necessary to examine the validity of the contingency based on the experience.

Keywords: remeasurement contract, renovation work, housing complex, bills of quantities.

BACKGROUND OF THIS STUDY

When housing complexes are renovated, renovation contracts are made by the owners associations (ordering party) according to the resolution of their general meetings. Therefore, they tend to prefer lump-sum fixed-price contracts, which carry no risk of price changes after contracts have been agreed. However, the details of renovation work are rather uncertain because repair-work specifications and the assessment of work quantities depend on the accuracy of preliminary inspections. Owners associations are usually unwilling to spend much money on preliminary inspections, and there are many renovation consultants who plan repair budgets based on rough estimation per housing unit (or per floor area). Despite uncertain factors in details of renovation work, lump-sum fixed-price contracts are employed in most renovation projects.

If there are uncertain factors in renovation plans, the risks of lump-sum fixed-price contracts are to be borne by contractors. If extra places were found to be in need of repair in the course of renovation work, they would have no choice but to modify

[1] akiyama@eng.toyo.ac.jp

renovation procedures since prices cannot be increased or decreased. This situation can also cause quality problems.

Some recent standard specifications prepared by expert consultants for renovation work on housing complexes have included repair-work items that are to go through quantity remeasurements at later stages. For example, looking at “Practical Specifications for Renovation Work on Housing Complexes and Explanations”, produced under the supervision of the Japan Institute of Architects (JIA 1998), certain items that should undergo quantity remeasurements are listed in particular specifications. Thus, specifications clearly indicate that it is impossible or very difficult to determine the exact quantities of certain items at the time of agreeing a contract. This is because when drawing up estimation breakdown sheets, most consultants (designers) grasp damage conditions only through visual inspections without scaffolding or through hammering tests on limited areas. The quantities of rusted reinforced steel, cracks, and loose mortar and tiles are assessed based on the contractor’s experience and judgment.

OBJECTIVES AND METHODS OF THE STUDY

Objectives and methods of the study

Although lump-sum fixed-price contracts are commonly used in renovation projects, some progressive consultants are actively introducing remeasurement contracts and requesting the adjustment according to actual figures or contingency in order to prepare for uncertainties in renovation work.

This study analysed four consultants (architect offices) that employ remeasurement contracts for renovations of housing complexes to find out the following: (1) the characteristics of renovation contracts containing remeasurement items; (2) budget planning and contingency of renovation works; and (3) the difference between the provisional quantities written in contracts BQ and the remeasured actual quantities written in final documents after the completion of renovation works.

For this study, contractual renovation priced BQ and remeasured actual renovation priced BQ were collected from 27 renovation projects that were designed and supervised by the four consultants and completed in 2000–2004.

The aspect of the main analysis is the actual condition of the cost change according to the increase and decrease of the bills of quantities and additional works and the deleted works, and the attribution analysis.

Profiles of surveyed consultants

The following four consultants were surveyed.

Consultant A

Consultant A engages in renovation on housing complexes mainly in the Kansai region. Its representative also heads a non-profit organization corporation, the “Housing Complex Improvements Center”. Basically, this consultant does not spend much time and effort on damage inspections. It considers that spending money on preliminary inspection is ineffective because no matter how rigid inspections are, quantity revisions are inevitable for remeasurement items. When asked for estimates, consultant A provides provisional (projected) quantities based on previous experience and results. Notably, its written contracts come with itemized statements that record any questions and answers. The minutes of owners-association meetings are generally attached to renovation contracts; some minutes specify the amount of contingency.

Consultant B
This consultant specializes in renovation work and operates mostly in the Tokyo metropolitan area. It is a member of Renewal Technology Development Committee, of which the chairperson is the representative of Consultant B. When undertaking renovation of housing complexes, it conducts extensive damage inspections before drawing up estimations. Its estimation sheets describe provisional quantities for remeasurement items and reference quantities. If reference quantities are to be altered, contractors must explain the reasons for this; thus, reference quantities should be quite close to committed quantities.

Consultant C
This consultant operates in the Tokyo metropolitan area and also conducts design and consulting for new houses. Its representative is a principle member of JIA's condominium committee and an editorial supervisor of JIA's "Practical Specifications…" document (1998), which was issued by the committee. This consultant also inspects buildings briefly for the same reason given by consultant A. It firstly sets per-housing-unit costs based on its experience, and then calculates total renovation costs by taking into account the specifications of renovation works. The composition of estimation sheets is similar to that of consultant A. Consultant C is planning to develop a database of estimations and others.

Consultant D
This consultant operates mainly in the Tokyo metropolitan area, focusing on design and consultation for renovation on housing complexes. Its representative is also a principle member of JIA's condominium committee and an editorial supervisor the afore-mentioned report, along with the representative of consultant C. This consultant does not spend much time and effort on damage inspections. It is a characteristic of this consultant to conduct a second round of renovations for existing condominium buildings. This consultant is active in the improvements of building structures, including the introduction of the external thermal insulation method.

All these four consultants adopt remeasurement contracts, but they use different terms in remeasurements (e.g.: provisional quantities, projected quantities, specified quantities, predicted quantities, contract quantities, etc.) They also differ in the way in which they explain the necessity of remeasurement-related contingency to owners associations and in the methods of instructing contractors about such funds. Thus, each consultant is independently conducting business based on his own experience.

THE ESTABLISHMENT OF REMEASUREMENT ITEMS

The "Practical Specifications…" report, issued by the condominium committee of JIA (1998), describes: "1) Remeasurement items, listed in particular specifications, should be adjusted through the calculation of difference between contractual quantities and actual quantities based upon unit price; and 2) The tentative quantities for remeasurement items as a basis for contracts are referred to in particular specifications." In other words, the existence of remeasurement items is mentioned in "general common items (general conditions)" of specifications, and specific items are stated in particular specifications. Consultant A provides "projected quantities" for remeasurement items in itemized lists, which are attached to renovation contracts. In the case of consultant B, the presence of remeasurement items is mentioned in its “general common items”, which read: “Estimated quantities : After on-site meetings, if contractors should have questions regarding presented estimation quantities (excluding remeasurement items in the reference column of estimation itemized lists).” Remeasurement items are separately described in its itemized estimation lists. The specifications of consultant C and D follow JIA’s style.

Each consultant sets up remeasurement items according to their experience (Table 1). This study compared each consultant’s remeasurement items presented in written estimates with remeasurement items in JIA’s material (1998) as the basis of comparison. Looking at the remeasurement items of each consultant in comparison to those of JIA, it can bee seen that almost the same work items are listed as major categories (repair work on tiles, mortar, sealing, exterior-wall painting, waterproofing and steel parts). However, on the subcategory and item levels, each consultant uses different terms to describe the details of remeasurement items.

All the consultants show provisional quantities for remeasurement items. For some items, only unit price is provided without quantities because those items were not expected when signing contracts but they may possibly arise in the course of renovation work.

Table 1: The composition and details of remeasurement items in remeasurement reports

JIA	Consultant A	Consultant B	Consultant C	Consultant D
1. Improvement of concrete frame	1. Repair of damaged furring	1. Improvement of building frame	1. Repair of cracks	1. Improvement of exterior wall and frame; waterproofing
2. Repair of cracks on concrete frame and mortars	2. Repair of reinforcing bar	2. Improvement of mortar	2. Repair of exposed reinforcing bar	
3. Repair of loose mortar and peeled or damaged interface	3. Repair of exterior tiles	3. Improvement of waterproofing on rooftops	3. Repair of loose materials	
4. Improvement of exterior tiled area	4. Repair of cracks	4. Improvement of metallic parts	4. Repair of leaking mortar parts	2. Spraying and painting of exterior wall
5. Improvement of sealing	5. Caulking and sealing work	5. Improvement of doors and windows	5. Improvement of furring and exterior wall	
6. Improvement of mortar waterproofing	6. Waterproofing work	6. Miscellaneous works	6. Caulking and Sealing work	3. Improvement of waterproofing
7. Repair of steel/ hardware parts	7. Painting work	7. Caulking and Sealing work	7. Painting work on steel parts	4. Improvement of metallic area; painting of steel part; polishing and cleaning
		8. Painting work		

BUDGET PLANNING AND CONTINGENCY

The consultants sum up the contingency before undertaking the contract because of the remeasurement contract. The amount of contingency requested by each consultant is as follows. The ratios of these contingencies are not set based on the experience of each consultant, and are not based on accurate grounds. Consultant A asks for 5% of contracted prices (renovation costs including overhead expenses incurred) or 10% of those if budgets are sufficient; consultant B asks for 10% as contingency; consultant C asks for 5% of contracted prices; and consultant D asks for 5–10%. In the case of consultant A, which attaches the minutes of owners-association meetings to renovation contracts, the amount of contingency is sometimes specified in the minutes of these meetings. This consultant aims to gain the understanding of owners associations (ordering party) regarding the necessity of contingency, and also to establish the consensus of association members through their discussions. In this method, the contingency budgets are disclosed to contractors, which requires consultants to be more responsible and skilful in cost management in the supervision process.

The explanation of the necessity of the contingency at budget plan stage and the presentation of an appropriate ratio of the contingency and the severe cost management capability at construction stage is expected to be the consultant's role.

HOW TO DECIDE PROVISIONAL QUANTITIES IN RENOVATION PLANS

The surveyed consultants showed the difference in attitude about the costs of preliminary inspections conducted before drawing out renovation plans.

There are two types of inspection. One is a simple inspection based on visual inspection within the extracted parts that can be inspected easily. The other is a detailed inspection with a partial destruction test and as much as possible to be inspected.

Consultants A, C and D conduct visual inspections and estimate provisional quantities per housing unit or floor area based on their experience, rather than carrying out rigid inspections and spending more money. Their opinion is that estimated quantities are subject to change no matter how rigid preliminary inspections are, and that it is reasonable to allocate more budget to repair works rather than spending money on preliminary inspections.

On the other hand, consultant B conducts rigid inspections, so inspection costs are relatively high. This consultant is pursuing the accuracy of renovation plans through extensive inspections. For example, the consultant uses scaffoldings for some parts of the inspection. Based on such detailed inspections, consultant B calculates estimation quantities for an entire project at the first stage. Then, it applies safety factors based on its experience and determines provisional quantities for each damage item (such as the exposure of reinforcing steel, cracked tiles, cracks in painted areas, loose tiles, leaks and partial breakages) and also for each repair work. The consultant prepares for contingencies by making estimations with safety factors for some remeasurement items that may cause major cost alternations. The ratio of the contingency of consultant B presents 5% because of their close inspection.

As mentioned above, in renovation work on housing complexes, the methods of deciding provisional quantities depend on consultants. There are two major approaches: one is to provide rough estimation per housing unit (or floor area) based on their experience, and another is to work out quantities through rigid inspection.

THE ANALYSIS OF CONTRACTUAL/PROVISIONAL QUANTITIES AND REMEASURED QUANTITIES

For this study, contractual renovation priced BQ and remeasured actual renovation priced BQ were collected from 27 renovation projects that were designed and supervised by the four consultants and completed in 2000–2004. Their remeasurement BQ reports contain specified work items for remeasurement, specifications, work units, unit rate, provisional quantities, provisional rate, remeasured quantities, remeasured rate and differences in amounts.

At first, I attempted to study the rates of change in quantities for each work item. However, since work items were dispersed and some of the specifications had been altered, I analysed differences in costs through multiplying quantities by unit cost. In this analysis, the specification change becomes a cost reimbursement treatment by not the remeasurement but additional construction. As for the specification change, a detailed analysis of the addition is necessary.

Table 2: Details of the difference between provisional costs and remeasured costs (shown in thousands of yen)

	Contractual net renovation cost	Change in cost	Cost rise due to quantity increase	Cost fall due to quantity decrease	Cost rise due to additional work	Cost fall due to deleted work
A-1	159,924	9.02%	13.58%	-1.79%	11.51%	-14.29%
A-2	199,830	5.01%	10.03%	-5.38%	2.59%	-2.23%
Average of A		7.02%	11.81%	-3.59%	7.05%	-8.26%
B-1	78,367	-7.68%	4.74%	-5.96%	2%	-8.46%
B-2	57,153	7.39%	2.60%	-6.27%	23.14%	-12.09%
B-3	36,247	0.36%	3.11%	-12.04%	11.66%	-2.37%
Average of B		0.02%	3.48%	-8.09%	12.27%	-7.64%
C-1	29,733	1.11%	2.43%	-1.32%	1.56%	-1.56%
C-2	44,705	0.92%	0.73%	-1.86%	2.72%	-0.67%
C-3	47,878	1.75%	1.19%	-0.22%	2.02%	-1.24%
C-4	43,883	3.85%	2.44%	-0.64%	3.30%	-1.24%
C-5	42,016	-1.26%	0.56%	-3.13%	1.89%	-0.58%

Average of D7,D8		-1.85%	2.70%	-6.27%	5.13%	-3.41%
Total average	1,613,520	3.00%	5.21%	-4.35%	8.53%	-6.40%

Column 1; contractual net renovation cost (shown in thousands of yen)
Column 2; the rates of change in cost = the sum of cost change after remeasurement/contractual net renovation cost

Column 3; the rates of cost rise due to quantity increase = the sum of cost rise due to quantity increase/ contractual net renovation cost
Column 4; the rates of cost fall due to quantity decrease = the sum of cost fall due to quantity decrease/ contractual net renovation cost
Column 5; the rates of cost rise due to additional work = the sum of cost rise due to additional work/ contractual net renovation cost
Column 6; the rates of cost fall due to deleted work = the sum of cost fall due to deleted work/ contractual net renovation cost

In addition, ordering parties and consultants decide on contingencies by setting the amount of the total project cost as 100%. However, ordering parties and contractors usually conduct cost negotiations and miscellaneous expenses (such as field overheads and general administration costs) are often deducted from total project costs. In some cases, project costs are virtually reduced through the one-sided discount from contractors. Therefore, the meaning of work quantities derived by adding up itemized quantities and the meaning of unit cost come to be obscure. In this study, the rates of change between provisional costs and remeasured costs have been calculated on the basis of net renovation costs (direct renovation costs + temporary work costs).

The analysis below focused on the difference between provisional and remeasured costs provided by the four consultants. Table 2 shows the following cost-variation rates to contractual net renovation costs for each project: rates of cost change after remeasurement; rates of cost rise due to quantity increase; rates of cost fall due to quantity decrease; rates of cost rise due to additional work; and rates of cost fall due to deleted work.

Overall trend
This data focused on 27 renovation projects conducted by the four consultants (the aggregate renovation costs of 1.6 billion yen; 62 buildings, 2,332 housing units). According to this, the remeasured renovation costs increased by an average of 3.0% from initial and contractual net renovation costs. In detail, the average rate of cost rise due to quantity increase was 5.2%, and the average rate of cost fall due to quantity decrease was 4.4%. As a result, the rate of cost change due to the change of quantities was plus 0.8%, which was a small difference.

On the other hand, the rate of cost rise due to additional work was 8.5%, and the rate of cost fall due to deleted work was 6.5%, showing larger differences than those resulting from quantity changes. The increased costs due to additional work were largely offset by the decreased costs due to deleted work, but resulting in a cost increase of 2.0%. It appears that preliminary renovation plans should be more specific about additional work.

Remeasured results of consultant A (2 projects: 5 buildings with 270 units; and 6 buildings with 200 units)
The remeasured renovation costs increased by 7.0% from the provisional costs. This is a fairly high rate and the increased amount needs to be covered by contingency. Looking at its breakdown, the rate of cost rise due to quantity increase was considerably high at 11.8%. Meanwhile, the rate of cost fall due to quantity decrease was 3.6%. The rate of cost rise due to additional work was also high at 7.1%, which was offset by the rate of cost fall due to deleted work. Even if eventual increase in cost fell within the amount of contingency, there were a lot of cost fluctuations.

Remeasured results of consultant B (3 projects: 1 building with 88 units; 1 building with 105 units; and 1 building with unknown number)
This consultant conducts rigid preliminary inspections compared to consultants A, C and D. Its average rate of cost change from provisional costs was 0%. The rate of cost rise due to quantity increase was low at 3.5%, while showing the highest rate of cost fall due to quantity decrease of 8.1%. These results reflect the effects of its rigid preliminary inspections and quantity calculations with safety factors. However, the rate of cost rise due to additional work and the rate of cost fall due to deleted work were both high at 12.3% and 7.6%, respectively, and these rates of change greatly depended on projects.

Remeasured results of consultant C (14 projects: 30 buildings with 745 units (divided into 8 sections); and 6 buildings with 456 units (treated as 6 projects))
The data on consultant C are based on renovation projects on two large housing complexes. In Table 2, projects on one of the housing complexes are described as C-1 to 8 and projects on the other as C-9 to 14. They are treated as separate projects because of the difference in design, structures and accountings of contingency. The rate of change from the provisional costs was relatively stable at > 3.5%. The rate of cost rise due to quantity increase was 5.6%, and the rate of cost fall due to quantity decrease was 4.0%. The rate of cost rise due to additional work was 6.0%, and the rate of cost fall due to deleted work was 4.0%. The rates of cost change due to additional or deleted work were relatively low and stable.

Remeasured results of consultant D (5 buildings with 171 units (treated as 5 projects); 5 buildings with 115 units; 1 building with 91 units (second-time renovation); and 1 building with 91 units (second-time renovation))
Consultant D has provided data on first-time renovations (D-1 to 6) and on second-time renovations (D-7 and 8). These were analysed separately.

Looking at the results on the first-time renovations, the rate of cost rise due to quantity increase was 3.9%, and the rate of cost fall due to quantity decrease was 2.9%, both showing stability. However, the rate of cost rise due to additional work and the rate of cost fall due to deleted work were both high at 14.2% and 11.7%, respectively. These high rates of change were ultimately offset by each other.

Focusing on the second-time renovations (consultant D did not take part in their first-time projects), the remeasured renovation costs decreased from the initial contractual costs by 1.9%. This result reflects a high rate of cost fall due to quantity decrease of 6.3%, while the rate of cost rise due to quantity increase was 2.7%. The rate of cost rise due to additional work was 5.1%, and the rate of cost fall due to deleted work was 3.4%. Compared to the first-time renovations, the rate of cost fall due to quantity decrease was high in the second-time renovations. It also appears that renovation history helped them reduce the occurrence of unexpected events.

Cost fall due to quantity decrease and cost rise due to quantity increase (Figure 1)
Figure 1 shows the ratios of cost rise due to quantity increase and those of cost fall due to quantity decrease for each consultant. There are differences among the consultants. The results of consultant D were within the range of plus or minus 5% both for cost rise and fall. As for consultant B, the rates of cost fall were higher than those of cost rise. On the other hand, consultant A shows higher cost-rise rates and lower cost-fall rates. The results of consultant C were divided into those within the range of plus or minus 5% and those showing high rates of cost rise, indicating difference depending on housing projects.

Cost rise due to additional work and cost rise due to quantity increase (Figure 2)
Each consultant knows that the rates of cost rise due to additional work were larger than those of cost change due to quantity change. The consultants tried to offset cost rise from additional work by cost fall from deleted work, but ending up in a cost increase. Cost rises of over 10% or 20% are seen in consultant B and D (first-time renovation). However, there was much variation among the projects of each consultant.

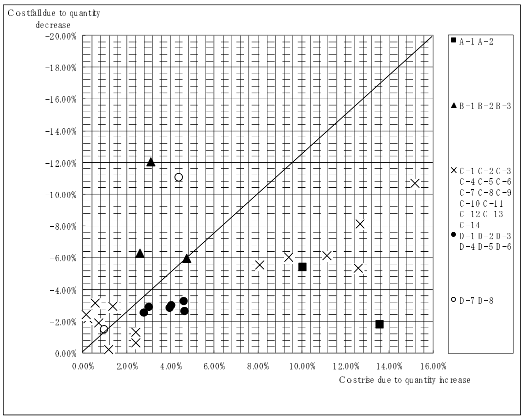

Figure 1: Cost fall due to quantity decrease (Y-axis) and cost rise due to quantity increase (X-axis)

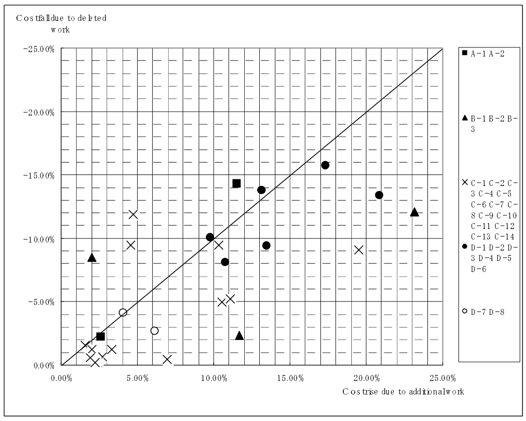

Figure 3: Cost rise due to additional work (X-axis) and cost fall due to deleted work (Y-axis)

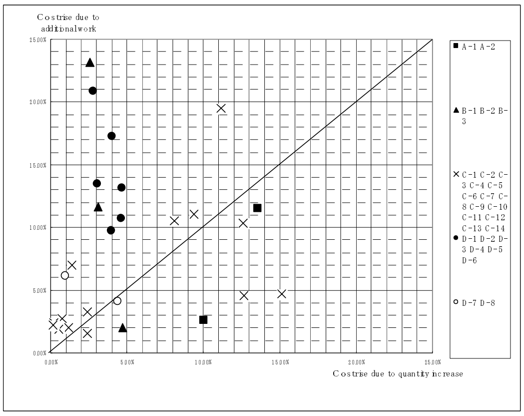

Figure 2: Cost rise due to additional work (Y-axis) and cost rise due to quantity increase (X-axis)

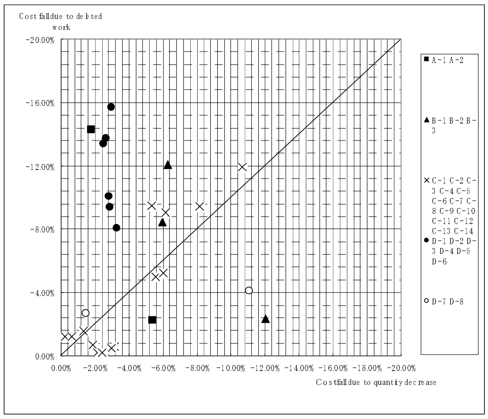

Figure 4: Cost fall due to deleted work (Y-axis) and cost fall due to quantity decrease (X-axis)

CONCLUSION

Renovation projects on housing complexes have uncertain factors at the time of conclusion of contracts, and there is a high possibility of designs and specifications being revised after actual work has started. Therefore, it is necessary to reconsider the forms of contracts, and to include provisional costs and contingencies as with remeasurement contracts.

In order to cope with cost fluctuations, the surveyed renovation consultants, who employ remeasurement contracts, request ordering parties to prepare contingencies ranging from 5% to 10% of the total project costs based on a current experience.

It has also been found that the difference between initial provisional cost and remeasured cost was managed to fall within the amount of contingency.

As for the cost increase and decrease of each renovation item, the difference of each project is large. Especially, the difference of the repair of the outside wall finish (mortar and tile) is large.

However, patterns of the cost change resulting from quantity change varied depending on consultants. The increase tended to be by consultant A and C, which set tentative amounts based on visual inspections and their experience. On the other hand, consultant B's was reduced due to its initial close inspections.

There were also differences depending on whether this was a first- or second-time renovation project.

Cost rises due to additional work had a great influence on renovation costs, and such cost rise depended more on projects than on consultants. It is important to present provisional costs that would correspond to possible additional work.

One method to enhance the accuracy of provisional quantities is to spend money on conducting rigid preliminary inspections. However, some consultants indicated the limitations of preliminary inspections and it is unlikely that this method will gain general acceptance. In these circumstances, the accuracy of quantity estimations needs to be improved through the development of a database of quantity remeasurement reports.

Moreover, although it doesn't make comparative study at present, it seems there is more research based on BQ contract accumulation in countries other than Japan. This is something I will consider to undertake in the future.

558 SITE-MEETING MINUTES FROM 20 COMPARABLE PROJECTS – A QUASI-EXPERIMENTAL EVALUATION OF PARTNERING

Johan Nyström[1]

Building and Real Estate Economics, Royal Institute of Technology, Drottning Kristinasväg 30, 100 44 Stockholm, Sweden

558 site-meeting minutes from 20 publicly procured projects have been analysed to extract differences between partnering and non-partnering projects concerning cost and quality, where time delays, the amount of disputes, financial outcome and contract flexibility have been used as indicators. In order to find the unique effect of partnering and control for other affecting variables, a quasi-experimental evaluation has been carried out. This approach strives to match partnering projects with identical non-partnering projects on every relevant variable except partnering. By trying to provide more tangible data and an improved structure, this study can be seen as reaction to the criticisms of earlier empirical evaluations. The paper has pushed the frontier for partnering evaluations forward concerning method and data. No systematic or general trends can be seen in the material. The result casts a shadow over the positive results from earlier evaluations and suggests that the main contribution of partnering might lie in its intangible effects. Partnering can be seen as something that is intended to improve the general perception of a construction industry, a declaration of a will to change.

Keywords: evaluation, partnering, quasi-experiment, research methods.

INTRODUCTION

The concept of partnering in the construction industry has, since the Latham report (1994), been a topic of discussion both in the business press and in academic circles. Evaluations of the use of partnering most often indicate good outcomes concerning cost, quality and time. The majority of these studies are made in a similar manner, and a number of authors have questioned the quality and neutrality of the evaluations (e.g. Green 1999; Bresnen and Marshall 2000; Bresnen 2007). Based on this criticism, Nyström (2006) set out to improve the method in which partnering is evaluated. The study concludes on some fundamental shortcomings in the current bulk of partnering evaluations. Case studies cannot make statistical generalizations, questionnaire results have a problem with the respondents' self-justification and a comparative analysis is needed for drawing conclusions. The study does not dismiss case studies and questionnaire as scientific tools but makes an argument that the quasi-experiment is more suitable for evaluating partnering. Moreover, the marginal benefit of a quasi-experimental study should be high since there are no conducted before. The data consist of over 558 site-meeting minutes from 20 projects also including tendering documents, contracts, reviews and economic outcome.

[1] johan.nystrom@infra.kth.se

THE QUASI EXPERIMENT

The classical experiment takes a sample of people/objects and then randomly divides them into two groups. One group get some sort of treatment (treatment group) but the other does not (control group) and conclusions can be drawn whether the treatment caused an effect. This is according to Rossi (1989) the most prominent way of doing evaluation. Often when wanting to evaluate some social programme or policy the evaluator does not have the privilege of randomly dividing groups to compare. Instead the treatment group is given, as it appears “naturally” in society. Under such circumstances, Rossi (1989) suggests that the quasi-experiment is suitable. The problem is then to find the best possible match to the predetermined treatment group concerning all relevant independent variables except the one to study. The difference in definition between an experiment and a quasi-experiment is that the latter uses matching instead of random sampling when attaining the control and treatment groups (Vedung 1998). The partnering projects in this study were given, which entailed a quasi-experimental design of the evaluation in order to satisfy the conditions stated in Nyström (2006).

DATA COLLECTION

The list of partnering projects analysed in this study was taken from Nyström (2005a), in which the tendering stage of 18 partnering projects were studied. The number of partnering projects was extended to 22 through contacts with a number a people in the industry, and it is likely that most Swedish publicly procured partnering projects during recent years in the construction industry have been investigated. However, twelve of these projects had to be excluded for the following reasons: three were not completed; in two cases, it was not possible to find a similar non-partnering project; and in seven cases, enough data could not be provided. With 10 partnering projects, the process of finding them comparable non-partnering projects started. This was done by contacting well-informed people, searching the Internet and going through literature. The searching procedure avoided asking the mangers of the partnering projects directly in order to avoid a biased selection. This was successfully avoided in all but two matches. Tendering documents for all projects were collected and studied concerning the matching variables (see below) in order to control for the partnering and the non-partnering projects being comparable. The strategy was to focus on attaining site-meeting minutes, which gives a good picture of how the projects progresses. Site-meeting minutes could also be seen as an easier way of getting representative data compared to interviews and questionnaires. Contracts, economical outcomes, different forms of outcome reports, e.g. final inspections and reviews, were also gathered. In closure, the data gathering focused on collecting site-meeting minutes, but used all interesting material that could be found. All parties involved were contacted and no energy was spared in order to get relevant information on each project.

THE DEFINTION OF PARTNERING AND MATCHING VARIABLES

A critical question in any evaluation of partnering is to identify what differentiates partnering projects from non-partnering projects. Many evaluations are problematic because they do not identify partnering projects on ex ante information. Identifying partnering ex post makes it possible for a partnering enthusiast to wave off negative results from the evaluation by arguing that the project studied were not “proper partnering”. As the project was not a success, it could not have been a real partnering project. To avoid this problem, a partnering project in this study was defined as a project where partnering/partnership/collaboration or something similar is mentioned in the tendering documents. Adopting this approach creates another problem of the partnering projects not being carried out differently than traditional projects, i.e. not incorporating partnering components. The conditions in the tendering might not have been followed. This will be controlled for when getting information about the projects and in the analysis the projects will be grouped in relation to the partnering flower (Nyström 2005b). Partnering is here seen as a “thing” rather than a discourse, which is too vague and imprecise in order to base the definition on ex ante information.

Matching variables

The following control variables were used to match the projects.

The Act on Public Procurement

All clients in this study are publicly owned entities, which are the Swedish Road Administration (SRA), the Swedish Rail Administration (Banverket), municipalities and publicly owned housing companies. These entities are subject to the act of public procurement entailing that all projects in this study were publicly procured.

Type of project

Projects were first divided into maintenance and housing projects. The projects within the same match needed to be of the same type and involved in the same line of work. A deeper analysis concerning the type of work was also required since projects differed within these two broad categories. All of the matches also took into account size, measured both in physical size (e.g. length of roads, number of apartments etc.) and in monetary terms.

Type of specifications

The Swedish construction industry has two kinds of generic conditions facilitating contracting. ABT and AB support design-and-build-contracts and prescriptive contracting, respectively. These conditions can be referred to in the contract, which means that a number of things are regulated automatically. These general contract specifications are developed and accepted by both clients and contractors organizations.

Type of contract

It is safe to say that monetary incentives have an effect on the outcome of projects. There are generally three different contract forms; cost plus-, fixed price- and target cost contracts. However, the payment schemes are often more complicated than these three extremes, which needs to be and was accounted for.

Organizational size

The contractor market in Sweden generally consists of four nationwide firms and small regional ones. Contractor size provides different opportunities for the projects, for example, because of financial muscles, which is why this variable needed to be controlled for. The size of the clients also provides different opportunities.

Geographical closeness

Most types of empirical studies have the problem of controlling for all relevant variables. One way of facilitating this is to choose control variables that can cover a number of circumstances that otherwise would be hard to control for. Matching projects according to geographical closeness takes care of many general variables that might affect the outcome, for example weather conditions. Geographical closeness was interpreted as being in the same Swedish region.

Summary of the matching
The above variables could not be fulfilled in all matches, with contract type being the most important problem. Most partnering projects used some version of a target cost contract, which was hard to find in traditional projects and could not be controlled for. This means that possible conclusion of partnering's effect on outcome cannot be separated from the effect of the target cost contract. In closure, it can be said that 10 matches were found where both twin projects were publicly procured according to the Swedish public procurement act, consisted of the same type of work, had the same type of specifications, were comparable in size and had the comparable clients and contractors. The matching had shortcomings but the database provides an improved foundation to evaluate partnering.

ARE THERE ANY DIFFERENCES BETWEEN PARTNERING AND NON-PARTNERING?

This section will give data on the twin projects concerning the matching variables from above and provide the conclusion of each comparison. The analysis of the material focused on the variables time, contract flexibility, disputes, indicators of quality and economic outcome (see Nyström (2006) for more detailed description). Most projects did provide the financial outcome but since organizations define and report costs in different ways it was hard to make an exact comparison. The strategy was to remove everything but the contractors' invoices to the client for building/maintenance and for additional work in order to make a comparison. This excludes government subsides, overheads, insurance, land cost, etc. Since the material is heterogeneous, the analysis of each match will start by describing the data that the analysis was based on and then provide some information on the matching variables to conclude with the outcome of the comparison. Information on the matching variables will be cut down to a minimum due to lack of space.

Match 1, road maintenance

The material from the two projects consists of 77 minutes from site meetings, where 34 were from the partnering project. The client's project manager, who was the same person for both projects, had written both sets of minutes. This meant that the meetings were structured in a similar way for both projects, with paragraphs discussing how the work developed, keeping track of the budget and quality matters. Tendering documents, the contract and the economic outcome were collected for both projects. Two internal reviews were gathered and two partnering meetings were attended. In 1992, the SRA separated their production unit and exposed them to private competition. Both contractors in this match belong to the SRA production unit but had to compete with private companies for the contracts. The projects are geographically adjacent and have the same project manager from the client. The contract in the partnering project was three years long with an option for another three years (henceforth 3+3), while the non-partnering contract was for six years. A fixed price was used in the non-partnering project, while the partnering project had a target cost with incentives. The analysed material indicates that there were more constructive type of dialogues concerning improvements in the partnering project. These discussions led to some tests of new ideas with positive results. The partnering project showed signs of flexibility with contract amounts renegotiated in both directions. It can be seen that none of the contractors delivered an exceptionally poor level of quality, which would have been indicated by the site meeting minutes. The economic outcome was better in the partnering project and the general conclusion from the analysed material concerning this comparison was that the outcome is in favour of the partnering project.

Match 2, road maintenance
The data in this comparison consist of the minutes of 79 site meetings; 32 from the partnering project. Contracting documents, the contract and economic outcome were also gathered for both projects. The author attended one partnering meeting. Just like the above match, these projects are geographically adjacent and have the same contractor companies, which formally belong to the same organization. The partnering was for three years, while the non-partnering project had a 4+2 contract. A target cost was used for the partnering project and a fixed price for the non-partnering project. Despite the fact that there was more frequent discussion of improvements in the partnering project, this did not lead to more recorded efficiency-enhancing activities. Both projects indicated a willingness to try new ideas and showed flexibility in their way of working. No recorded problems with quality can be observed in either of the projects. Based on the economic outcome and the good communication with the public, the general conclusion on the projects is somewhat in favour of the partnering project.

Match 3, rail maintenance
The analysed material consists of 57 meeting minutes, where 18 were from the partnering project. Both projects also provided the contracting documents and the economic outcome. However, the economic outcome was not detailed enough to make a comparative analysis meaningful. A review was also collected from the partnering project and one partnering meeting was attended. Banverket has the same type of arrangement as SRA with a separated production unit competing on the market for maintenance contracts. The partnering contractor in this match is belongs to Banverket but the non-partnering contractor is a private company. Both projects are geographically close and had comparable type and amount of traffic. A target cost was used for the partnering project and a fixed price for the non-partnering project. The partnering contract was for 5+2 years, while the non-partnering project had a 3+1 contract. In both projects, there was a good relationship between the parties. However, the analysed material revealed that there were fewer disputes in the non-partnering project and all discussions in that case could be handled at the project level. There were more new initiatives taken in the non-partnering project, e.g. discussions with the snowmobile club and the idea of a special budget for preventive maintenance. All variables examined were in favour of the non-partnering project.

Match 4, rail maintenance
The data analysed for this comparison come from the minutes of 41 site meetings; 14 from the partnering project. Tendering documents and the contract were also collected for both projects. The matching variable of geographically closeness could not be satisfied here. More weight were put getting comparable projects concerning type and amount of traffic. The partnering contractor was a private company and Banverket's production unit won the tendering for the non-partnering project. A target cost was used for the partnering project and a fixed price for the non-partnering project. The partnering contract was for 5+2 years, while the non-partnering project had a 3+2 contract. Both projects put great effort into developing the fundamental routines,

which could explain why there was a lack of tests of new ideas and innovations. A difference between the projects can be seen concerning the way questions were solved. The non-partnering project arrived at solutions by discussion, which in most cases, however, was unconstructive. In the partnering project, the dialogue was led by the experienced client. Despite this, there were no major problems in the partnering project and the removal of defects were substantially better, which concludes in favour of the partnering project.

Match 5, road maintenance

The data consist of the minutes of 50 site meetings; 37 from the partnering project. Both projects have also provided tendering documents and the contract. The client in the partnering project wrote a summary of each year, two of those were collected as well as a comprehensive report of the first four years of the project. An external review of the partnering project was also included. The projects are both located in the suburbs of Stockholm and handled the same kind of traffic. Park maintenance was also included in the partnering contract but to a small part. There was a difference concerning specifications in this match. This problem is not so severe concerning maintenance and both projects were based on performance contracting, which entailed contractual deviations from the general specifications. Both projects had a fixed price and the partnering project had a contract for 5+2 years, while the non-partnering project had a 2+2 contract. The lack of informative material in the non-partnering project complicates this comparison. However, the material for the non-partnering project did not reveal any disputes, which were current in the partnering project, according to the site meeting minutes. The problems in the partnering project were mainly related to administrative issues while the actual maintenance ran smoothly, with a fulfilled level of quality. The analysed material reveals more problems in the partnering project.

Match 6, municipality house maintenance

The material analysed for the partnering project consists of the minutes of 106 site meetings, a questionnaire on customer satisfaction and an external review. The minutes of 15 site meetings and a manuscript from an in-depth interview with the project manager were provided from the non-partnering project. The projects in this match are geographically separated but are both situated in average sized cities in Sweden. Both projects had a fixed price and the partnering project had a contract for 5+2 years, while the non-partnering project had a 3+2 contract. Both projects were procured for the first time and both contractors had problems fulfilling their obligations in the first year of the contract. An explanation might be found in the large extent of performance contracting. This gives the contractor many degrees of freedom, which they might not have been ready for. The problem in the partnering project was mainly a lack of fulfilment of some of the administrative duties, but there are no indications of the contractor not performing their practical duties. There were more severe problems in the non-partnering project, with the contractor not fulfilling administrative duties and performing the maintenance poorly. The quality level in the non-partnering project, by all indications, must be interpreted as being lower. Despite problems in both projects, the partnering project emerges as having the least amount of problems.

Match 7, water supply and sewage maintenance

The data consist of the tendering documents and the contract for both projects. The minutes of 54 site meetings were gathered, with 44 from the partnering project. Two external reviews were provided from the partnering project. An interview was also conducted with an employee of the contractor that had experience of both projects. The projects are both located in the suburbs of Stockholm and the contractor is the same firm for both projects. A cost plus contract was used in the non-partnering project and a fixed price in the partnering project. The partnering project had a contract for 9+2 years, while the non-partnering project had a 3+2 contract. Analysing the material produces a picture of more problems in the partnering project, with the big dispute on how to interpret the contract affecting the relationship in the project. The non-partnering project seems to run well without any major problems, which might be explained by the attention to clarity between the parties and a better-defined contract than in the partnering project. Despite that, the partnering project improved over time, mainly with the settlement of routines. However, the result of the comparison concerning disputes and flexibility points to an advantage of the non-partnering project.

Match 8, road maintenance

The material analysed in this match consists of the minutes of 39 site meetings. Twenty-nine of them are from the partnering project, which also provided tendering documents, the final inspection report and three external reports. Tendering documents, the contract and a review with a follow-up meeting were collected from the non-partnering project. The municipalities in this match are geographically separated. Tendering and the day-to-day activities in the partnering are not handled directly by the municipality but by a company that is to a 100% owned by the municipality. The difference between the two client divisions is not big and does not interfere with this matching. A cost plus contract was used in the non-partnering project and a fixed price in the partnering project. The partnering project had a contract for 5+2 years, while the non-partnering project had a 3+2 contract. The analysed material indicated some fundamental problems in the non-partnering project. These problems were, however, approached by both parties with serious intentions of change. Discussions on improvements in efficiency and a curiosity about new ideas were more frequent in the partnering project, but not many actual improvements were recorded. The partnering project also indicated more flexibility in the contract. Fundamental problems in the non-partnering project, which could not be found in the partnering project, conclude this match in favour of the partnering project.

Match 9, flats

The data analysed consists of minutes of 79 site meetings, with 68 from the partnering project. Both projects have also provided tendering documents, economic outcome and the final inspection report. These projects are geographically separated. Evaluation of the tenders in the partnering project was only based on soft parameters. The tendering was only based on soft parameters and the budget was developed together since no price was delivered in the tendering process. A cost plus contract was used in the partnering project and a fixed price in the non-partnering project. Design and build contracts in comparison to prescriptive contracts are thought not to require much client involvement. The non-partnering project was an example of when this works. Client involvement went no further than reminding the contractor of logos in the shower, and the construction was done satisfactorily without much involvement on the part of the client. In comparison, the partnering project had a lot of client involvement. This has been expressed as a positive feature in reports from the project and the client-driven partnering process did actually lead to some improvements from the contractors and subcontractors. Despite different methods, both projects must be characterized as good and no significant difference can be seen concerning construction time. The number of faults in the final inspection and economic outcome, however, are decisive in favour of the non-partnering project.

Match 10, flats

The analysed material consists of the minutes of 26 site meetings, with 15 from the partnering project. Both projects provided the final inspection and the economic outcome. A review and minutes from the client's board meetings concerning the partnering project were also included in the analysed material. The projects in this match can derived to the same region of Sweden. A cost plus contract was used in the partnering project and a fixed price in the non-partnering project. None of the projects ran into any major problems. The big difference concerned client involvement in the partnering project, which could be interpreted as a disturbance for the contractor or as an effective monitoring mechanism, e.g. about the choice of materials. Given the comprehensive data it is most likely that client involvement had negative effects by delaying decisions, especially since the client already had a chance of doing this ex ante. The partnering project did not perform poorly in comparison with the non-partnering project, however – both had the tenants moving in on time and for a similar cost. The non-partnering project did give some indications of more flexibility, with suggestions being adapted more easily than in the partnering project. There are indications of the partnering project being cheaper and faster, but the non-partnering project seemed to be more flexible. No difference can be concluded regarding quality. Hence, no clear difference in outcome can be observed in this match.

ANALYSIS AND DISCUSSION

The comparisons of the projects presented above conclude in favour of the partnering project in five out of the 10 matches, as seen in Table 1.

Table 1: Summary of evaluations per match

	Overall	Quality	Lowest cost	Contract flexibility	Avoidance of disputes	Time*
Match 1	Partnering	No difference	Partnering	Partnering	No difference	-
Match 2	Partnering	No difference	Partnering	No difference	No difference	-
Match 3	Non partnering	No difference	-	Non-partnering	Non-partnering	-
Match 4	Partnering	Partnering	-	No difference	Partnering	-
Match 5	Non partnering	No difference	-	No difference	Non-partnering	-
Match 6	Partnering	Partnering	-	No difference	Partnering	-
Match 7	Non partnering	No difference	-	Non-partnering	Non-partnering	-
Match 8	Partnering	Partnering	-	Partnering	Partnering	-
Match 9	Non partnering	Non-partnering	Non-partnering	Partnering	No difference	No-difference
Match 10	No difference	No difference	No difference	No difference	No difference	Partnering

* not applicable for maintenance

- indicates no data available

No general trend can be seen in the outcome variables above. A distinction can, however, be made among the matches based on how partnering is interpreted and implemented in the specific project. Identifying partnering projects from what is stated in the tendering documents avoids the problem of only focusing on successful partnering projects, but it entails the potential dilemma of evaluating "partnering projects" carried out without the usual partnering components. A solution to this problem is to use the partnering flower from Nyström (2005b) to ascertain that the "partnering" projects evaluated really included partnering components. In order to be classified as a "real" partnering project, a project should then at least include common goals. Examining the partnering project in the matches above, it can be concluded that although five projects mentioned partnering in the tendering documents they did not really include the central partnering components in the actual work. Observe that this exclusion is not based on the outcome but on which variables that were actually included. Matches 1, 2, 3, 8 and 9 included common goals at least and can, given these criteria, be considered as partnering projects. Even with the focus on this more homogenous group of "real" partnering projects, no overall trends in the outcome can be seen in the material.

Discussion

A review of partnering evaluations (Nyström 2006) showed that the most frequent outcomes of partnering were improving communication, improving the relationship between parties and better quality. These effects in favour of partnering could also be found in some of the matches analysed, but not to a systematic and general extent. Nyström (2006) argues, from an economist's point of view, that cost and quality are the variables that create value. To this can be added the comments on the absences of tangible effects of partnering in Gransberg *et al*. (1999) and Beach *et al*. (2005). Another related concern is the way in which earlier studies have been conducted by providing mostly anecdotal evidence (Bresnen and Marshall 2000, Bresnen 2007). This paper has tried to fulfil the demands of these critics and pushed the frontier for partnering evaluations forward. The lack of a common systematic and general trend in the evaluation casts a shadow over the earlier evaluations due to the fact that this study was conducted with better data and with an improved method, even if the number of observations is small. Intangible effects, like more fun at the workplace, a more attractive profession, an improved picture of the construction industry, etc was deliberately neglected in favour of more tangible effects. However, a reasonable question is whether partnering has its greatest impact concerning cost and quality and other tangible effects. Partnering in the UK and Sweden emerged as a reaction to critical governmental reviews of the construction industry. An appealing idea is that partnering could be seen as something that is intended to improve the general perception of a construction industry, a declaration of a will to change. Both the clients and the contractors in the UK and Sweden have had a common interest in achieving this, in order to e.g. attract a qualified younger generation to the sector. Partnering is likely to disappear as a specific term in time and many of its components will be included in "traditional projects" and become the natural way of working.

CONCLUSIONS

In this paper, notice has been taken of the arguments put forward by critics of earlier partnering evaluations and the improved methods that have been developed in Nyström (2006). The conclusions there have been applied in this study by using a quasi-experimental approach to the evaluation of partnering. One, not very surprising, finding is that half of the projects that mentioned partnering in the tendering documents did not include partnering components during the project. Removing these projects, still no general trend concerning the outcome in terms of cost, quality, contract flexibility, avoidance of disputes or construction time can be seen. This result can be contrasted to earlier studies showing optimistic outcome of partnering based on less detailed data and with an inferior method compared to this study. The main contribution of partnering might lie in its intangible effects, where the concept can be seen as a declaration of a will to change and improve the general perception of an unhealthy construction industry.

PARTNERING ISSUES: THE EVALUATION OF LOCAL AUTHORITY ADOPTION OF PARTNERING IN SCOTLAND

Bassam Bjeirmi,[1] Paul Begg and Jonathan Scott

The Robert Gordon University, The Scott Sutherland School of Architecture and Built Environment, Garthdee Road, Aberdeen, AB107QB, UK

This paper focuses on the practical implementation of partnering arrangements within local authorities. The construction industry is the subject of ongoing criticism for poor performance on all types of construction throughout the construction process. Analysis of the construction industry highlights that historically there has been significant fragmentation and a poor record in terms of quality, waste, financial claims, safety and efficiency. Arguably, this is caused by the lack of communication throughout the construction process. This has resulted in calls for changes to the procurement methods and for the adoption of new processes that aim to improve construction performance through communication. Partnering is one such procurement method that claims to aid discourse, increase productivity, lower costs and provide stability and open accountability for each stage of the construction process. It offers an alternative to the widely used traditional procurement process. This paper investigates the issues associated with the implementation of partnering agreements within local authorities in Scotland. After discussing the reasons behind the development of partnering arrangements and the expected benefits, it presents a number of issues identified as a result of a research project into several partnering projects. These issues are prevalent during all the stages of the construction process with one of the main issues being the process of setting up the partnering arrangement including the criteria used for the selection of partners. Other issues include the role and the attributes of the partnering facilitator, the effect on project design, social training required and the role of the client and his/her quantity surveyor within the partnering arrangement. These issues have affected the success of the partnering arrangement.

Keywords: contractor selection, facilitator, partnering, project management, value management.

INTRODUCTION

Construction industry literature has been exhausted with investigative reviews and research on the state of the construction industry and its processes. The remit for the Simon report in 1944 was to produce ‘recommendations to ensure that building organization shall be so improved as to provide the best possible service to the nation while maintaining an efficient and prosperous industry’. Subsequent reports such as “Constructing the Team” by Sir Michael Latham (1994) and “Rethinking Construction” by Sir John Egan (1998) had similar remits. Investigation and analysis of the traditional methods of construction describe a process that is often fragmented, of low quality, high waste and high claims (NAO 2001). Consequently, the

[1] b.bjeirmi@rgu.ac.uk

construction industry consistently under-performs on issues such as cost, quality, value, time and function (Fisher and Green 2001).

One of the conclusions of the 1944 Simon Report was the need for ‘complete collaboration between building owner and contractor’. This is a repeating theme in subsequent reports resulting in recommendations for the adoption of new processes that, it is claimed, will improve the performance of the industry (Egan 1998). It is suggested that improved collaboration can be realized through partnering and, consequently, there has been increased interest in this form of procurement that has been seen by many as an important way of improving construction/project performance. Benefits from partnering are claimed by Sanders and Moore (1992), Abudayyeh (1994), ECI (1997), Black *et al*. (2000) and Drexler and Larson (2000) and NAO (2001). In particular, Abudayyeh (1994) notes that partnering offers a ‘win-win’ scenario for the client and contractor by “[improving] problem solving and fostering synergistic teamwork”.

There is no doubt that in certain situations partnering has been very effective in developing better working relations and in producing good quality projects, particularly in the form of strategic partnering. Alternatively, on other occasions, it has failed to be an improving factor and has produced lower value projects resulting in higher costs. This dichotomy is highlighted by Fisher and Green (2001) and is echoed by Bresnen and Marshall (2000) and Cartlidge (2002).

Public bodies are constrained by the necessity to be transparently accountable for the expenditure of taxpayers’ money (ECI 1997). Consequently, there are administrative procedures where committees approve estimates and tenders and any potential overspend during construction requires to be reported and explained. A traditional tendering system assists in meeting these criteria by avoiding commercial arrangements that might be seen to be open to possible corruption. Against such a background, it is likely that the implementation of partnering by a public body, whose procurement has historically been pursued along traditional lines, would potentially raise more issues in relation to partnering implementation than within the private sector.

Ng *et al*. (2002) refer to only two notable pieces of literature on partnering in the public sector and these suggest that, paradoxically, administrative procedures in this sector designed for accountability often work against open relationships with contractors. This can jeopardize the partnering objectives originally established for the project, which would generally emphasize open accountability.

Additionally, there is a lack of information describing the issues involved in the intricate, day-to-day management of partnering arrangements. In particular, Fisher and Green (2001) note that there is little benchmarking of the process in order to understand the relative effectiveness of different strategies.

The aim of this paper is to identify the main issues associated with the implementation of partnering arrangements within local authorities and evaluate them against the theory as determined from the literature. This will be achieved by an investigative study into a series of projects to identify issues throughout the process. Although these issues have not resulted in any formal challenging of value or accountability in any of the projects studied, they were consistently present and constitute a significant debate in relation to partnering in local authorities.

RESEARCH METHODOLOGY

After an initial literature search and a pilot study investigation, it became clear that there were a number of issues that affected partnering relationships in the local authority environment. These issues involved contractor selection procedures, training and facilitation, the effect on the quality of design, dealing with changes to the work and the roles of key parties. A series of interviews were then conducted to investigate how the issues affected specific projects. A cross-case analysis was then used to compare each case studied.

The data reported here is derived from the investigation of six case studies of relatively large-scale partnering projects undertaken by experienced local authority clients. Three of these projects were already completed, two were ongoing at the time of the investigation, and the last was in its early phases where negotiation to reach an Agreed Maximum Price (AMP) was still in progress. All were building projects with a high degree of complexity and ranged from 2 to18 million pounds. Seven professionals were interviewed consisting of two clients, three architects and two facilitators.

The evaluation and appraisal of the issues is based on qualitative data. In each case, a semi-structured interview based around a number of key themes was carried out with each of the team members. Interviews were conducted over a six-month period and covered all aspects of initiating and implementing the partnering projects.

All questions were open-ended questions, which allowed for further elaboration and discussions. The resultant interview transcripts were coded manually to capture data on common themes, issues, unique circumstances and events across the cases.

PROBLEMATIC ISSUES IN PROJECT PARTNERING

An analysis of all projects was carried out to identify the main issues facing project partnering and evaluate how these issues affected the partnering arrangement in local government construction projects. A total of five categories of issues were identified as follows:

- Selection of the partnering contractor.
- Partnering training.
- Pre-construction issues.
- Construction phase issues.
- Key roles.

Selection of the partnering contractor

Black *et al.* (2000) highlight a report which notes that “Partnering implies selection (of partners) on the basis of attitude to team-working, ability to innovate and to offer efficient solutions”. However, some commentators suggest that partnering does not need to rely solely on openness, good communication and teamwork to produce value but may also need an element of competition (NAO 2001). Additionally, Baxendale and Greaves (1997) argue that competition and partnering are compatible in certain circumstances.

On the other hand, Ng *et al.*’s (2002) findings state that the use of any competitive tendering arrangement was the origin for many subsequent problematic issues including the level of commitment of stakeholders to the project partnering arrangement. In the cases that he studied, the profit margin was very low and cost control during the project was difficult with regard to defending the margin. As a result, the contractors would systematically change their priorities from the project partnering arrangement to a ‘‘win–lose’’ profit protection attitude (Ng *et al*. 2002).

Further information on the selection of partners in local authority scenarios is provided by ECI (1997). This suggests that it should be based on compatibility of the partners, their experiences, reputation and past relations. Different partnering arrangements that can be used by the public sector, which are tailored to avoid contravening the anti-competitive legislation, are highlighted. Much of the literature advocates the selection of the main contractor on an analysis, which addresses both the ‘hard’ issues (for example, finance) and the ‘soft’ issues (for example, environmental considerations) (NAO 2001; OGC 2003).

However, local authorities must justify expenditure of taxpayer’s money, which means that they must open up construction work to competitive tender on a project-by-project basis and ensure that the main contractor is bound by contract. This does not inherently encourage long-term relationships as advocated by CIC (2005). Local authorities can also be restricted by EC anti-competitive rules. The result is that the extent to which they can use one contractor, and therefore partnering in its pure form, on a series of projects without intervening competition, is limited.

In the cases studied, a selection process had been designed which ensures that the necessary transparency is retained. The contractors who initially respond to an advertisement inviting interest are required to complete questionnaires on commercial standing, specific experience and business methods, with the latter specifically relating to attitudes to partnering. The form is required to comply with EU rules for projects over £3.6 million. A small number of contractors then continue to the next stage of the selection process.

This second stage is based on a selection interview model developed by the Scottish Executive (2004) where the contractor answers questions that are weighted in terms of price and quality. These weightings can be adjusted as appropriate but were generally 60/40 in relation to price/quality respectively in the cases studied (price is based on the contractor’s on-costs submitted for the prime costs of construction). Each contractor’s answers are scored by a selection panel, which is made up of client and consultant team representatives. The scores are analysed by software that rates each contractor, resulting in a preferred contractor. The process retains transparency and provides a degree of competition on on-cost, but not on the prime cost of the work.

The third stage of the process is negotiation to agree the Agreed Maximum Price (AMP). This stage is potentially adversarial since it involves costing the work to set this price. In the absence of significant changes to the project, the contractor is paid on a cost plus basis until this maximum is reached, but not beyond. The contractor and client fulfil the formal contractual requirements by concluding a JCT Prime Cost Contract with sharing arrangements for savings.

There is an issue here as to whether this is partnering in the true sense, as agreeing the AMP has the potential to become an adversarial process that does not seem to encourage the trust and confidence that, the literature emphasizes, is required.

Furthermore, the AMP depends to a substantial degree on subcontractors and suppliers’ quotations. This means that the competitive element has effectively been moved down the supply chain to be managed by the main contractor. This has some similarities to management contracting where the management contractor receives a percentage fee from a client for pre-construction advice services and then for managing works contractors on site. Is there a necessity, therefore, to spend time and money on the complicated contractor selection process, training, the provision of a facilitator, negotiations, etc., when the competitive selection of a management contractor might be more appropriate?

In some situations, the selection process is not as formal as that described above and ranges from negotiations with a number of contractors over issues of cost and partnering attitudes, to the direct appointment of a known contractor based on historical performance where time is a critical constraint. Whilst, as Cartlidge (2002) highlights, this indicates that partnering is an approach that is flexible to suit specific circumstances, it also raises issues of transparency and accountability.

Partnering training

Cartlidge (2002) notes that trust is not found in abundance in the construction industry but it is crucial within and between partnering organizations for the process to work (ECI 1997). NAO (2001) offers a number of practical case studies, perhaps over emphasizing the positive aspects of partnering, but nevertheless emphasizing the need for social training for staff. All the literature states that partnering is a collaborative agreement based on the need for communication and trust. In an industry where this is not prevalent (Latham 1994; Egan 1998), this requires training. NAO (2001) and ECI (1997) suggest training methods that start with the client but should cover all members involved in partnering. Training workshops are essential and should be used throughout the project. These should focus both on teamwork, communication and trust and also on the practical needs of construction projects, such as conflict resolution and the need for measurement of progress (ECI 1997; Critchlow 1998). The theory is that over time trust will build up between parties, particularly with strategic partnering but also with project partnering. Bresnen and Marshall (2000) caution that to suggest partnering will change attitude in the construction industry, however, is too simplistic.

The training in the cases studied involved a single generic workshop for the Architectural Services Department and a few invited contractors that took place around ten years ago. It was organized as a result of the Latham recommendations and was mainly an information session on the principles of partnering and its benefits. Beyond this, there have been no formal training sessions. Facilitators had not received any specific training. On individual projects, a partnering workshop is held after agreement of the AMP and all the parties, including the client, attend this. There is a case for partnering workshops prior to agreeing the AMP since this is a period of negotiation that has the potential to become adversarial. However, there is an issue with the fact that the contractor has not been formally appointed prior to agreeing the AMP and therefore an event that directly implies that he has been appointed is problematic.

The training in the projects studied did not appear to continue after the initial workshop and the important position of facilitator seemed to be neglected in relation to training. In general, training did not seem to comply with the recommendations from the theory. Organizations need to use existing staff and all the participants in the above cases had extensive experience of traditional, adversarial project management. There is an important issue, therefore, concerning how the necessary attitudes for dealing with the traditional adversarial system of project administration could be transformed into attitudes appropriate for partnering with a single workshop.

Pre-construction issues

In 1962, the Emmerson Report into the construction industry advised that 'in no other important industry is the responsibility for design so far removed from the responsibility for production'. All the literature suggests that there will be increased quality in the overall design of a project that uses partnering. This stems from the early integration of the design process into the partnering arrangement, ensuring that design is not a separate exercise done in isolation. Fisher and Green (2001) suggest that partnering leads to better innovation in particular. This stems from the input from the various partners into the assessment of the design, particularly in relation to buildability, during the early stages of the process. This minimizes design changes during the construction of the project, which can lead to significant cost increases (NAO 2001). Cartlidge (2002) emphasizes that partnering increases the amount, reliability and speed of information that can inform a design thereby avoiding changes later in the construction phases. This is particularly the case with information from parties further down the supply chain.

ECI (1997) also notes that improved quality in the finished product results from partnering, which is achieved through quality management systems, which all the literature encourages throughout the project. However, a partnering team that is committed to a particular design should not significantly change this design but concentrate on the problem solving aspect of how to construct it. A contractor involved in a partnering scheme, therefore, should not unilaterally change whole aspects of a design on the basis of reducing risk or finance (ECI 1997).

The process of agreeing the AMP, which involves the contractor's quantity surveyor, the client and his/her quantity surveyor and the designers, raises the important and sensitive issues in relation to design. Ostensibly, the task is to ensure that the client's requirements are met within the available budget. However, clients and designers perceive that the process drives inevitably towards paying premium rates for the simplest building to construct – a box in other words. Negotiations are often carried out using costs from previous projects as a basis, but clients have the perception that where elements of the new project are different, the costs of these elements generally seem to be added to and not substituted for the previous costs. Also both designers and clients tend to feel that the pressure is on them to defend the design or to accept cost-cutting design changes, which may impair the operational effectiveness of the facility, rather than on the contractor to defend his prices. The process can become one where the contractor simply advises continually that the design is too expensive and asks for cheaper alternatives. The contractor has a perceived interest in maximizing the AMP so confidence in the system depends on careful scrutinization of costs by the client's quantity surveyor. The process can be 'tense', although it is generally without animosity, and it needs strong input from the client's quantity surveyor and the facilitator.

There is also an issue concerning the level to which the design requires to be complete by the negotiation stage. For maximum benefit, the contractor's input to the design should be at an early stage. However, this is not realistically possible before the AMP has been fixed because the contractor has not been formally appointed. The need to fix the AMP requires that there is sufficient design to do this effectively and a value of 80% complete was the quoted figure for the cases studied. Failure to do this leads to a situation where later design requirements will result in increases in the AMP and potential cost overruns. This again tends to undermine the value of partnering since improving the quality of design; meeting the budget and reducing the period required for the construction process are not necessarily mutually compatible.

There is also a perception that the quantity surveyors involved in the process of fixing the AMP are driving design decisions on the basis of finance and time, with the result that the designer's authority is being reduced without diminishing his/her responsibility. The perceived necessity for speed can lead to poorly thought-out design decisions, which cause consequential problems and are therefore not necessarily more cost-effective in the long run.

There were clearly significant and sensitive issues in the pre-construction phases of the projects studied which do not sit comfortably with the theory of partnering, particularly in relation to design and the control of cost.

Construction phase issues

The partnering literature focuses on the selection phase of construction, which is admittedly the key area, being the foundation of any partnering arrangement. The ECI (1997) explains, however, that after the selection process is completed it is important to keep the process running. The OGC (2003) adds that all methods of communication, risks and evaluation of work during construction should be assigned prior to construction beginning.

Egan (1998) noted that the lack of quantitative information during construction was a major factor that affected the success of future projects. Workshops should be held by the facilitator regularly to keep up to date on the performance of the project in relation to the objectives agreed to prior to the start of construction in order to show whether improvements could be made and to meet to avoid any disputes. During the construction process, all members are encouraged to be honest and forthright with any issues to avoid future conflict (ECI 1997). These issues should be summarized in a monthly performance evaluation report.

The NAO (2001) highlight that the construction phase is essential to the success of a project and the appropriate project management framework is required. This, again, needs to be clearly set out prior to the commencement of construction (NAO 2001). The lack of clear roles and responsibilities in a partnering arrangement could lead to confusion and projects being late or over budget (NAO 2001).

In general, clients perceived that there were fewer problems with the practical side of construction in partnering projects and that those which did arise were easier to resolve. Quality was perceived to be better with respect to meeting the client's requirements but there were still issues with respect to budget control, programming, risks, financial responsibility for design/specification changes and use of contingency allowances.

It must be emphasized that the AMP is not a fixed sum. Because the design is not complete when the AMP is agreed and ideas are still being developed as the project proceeds, the AMP can change. There is a clear perception with clients and designers that risk generally lies with the client with the result that the AMP always increases and the project programme is always extended. There is an issue concerning how this integrates with the spirit of partnering where the emphasis should be on the parties to find solutions jointly to minimize cost.

There is also an issue with defining whether changes to the project or the occurrence of risk events should result in changes to the AMP or whether they are already included in the AMP. In terms of changes, the general rule seems to be that trivia are ignored but the definition of what constitutes 'trivia' is not clear and this leads to uncertainty on the part of the different parties, especially the client. In addition, the AMP generally includes a 5% contingency allowance. However, it is unclear whether this is to allow for risks attributable to the client, or the contractor, or both.

Overall, the view is that if the money available is enough then there will be no major problems. Latham (1993) explained that, "where the money payable is inadequate, vital trust will be absent and the project will always suffer through lack of teamwork and adversarial attitudes." Facilitators on the projects studied were of the view that there would be a major issue if a project went seriously wrong financially, and that this would inevitably lead to a protracted contractual dispute.

Key roles

Role of the facilitator

CIC (2005) states that, "once the selection panel has been assembled a coordinator should be nominated", this being the facilitator who is responsible for the smooth running of the project throughout its duration.

The facilitator should be knowledgeable about the partnering process and experienced in the field of construction. CIC (2005) notes that the facilitator is the coordinator of the workshops between the various parties involved. The ECI (1997) further note that his activity is only a passive one and that the facilitator is there only to facilitate discourse. OGC (2003) describes the facilitator as responsible for bringing the parties together and leading workshops "to set out the principles, attitudes and ideas that will characterize the arrangement". The facilitator is involved primarily after the selection of the preferred contractor although on many occasions, as was the situation in the cases studied, the facilitator can be a member of the contractor selection panel.

The role and the skills required of a facilitator was one of the major issues creating confusion among those involved in the partnering arrangement. From the facilitators' point of view, it was debatable whether he/she should be a project manager or a facilitator and they found it difficult to differentiate between these roles. Neither of the facilitators interviewed had received training on what the role should involve and where their authority and responsibility lies. This created confusion, not only for the facilitator, but also for the rest of the team.

Also in the cases studied, the other parties had an expectation that the facilitator would function as an independent adjudicator and were critical if this did not appear to be the case. Facilitators saw their role variously as a form of 'hands off' project manager to guide the project along or as a 'chairman of a board' who listened to everyone's views before coming to a decision on their behalf. None of these concepts of the role seems to conform to the theory. This reinforces the issue in respect of the need for training for facilitators as to the nature of their role and in the social skills required to carry it out.

ROLE OF THE CLIENT

Black *et al*. (2000) and the ECI (1997) state that one of the main factors in introducing partnering successfully is to ensure that the senior management in the client's firm is committed to the process. Egan (1998) recommends more involvement from the client, recognizing that its absence may exacerbate the misunderstandings that cause disputes. ECI (1997) suggests the role of a ‘champion’ in the client organization to ensure that each member of the staff is familiar, and is in favour of, the adoption of partnering. The Champion is not necessarily a construction professional, but will know partnering intimately and will also take part in the ‘social training’ of the partnering team members. However, it is important that the changes involved in adopting partnering are ‘deep enough’, otherwise partnering will not take root (Bresnen and Marshall 2000). In essence, the client should be more involved in the construction process in order to encourage trust between the various parties in the partnering team (NAO 2001). As has been noted, it is the client who will accrue the greatest benefit from this process and it is important, therefore, for the client to be fully conversant with forward thinking and innovative partnering procedures.

The clients in the case studies were involved in the process throughout. However, the nature of that involvement was not to the extent suggested as desirable by the literature. In the pre-AMP phase, the clients’ main aim was to ensure that design changes did not have adverse operational consequences, e.g. changes to heating systems, security systems, etc. During the construction phase, the client attended the partnering meetings for the same reason and to be familiar with project progress and cost. However, beyond this, the management of the process was conducted by the facilitator and the professional services. There is an issue here in relation to the extent of client involvement and the possibility of the facilitator being appointed by the client, although there were reservations that the client would not have sufficient technical knowledge or experience of the construction process to fulfil this role.

ROLE OF THE CLIENT’S QUANTITY SURVEYOR

The role of the client’s quantity surveyor in relation to value for money became apparent as an issue within the partnering arrangements studied. In traditional contracting, the bill of quantities is a form of assurance to the client that a certain level of value is being achieved. With partnering, the early involvement of the contractor means that the project will not be fully billed and therefore the negotiation of the AMP takes place without complete information, thereby creating additional risk. Theoretically, the contractor’s prices should be transparent and the client’s quantity surveyor should be able to trust them. Nevertheless, there was a perception by clients and designers that this trust could be misplaced and that the client’s quantity surveyor should question the contractor’s prices more thoroughly to ensure value for money. There is an issue about the extent to which this may undermine the spirit of partnering, however.

CONCLUSIONS AND RECOMMENDATIONS

This paper has investigated the issues associated with the implementation of partnering agreements within local authorities in Scotland. Ultimately, the objective must be to have satisfied clients and in all the cases studied clients considered that partnering was beneficial, particularly on difficult projects. Practical problems during the construction phase are easier to solve and the ability to finalize the costs quickly on completion is particularly welcome within the local authority environment. It is also possible to moderate potentially higher prices when the construction sector is busy. Furthermore, the construction phase of projects is also generally perceived as better. However, there are still substantial issues with the form of partnering adopted which, if not addressed, may be sufficient to result in it falling from favour. These issues relate predominantly to financial arrangements, design and training.

The negotiation of the AMP had the clear potential to undermine the spirit of partnering and this was closely connected with the perception by clients and designers that the quality of design would be eroded unless they took a firm stance at this stage. Again, this does not seem to correspond with the collaborative philosophy of partnering, but accountability constraints on government bodies need to be considered. Once the AMP has been agreed, there is a lack of clarity as to the precise extent of what is included in it and when a change to the project should result in a change to the AMP. Clients have the clear perception that they are carrying all of the financial risk. Nevertheless, they are positive about the value of partnering in general terms but are less so about the control of the cost element. In particular, it is difficult to reconcile the role of the client's quantity surveyor during negotiation of the AMP with the philosophy of partnering. Partnering should be a collaboration and prices submitted by a contractor should be transparent. However, there is a perception that a lack of in-depth examination of these prices may result in reduced cost control.

There is a lack of ongoing training for all parties and training for the important role of facilitator is absent. This is a particularly important issue because the facilitator has little real power and depends on social skills to achieve results.

Whilst the clients are involved throughout the process their role tends to be to ensure that design changes do not impair the operational effectiveness of the finished project and to monitor overall cost. There is a debate around the issue of clients adopting a greater leadership role in the partnering process to the extent of providing a 'partnering champion' or even taking on the role of facilitator.

Ultimately, there is a question as to whether the existence of the issues identified suggests that the arrangements in the cases studied do not, in fact, amount to true partnering.

It is submitted that if partnering is to continue as a preferred procurement route then consideration should be given to abandoning payment of the contractor by means of a fixed AMP. A true partnering philosophy of collaboration to achieve best value should be followed. Significant training would be required to achieve this. Alternatively, if the constraints on the local authority do not allow full partnering, then consideration could be given to using a form of management contracting. This would allow useful early input from a contractor without the perceived erosion of design quality and would also maintain a transparent competitive element for the work itself.

RESOURCE ALLOCATION IN CONSTRUCTION PROJECTS: THE CONTRIBUTION OF RESOURCE-CONSTRAINED PROJECT PLANNING MODELS

Frank Schultmann[1] **and Nicole Sunke**

Chair of Business Administration, Construction Management and Economics, University of Siegen Paul-Bonatz-Str. 9-11, 57068 Siegen, Germany

This paper puts emphasis on the application of modelling for resource allocation of a variety of construction project planning problems and shows a recommended future path for the development of construction project planning. A resource classification scheme indicating the degree of planning effort for different types of resources is proposed and a taxonomy for project planning models as well as a generalized resource-constrained project scheduling model (RCPSP) are introduced as theoretical basis. Based on the RCPSP, several particularities for construction projects, of which some of them have already been addressed separately in literature for similar planning approaches, are discussed. Among these are different construction project's objectives, different constraints like the availability of construction workers and machinery, and different alternatives or modes to perform activities as discussed as time-resource and resource-resource trade-offs.

Keywords: construction planning, project management, operational research, models.

INTRODUCTION

Enterprises of the engineer-to-order sector, such as construction and engineering firms, are usually operating on a project level and are usually organized as matrix or project based organizations. Planning situations in matrix and project based organization are typically unique and differ from project to project. Additionally, more than 90 percent of these firms face a situation where they have to cope with more than one project at a time (Payne 1995: 163) competing for limited resources. The performance of a project, here understood as the adherence to delivery dates and budget as well as stakeholder satisfaction, is significantly influenced by the quality of the project management. Project management comprises the conception, definition and planning of a project as well as its execution and termination. Project planning is also described as project structuring, which consists of project scheduling and resource allocation. Whereas the aim of project scheduling is to determine start and finishing dates of project activities, the objective of resource allocation is to ensure the sufficient and timely supply of usually scarce resource for project execution (Klein 1999).

The planning effort of projects rises as the complexity of the project increases. The complexity of a project is determined by, for example, the number of project participants, the number of project stakeholders, the time span of the project, the number of project activities and the diversification of the project environment and

[1] frank.schultmann@uni-siegen.de

other restricting factors, such as the regulatory framework, for instance for waste treatment in construction.

Usually, common project planning approaches such as the Critical Path Method (CPM), the Metra Potential Method (MPM), as well as the Program Evaluation and Review Technique (PERT) focussing on time oriented objectives are used in practice. Their main advantages are the explicit representation of activity relations and their easy application. Paradoxically, however, even though a lot of scheduling procedures have been developed and tested for construction purposes, the scarceness of resources is often either neglected in scheduling approaches or seen as of minor importance in initial schedule generation in practice. In addition, methods for particular project types, such as the line of balance (LOB) method for linear and repetitive projects, or simulation have been applied. Though these methods can be applied in construction project planning, their applicability is limited to a specific project type. Focussing especially on resource allocation influencing a project schedule as critical success factor for a project, quantitative planning approaches should be preferred, such as the resource-constraint project scheduling problem (RCPSP). The resource-constrained project problem does not only provide the opportunity to pursue objectives like cost minimization or resource levelling but also considers resource limitations for project execution.

As the complexity of quantitative models for practical problems exponentially rises in dependency on the number of activities and resources to be considered, an efficient resource allocation strategy has to differentiate between critical and non-critical resources for the project planning to make quantitative models applicable to real world problems.

Hence, the objective of the paper is twofold. Whereas the first aim is to develop a resource classification scheme, the second focus lies on the presentation of a future path for the development of construction project planning by discussing the opportunities of application of the RCPSP.

The remainder of the paper is thereby organized as follows: First, we give a classification and characterization of projects based on project planning problems found in practice that is followed by a suggestion on how resources can be structured according to their criticality in the project planning process in order to allocate resource more efficiently.

Secondly, we introduce a general RCPSP model for resource-constrained project scheduling as counterpart to traditional project planning models. Based on this general model we show various extensions for different problem classes. This especially addresses various project objectives as well as the choice of technologies out of a bundle of alternative to achieve best possible objective fulfilment. Finally, examples for successful applications of the RCPSP in construction are given.

CHARACTERIZATION AND CLASSIFICATION OF PROJECTS

The literature about project management holds quite a large number of definitions for the term “project”. According to Klein (1999: 3) and Slack *et al*. (1998), a project is characterized by the following elements (for detailed information see also, e.g., Shtub *et al*. 1994; Spinner 1997): objective, uniqueness, complexity, temporary, resources, uncertainty and life cycle.

In order to organize and to optimize the management of projects, project planning problems can be formulated. For the specification of project planning problems focussing on resources availabilities, we further distinguish the complexity of a project into micro and macro complexity. Whereas the micro complexity of a project describes characteristics within and between projects, the macro complexity addresses constraints at the interfaces to the project environment. For a unique description of a project, these determinants are exemplarily specified as shown in Table 1.

Table 1: Characteristics and determinants of projects

Project characteristics	**Key determinants**	**Specification**
Objective	Type of project	• Research and development project, design project, software project, construction project etc.
	Type of objective	• Time, cost, resource, environment
	Number of objectives	• Single, multiple
Complexity micro	Number of projects	• Single, multiple
	Project structure	• Repetitive, linear, complex
	Precedence constraints	• Finish-to-start, start-to-start, min-max-timelags
	Processing modes	• Single, multiple
	Set-up times	• Negligible, static, mode-sequence dependent
Complexity macro	Participants	• Shareholder: owner, bank, contractor, ... • Stakeholder: owner, bank, contractor, designer, government, interest groups, …
	Regulatory framework	• Economic, social, ecological legislation
	Conditions for operation	• Enterprise internal regulations • Industrial interventions • Project environment: space, climate, culture, ...
Temporary	Time horizon	• Determined • Non-determined
Resources	Resource type	• Renewable, non-renewable
Uncertainty	Resource availability	• Deterministic, stochastic, possibilistic
	Activity durations	• Deterministic, stochastic, possibilistic
	Precedence relations	• Deterministic, stochastic, possibilistic

The purpose of project planning is the allocation of resources to the activities of the project, such that a particular project objective is attained. Since the late 1950s, the Critical Path Method (CPM) and the Program Evaluation and Review Technique (PERT) have been the focus of intensive research effort and acknowledged a wide spread use by practitioners in management and control of large-scale construction projects. However, the construction industry differs significantly from other industries because of changing production sites, multiple simultaneous projects and, hence, allocation of resources from site to site. Bearing the complexity of the construction project planning problem in mind these project planning techniques cannot satisfy the specific needs of project planners in the construction industry. Even current project management software, like Microsoft Project®, Suretrak® and Primavera®, cannot fully satisfy requirements of project planners and do not always guarantee a user friendly and easy to comprehend application (Herroelen and Leus 2005: 104).

Instead, simulation or planning approaches from Operations Research, such as resource-constrained project scheduling, represent an appropriate alternative to traditional planning methods. Thereby, the choice of solution method to solve a particular resource allocation problem strongly depends on the combination of the specifications, i.e. on the type of construction project referring, for instance, to its objective, the number of projects to be planned, the resource types and availabilities as well as the time horizon and project participants. Hence, different project types can be identified for which planning strategies can be derived.

RESOURCE ALLOCATION IN CONSTRUCTION PROJECTS

Primarily in construction, resource allocation is a major topic that discusses project planning in detail. The result of project planning is a project schedule, i.e. a definition of a set of starting and finishing times of project activities under consideration of limited resource availability. A project schedule is not just a valuable instrument in communication and coordination processes with external partners in the company's inbound or outbound supply chain, but serves both the planning of project activities and a related resource assignment to each activity considering some measure of performance as well as the planning of external activities (Herroelen and Leus 2005: 107).

In the planning and resource allocation process, various objectives are considered. These objectives are usually management-driven and focus on time, costs as well as other aspects as depicted in Table 1. Common objectives in construction project management and scheduling are, for instance, the minimization of project durations under multiple resource constraints (Moselhi and Lorterapong 1993), the minimization of the total project delay (Tsai and Chiu 1996) as well as the minimization of costs of total resource consumption, including time and a levelled resource distribution (Karshenas and Haber 1990). Furthermore, objectives like maximizing the total project net present value by considering project delay penalties and early completion bonuses (Chiu and Tsai 2002) as well as finding the optimal resource selection optimizing time and cost objectives of a construction project (Burns *et al*. 1996) are pursued. Additionally, considering the case of repetitive activities, objectives might address the minimization of idle crew time (El-Rayes and Moselhi 1998). Also, project management can address the generation of a schedule-dependent site layout planning (Elbeltagi *et al*. 2001).

The achievement of the project's objectives significantly depends on the availability, the amount and the costs of resources to be allocated to projects and their corresponding activities over the project time horizon, hence the quality of the project schedule. For construction projects, these resources can be distinguished according to different criteria. In practical planning environments in the construction industry, the resources allocated usually comprise money, labour, equipment and construction materials.

For the application of quantitative planning models, the differentiation of project resources according to their renewability is necessary. Renewable resources are resources that are only available in a limited amount per period, for instance machines or workers. If resources are non-renewable, they are constrained over the whole planning horizon or project duration, e.g. budgetary constraints (Slowinski 1979: 455–6; Weglarz 1979: 522).

To reduce the complexity of the project planning problem and to provide a basis for a selection of particular resources for detailed resource planning, further classification criteria, besides the renewability, are applied. Thus, each of the resource types mentioned above can further be distinguished and evaluated according to the criteria: technology/know-how, value, mobility, supply, supply variance and procurement pattern. For instance, a patented construction technique with the enterprise holding a unique selling proposition can be considered as cost-intensive and highly specialized construction equipment. This construction equipment is characterized by a constant supply and the absence of the opportunity of third party supply, i.e. renewable resource. In contrary, concrete is a non-renewable low-mass building material with an order dependent, hence variable, quantity and is consumed (non-renewable) during the project progress.

Sophisticated resource allocation does not necessarily mean to precisely allocate all resources of a project. In order to reduce complexity of the planning procedure, it might be advisable to rank resources or their impact on the stability of the project schedule according to certain criteria. A well-established procedure for the ranking and classification of objects is the ABC/XYZ analysis known from material requirements planning. Figure 1 depicts the classification of resources into critical, non-critical, and risk-prone resources with the ABC/XYZ analysis of resource allocation.

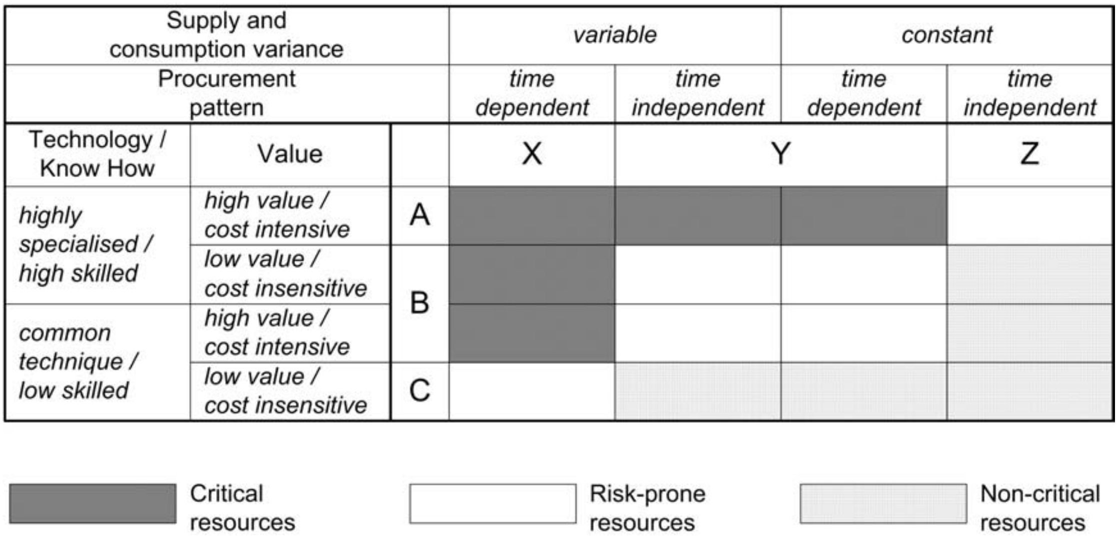

Figure 1: Classification of resources into critical, non-critical and risk-prone resources

While detailed project planning is recommended for critical resources, less effort shall be put into non-critical resources. For instance, low mass, low value construction material can be classified as materials of CZ-category. Its supply is a necessary condition to execute the project, but due to the low criticality of the resource it is not subject of a detailed resource allocation planning.

FUTURE PATH FOR THE APPLICATION OF RESOURCE-CONSTRAINED SCHEDULING IN CONSTRUCTION

Construction industry projects involve complex packages of work, for which design and contracting organizations are responsible; the product is generally large, discrete and prototypical (Abeyasinghe *et al*. 2001). The main particularities of the construction industry and construction industry projects are: design-to-order production; shifting production sites; spatial constraints; seasonal dependency; construction specific legislation, in particular environmental legislation; time/resource trade-offs; simultaneous multiple projects; and a combination of multiple objectives of time, cost, quality and resource levelling.

To demonstrate how quantitative project planning models can be successfully introduced to construction we introduce a generalized resource-constrained project scheduling model in the following. The formulation of this model is further customized to the context of construction projects. In particular, the customization focuses on the characteristics objective and complexity of projects as listed in Table 1.

A generalized resource-constrained project scheduling model

Approaches to project planning, scheduling and resource allocation in construction cover techniques based on the line of balance (LOB) concept (e.g. Tokdemir *et al.* 2006) for linear scheduling and repetitive construction operations, as well as heuristics and optimization models, such as the resource constrained scheduling problem.

The classical resource constrained project scheduling problem (RCPSP) describes a single project that consists of $j = 1,...,J$ activities, also known as jobs, operations or tasks, with a known constant duration of d_j periods. It is characterized by a deterministic finish-to-start precedence relation in an activity-on-node (AON) network, which means that an activity cannot be started before all its predecessors have been finished. Furthermore, pre-emption of the jobs is not allowed, i.e. whenever a job has been started at the beginning of period t it must be performed without interruption in the time periods $t,...,t + d_j - 1$. Additionally, resource constraints have to be observed during the procession of the jobs, whereas job j requires constant q_{jr} units of the renewable resource type $r \in R$ during every period of its duration. The resource type r is known and available in a constant amount Q_r over the whole planning horizon. Thus, jobs might not necessarily be scheduled at their earliest possible (precedence feasible) start time. The objective of the RCPSP is to find a non-pre-emptive schedule (i.e. a feasible schedule) by assigning starting times to the jobs such that the precedence and resource constraints are satisfied following one or more targets. An early mathematical programming formulation was given in Pritsker *et al.* (1969).

The most commonly considered objective of the RCPSP is the minimization of the project finishing time. This is mainly due to the following reasons (Kolisch 1996: 180):

1. The majority of income payments of projects occurs at the end of a project or at the end of predefined project phases. Finishing the project early reduces the amount of tied-up capital.
2. The quality of forecasts tends to deteriorate with the distance into the future of the period for which they are made. Minimizing the project duration reduces the planning horizon and, therefore, the uncertainty of data.
3. Finishing products as early as possible lowers the probability of time-overruns of the project.
4. By freeing resource capacity as early as possible, the flexibility of the company can be raised in order to better cope with changes of the economic environment.
5. Additionally, a high resource utilization at the beginning of the planning horizon leads to a larger amount of free resources at the end of the planning horizon and, thus, rises to ability to accept and process new projects.

With the assumptions made, the RCPSP can be modelled as mixed integer program (MIP) as introduced in the following:

$$\text{MIN} \quad \Phi = \sum_{t=EF_J}^{LF_J} t \cdot x_{Jt} \tag{1}$$

subject to

$$\sum_{t=EF_j}^{LF_j} x_{jt} = 1 \qquad j = 1,\dots,J \tag{2}$$

$$\sum_{t=EF_h}^{LF_h} t \cdot x_{ht} \le \sum_{t=EF_j}^{LF_j} (t - d_j) \cdot x_{jt} \qquad j = 1,\dots,J\,;\ h \in P_j \tag{3}$$

$$\sum_{j=1}^{J} \sum_{\tau=t}^{t+d_j-1} q_{jr} \cdot x_{j\tau} \le Q_r \qquad r \in R\,;\ t = 1,\dots,\overline{T} \tag{4}$$

$$x_{jt} \in \{0,1\} \qquad j = 1,\dots,J\,;\ t = 1,\dots,\overline{T} \tag{5}$$

The objective function (1) minimizes the project finishing time with $\overline{T}$ being the end of the planning horizon. Constraints (2) ensure that every job is processed once. Constraints (3) are precedence constraints of jobs with P_j denoting the set of immediate predecessors of job j. The duration of job j is represented by d_j. Constraints (4) limit the resource demand q_{jr} of the renewable resource $r \in R$ of jobs j, which are currently processed in order not to exceed the constant resource availability per period Q_r. Finally, constraints (5) define the decision variable $x_{jt} \in \{0,1\}$ as binary, with $x_{jt} = 1$ if job j ends in period t, 0 else.

Objectives of project scheduling

While the most commonly considered objective of the RCPSP is, as already pointed out, the minimization of the project finishing time, construction project management in general covers a much wider scope of objectives. The aggravating factor in construction project planning, which is closely related to the complexity of the project, is the type and the number of participants involved in a project who claim the fulfilment of their various interests (Schultmann and Sunke 2006). Objectives might hereby be induced either by the project owner, its stakeholders, such as subcontractors or material suppliers, but also be imposed by a regulatory framework or other external conditions. These objectives can address different issues such as time, cost and resource allocation etc. For a comprehensive overview of various objectives as an extension of the RCPSP, see Klein (1999) and Kolisch and Padman (2001).

Time objectives address the optimization of measures related to finishing times, make spans, tardiness of jobs and projects. Among these are the minimization of the make span of a project i and the minimization of the (weighted) flow time of activities j. A collection of time related objectives can be found, for example, in Schultmann (1998: 123–30) and Kolisch and Padman (2001: 250–1).

Monetary oriented project objectives comprise resource-cost oriented objectives, activity-cost oriented objectives and objectives concerning the net present value of a project (Kolisch and Padman 2001: 251). Resource-cost oriented objectives are reflected in two extensions of the RCPSP: time-constrained project scheduling problem (TCPSP) and resource investment problem (RIP). The objective of the TCPSP is the minimization of additional resource costs for additional resource consumption if the project finish is set. The RIP aims at determining a non-delay schedule and the amount of each resource provided minimizing total costs (e.g. Demeulemeester 1995; Möhring 1984). Considering activity-cost oriented objectives so called time/cost trade-off problems occur. The underlying assumption is that the activity duration might be influenced by the amount of money spent for processing (e.g. Demeulemeester *et al*. 1996; Vanhoucke 2005; Icmeli and Erenguc 1996). Additionally, bonuses and penalty costs for project finish, or both, negative as well as positive cash flows as reflected in the net present value (NPV) of a project can be considered. Problems aimed at maximizing the NPV depending on the time at which cash flows occur are called resource constrained project scheduling problem with discounted cash flows (RCPSP-DCF) (e.g. Chui and Tsai 2002) with various extensions, for instance, multiple-projects, multiple-processing modes (e.g. Ulusoy *et al*. 2001; Józefowska *et al*. 2002; Kim and Leachman 2003; Lawrence and Morton 1993; Mika *et al*. 2005).

While costs are the essential part in the TCPSP, the focus of *resource-oriented objectives* is not to allocate resources to activities minimizing costs or maximizing benefits but to allocate resources in a way such that deviations in resource consumption per period are minimized. This problem is considered as resource levelling problem (RLP) (e.g. Bandelloni *et al*. 1994; Hegazy 1999; Neumann and Zimmermann 2000).

While the first three categories of objectives have already been studied extensively in literature, environmental objectives have not yet been paid reasonable attention to in project scheduling considerations although widely discussed regarding environmental conscious behaviour related to sustainable development. In particular, these objectives can address the maximization of material to be recovered in deconstruction projects (e.g. construction materials such as wood, bricks, steel, modules, sanitary installation etc.) and the minimization of emissions (noise, pollution, etc.) during construction projects.

Complexity

The complexity of a project or a project planning problem is determined by numerous factors related to the micro and macro complexity of a project (see Table 1). Particularly concentrating on the complexity caused by different execution alternatives of a construction or deconstruction activity, as very common in practice, so called trade-offs between input of resources and the duration of that activity occur.

In the RCPSP, however, each job is processed in a single alternative, i.e. each job is assigned a deterministic resource consumption and a corresponding duration (e.g. Christofides *et al*. 1987; Davis and Patterson 1975). If a job can be processed in more than one way, these alternatives are described as modes. These modes are representations of time/resource trade-offs (in contrast to time/cost trade-offs as addressed). Time/resource trade-offs occur when the duration of a job is affected by the bundle of input resources and can therefore be decreased/increased at the expense of providing additional/less resources or by using different resources. “For example, an excavation may be dagged by five construction workers within a week, whereas the same work may be performed by an excavator within a single day.” (Klein 1999: 96). Resource/resource trade-offs are a special case of time/resource trade-offs and represent the substitution of resources needed to execute a job without affecting the duration of the job (Demeulemeester and Herroelen 2002: 500).

The relevancy of this problem is evident in deconstruction processes of buildings. As disposal costs for building waste or deconstructed material raises a separation of different types of material is a necessary condition to enable a reuse and recycling of building waste and material. The quality of the deconstructed material and its suitability for reuse and recycling can be influenced by the technical and organizational planning of the deconstruction process and, hence, the chosen processing option, respectively mode, of each job (Schultmann 2003: 335; Schultmann 2003: 56-7).

The modelling of the RCPSP using modes results in the multi-mode resource constrained project scheduling problem (MMRCPSP). In the MMRCPSP formulation each job *j* is assigned a mode *m* defining the relation between resource consumption q_{jmr} and job duration d_{jm} in one of several different modes $m = 1,..., M_j$. The primary objective of the MMRCPSP is, according to the RCPSP, to minimize the project finishing time by selecting an execution mode for each activity and assigning feasible finishing times of the jobs according to the resource and precedence constraints.

SOLUTION PROCEDURES AND APPLICATIONS

Solution procedures for the RCPSP and its extensions MMRCPSP and MMRCMPSP have attracted intensive research since the late 1950s. These solution procedures are divided into exact algorithms and heuristic approaches. Comprehensive reviews for the RCPSP and its solution procedures can be found in (Brucker et al. 1999; Demeulemeester and Herroelen 2002; Kolisch 1996; Kolisch and Padman 2001; Kolisch and Hartmann 2006).

Despite the theoretical evaluation some practical applications are given in literature to proof the appropriateness of proposed solution procedures for practical planning problems. In the construction industry, case studies were undertaken, for instance, by Tsubakitani and Deckro (1990) and Chiu and Tsai (2002). A successful application of the RCPSP with multiple modes was given by Schultmann and Rentz (2002), who applied the model to deconstruction projects.

CONCLUSIONS

Our investigations to project planning and scheduling models showed a high potential for these in construction planning. The RCPSP can be applied to a variety of different classes of construction projects. It serves not only as a framework for resource allocation in construction project planning, but it can also easily be adapted to different project structures and different project environments. This includes, for instance, repetitive, multi-mode or multiple projects as well. Therefore, no differentiation between problem classes is necessary, such as applying the LOB concept exclusively to projects of repetitive nature. Additionally, the RCPSP provides freedom to integrate external constraints (e.g. legislation, market regulations) and multiple objectives.

However, although the RCPSP and its extensions seems to be a universal solution approach for a variety of project planning problems in practice and in construction in particular, one should not abstract away from the fact that special cases, like repetitive projects might be better solved with customized methods, such as LOB with the exceptions, that external constraints and multiple objective function are not considered. Therefore it is necessary, to further evaluate and prove the appropriateness of the RCPSP for the various project planning problems in real world situations in construction.

In this paper we have assumed a deterministic project environment. Approaches to consider uncertainty, e.g. simulation or fuzzy scheduling, have not been addressed. The same holds true for the consideration of multiple objectives as well as for planning projects simultaneously. Moreover, we have to pay attention to the fact that even a nearly perfect planning, considering resource constraints, different environments, uncertainty, vague information etc. can not replace a proper project control. Taking this into account, the need for more “intelligent” approaches like reactive scheduling, opportunistic principles in planning and control becomes obvious.

APPLYING ANT COLONY SYSTEM TO SOLVE CONSTRUCTION TIME-COST TRADE-OFF PROBLEM

Yanshuai Zhang, S. Thomas Ng and Mohan M. Kumaraswamy

Department of Civil Engineering, The University of Hong Kong, Pokfulam, Hong Kong

Time-Cost Trade-off (TCT) is a very common problem in the construction domain. The concept of TCT is to minimize either the total cost or total duration of a project at a predetermined construction duration or amount respectively. Many techniques have already been proposed for solving the TCT problems, and examples of these include the heuristic methods, mathematical approaches and evolutionary-base optimization algorithms (EOAs). Among these techniques, the EOAs such as the genetic algorithms, ant colony optimization, particle swarm algorithms, etc. are considered more promising for TCT due to their ability to cope with the dynamic behaviour and their efficiency. The Ant Colony System (ACS), being an extension of the basic ant colony optimization algorithms, has good potential for solving network problems like TCT due to its excellent ability to identify the best path of a network. In this paper, an ACS model for discrete TCT problems is introduced. Having developed the model in Visual Basic and integrated with Microsoft Project, a series of computational experiments is conducted to compare the performance of the proposed ACS model with other previous developed methods. The performance and weakness of the ACS model for TCT problem is highlighted to conclude this paper.

Keywords: time-cost trade-off problem, project management, ant colony system.

INTRODUCTION

One of the most important roles of a construction planner is to allocate appropriate and adequate resources to a construction project to ensure it is completed on time and within budget. Selecting an appropriate equipment output and crew size as well as establishing the correct sequence and duration for activities in a construction project so as to meet the contract duration at the minimum cost is therefore the focus of a Time-Cost Trade-off (TCT) analysis.

Several techniques have been proposed for the TCT analysis, and these include the heuristic methods, mathematical approaches and Evolutionary-based Optimization Algorithms (EOAs). Heuristic methods are non-computer approaches that rely on the rules-of-thumb of decision-makers. Mathematical approaches convert the TCT problems into mathematical models and utilize the linear programming, integer programming or dynamic programming techniques to solve the problems. Both the heuristic and mathematical methods have their own limitations, of which, the most critical constraint is their inability to guarantee the generation of an optimal.

In this paper, an EOA known as the Ant Colony System (ACS) is proposed to solve the construction TCT problems. The paper proceeds by a brief introduction of the EOAs. This is followed by highlighting the key features of the ACS-based TCT model. A case project is used to illustrate the performance of the proposed model, and the paper is concluded by comparing the results of the ACS-based TCT model and those generated by other modelling approaches.

EVOLUTIONARY-BASED OPTIMIZATION ALGORITHMS

Striving to identify a global optimal solution, many researchers have been exploring the potentials and pitfalls of adopting EOAs for TCT problems. EOAs are stochastic search methods that mimic the metaphor of natural biological evolution and/or the social behaviour of natural species. According to Lovbjerg (2002), such behaviour is guided by learning, adaptation and evolution.

Apart from genetic algorithms (GAs) (Feng *et al*. 1997, 2000), other EOAs being inspired by the natural processes include the Ant Colony Optimization (ACO) (Dorigo *et al*. 1996), memetic algorithms (Moscato 1989), particle swarm optimization (Kennedy and Eberhart 1995) and shuffled frog leaping (Eusuff and Lansey 2003). The concepts of these methods and their application on construction TCT problems can be found in Elbeltagi *et al*. (2005).

While all these EOA techniques discussed above can be used for solving discrete TCT problems, the results of Elbeltagi's study show ACO outperformed the others in terms of both the solution quality and its process time. Acknowledging the strength of ACO, it is interesting to find out whether another member of the ant algorithms family – the Ant Colony System (ACS) can further improve the quality of this type of decisions.

ANT COLONY SYSTEM

ACO was first proposed by Colorni *et al*. (1991) as a meta-heuristic scheme to locate near-optimal solutions. By simulating the behaviours of real ants moving along a weighted connected graph, it is able to solve many complex combinatorial optimization problems such as the Travelling Salesman Problem (TSP) through the ACO (Dorigo *et al*. 1996; Stützle and Dorigo 1999).

As reported by Dorigo and Stützle (2004: 68), the Ant System (AS) (Dorigo *et al*. 1992) which is the most primitive ACO algorithm was introduced for solving the TSP problem. Then, a count of extensions of AS were inspired to improve its performance such as ACS, the elitist ant system, the max-min ant system, etc. Different updating rules of the pheromone are indeed the main difference between the AS and its extensions (Dorigo and Stützle 2004: 68–9). Hence, the most important area in which the ACS outperforms the AS lies with the pheromone updating rule.

There are two components for updating its pheromone in ACS namely the local updating and global updating respectively. The experiment was conducted by the authors, and the results show that ACS outperforms the basic AS not only on the solution quality but also on the processing time. As a result, it is more likely to generate the near-global solutions much quicker while a premature convergence can also be avoided. Therefore, the ACS together with other ACO algorithms should have great potential for solving optimization problems like scheduling and flowshop problems.

ACS-BASED TCT MODEL

The discrete TCT problem can be represented by a weighted graph based on the ACS approach such that the activities as well as various construction methods for each activity constitute the networks. The objective function would be the total cost of a project which means the sum of direct cost and indirect cost as determined by:

$$f = \sum_{i=1}^{L} C_i + D \cdot ic \tag{1}$$

where f is the objective function; C_i is the direct cost of i^{th} activity; D is the project duration; and ic is the indirect cost which is a determined value.

Suppose there are L_i options for activity i, and an ant in activity i selects option k using the rule adapted from the ACS-TSP model originated by Gambardella and Dorigo (1996) as follows:

$$P_{ik} = \frac{\tau_{ik}}{\sum_{k=1}^{Li} \tau_{ik}} \tag{2}$$

where P_{ik} is the probability that k^{th} option of activity i being chosen; and τ_{ik} is the pheromone of k^{th} method option of activity i in the TCT problem.

As discussed, the pheromone updating rules of ACS model include two steps as illustrated bellow. The first step is comparable to the basic ACO approach as developed by Elbeltagi *et al*. (2005) for TCT modelling:

$$\tau_{ik} = \rho\tau_{ik} + \Delta\tau_{ik} \tag{3}$$

$$\Delta\tau_{ik} = (1-\rho)\tau_0 \tag{4}$$

where τ_{ik} is the concentration of pheromone; ρ is the pheromone evaporation rate (from 0 to 1); and τ_0 is a small constant.

The second step which makes ACS different from basic ACO is the global updating rule which is performed after an entire iteration is completed. The pheromone concentration will be updated in the options belonging to the best ant in this iteration according to the following equation:

$$\tau_{ik} = (1-\alpha)\tau_{ik} + \alpha \cdot R \cdot f_{iter\text{-}bestant} \tag{5}$$

where α is the evaporation rate in global-updating process; R is a constant referred as the pheromone reward factor; and $f_{iter\text{-}bestant}$ is the fitness value of the best ant in this iteration.

MODEL DEVELOPMENT

Based on the above concepts, an ACS-based TCT model is developed in four phases: (i) initializing the parameters including the number of ants and τ_0; (ii) for each ant, deriving a solution by travelling from the first activity to the last activity of the project according to the selection probability function as shown in Equation 2; (iii) for each trail, updating the pheromone locally and globally according to Equations 3 and 5 respectively; and (iv) checking the termination criteria which is the maximum number of iterations. Should the criteria be satisfied, the best solutions will be shown as output. Otherwise, the algorithm would be repeated. With that, a model was developed using Microsoft Visual Basic and the model is linked to Microsoft Project. Figure 1 shows the process involved in the proposed program.

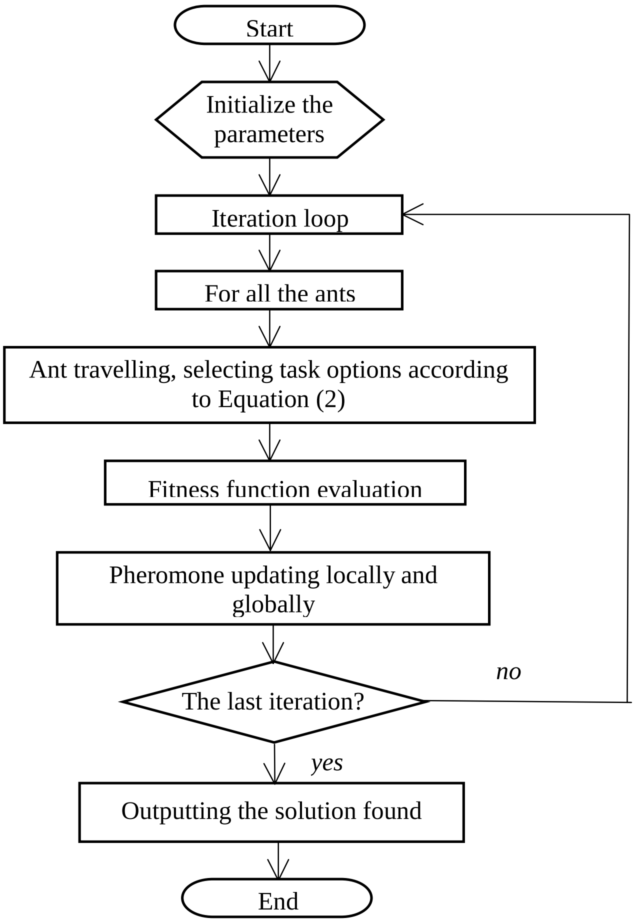

Figure 1: Flowchart for ACS-based TCT model

For comparison, the same case project employed in Elbeltagi's study (Table 1) was fed into the developed ACS-based TCT model. As shown in Table 1, the activities, their predecessors as well as their best guess duration and cost are presented. Besides, there are also five alternative methods of construction that vary from cheap but slow (option 5) to fast yet expensive (option 1). D1 to D5 represent the duration of those alternatives, while the costs of those options are highlighted by C1 to C5. After extensive experimentation, 10 ants and 50 iterations were found suitable for this case. The other parameters can be set as: $\rho=\alpha=0.9$, $\tau_0=0.1$, $R=50$.

Table 1: Details of case project (Elbeltagi *et al*. 2005)

Activity	Depends on	Option1		Option2		Option3		Option4		Option5	
		D1	*C1*	*D2*	*C2*	*D3*	*C3*	*D4*	*C4*	*D5*	*C5*
1	-	14	2,400	15	2,150	16	1,900	21	1,500	24	1,200
2	-	15	3,000	18	2,400	20	1,800	23	1,500	25	1,000
3	-	15	4,500	22	4,000	33	3,200				
4	-	12	45,000	16	35,000	20	30,000				
5	1	22	20,000	24	17,500	28	15,000	30	10,000

18	16,17	9	3,000	15	2,400	18	2,200				

In this project, if a planner or manager selects the last option for all the activities, a network as shown in Figure 2 can be produced, with duration = 169 days and total cost = \$184,240 (indirect cost = \$500/day).

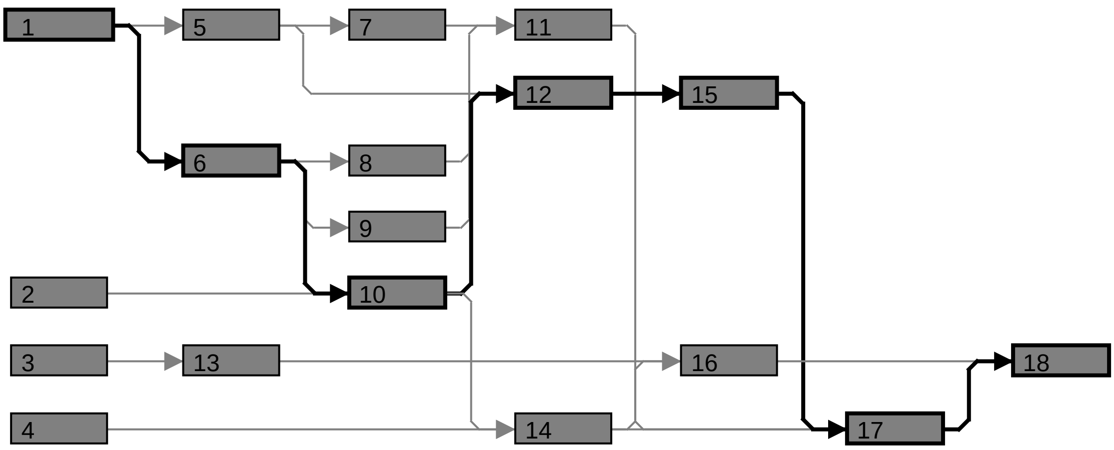

Figure 2: Activity-on-node diagram for the project with activities on critical path in bold

RESULTS AND COMPARISON

The indirect cost adopted in this case project is \$500/day. With the initial schedule exceeding a desired deadline of 110 days, it is necessary to search for an optimum set of options that meet the deadline at the minimum total cost. Figure 3 shows the convergence of this ACS-based TCT model in solving the above case project. It is noted that the total cost is very high at the beginning (\$186,820) but converges to its optimal value after a dozen of iterations. Even when 50 iterations was adopted in this case, the best result was achieved at the 41st iteration with a total cost of \$161,270 and a total duration of 110 days, which is in turn the desired deadline of this case project.

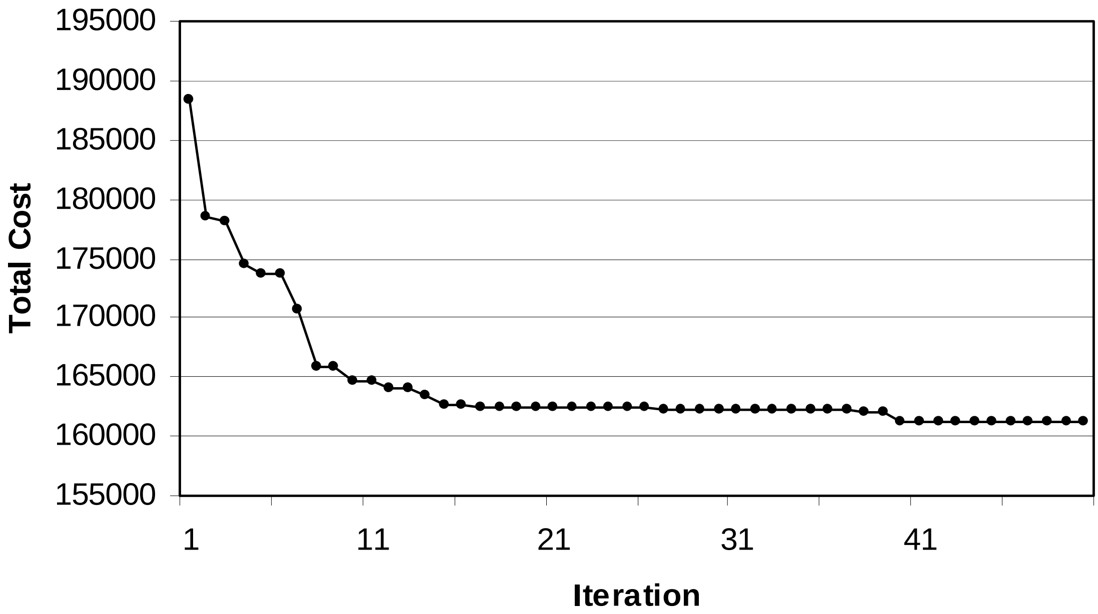

Figure 3: Convergence of project total cost

The results obtained from the ACS-based TCT model are compared with those generated by other EOAs found in previous studies (Elbeltagi *et al*. 2005). As shown in Table 2, the optimal solution of 110 days at a cost of $161,270 being generated by the current model is the same as that derived by the memetic algorithm and ACO models. However, the results generated by the GAs and shuffled flog lapping approaches are inferior to the proposed model. In the case of the GA model, the minimum duration was 113 days at a cost of $162,270 with a difference of three days and $1,000 for the duration and cost respectively.

Table 2: Results of EOAs in TCT problem

Algorithm	Minimum duration (days)	Minimum cost ($)	Processing time (s)
GAs	113	162,270	16
SFL	112	162,020	15
MAs	110	161,270	21
ACO	110	161,270	10
ACS	110	161,270	N/A

Without executing various models in the same computer, it is impossible to compare the time taken by ACS-based TCT model with that of other algorithms. Yet, as ACS is an extension of the basic ACO approach, it is sensible to compare the performance of these two algorithms. As shown in Table 3, the number of ants and number of iterations in the ACS-based TCT model are about 60% less than the ACO model respectively. Using the basic ACO model required 100 iterations to generate an optimal solution while only 41 iterations were taken by the ACS model. Hence, one can reasonably assume that the processing time of the current ACS model is much less than the basic ACO model and other EOA approaches (*cf:* Elbeltagi *et al*. 2005).

Table 3: Comparison between ACO-based model and ACS-TCT model

Description	ACO model	ACS model
Number of ants	30	10
Number of iterations to get the best solution	100	41

DYNAMIC THREE-DIMENSION VISUAL SIMULATION FOR DAM CONCRETE CONSTRUCTION PROCESS

Lihua Chen,[1] Mingliang Shen, Yajie Dong and Yadong Mei

State Key Laboratory of Water Resource and Hydropower Engineering Science, Wuhan University, Wuhan, 430072, China

The construction of a concrete dam is an extremely complicated system project with lots of influencing factors. The model of construction simulation by using queuing theory is established. The construction system is considered as an exceptive queuing serving system. It accords with the practice construction process to apply time-event driven method to drive change of state in system. This not only remedies the influence of simulation precision that time step brings, but also effectively deals with the relationship between master clock and secondary clock. According to the requirement of visual simulation in waterpower projects, we make a data model by using discrete contour line database TIN, establishing DTM by transforming random lattice to formula grid, organizing time and spatial data of construction blocks, so that a 3D digital model of the dam which corresponds with the spatial–temporal relationship is formed. The dynamic visual system of the concrete dam construction process was developed by the authors. Based on the characteristics of the XiangJiaBa project which lies in southeast China, we apply the construction machine model of construction with several kinds of device set. Based on GIS, we express the complex spatial–temporal relationship between all aspects of the project schedule, and provide the basis data of visual decision making for scheme optimization, construction machinery matching, optimizing the execution programme of work.

Keywords: concrete, construction management, dam, simulation, virtual reality.

INTRODUCTION

The construction of a concrete dam is an extremely complicated system project which involves lots of influencing factors: the quantity is huge, the construction period is long, dam blocks are large quantities, placement machines are of different types, the structure of the dam and construction techniques are complicated, and the construction intensity is high; so, the construction design of a concrete dam is a complex and flexible task (Yuan 1996; Zhou 1998). Based on GIS, the dynamic three-dimensional visual simulation could be realized by the simulation achievement data and information, and express the complex spatial–temporal relationship between all aspects of the project schedule (Zhong *et al*. 2004). This method provides visualizing analysis data for optimizing the construction procedure, exploring construction machinery matching and accelerated construction and verifying dam construction period, and greatly improves the construction design and construction organization.

[1] zgfjclh@163.com

THE DESIGN IDEA AND CONFIGURATION OF SYSTEM

The system simulation model is classified into two types, named continuous system model and discrete system model according to their characteristics (Sun 1997). A discrete system is an event-driven dynamic system in which states change in the form of jumping. System transfer happens by a trail of discrete events. In the study of construction process simulation, the state properties of entities such as the construction state and construction information of each block and construction machine, change with events which influence the system at random times. Those variables changing with time are discrete and jumping, so the model of a concrete dam construction system is regarded as a discrete system.

The concrete dam construction simulation system consists of the following components: original database, computerized selection of blocks to be concreted, 2D and 3D image simulating and so on, which are independent and united by the main interface.

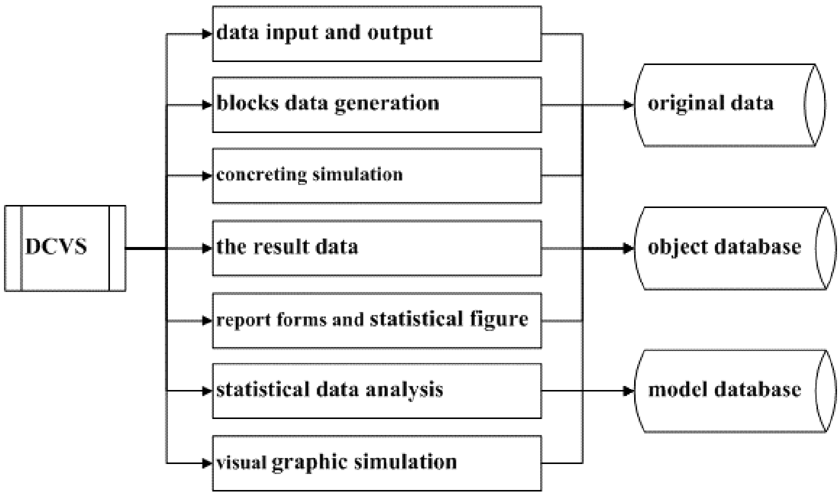

Figure 1**:** Schematic diagram of configuration in dynamic simulation system

THE KEY TECHNIQUES

Simulation comprehensive model

By using the simulated model of queuing theory, the construction system is considered as a special queuing serving system, which all kinds of construction mechanisms serve to the construction (Ioannou 1999). The queuing rules of construction are not according to first-come-first-served rule, after-come-first-served rule and priority rule, they are in accordance with the hierarchy of construction and the construct requirement of the height to queue. The construction serves of machine also does not instantly serve based on the queuing, it chooses the serving object on the consideration of the meeting of the constraints and the combination of first-construct of upstream dam (Trinh and Sharif 1996). The combination of time and event is used to drive the change of system state, which not only remedies the influence of simulation precision that time step brings, but also effectively deals with the relationship between master clock and secondary clock. A comprehensive model mostly faces with the transporting system and construction blocks, and provides time and spatial data for image simulation. The proceedings are shown as follows:

1. Simulation parameter input: initial machinery matching program, technical parameters and operating parameters of each construction machine, 3D

model, efficient working day, construction parameter (intervals between two layers, the time of removal model, height limitation of adjacent dam blocks, concrete initial setting time, the time of shore set, limitation in height caused by failing to dismantle, start time and end time of simulation and so on).

2. The data generation of blocks: The data generation has mostly relations with dam structure and the arrangement of concrete blocking and joint division. Concrete blocking is determined by the most width of the bottom of the dam, and the area and thickness of concrete pieces is determined by construction capability of the machine. By considering the spatial position and geometry dimension of the bottom outlets, the middle outlets, the top outlets, water diversion tunnel, ship lift dam section, generating diversion tunnel, sand escape, the top of weir on outlet dam section, the quantity and the spatial data of the block are calculated.

3. Construction simulation: First, we divide time limit for a project to day, to judge whether the day could work. Second, we divide a day to three teams (two team at high temperature season), and regard a team as a step. Third, each machine is scanned, if there is available block, drive the state of system by time and event driven method and transfer corresponding sub-model of construction machine serving (Wang *et al*. 2004).

4. The time and spatial data organization and visual simulation: the property of time of start and end of blocks incarnate the time characters, and show the dynamic process of concrete construction. The geometry property of blocks waiting to be concreted and the information of the blocks which have been concreted make up the whole data of time and space. The organization of time and spatial data is the basis of the 3D digital model which is used to carry out dynamic 3D visualizing by the function of GIS. Figure 2 shows the main process of simulation of comprehensive model.

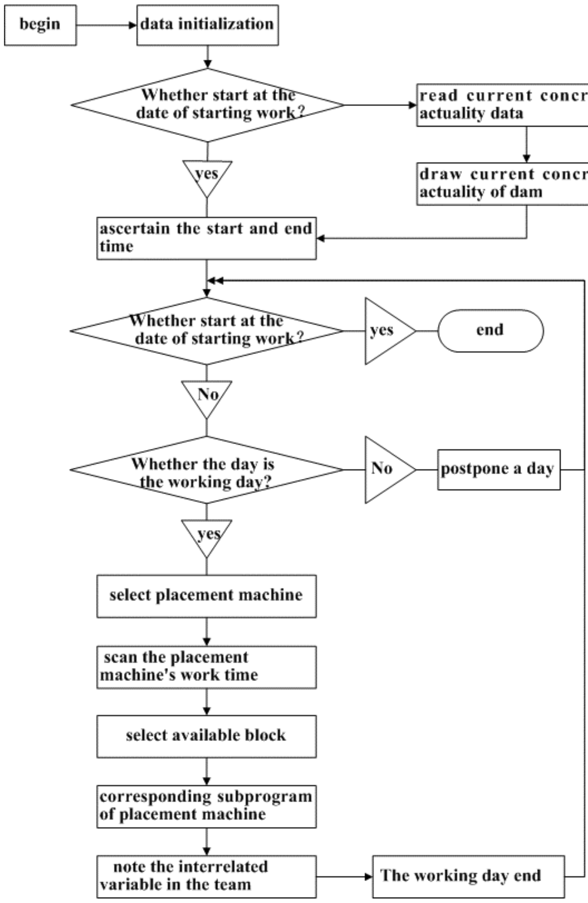

Figure 2: Comprehensive model flow chart

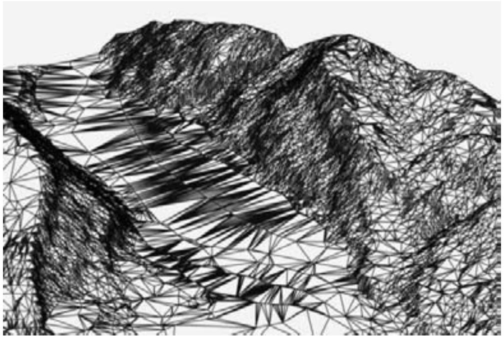
Machine service model

Aimed at the characteristics of different machines, continuous construction machines such as the tower-machine and belt conveyer, because of the symmetrical and continuous material, the running of the machine set is relatively easy in the construction process. Use dominant entity scan method and take the change of information and state of construction blocks as event influencing system. Discrete machines such as cable crane, gantry and tower cranes, belt conveyers, judge the available blocks by using dominant entity scan method and deal with the loading, loaded running, unloaded running, unloading and concreting process by time and event driven method.

Digital terrain model

DTM is used to express the digital model of 3D space with state of continuous gurgitation. There are many kinds of DTM, such as DEM, TIN, RNM and ECM.

Combining the characteristics of waterpower project construction systems, there are quite precise ground measures of data at former reconnaissance; making full use of the contour vector data in design data can reduce the cost of DEM data. This paper introduces a feasible method, that is, contour vector data are dealt with by eliminating evection, elevation insertion and generating the feature elevation point, data modelling makes by using discrete contour line database TIN, and random lattice transforms to formula grid, which establishes high precise DEM economically, quickly and reliably. When generating TIN, it can adequately think over the specialty of contour, and neatly adapts to any intricate image data, considers initial terrain, and can well present the intricate ground at the dam site. The DEM data have the advantage in precision and efficiency.



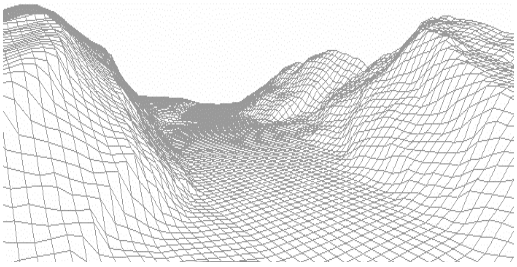


Figure 3: Triangulated irregular network **Figure 4:** Regular grid

Dam digital modelling

Spatial modelling of dam (Zhou 2003; Zhong 2003): the organization of spatial data relates to dam structure, the arrangement of concrete blocking and joint division and the requirement of temperature control. After ascertaining the geometry dimension data and space position data of thickness of construction, the bottom diversion outlets, the middle outlets, the top outlets, water diversion tunnel, ship lift dam, generating diversion tunnel, sand escape and the top of weir on outlet dam, by inserting calculation of control line of dam, it can get the information of number of dam blocks, thickness of construction, geometry dimension data of blocks, area and quantity of construction.

Spatial-temporal model of construction blocks: The geometry property of blocks waiting to be concreted is obtained by inserting calculation and the information of the blocks which have been concreted make the spatial-temporal model of blocks. The property of time of start and end of blocks incarnate the time character, and show the dynamic process of concrete construction. The organization of time and space data is the basis of 3D digital model which is used to carry out dynamic 3D visualizing by the function of GIS. This paper takes spatial-temporal model of bottom diversion outlets for example, as illustrated in Figure 5.

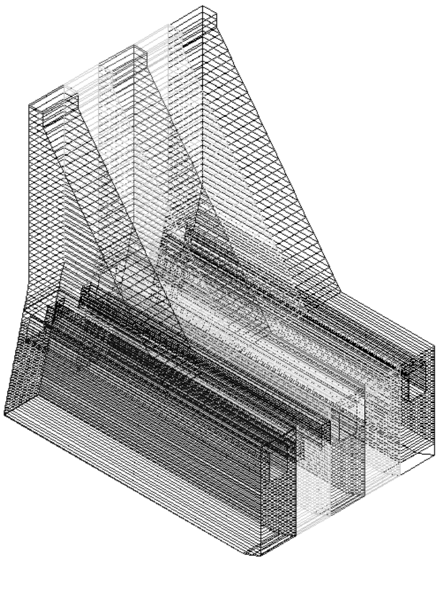

Figure 5: Spatial model of bottom diversion outlets

CASE STUDY

The XiangJiaBa project located in the county of Yibin in Sichuan province of China and in the county of Shuifu in Yunnan province of China, has the main function of generating electricity, and can anti-regulate upriver cascade hydropower stations. When completed, it can improve navigation, irrigation and sediment trapping conditions. According to the summary of conference checkup and opinion of experts, the two schemes (one scheme is three translation cable machine of 30t and three tower-machines (3+3), the other is three translation cable machine of 30t and two tower-machines) are both feasible. The former adds a tower-machine. The cost increases though it ensures the construction schedule, shortens the construction period, and brings the most economic interests causing by the first power generation in advance. Whereas the Three Gorges Project can provide three to four tower-machines for the XiangJiaBa project and avoiding wasting of resources, this paper makes a supplemental study on the ‘3+3’, and researches the disposal of cable machine, tower-machine and material supply line, purpose in Phases I and II, concretely working position, construction quantity, the scheme of joint division. It also studies the possibility of using pendulum-type cable crane in the XiangJiaBa project, by simulating different layout of pendulum-type cable crane of the scheme of two pendulum-type cable cranes, two translation cable machines and three tower-machines (2+2+3), on the ground of the present data and construction experience. Construction schedule, construction limit time, construction intensity and utilization ratio of pendulum-type cable cranes are compared. At this phase, simulating the schemes, the main parameters of various schemes are as listed in Table 1.

Table 1: The main parameters of various schemes

Scheme		**3□3**			**2□2□3I**			**2□2□3II**	
		none	one	two	none	one	two	none	one
Cable crane	Imax	39234	38575	39525	42347	44528	40043	41185	40218
	Iave	20835	19724	19559	23039	23143	23234	23982	22667
	Rave	43.12	39.24	37.34	47.42	45.29	44.06	48.66	44.57
	Rcom	56.38	54.52	51.88	62.00	62.92	61.21	63.63	61.93
Pendulum type cable crane	Imax	□	□	□	17467	15565	21621	19319	15675
	Iave	□	□	□	11726	9353	10704	12267	9494
	Rave	□	□	□	37.01	29.84	32.83	39.23	30.28
	Rcom	□	□	□	55.99	44.56	49.60	59.24	45.20
Tower machine	Imax	64444	65427	59040	59684	63799	62333	58075	62413
	Iave	43756	41681	41378	41823	40555	37388	42125	40732
	Rave	51.66	50.56	49.55	49.60	47.04	46.69	49.92	49.73
JGQ		□	57424	117597	□	57424	117597	□	117597
AImax		29.84	30.84	30.56	29.59	32.52	32.52	30.82	31.85
AIave		12.57	12.38	12.16	12.37	12.38	11.62	12.01	12.19
UI		2.37	2.49	2.51	2.39	2.63	2.80	2.57	2.61
TTL		64	65	66	65	65	69	67	66

Where Imax is the maximum intensity(10^4m^3/mon); Iave is the average intensity(10^4m^3/mon); Rave is the average utilization ratio (%); Rcom is the comprehensive utilization ratio (%); JGQ is the joint grouting quantity; AImax is all the maximum intensity of dam(10^4m^3/mon); AIave is the average intensity of dam(10^4m^3/mon); UI is the unbalanced index; TTL is the total time limit (month); none, one, two are the amount of the joint.

Compared with the '3+3' and '2+2+3I', '2 2 3II' is comparatively advanced in schedule, utilization ratio, construction intensity, construction limit time. The '3+3' and '2+2+3I' have advantages and disadvantages in the construction of concrete without a longitudinal joint and with one. The device set of the two schemes are feasible.

By combining simulation achievement with digital terrain model and data modelling of dam, it distinctly expresses the complex spatial–temporal relationship between all aspects of the project schedule. Phase I starts in September of the second year; stops construction when construction reaches 280.0m in December of the third year, as the diversion discharge of Phase II. Figure 6 shows the appearance. The dam is concreted above to 340m in June of the seventh year, and is able to keep off the 1% frequency flood, then, scour outlet dam section starts to be concreted, all of dam sections are concreted in the corresponding period; Figure 7 shows the appearance.

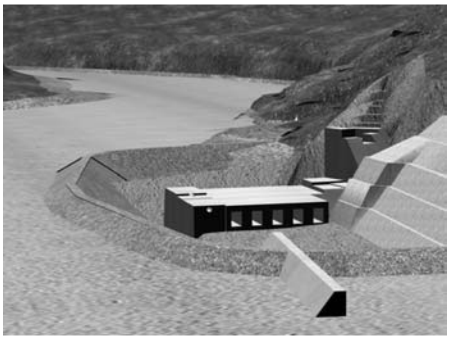

Figure 6: Construction appearance in December of the third year

Figure 7: construction appearance in June of the seventh year

CONCLUSIONS

The main influencing factors and the relationship of each other of the concrete construction is systemically analysed, the mechanism serve model and the construction simulated model are established, the dynamic emulation system of dam construction is explored. This system is used in the XiangJiaBa project, the technical and economical index such as construction schedule and construction image has been obtained. Based on the DEM and dam dimensional model, the dynamic three-dimension visual simulation with the harvest data is achieved by the using of the three-dimension technique, which distinctly expresses the complex spatial–temporal relationship between all aspects of the project schedule and provides a strong sustaining visual analysis data for construction design and management.

PROGRESS MONITORING OF ERECTION OF OFF-SITE PRODUCED UNITS USING PATTERN RECOGNITION

Ashraf Elazouni[1] and Osama Abdel-Wahhab[2]

[1]*King Fahd University of Petroleum & Minerals, Construction Engineering and Management Dept, PO Box 346, Dhahran 31261, Saudi Arabia*
[2]*University of Hail, Electrical Engineering Dept, PO Box 2440, Hail, Saudi Arabia*

Owing to numerous inevitable factors, the number of off-site produced (OSP) units of concrete structures being erected a day is generally not fixed but varies appreciably. Therefore, evaluating the completed work at a certain cut-off date by benchmarking against multiple possible outcomes becomes more meaningful than only one outcome. Pattern recognition (PR) techniques lend themselves well to accommodate evaluations based on multiple possible outcomes. The objective is to utilize PR to classify the work accomplishments achieved at predetermined cut-off dates. During the planning stage, a number of patterns are prepared at the cut-off dates and used to train the neural network (NN). During the construction stage, a pattern is prepared to describe the work accomplishment at a given cut-off date and entered to the trained NN. The NN will designate a date for the input pattern. Comparing the designated date to the actual cut-off date of the input pattern will indicate status of progress. The results were such that the developed NN could recognize patterns with an error rate of only 3.6%. Finally, the study proved that the concept and technique of PR offers a very effective and robust approach to monitor and evaluate the progress of construction projects.

Keywords: artificial intelligence, control, monitoring, off-site production, pattern recognition.

INTRODUCTION

Off-site production of concrete structures is a major accomplishment achieved during recent years which offers numerous benefits to the industry. Yet, the use by the construction industry of off-site production is limited. Blismas *et al*. (2006) argued that evaluating to what extent a building system should be produced off-site is inadequate within the industry. Blismas *et al*. advocated that the current evaluation methods for off-site production are cost- and not value-based, and therefore cannot account for the recognized benefits of off-site production. The consequence of this discrepancy is that off-site production invariably appears as an expensive alternative to the traditional on-site option. Blismas *et al.* concluded that the increasing complexity and value associated with off-site production mandates a more robust, transparent and inclusive evaluation methodology.

Beside the expeditious completion of construction, off-site production offers the merits of integrating design and manufacturing, thereby constructability issues can be properly

[1] elazouni@kfupm.edu.sa

addressed. In addition, the off-site production of the structural elements in an industrialized environment allows the achievement of high quality standards and expeditious production rates. The structural elements are produced in the manufacturing plant and transported to the job site, erected and serviced. Apart from production, other aspects of high relevance include the storage of the OSP units, the erection sequence and rate, and the definition of the construction path. Proper consideration should be given to each of these aspects so that the whole process will be smooth and efficient. However, the erection process of the OSP units represents the most critical activity that determines the total project duration. Thus, an effective progress monitoring and control system must be implemented during the erection process to ensure an expeditious project completion.

Owing to numerous factors, the number of OSP units being erected a day is generally not fixed but varies appreciably. These factors include the weather conditions, labour skill, manufacturing flaws, delivery rate, and the lifting-equipment capacity and conditions. These factors are out of control of the project manager and accordingly it becomes inevitable to accept their effect on the erection progress rate. Therefore, evaluating the number of the actually erected OSP units at a certain cut-off date by benchmarking against multiple possible outcomes becomes more meaningful and realistic than only one outcome. The pattern recognition concept lends itself well to accommodate evaluations based on multiple outcomes. The objective of this research is to utilize the pattern recognition concept and techniques to classify the work accomplishments achieved at regular predetermined cut-off dates. This classification will be used during the construction phase as a basis for monitoring and evaluating the progress of the erection process.

PREVIOUS RESEARCH

Several studies were reported in the literature related to computer-aided techniques that could be used for viewing site conditions and progress monitoring of construction projects. Hiroshi and Nobuoh (1993) described a filing system of construction pictures and its integration with a database. Abeid *et al*. (2003) described the development and implementation of an automated real-time monitoring system for construction projects programmed in a Delphi Environment. Riley and Whitesides (1999) conducted a study that assessed the feasibility, potentialities and best application for the implementation of digital image photography in the building design and construction process. Kubicki *et al*. (2004) focused on the use of building construction digital imagery as a computer-aided communication tool for improving coordination between the different actors involved in progress monitoring. Abd Majid *et al*. (2004) discussed the development of a conceptual integrated model that acts as a tool to monitor and evaluate the physical progress of a construction project at periodic intervals. The model integrates the 2D digital images captured from small-detail concrete structural elements at construction sites, the as-built AutoCAD drawings of these elements, and the standard scheduling tools such as Microsoft Project. Memon *et al.* (2005) discussed a digitalizing construction monitoring (DCM) model which integrates 3D CAD drawings and digital images to document as-built construction schedules.

Other studies were recently reported in the literature relating to techniques that could be used for progress monitoring and evaluating performance of construction projects.

Barraza *et al.* (2000) used a stochastic S-curve as an alternative to using the deterministic S-curve technique. Stochastic S-curves provide probability distributions for expected cost and duration for a given percentage of work completed. Monitoring project performance is performed by comparing the most likely budget and duration values, obtained from respective probability distributions for actual progress, with the project's actual data and cumulative cost. Cheng and Chen (2002) reported a study that focuses on developing an automated schedule monitoring system for precast building construction. The system, which is called ArcSched, is composed of a geographic information system (GIS) integrated with a database management system. Through systematic monitoring of the construction process and representation of the erection progress in graphics and colours, the scheduled components for erection are repetitively tracked. Construction progress is monitored through identifying the differences between the planned schedule and the real-time schedule. Nassar *et al.* (2005) presented a statistical approach, namely Weibull analysis, that can be used in conjunction with the earned value method to evaluate stochastically the schedule performance of construction projects. Poku and Arditi (2006) developed a system called PMS-GIS (progress monitoring system with geographical information system) to represent construction progress not only in terms of a CPM schedule but also in terms of a graphical representation of the construction that is synchronized with the work schedule.

It became obvious by surveying the previous research that utilizing pattern recognition concept and techniques in monitoring and evaluating the progress of construction projects, which is introduced in this study, is a novel approach in project management.

METHODOLOGY

During the planning phase of the project, cut-off dates separating periods at which the project will be regularly monitored during construction are specified. A monitoring period, typically a week, is determined when there is a need to describe a new stage of the project marked by the addition of an appreciable amount of work relative to the previous monitoring period. A special scheme is designed and used to indicate work accomplishments of the particular project. A scheme is basically a matrix with appropriate numbers of rows and columns which can be used conveniently to present the physical components of the building. The project work accomplishments at any time can be represented by filling in the appropriate cells of the schemes with 0–1 entries. As time goes on, the number of cells with entries of ones increases to reflect the extra work that was accomplished. During the planning stage of the project, a number of patterns are prepared for each cut-off date by filling in the cells of the schemes with 0–1 entries. The variation between the generated patterns at a given cut-off date is basically due to the variation of the daily number of erected OSP units. This set of schemes represents random patterns for the actual accomplishment at the project cut-off dates. The random patterns at all the cut-off dates along with the corresponding weeks will constitute the patterns to feed to the NN pattern recognition model. Some of the generated patterns will be used for training the NN and the remaining patterns will be kept for testing the trained NN.

After the construction stage of the project commences, the project monitoring is pursued regularly at the cut-off dates specified during the planning stage. A pattern is prepared to describe the work accomplishments at the desired cut-off date. This involves the measurement of work accomplishments already put in place up to the cut-off date. This pattern which represents the status of the project at the cut-off date is introduced as an input pattern to the trained NN model. The trained NN model will declare the week that the input pattern tends to converge to its patterns. Comparing the date of the declared week to the cut-off date of the input pattern will indicate the status of progress. Thus, the pattern recognition technique automatically implements the task of project monitoring and evaluation. A detailed implementation of the outlined methodology is demonstrated in the application section below.

APPLICATION

The study selected a real construction project as a test-bed to demonstrate the applicability of the pattern recognition technique. The test-bed project is a student housing project located in the campus of King Fahd University of Petroleum & Minerals (KFUPM) in Dhahran, Saudi Arabia. The facility constitutes nine identical L-shaped residential buildings, two common rooms and a Mosque. The superstructure of the buildings is constructed entirely using OSP concrete structural elements which are produced in a production plant and transported to the job site, erected and serviced. The OSP structural elements include load-bearing external and internal wall panels, parapets, beams, stair flights, solid slabs, hollow-core slabs and canopy. The external wall panel is 20cm thick, the internal wall panel is 15cm thick, the panel width ranges from 4 to 4.5 meters, and the panel height is 3.18m. The wall panels are fixed in place by means of sleeves and dowels. The design of the wall panel features four to five sleeves of 6cm diameter and 30cm depth at the bottom and the same number of dowels of 2cm diameter and 15cm length at the top. The hollow-core slabs are produced with dimensions of 1.2m width, 20cm thickness, and 2.2m–7m length. The hollow-core slabs can be saw-cut to the required length and width in the production plant to make the necessary adjustments for ending hollow-core slabs. The hollow-core slabs can be stored in site by stacking up the numbered units in a horizontal position according to the required sequence of erection, whereas the wall panels need costly special panel racks and thus are erected off-trailer.

The erection of OSP structural elements of only three residential buildings was considered for the purpose of demonstration in this study. Figure 1 shows the floor plan of a typical residential building with the wall panels numbered. Figure 2 shows the hollow-core slab layout with the hollow-core slabs, beams, and stair flights numbered. A scheme is designed to indicate work accomplishments of the project at the cut-off dates. The scheme is basically a matrix with 12 columns to represent three buildings each of three floors and roof parapet. The matrix has 254 rows comprising 81 wall panels, seven beams and 166 hollow-core slabs and stair flights for each of the three floors. The work accomplishments at any time can be indicated by filling in the appropriate cells of the matrix with 0–1 entries.

The construction engineer was interviewed and when asked to make an estimate of the number of erected OSP units a day replied that for the wall panels and parapet units the number ranges from 10 to 17 and for the hollow-core slabs, stair flights, beams and canopy the number ranges from 25 to 40. Accordingly, two statistical uniform distributions were established for the daily number of the erected wall panels and slabs.

Owing to the lack of actual data regarding the number of erected OSP units on daily basis, hypothetical uniform distributions were assumed, otherwise real statistical distributions would have been defined to reflect the type and location of the erected units. A uniform

distribution assigns equal probability to all values within the prescribed range to happen. Again, since there are no available data to support the hypothesis that different values have different possibilities of occurrence, the assumption of equal probability was made.

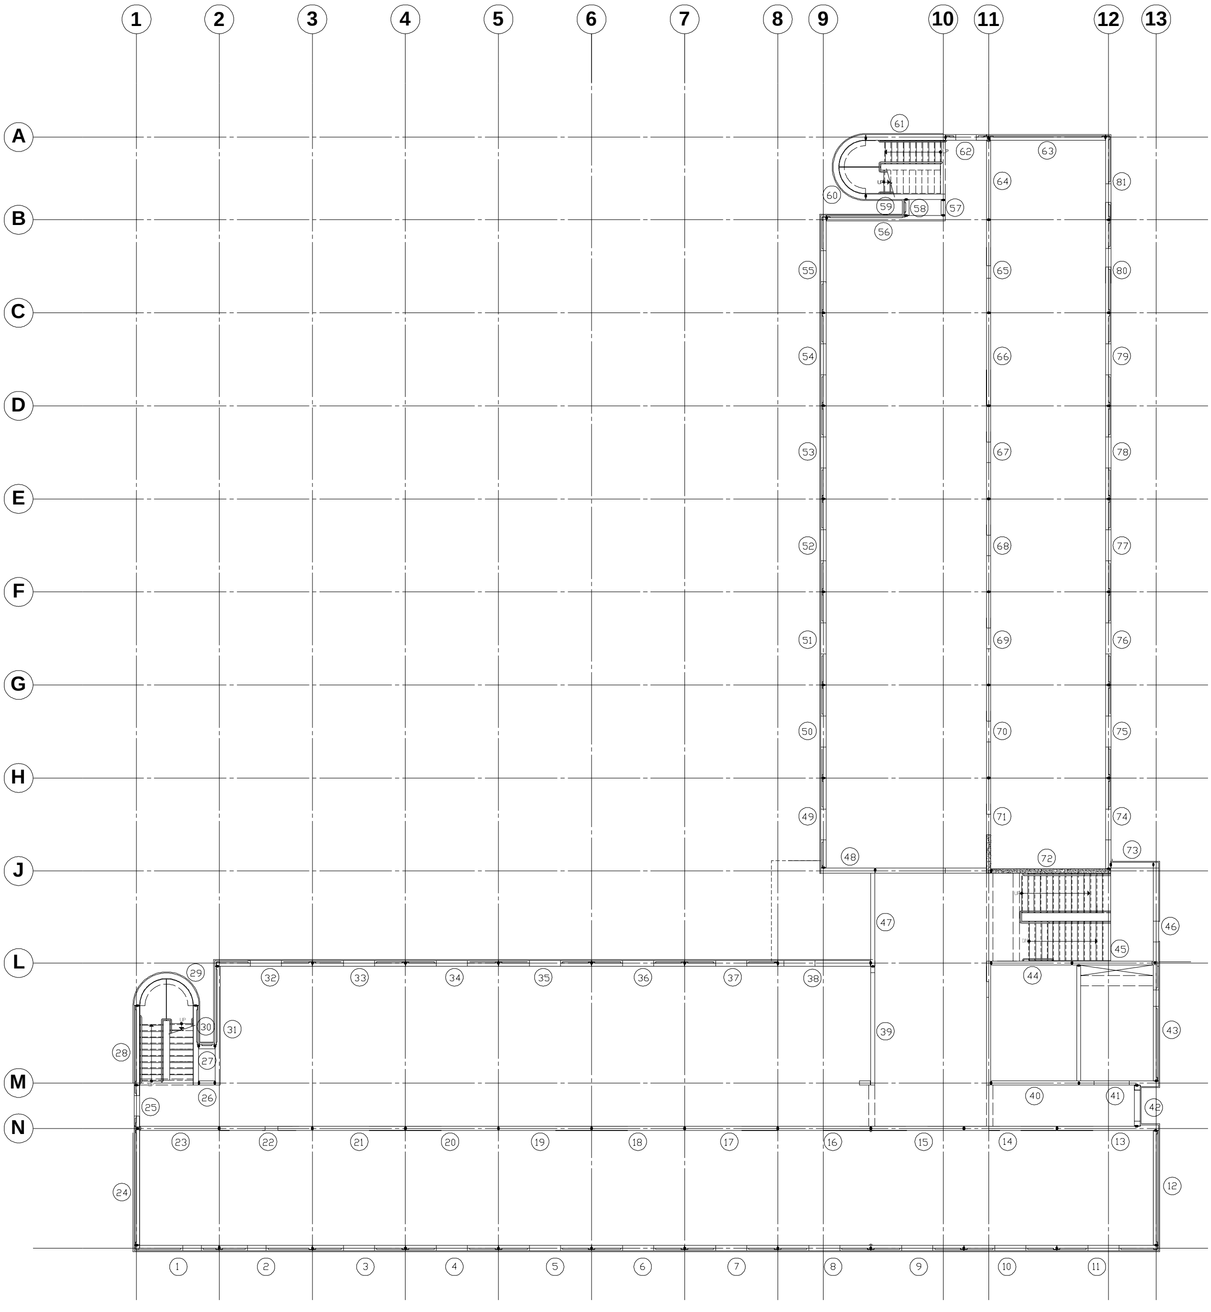

Figure 1: Floor plan of a typical residential building with the wall panels numbered

Figure 2: Hollow-core slab layout with the hollow-core slabs, beams and stair flights numbered

The erection work was simulated by randomly generating numbers to represent the erected OSP units on a daily basis using the established distributions. The appropriate cells of the matrix are filled in with ‘one’ entries following a given path of erection. The path of erection is such that wall panels of the first floor of the three buildings are erected followed by the hollow-core units of the first floor; then the work is repeated for the next two floors and finally the roof parapets. As time goes on, the number of cells with entries of ones increases to reflect the extra work that was accomplished. The simulation process was repeated 14 times to generate 14 random patterns for each cut-off date using different randomly generated numbers. Five patterns that correspond to week four are shown in Appendix I with shaded areas indicating cells with entries of ‘ones’. The five patterns feature the completion of the wall panels of the first floor of the three buildings as well as the hollow-core units, beams and stairs of the first building. The work is going on in the five patterns to erect hollow-core units, beams and stairs of the second building. It is to be noted that the variation among the generated patterns of the fourth week is basically due to the variation of the daily number of erected OSP units. The total erection time of the three buildings ranged from 20 to 21 weeks.

IMPLEMENTATION

The NN was trained using the algorithm developed by Abdel-Wahhab and Sid-Ahmed (1997). This algorithm proved to be faster and more stable than other algorithms presented in the literature. The set of data for training and testing the NN patterns constitutes 20 weeks; each week has 14 random patterns with a total of 280 patterns representing the input patterns. Since most of the random patterns of week 20 indicated project completion status, the patterns of week 21 were discarded to avoid the close similarity with the patterns of week 20. Associated with each input pattern there is an output pattern of a vector of 20 entries indicating entry of ‘one’ for the week of the pattern and ‘zero’ for the entries of the other 19 weeks. Some of the generated patterns are used for training purposes and the remaining patterns are kept for testing.

The inputs to the NN are 3048 elements representing elements of 12 columns and 254 rows and the output represents 20 weeks of the project duration. The NN was configured by changing the number of hidden layers and the number of neurons in each hidden layer. It was observed that the best performance was obtained at a configuration of one hidden layer containing 10 neurons. The NN was trained on pattern groups 1 to 10. The 10 training data were split further into two pattern groups, the first eight pattern groups and the remaining two pattern groups. The individual patterns of the eight pattern groups were used for updating the network weights and biases and were entered randomly to the neural network. The remaining two pattern groups were used for validation purposes. The validation process is a stopping criterion such that when the recognition error increases, the training session is stopped, and the weights and biases at the minimum value of error are returned. This method, which is called cross-validation, enables the generalization performance of the network to be monitored and prevents the network from overfitting the training data.

The trained NN was tested using pattern groups 11 to 14 which were not introduced to the NN during the training session. When a particular test pattern is entered to the trained network, the recognized week is the week exhibiting the highest output among the 20 weeks. The results are presented in Table 1 which indicates that the patterns of pattern groups 11 and 14 were all recognized correctly. However, two patterns of pattern group 12 and one pattern of pattern group 13 were recognized erroneously. In pattern group 12, the patterns of weeks 15 and 19 were recognized as patterns of weeks 16 and 20 respectively whereas in pattern group 13, the pattern of week 19 was recognized as pattern of week 20. However, it was observed that the NN outputs that represent the correct weeks for the three erroneous cases were slightly less than the erroneous declared weeks and the erroneous recognitions didn't exceed the next upper weeks. Generally, the NN could correctly recognize 81 members out of 84 with a recognition error of 3.6%. This low error value indicates that the proposed PR approach proved its effectiveness as a progress monitoring and evaluation technique for construction projects.

Erroneous recognitions could be attributed to the width of the ranges of the uniform distributions representing the number of precast units erected a day. The random selection from a distribution of a wide range to construct patterns of 21 weeks caused some patterns at a given week to show identical, or maybe less, work accomplishment compared to other patterns of the preceding week. This phenomenon is more likely to happen at the later weeks of the project when the effect of random selection from wide-range selection starts to build up. Through visual inspection of the patterns of the 20

Table 1: Pattern recognitions of the four test pattern groups

Week	**Test patterns**			
	Pattern 11	**Pattern 12**	**Pattern 13**	**Pattern 14**

***** Erroneous recognitions

BENEFITS OF USING PR TECHNIQUE

The collection of actual data in construction sites is prone to high degree of imprecision. Russell and Fayek (1994) noted that the issue of detection in the field contains a large extent of uncertainty and inconsistency. They imputed this problem to the considerable variance in levels of education and experience as well as attitudes toward recording daily site information by field personnel. Personnel responsible for recording daily site information range from experienced and educated engineers who are willing to accurately document work progress and productivity to inexperienced and uneducated personnel who struggle hard to document daily site information. Russell and Fayek (1994) noted that the attitude of personnel is to align themselves either with the field or with the office. Those who are pro-field personnel tend to avoid paperwork. In addition, the detection of work progress by the general contractor's personnel can be biased against the subcontractors.

Another problematic attitude of field personnel is to conceal the slow progress of some activities to appear in good shape. Knowing that the actual data will be compared directly against planned data on an activity-by-activity basis, the personnel reporting actual progress tends to covert the bad performance of stumbling activities by generously reporting the actual progress. They speculate that the problems are not really serious and some remedial actions will definitely speed up progress and produce better results by the subsequent cut-off date. Another reason to conceal slow progress is that being evaluated on an activity-by-activity basis and not on the holistic project performance, the bad performance of stumbling activities will camouflage the outstanding performance accomplished in some other activities. All these problems result in a great deal of variation in the quality of information collected in the field.

The process of traditional monitoring which compares the actual collected data of individual activities against single-valued benchmarks invariably results in great variation in the quality of data collected, owing to reporting skills as well as willingness to record accurately. The generalization feature that the NN brings about offers a potential environment to overcome this problem. The PR technique generalizes a virtual benchmark to represent the whole project based on multiple possible outcomes generated at each cut-off date. The merits that the generalized benchmark offers include:

- The effect of the imprecision in data collection (which is due to either the lack of experience or the nature of the work, making it difficult to figure out the accurate amount of completed work) on the evaluation of the status of activities and the whole project is significantly diminished.
- The impetus for personnel to inaccurately report data on purpose is entirely negated as actual progress is being evaluated against a virtual benchmark.
- A fair overall evaluation of the project considering both slow-progressed and well-progressed activities is presented to the field personnel while keeping the single-valued benchmarks of the individual activities exclusively to project managers to analyse situations and make decisions.

CONCLUSION

The objective of this study was to investigate the utilization of the concept and technique of pattern recognition to monitor and evaluate progress of the OSP concrete units. The results were such that the NN could correctly recognize 81 members out of 84 with a recognition error of 3.6%. This low error value indicated that the concept and technique of pattern recognition proved effective and robust to monitor and evaluate the progress of construction projects.

ACKNOWLEDGEMENT

IMPROVING TIME MANAGEMENT OF CONSTRUCTION PROJECTS

Jasper Mbachu[1]

Institute of Technology & Engineering, College of Sciences, Massey University, PO Box 756, Wellington, New Zealand

Time overruns besetting the global construction industry have negative consequences, including client dissatisfaction. Empirical surveys were carried out on the key constraints to effective time management and ways of improvement. The surveys involved registered members of the CIOB Southern Africa. Responses were analysed using multi-attribute method. Results revealed controllable and uncontrollable sources of constraints to effective time management. Constraints within the project team's control emanate from: contractors, subcontractors and suppliers; clients; consultants; and project characteristics. The most profound ways in which each source impacts negatively on effective time management are as follows. Contractors, subcontractors and suppliers: poor financial management and the associated cash flow problems. Clients: frequent changes to the scope of work. Designers: poor needs assessment and lack of foresight. Cost consultants: inaccurate estimation and pricing. Management consultants: poor strategic and risk management. The most influential uncontrollable set of constraints comprises government/statutory controls, chiefly, rules and regulations that impact on construction resources and progress. Overall, minimizing late changes through adequate briefing and feasibility studies was recommended as the most effective means by which the project team could improve time management in the construction industry.

Keywords: construction planning, contract administration, project management, project performance, scheduling.

INTRODUCTION

Time is probably the most valuable asset available to people and organizations. The guide to the Project Management Body of Knowledge (PMBOK) (PMI 1996) expresses project time management as the processes required to ensure on-time completion of the project. Time management in this context includes activity definition, sequencing and duration estimation, and schedule development and control. Since decisions made at the outset of a project are most crucial to a successful outcome (Rowlinson 1999), good time management should commence at the outset of a project development, and should include feasibility assessment, planning, scheduling, organizing, coordinating, monitoring and control of the implementation of construction projects within the constraints of available resources, and the internal and external environments within which the project is to be conceived and completed.

Effective and efficient time management of construction projects has been found to hold benefits for organizations and the construction industry in many respects (Nkado 1992; Cooke and Williams 1998; Chege and Rwelamila 2000; Bowen *et al*. 2002; Mbachu and Nkado 2007). For instance, Nkado (1992) argues that construction time

[1] j.i.mbachu@massey.ac.nz

performance is a basis for evaluating the success of a project and the efficiency of the project organization. In addition, Chan and Kumaraswamy (1998) observe that completing projects on time is symbolic of an efficient construction industry. Nkado (1992), Raftery (1999) and Mbachu and Nkado (2006) concur that the basic expectation of the client in respect of fulfilling the development needs and objectives is, essentially, receiving the project at the desired quality level, in the desired time frame and at the minimum cost compatible with this. This means that on-time project delivery is at the heart of client satisfaction, and is the bulwark upon which the confidence reposed in the project team is anchored.

Efficient time management has been a thorny issue in the global construction industry. Evidence abounds to suggest that time overrun is the norm (Alkass *et al*. 1996; Ogunlana *et al*. 1996; Kumaraswamy and Chan 1998; Ng. *et al*. 2004; Faridi and El-Sayegh 2006). Mantel *et al*. (2001) observe that between 60% and 85% of projects fail to meet their time, cost and/or performance objectives.

The consequences of inefficient time management and the resulting delays present the key problems militating against the development and viability of global construction. Some clients, especially the owner-occupiers, do prioritize time as being the constraint of utmost importance in the procurement process, owing to the high risk of default in time management. In this connection, Turner (1990) cites an instance where an industrialist or retailer may decide to extend accommodation in order to house a new process or respond to a new marketing approach. The cost of the building may only be a small part of the total project costs whereas a delay of two or three months in construction completion may delay a new production line or a new service, and could lead to loss of orders, missed opportunities, and ultimately to a ruined reputation. Generally, poor time performance diminishes the confidence reposed in the industry and its operators by financiers, insurers and clients, resulting in high interest rates, high insurance premiums, low patronage and ultimately downturns, liquidations and bankruptcies. Perhaps this lends credence to Cormican's (1985) remarks that the '(UK) construction industry is usually the most risky of the manufacturing industry and usually at the top of the bankruptcy league' (p. xi).

Time management complications inevitably arise with a construction project that involves management and coordination of several organizations and people who are all contributing to its completion. Several factors have been associated with inefficient time management and construction delays. Mantel *et al*. (2001) list possible causes of construction project delays to include improper or inadequate planning; late subcontractor deliveries; bad weather; unreasonable deadlines; equipment failure; and complex coordination problems. Delays could also arise because of estimation errors; variations in the specifications of the project deliverables; or changes to the rules of conduct or regulatory policies under which the project had been operating, all of which alter the initial plan of the project. Faridi and El-Sayegh (2006) list the most significant causes of delays in the UAE construction industry as including preparation and approval of drawings; inadequate early planning of the project; slowness of the owner's decision-making process; shortage of manpower; and poor site supervision.

Meredith and Shafer (2002) argue that planning is the most single important element in the success or failure of a project. From this perspective, the authors add to the list of factors underlying poor time performance: multi-tasking involving switching from a task associated with one project to another task associated with a different project; misuse of time contingency or buffers; lack of clear priorities; inflation of time estimates and the fact that work tends to fill available time; and conflicts in the project team formation arising mainly from priorities and procedures. Goldratt (1997) provides further insights into the causes of poor time management: student syndrome involving delaying the start of an activity that has good float resulting in inability to deal in a timely way with hidden constraints, the assumption that activity times are known with certainty, as well as wrong assumptions about precedence relationships and resource dependencies.

Suggested ways of improving time management of construction projects could be categorized into three broad groupings of solutions: improvement of procurement systems through the choice of integrative and collaborative approaches (Latham 1994; Love *et al*. 1998; Rwelamila and Meyer 1999; Chege and Rwelamila 2000; Toukey *et al*. 2001); improvement of the planning and scheduling processes (Cormican 1985; Goldratt 1997; Cooke and Williams 1998; Mantel *et al*. 2001); and the improvement of the organization and the delivery processes through the use of innovative systems (Ng *et al*. 2004). However, a key gap in the literature was that the suggested ways of improving time management comprise a listing of causes of delays and improvement approaches without some quantification of their likely impact on the time management efforts.

This study adopts the risk management perspective in exploring ways of improving time management of construction projects. The focus was on risk identification and risk quantification. Considerable research had been undertaken in the area of construction project risks, and ways of improving efficient time management and minimizing project delays have been suggested. However, the key gap identified in the literature was that possible sources of project risks or causes of poor time performance were listed without some quantification of their likely impact on time overruns. The study contributes to filling this gap by undertaking further risk identification and quantification, and ways of improving on-time project delivery. This involved a survey of contractors and consultants in the South African building industry who were registered members of the CIOB-Southern Africa. The following sections present findings of the literature and the empirical investigations.

METHODOLOGY

Research method

The descriptive survey method was used to explore further ways of improving time management of construction projects. The focus was on identifying constraints to effective time management and suggestions for improvement. This involved questionnaire surveys conducted with contractors and consultants in the South African construction industry who were registered members of the CIOB-Southern Africa.

Data analysis

The multi-attribute method was used to analyse the ratings of the respondents with a view to establishing a representative or mean rating point for each group of respondents. The analysis drew from the multi-attribute utility approach of Chang and Ive (2002), and Mbachu and Nkado (2006). It involved the computations of the mean rating (MR_i), which indicates the representative rating for a group of respondents as to their perceived level of influence or effectiveness of each attribute within a subset. In each computation, the total number of respondents (TR) rating each attribute was used to calculate the percentage of the number of respondents associating a particular rating point to each constraint as shown in the equation below.

$$MR_i = \sum_{k=1}^{5} (R_{pki} \times \%R_{ki})$$

where: MR_i = mean rating for attribute *i*; R_{pki} = rating point *k* (ranging from 1 to 5); $\%R_{ki}$ = percentage response to rating point *k*, for attribute *i*).

Using 2.5 as the threshold of influence in a five-point rating continuum – 5 being very influential, and 1 being not influential – the MR value served to prioritize and segregate the influential and not-influential constraints, based on the combined ratings by a respondent grouping.

FINDINGS

Survey results

In total 550 questionnaires were distributed to randomly selected representative samples of respondents from the sampling frame. By the cut-off date set for the return of the questionnaires, only 187 responses were received, out of which 178 were usable. This represented an effective response rate of 32%. The discarded responses were those that did not meet the quality criteria or consistency checks used to screen the responses.

Constraints to effective time management

The results of the analysis of the survey responses reveal that improvement in time management of construction projects could be achieved by addressing constraints to effective time management in five areas (see Figure 1): the client system; consultants; project characteristics; contractors, subcontractors and suppliers; and the external constraints.

Client-related constraints

The analysis of the client-related constraints in Table 1 shows that frequent changes to the scope of the work, especially at critical stages of the implementation process, were perceived as the most influential constraints to effective time management in the construction industry. This agrees with the observations of Sutterfield *et al*. (2006) that changing the project requirements after much of the basic project planning was performed and without a corresponding change in other variables could result in an inability to effectively estimate and control project deliverables.

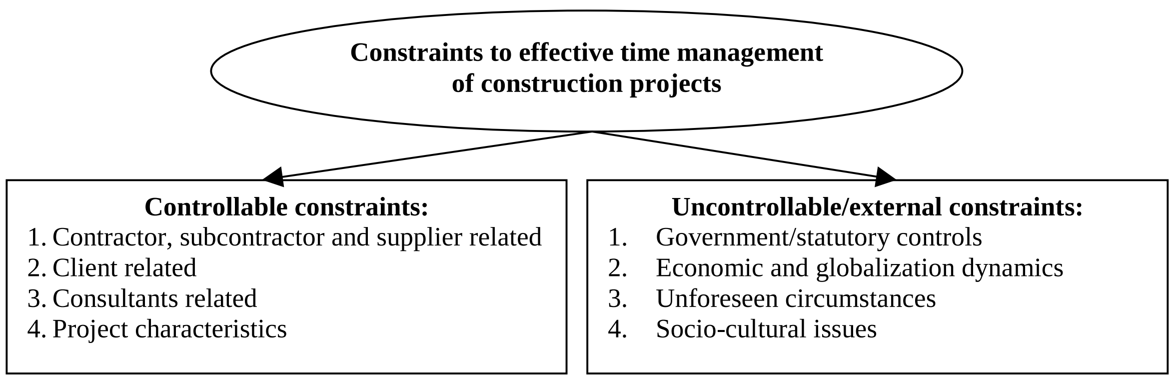

Figure 1: Broad categories of constraints to effective time management of construction projects

Table 1: Constraints to effective time management: client related

		Constraints to effective time management	VH 5 %	H 4 %	M 3 %	L 2 %	NI 1 %	TR	MR
Influential constraints: MR ≥ 2.5	1.	Frequent changes to the scope of work, especially at critical stages	39	29	24	6	2	178	3.98
	2.	Delayed or incomplete payment for works duly completed	37	34	17	9	3	177	3.93
	3.	Imposition of unrealistic deadlines	28	40	17	11	4	177	3.77
	4.	Delay in supplying required information	28	33	28	9	2	178	3.76
	5.	Insistence on preferred procurement route and contract forms, even when these are not appropriate	18	41	21	14	6	171	3.49
	6.	Impatience: not allowing sufficient time for feasibility studies, detailed design and planning before inviting tenders	17	21	44	14	4	173	3.33
	7.	Unclear scope of work: inability to comprehensively articulate and communicate project needs and requirements	29	17	34	21	5	175	3.32
	8.	Insistence on lowest tender as sole criterion for contract award	14	32	37	15	5	175	3.30
	9.	Insufficient funding to ensure progress and timely completion	11	26	35	17	10	176	3.11
	10.	Undue interference at construction stage	7	10	35	23	25	173	2.51
	11.	Void in project management responsibility: inability to delegate authorities for decision making; inexperience; lack of project management knowledge	6	17	21	33	23	174	2.49

*Levels of influence: 5 = Very high (VH); 4 = High (H); 3 = Moderate (M); 2 = Low (L); 1 = Not influential (NI). TR = Total number of respondents; MR = Mean rating.

Project characteristics

Constraining influences of the project characteristics were analysed as in Table 1; Table 2 summarizes the results. Project complexity, innovation/uniqueness, buildability issues and specification problems, all constitute the most influential project characteristics that impact negatively on time management. Shimizu and Hitt (2004) partly confirm this by observing that if specifications are not clear, inconsistent or incomplete, they become a source of uncertainty and risk which could undermine on-time project delivery.

Table 2: Constraints to effective time management: project characteristics

1.	Project complexity; innovation/uniqueness; design/buildability; specifications
2.	Difficulties arising from project size/scope of work
3.	Strategic importance of the project and the accompanying levels of expectations; number of stakeholders; conflicts of interests
4.	Site characteristics/environmental constraints: sub-soil conditions, terrain, hazards, underground services, etc.
5.	Site location: access, site restrictions, traffic congestion, parking space, services/infrastructure
6.	Availability of technology/resource requirements: labour, capital, plant, materials
7.	Social, environmental, statutory, legal, political or planning requirements for the type of project

Consultants' influences

The consultants' influences constraining efficient time management were analysed in Table 1; Tables 3–5 summarize the key constraints. Designers' most constraining influences were associated with poor needs assessment, including inability to comprehensively articulate clients' needs and requirements and foresee future changes. This result is not surprising, as without proper briefing and feasibility analysis, the planning will be based on inadequate information. In this context, Kerzner (2003) argues that good upfront planning may reduce the number of changes required in the project.

For the cost consultants, inaccurate estimation and pricing owing to the use of generic or outdated cost information was perceived as having the worst influences on time management. Perhaps the key issue here is the fact that contractors often use estimates provided by the cost consultants as benchmarks for expenditure and schedule controls (Cooke and Williams 1998). Inaccurate benchmarks would obviously lead to undesirable outcomes, including delays.

In Table 5, it was shown that poor strategic and risk management, failure to scan and respond proactively to the external environment, and inadequate contingency plans, all add up as the most profound ways in which management consultants could contribute to constrain effective time management. The next in importance is poor scope definition and management of scope creep, both of which fall within change management. Kerzner (2003) lends credence to these results by asserting that, 'if changes are unmanaged, then more time and money are needed to perform risk management, which often takes on the appearance and behaviour of crisis management' (p. 695).

Table 3: Constraints to effective time management: design consultants related

1.	Poor needs assessment: inability to comprehensively articulate client's needs and requirements and foresee future changes
2.	Delays in confirming instructions or supplying information required
3.	Buildability problems: designs not compatible with contractor's methods and equipment
4.	Design ineffectiveness: failure to sufficiently address client's needs and preferences, resulting in frequent and often covert revisions
5.	Insufficient details in project documentation
6.	Design/detailing errors and accompanying frequent revisions
7.	Poor/incorrect specifications and not taking responsibilities for errors or omissions
8.	Lack of flexibility in design to efficiently accommodate client changes
9.	Multi-tasking: being involved in too many jobs at the same time

Table 4: Constraints to effective time management: cost consultants related

1.	Inaccurate estimation and pricing mainly due to use of generic/outdated cost information
2.	Inaccurate or biased valuation of works, payments and claims, resulting in disputes
3.	Lack of knowledge of contractor's construction methods and equipment, resulting in cost management processes that are in conflict with contractor's expectations, and the associated animosities
4.	Lack of knowledge of broader issues affecting project costs resulting in invalid or unreliable cost advice
5.	Errors/omissions in bills of quantities
6.	Unprofessional conducts, especially being biased towards the client to the detriment of the contractor
7.	Lack of knowledge and experience in the methods of dispute resolutions and conflict management

Table 5: Constraints to effective time management: management consultants related

1.	Poor strategic and risk management, failure to scan and respond proactively to external environment; inadequate contingency plans

2.	Poor scope definition and management of 'scope creep'; poor change management
3.	Inadequate supervision, control and monitoring of contractors and works progress; inadequate visits to site
4.	Poor planning, forecasting/budgeting, organization and coordination of the project team and resources
5.	Weak project teams; lack of motivation and synergy
6.	Poor leadership owing to lack of technical and managerial skills/experience
7.	Poor communication and relationship management, especially inability to deal with conflicting organizational cultures
8.	Poor understanding and translation of client requirements owing to lack of clear understanding of client's business and overall strategic objectives for the project

Contractors', subcontractors' and suppliers' influences

Contractors', subcontractors' and suppliers' influences constraining effective time management were analysed as in Table 1, and summarized in Table 6. For the contractors and subcontractors, cash flow problems arising from lack of fiscal discipline, and lack of creditworthiness with suppliers and lenders, exert the most negative influences on on-time project delivery. On the other hand, delays in the supply of materials, components and equipment constitute the suppliers' worst influences on on-time project delivery efforts. This result agrees with the findings of Faridi and El-Sayegh (2006), that delays by suppliers are significant factors causing delays (in the UAE construction industry).

Table 6: Constraints to effective time management: contractor, subcontractor and supplier related

	Contractor and subcontractor related
1.	Cash flow problems: poor financial management/lack of fiscal discipline; lack of creditworthiness with suppliers and lenders resulting in inability to raise funds to complete the project on schedule, as well as delayed payments to subcontractors and suppliers
2.	Low productivity owing to inadequate motivation of workforce, use of ineffective methods and equipment, poor workmanship and abortive works
3.	Lack of proper coordination of own workforce and subcontractors; inadequate supervision, monitoring and control
4.	Poor planning, budgeting and scheduling; inadequate risk management and contingency plans
5.	Over capacity: handling too many jobs at the same time
6.	Lack of technical and managerial competencies; lack of experience on current job
7.	Inability to manage employer's changes/variation orders effectively
8.	Disruptions, costs and delays due to contractual disputes; adversarial relations, court/arbitration cases; poor relationship management; attitude to service
9.	Poor management of occupational safety and health issues, resulting in costly and disruptive accidents and associated penalties
10.	Shortage of skilled workforce; inability to attract and retain skilled workers
11.	Underbidding; cutting corners to save costs, tendering errors, frivolous claims
	Supplier related
1.	Delays in the supply of materials, components or equipment
2.	Supply of defective or incomplete materials/components
3.	Insistence on upfront payments; unwillingness to deliver to some areas
4.	Misunderstanding of material specifications and associated errors in supplies

Uncontrollable constraints

The identified uncontrollable constraints to effective time management were analysed as in earlier tables. The results are summarized in Table 7. The most influential in this grouping is a set of government/statutory control mechanisms comprising rules and regulations impacting on construction resources and progress, legal/statutory controls and overly prescriptive and overbearing enforcements.

Table 7: External/ uncontrollable sources of constraints to effective time management

1.	Government/statutory controls: rules and regulations impacting on construction resources and progress: monetary/fiscal policies (level of infrastructure spending, taxation, import restrictions, lending rates, etc.); legal/statutory controls (delays in giving project approvals by local authorities; town planning laws; permits/licensing; frequent amendments to existing policies); regulatory framework (building regulations, too prescriptive and overbearing enforcement of regulations such as OSH, etc.)
2.	Economic and globalization dynamics: delays arising from constraints on resources and demoralization due to volatility of exchange rate, inflation, interest rates, energy crises, demand and supply levels, etc.
3.	Unforeseen circumstances: delays arising from destructions and/or stoppages associated with site accidents, inclement weather conditions, natural hazards, etc.
4.	Socio-cultural issues: delays arising from stoppages, and demoralization due to industrial action, health issues (cancer; HIV/AIDS), socio-cultural attitude to work, alcoholism, absenteeism, vandalism, socio-cultural conflicts, disputes and racial tensions, xenophobia, etc.

Relative levels of influences of the broad categories of constraints

The relative levels of influences of the broad categories of constraints to effective time management were analysed in Table 8. The most influential grouping was perceived to be that of contractor, subcontractor and supplier related constraints. However, this result contrasts with earlier findings of Mbachu and Nkado (2006) who see this group of service providers as mere instruction-takers who must comply with the directives and supervisions of the consultants – the main group responsible for piloting the project to successful outcomes. The mean ratings of all five groupings were above 2.5, implying that they were perceived to exert significant influences on time management of construction projects. This finding concurs with earlier results – Faridi and El-Sayegh (2006) and Mbachu and Nkado (2007) – who adopted a similar pattern of classifying factors constraining successful project outcomes.

Table 8: Relative levels of influences of the broad categories of constraints to effective time management

		Broad categories of constraints to effective time management	Levels of influence*						
			VH	H	M	L	NI		
			5	4	3	2	1		
			%	%	%	%	%	TR	MR
Influential: MR ≥2.5	I.	Contractor, subcontractor and supplier related	34	39	24	1.7	1	178	4.03
	II.	Client related	25	39	32	1.1	3	178	3.82
	III.	Consultants related	3	24	24	41.0	7	178	2.75
	IV.	Project characteristics	2	8	57	26.0	7	177	2.72
	V.	External/uncontrollable factors	1	11	35	42.9	10	177	2.51

*Levels of influence: 5 = Very high (VH); 4 = High (H); 3 = Moderate (M); 2 = Low (L); 1 = Not influential (NI). TR = Total number of respondents; MR = Mean rating

Suggested ways of improving time management

Respondents made further suggestions on how to improve time management in the construction industry. The relative levels of effectiveness of the suggested ways were analysed as before; Table 9 summarizes the results. The most effective strategy was perceived to be minimization of the late changes by clients and consultants through adequate briefing and feasibility studies. This lends credence to the observations of Rowlinson (1999), that decisions made at the outset of a project are most crucial to a successful outcome. It is therefore perceived that by carrying out proper briefing and feasibility studies, clients' and users' future changes could be predicted and addressed in the design. This would go a long way to reduce the preponderance of client changes at critical stages of the project implementation and ultimately to on-time project delivery.

Table 9: Suggested ways of improving time management in the construction industry

1.	Minimize late changes by clients and consultants through adequate briefing and feasibility studies
2.	Effective planning: adequate time should be allowed for proper planning and verification of key facts at the outset
3.	Minimize cash flow problems by making sure that adequate funds are available before the commencement of the project, and that works duly completed are promptly paid for
4.	Award of contract should be based on capability, rather than lowest tender
5.	Team work should be engendered through proper coordination and communication, trust, openness, and emphasis on fairness and win-win outcomes
6.	Adequate project supervisions by both project managers and contractors
7.	Consultants should prepare detailed and complete contract documentations before calling for tenders
8.	Provide easy access to project finance for contractors, especially the SMEs; more government assistance in providing contract guarantees
9.	Continuous training and development of the workforce

CONCLUSION

The key gap identified in the literature was that possible sources of project risks or causes of poor time performance were listed without some quantification of their likely impact on time overruns. This study contributes to filling this gap by undertaking empirical investigations to identify further priority constraints to effective time management and ways for improvement, as well as the analysis of their relative levels of impact. The results reveal two broad categories of constraints to effective time management of construction projects: constraints within the project team's control (emanating from contractors, subcontractors, suppliers, clients, consultants and project characteristics), and external constraints. Under each source, the most profound ways in which effective time management could be constrained are listed as follows. Contractors, subcontractors and suppliers: cash flow problems due mainly to poor financial management/lack of fiscal discipline, and lack of creditworthiness. Clients: making frequent changes to the scope of the work, especially at critical stages of the implementation process. Designers: poor needs assessment, i.e. inability to comprehensively articulate clients' needs and requirements and foresee future changes. Cost consultants: inaccurate estimation and pricing due to the use of generic or outdated cost information. Management consultants: poor strategic and risk management approaches, including failure to scan and respond proactively to external environment and having inadequate contingency plans.

In the order of significance of influence on time management, the groupings of constraints which are outside the project team's control comprise the government/statutory controls, economic and globalization dynamics and unforeseen circumstances. Overall, minimizing late changes made by clients and consultants through adequate briefing and feasibility studies was recommended as the most effective means by which the project team could improve time management in the construction industry.

ACKNOWLEDGEMENT

The author wishes to thank Ernest Yeboah-Acheampong of the School of Construction Economics and Management, University of the Witwatersrand, Johannesburg, for his assistance in the second phase of the questionnaire surveys.

CONSTRUCTION COORDINATION FUNCTION – A PERSPECTIVE BASED ON THE ‘STACEY DIAGRAM’

D. Darshi De Saram,[1] Pradeep G. Chettri[1] and Paul W. Fox[2]

[1]*Department of Construction Management and Engineering, North Dakota State University, Fargo, North Dakota 58105, USA*
[2]*Department of Building and Real Estate, The Hong Kong Polytechnic University, Hung Hom, Kowloon, Hong Kong*

The critical incident technique (CIT) was used in this study to gather qualitative data on quality aspects of construction coordination. As a first step in sorting the data, 82 critical incidents were mapped on the Stacey Diagram. The result indicates that incidence of negative incidents is low at the bottom of the diagram, where there is high agreement among the parties to an issue in question. Possibly, the way construction projects are managed, practitioners are better prepared to make judgmental decisions required in these situations. Conversely there is much greater incidence of negative incidents at the top of the diagram, where there is low agreement among the parties to an issue in question. This maybe an indication that construction practitioners are less equipped to handle matters of organizational dynamics required either to align the parties concerned or to arrive at a compromise.

Keywords: complexity, coordination, critical incident technique (CIT), organizational dynamics, site operations.

INTRODUCTION

Construction coordination is found to be a very complex function with a vast scope of activities. Chitkara (1998) and Martin (1976), state that a project manager has to carry out planning, organizing, staffing, directing and controlling. Chitkara (1998) further modifies these duties to suit the construction project environment as planning, organizing, procuring, leading and controlling. Then he states that common to all these functions is the function of coordination. It is noticeable that most duties and responsibilities of a construction project manager contribute to achieving coordination. Walker (1996) states:

> It is clearly the case that success of the construction process depends to a large extent upon the way in which the architect, engineer, quantity surveyor, contractors and others work together. It depends upon them perceiving the same objectives for the project and recognising that what each of them achieves depends upon what the others do. With this view they should be able to stand above the particular interests of their own contribution and see the problem posed by the project as a whole. The advent of the project manager has, to a large degree, come about as a result of the inability of the contributors to consistently achieve this and in response to the consequent need for someone to concentrate solely upon integrating the various contributors in the interest of the client.

[1] darshi.desaram@ndsu.edu

Crichton (1966) has described the reality in a construction site as a social system in which ‘a group of people are systematically sharing control of a common process, where the relationships among the group are based on mutual independence and contributions to the common task are based on sequential finality’. He further states that this system ‘does not seem suited to effectively control a process characterized by interdependence of operations, fraught with uncertainty, requiring carefully phased decisions and continuous application of all control functions’. In such a context, ‘coordination is essential both within and among the various departments to fill up the voids created by changing situations in the systems, procedures and policies … coordination is one of the most sensitive functions of the management’ (Chitkara 1998).

There are reasons that make it difficult for industry practitioners and researchers to align the construction coordination function with the ‘classic’ quality improvement models of total quality. Tenner and DeToro (1992) have indicated that it is difficult to apply the ‘classic’ tools of total quality to service processes that are characterized by low degree of repetition (low repetition), intangibility and high customer participation in the processes themselves (co-production). Further, Crichton (1966) points out that coordination in the building industry is carried out quite informally. De Saram (2002) observed that the two characteristics of the coordination processes: (1) customers not actually soliciting the service (unsolicited service); and (2) the problem-solving nature of the coordinators’ work also make it difficult to manage construction coordination as a systematic service process.

Possibly because of such reasons, construction coordination function remains under-researched. In this context, De Saram (2002) presents an argument that multi-attribute quality measurement methods are not suitable for measuring the quality of the construction coordination function and proposes the critical incident technique (CIT) as a more effective method.

This paper presents a part of an investigation that was carried out to explore the value of applying the critical incident technique (CIT) to the construction coordination function, in particular to see if coordination quality can be measured effectively through the technique. Over 100 critical incidents (defined below) of construction coordination were collected from site personnel in a number of countries of Asia and North America. On sorting and cataloguing the incidents collected, a significant difficulty was encountered in using ‘coordination processes’ as one level of classification. The results appeared to vindicate the statement by Schön (2002): ‘Artistry is not reducible to the exercise of describable routines’. To overcome this hurdle, and to carry out the classification in a meaningful way, an attempt was made to map the critical incidents on the ‘Stacey Diagram’ (introduced below). The mapping thus revealed a different perspective of the construction coordination function. In most industries, coordination is seen as a function requiring technically rational management. This segment of the research examines how the construction coordination function maps outside the area of certainty.

OBJECTIVE OF THE RESEARCH

The objective of the research presented is to: map critical incidents of construction coordination on the ‘Stacey Diagram’, so as to enable construction practitioners to be better informed in selecting management methods they may apply.

CRITICAL INCIDENT SORTING IN PREVIOUS RESEARCH

Another significance of this research is that the exercise of mapping on the Stacey Diagram could be considered as a meaningful way to sort critical incidents, departing from paths taken by previous research applying CIT in a number of other studies. In many previous research studies using CIT that were available for review, critical incidents were sorted into various categories as given in Table 1. Because of the very wide scope of the coordination function, attempts to adopt similar techniques to decide on sorting categories yielded too many categories and subcategories to be useful. In this context it was anticipated that mapping critical incidents on the Stacey Diagram would not only be a meaningful way of sorting, but would also reveal a new perspective of this complex and less tangible function.

Table 1: Sorting critical incidents in previous research

Publication	Method	No. of categories
Smith and Kendall (1963)	Qualities or characteristics to be evaluated (by sorting the incidents) were listed by the team performing analysis and further refined over an iterative procedure	9
Fineman and Payne (1973)	Sorted by each of the researchers independently into apparent clusters	7
Campbell *et al.* (1973)	Sorted into what appeared to be homogeneous categories and further refined during discussions held as analysis progressed	10
Latham and Wexley (1977)	Incidents which describe essentially the same behaviour were grouped into one cluster	78
Hamlin and Reidy (1997)	Subjectively classified and clustered	8

THE STACEY DIAGRAM

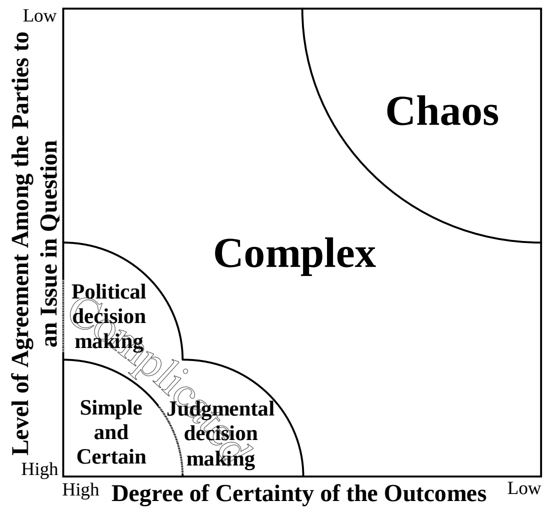

Figure 1: The Stacey Diagram (Zimmerman 2001)

The ‘Stacey Diagram’ (Zimmerman 2001), also known as the ‘Landscape Diagram’ is based on two perpendicular axes representing the degree of certainty of the outcomes and the level of agreement among the parties to a management issue in question (see Figure 1). In the quadrant thus formed, the area adjacent to the lower left corner represents issues of greater certainty to which the technically *rational* management may be applied, where most scientific and engineering management theories are focused. The area adjacent to the opposite (upper right) corner represents *chaos*, a condition most managers and researchers may wish to avoid. When moving away from the lower left corner, one first encounters a zone where, as shown in Figure 1, management begins to become complicated requiring *judgmental* decision making (more in the direction of the horizontal axis) and *political* decision making (more in the direction of the vertical axis). In between the zones described so far, there is a large area, stretching from the upper left corner of the quadrant to the lower right corner, where dynamics of *complexity* are more significant. In this region, the self-organizing and evolving nature of organizations becomes more visible and concepts of complexity become significantly applicable.

The Stacey Diagram, as discussed above, is a perspective of how different management approaches maybe interrelated. Construction coordination, being a complex and diverse function requiring diverse management approaches, may map into various areas of this diagram.

USE OF THE CRITICAL INCIDENT TECHNIQUE TO STUDY CONSTRUCTION COORDINATION

Stauss (1993) further states that the CIT is essentially a means of assembling and classifying stories or ‘critical incidents’ by employing content analysis, and that Flanagan originally developed this method in 1954 to identify requirements for effective job performance. He defined an incident as ‘any observable human activity that is sufficiently complete in itself to permit inferences and predictions to be made about the person performing the act’, and is called critical ‘if it makes a “significant” contribution, either positively or negatively, to the general aim of the activity’. Thus, CIT focuses on events that have been ‘seen to lead to success or failure in accomplishing a task’ (Stauss 1993).

Stauss (1993) states that a survey of critical incidents involves two questioning steps. The first requests a ‘comprehensive description of the incident in the customer’s own words’, followed by a query as to ‘which circumstances were decisive for the customer’s evaluation’. Based on these guidelines and taking the survey described in Bitner *et al.* (1990) as an example, the very simple set of two questions was developed, as described below:

> Think of a time when, as a construction project participant (at the construction stage), you met with a particularly satisfactory (or unsatisfactory) incident of site coordination by the main contractor.
>
> 1. How exactly did the incident happen? (Need not disclose the names of the site or companies or individuals involved. Use their designations only, e.g. client, main contractor, project manager, site engineer, QS.)
> 2. What actions in that incident exactly made you feel satisfied (or dissatisfied)?

Our inquiry was not focused on any particular site, because this might create both a lack of willingness to furnish information and a lack of confidence to supply authentic information, and it was decided to collect data only from industry personnel who were volunteering to participate. Therefore, as evidenced by the first question above, the respondents were made to feel comfortable by allowing the critical incidents described to be unattributable. Nevertheless, it was necessary to establish the type of stakeholder responding to the survey, and a third question was therefore asked as follows:

3. In that site, what was your position?
   ……………………………………………… working for the Client/Consultant/Main Contractor/ Other (please specify) …………

   (Delete inapplicable)

Over 100 critical incidents of construction coordination were collected from site personnel in a number of countries of Asia and North America.

MAPPING CRITICAL INCIDENTS ON THE STACEY DIAGRAM

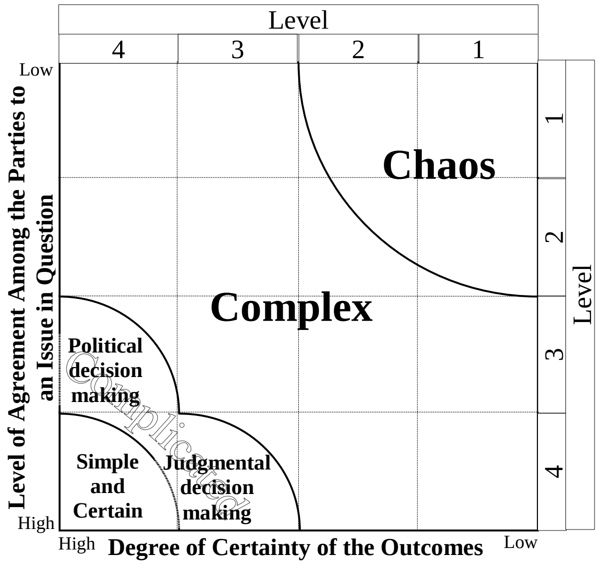

Figure 2: The Stacey Diagram showing four broad levels along each axis

A total of 82 critical incidents were mapped on the Stacey Diagram. As the critical incident survey collected qualitative data, it was necessary for the researchers to analyse each incident and decide how they map on the diagram. The procedure was to read each incident carefully and decide:

1. what degree of certainty of the outcomes (along the horizontal axis); and
2. what level of agreement among the parties to an issue in question (along the vertical axis)

is reflected. After careful analysis, critical incidents were categorized into four broad levels from 1 to 4 (1 being the lowest and 4 being the highest) along each axis as indicated in Figure 2. To illustrate this process of categorization, four examples are given below.

Example 1

Critical Incident No. 0003

Responding stakeholder: Client

> There are instances where the contractor has to make floor penetrations of sizes ranging as small as 50–75mm to as big as 300mm. The contractor will miss out – human beings – so end up needing coring. In some areas, if you miss out, coring will not be possible due to the structural concept – the structural engineer will say you cannot core within 600mm of the column.
>
> Here [in that site] they missed a row of penetrations for rainwater down pipes. They were next to the columns and as a result they wanted to go through a point 600mm away. If they were going through the original location they could have made a neat and small 150mm box-out next to the column. Now they would need a huge box-out. I refused because the furniture will not fit in anyway and it is an utter waste of space – some 750mm just for a rain water pipe! I wanted the rain water system to be redesigned and the architect came with a scheme that was not all that nice.
>
> I am dissatisfied because it was a terrible mistake. It is very difficult to correct. There are so many people out there [onsite] to check these things and coordinate.

In the above critical incident, the mistake appears to be genuine. The contractor appears to have had every intention of making the floor penetrations as designed. The level of agreement among the parties to the issue in question (along the vertical axis) could hence be considered as very high, i.e., ‘Level 4’. On a construction site, this is usually an activity watched by many pairs of eyes, hence, the degree of certainty of the outcomes (along the horizontal axis) is very high, i.e. ‘Level 4’, although it had failed this time. This incident would, as a result, map on to the region close to the bottom left corner of the Stacey Diagram, where the management approach is considered simple and certain.

Example 2

> Critical Incident No. 0007
>
> Responding stakeholder: Executive Engineer (working for the client)
>
> Because we are working close to an MRT [underground railway (Singapore)] reserved line there are certain load restrictions that are imposed at certain locations of the construction site. Initially, there were some overloading issues where they stockpiled too much debris at certain sensitive areas. Having informed them on this and requested to enforce stricter control, some initiative the contractor took was to, besides just imposing the controls, put up flag lines, printed and put up placards indicating certain demarcation zones, at certain locations defining clearly what the loading requirements are.
>
> These are the initiatives contractors took though we did not really expect. I think these are good controls.

In the above critical incident, the contractor’s management shows a genuine commitment to prevent overloading the ground at the sensitive locations of the site. Hence the agreement among the parties to the issue in question (along the vertical axis) could be considered as very high, i.e. ‘Level 4’. The degree of certainty of the outcomes (along the horizontal axis) was categorized as ‘Level 2’ because there is the risk of site operatives making a mistake.

Example 3

> Critical Incident No. 0015
>
> Responding stakeholder: Quantity Surveyor
>
> It was a measure and pay contract and a huge site where they were constructing many buildings, concrete aprons, services, roads and so on. Contractor was laying external water and sewage mains. Usually they will excavate a trench of sufficient length for laying 3 or 4 six-metre lengths of pipe. Then, they lay the pipe and backfill with a minimum sand cover of 150mm. Backfilling is done immediately after the laying of the pipe to avoid the danger of the PVC pipe getting displaced if it rains and the trench gets flooded. However, this process takes around a day, during which my staff take the measurements. The problem happened when the contractor had to do a 100mm water supply branch line to a remote corner of the site. The length of the branch was nearly 100m long – a job that would have taken maybe three days at their normal pace. However, the ground was found to be extremely sandy and starting the work after lunch one day, they had excavated the entire length of the branch in maybe couple of hours. The specification was that the minimum width of a trench was to be 600mm. However, because of the very sandy conditions and because of the absence of rocks or any foreign matter, the consultant had not insisted on the sand cover and allowed them to lay the pipe in a just 300–400mm wide trench and use some of the excavated material itself in the cover. Being just a 100mm pipe, they had very easily fitted it and the whole job was over by the end of that day. Being a very large site my staff have not been aware of this rapid progress and were not there to take the measurement. Nobody cared to inform us to take the measurements. Usually they did not have to inform us because our staff take all these measurements on our regular rounds.
>
> When the interim valuation came, it was prepared as if the work went as per specification – 600mm trench, supplied sand cover and so on. Together with the consultant we disputed this.
>
> I was dissatisfied because we were not informed before backfilling the trench and the contractor tried to use the situation to claim for more than what was actually done.

Parties to the above critical incident pursued their own agendas. The agreement among the parties to the issue in question (along the vertical axis) could be considered as very low, i.e. ‘Level 1’. The degree of certainty of the outcomes (along the horizontal axis) was assessed as ‘Level 3’ because all were trying to follow some specifications, norms and bills of quantities.

Example 4

> Critical Incident No. 0021
>
> Responding stakeholder: Site Engineer

> In this [building] site we have a chaotic situation. The electrical subcontractor was to lay the conduits. It had been sub-sublet and we had lots of problems. Initially, the material did not come on time, enough men were not brought in … We had to bring in their senior personnel and make a lot of fuss to get them moving. Still there was a lot of shoddy work and abortive work. Now, this affected many trades starting from concreting, masonry to finishes … I can say everybody was delayed. The Project Manager should have called everyone and said, 'OK we now have a problem lets see the schedule', try to readjust, refocus where we need to focus, get everyone to say how they will adjust their schedule and then check where they clash and readjust and say, 'Well, yeah we are stuck and this is the problem this is where we are going'. Instead he just kept on asking the people 'When can we finish this? – When can we finish that?' Now, the whole site does not have a focus, you do not know where you are going and many of us lost interest. Now this fellow wants to do this [work], that fellow wants to do that [work] and when they clash both argue that they are delayed and cannot wait for the other's work. So, I will put the problem to the Project Manager. He takes instant decisions to let one fellow override the other. That made many of them angry.
>
> The site is moving at a much slower rate than compared to good support from higher management plus a lot of people are frustrated though staying on this site, I want to request to be transferred out.

The above critical incident was considered as a good example where both the agreement among the parties to the issue in question (along the vertical axis) and the degree of certainty of the outcomes (along the horizontal axis) are at their lowest, i.e. 'Level 1'. As admitted by the respondent, a chaotic situation prevails!

RESULTS

Eighty-two critical incidents collected were mapped on the Stacey Diagram as shown in Figure 3. In addition to the number of incidents that mapped into each square, the diagram presents the number of positive incidents among them. (An incident is called *critical* 'if it makes a "significant" contribution, either positively or negatively, to the general aim of the activity' (Stauss 1993). All incidents, hence, were either positive or negative).

It is apparent that none of them mapped on the squares (1,3), (1,4), (4,1), (4,2) and (4,3) (determined by 1–4 scales along the two axes), indicating a possibility that there are not many instances pertaining to the construction coordination function where it is either 'low in certainty while high in agreement' or 'high in certainty while low in agreement'. A very high number of incidents (73.17%) mapped on the column where the 'degree of certainty' was Level 3, suggesting that it is an area of where much of the coordination activities take place. Therein, 36.59% incidents (70% of them negative) mapped on the square (3,2) (corresponding to Level 2 in agreement).

It is observable from the results that incidence of negative incidents is low at the bottom of the diagram, where there is high agreement among the parties to an issue in question. Possibly, the way construction projects are managed, practitioners are

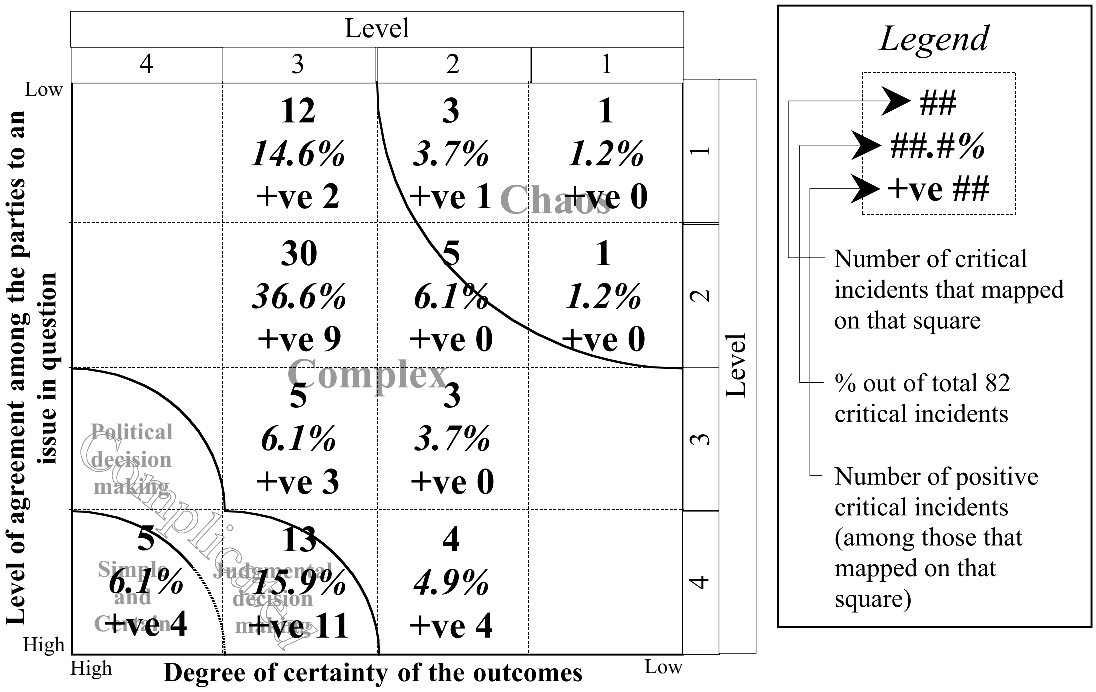

Figure 3: Mapping 82 critical incidents on the Stacey Diagram

better prepared to make judgmental decisions required in these situations. Conversely there is much greater incidence of negative incidents at the top of the diagram, where there is low agreement among the parties to an issue in question. This may be an indication that construction practitioners are less equipped to handle matters of organizational dynamics required either to align the parties concerned or to arrive at a compromise.

The two incidents that mapped into the square (1,1) and (1,2) were rather extreme situations where the project managers were very poor at bringing project teams together and focusing their efforts.

The positive incident that mapped on the square (2,1) was due to a very good policy decision by one contracting company, which enabled excellent grasp of the project requirements by the construction team as follows (stated by an architect):

> Contractors have a QS team for tendering. They are not technical people. Once the tender is awarded, construction personnel complain of various buildability problems; especially, the foremen and the technical staff keep coming to me. One contractor employs the prospective project manager to do the bidding. The project manager and senior personnel at the site, as a result, had a good grasp of the project and the design problems.

Twelve incidents that mapped on squares (3,1) and (3,2) were mostly due to some of the parties not aligning with the project objectives and complicating matters that may have been otherwise resolved. The high incidence of such critical incidents, especially negative ones, indicates the necessity for project managers to be equipped with skills in managing organizational dynamics required in such situations. Incidents on the square (3,3) are situations where project managers went a step further to make certain parties (who usually would not work together) to a construction project work together.

A number of incidents in the bottom row of the diagram are positive incidents due to partnering. The few negative incidents are due to oversight by some personnel. Results, hence, indicate that much progress has been made by the construction industry in handling issues in this area of the diagram.

CONCLUSIONS

Construction coordination is a complex function with a very wide scope. Mapping 82 critical incidents of construction coordination on the Stacey Diagram was expected to reveal what areas of operation would pose greatest challenges to construction practitioners, in terms of coordination.

The results indicate that, as shown by the number of incidents that map, there are not many instances pertaining to the construction coordination function where it is either 'low in certainty while high in agreement' or 'high in certainty while low in agreement'. A very high number of incidents mapped on the column where the 'degree of certainty' were at Level 3, suggesting that it is an area where much of coordination activity takes place. Especially, the high number mapped on the square (3,2) (corresponding to Level 3 in certainty and Level 2 in agreement) and the high number of negative incidents therein suggests that it is an area where future improvement effort needs to be focused.

The results indicated that there is a low incidence of negative incidents in the region where the level of agreement among the parties (to an issue in question) is high. The few negative incidents are due to oversight by some project personnel. Results further suggest that present-day construction practitioners are relatively well prepared to handle issues requiring judgmental decision making encountered as one moves to the right along the horizontal axis.

Much greater incidence of negative incidents is observed in the region where there is low agreement among the parties to an issue in question. This maybe an indication that construction practitioners are less equipped to handle matters of organizational dynamics required either to align the parties concerned or to arrive at a compromise. It was observed that partnering made a number of positive critical incidents that mapped in the high agreement area, among parties that would otherwise have had low agreement. It, hence, highlights the value of endeavours such as partnering that would align disparate parties to a construction project. The results, nevertheless, show the need for construction project managers to be better equipped with skills in managing organizational dynamics required either to align the parties concerned or to arrive at a compromise.

ACKNOWLEDGEMENT

The authors wish to express gratitude to the respondents to the surveys, whose kind cooperation, time and effort made this research possible. We also wish to acknowledge the research grants G-YX23 and G-V458, and other facilities provided by The Hong Kong Polytechnic University, and the funding and support by the North Dakota State University.

PROJECT MANAGEMENT – LEARNING FROM BEST PRACTICE

Thorbjørn Ingvaldsen[1] and Dag Fjeld Edvardsen

SINTEF Byggforsk (Norwegian building research institute), PO Box 123, 0314 Oslo, Norway

A research project (2002–2006) has developed a method for measuring efficiency in the construction industry. This method has been applied on a sample of blocks of flats projects. The objective is to establish a solid basis for systematic improvements in construction companies. The approach includes use of custom-made computer programs for statistical analysis. The efficiency scores of 122 building projects have been measured using Data Envelopment Analysis. A total of 407 hypotheses of efficiency were established, mainly related to environmental conditions and managerial factors. The hypotheses were tested against the efficiency scores. Fourteen variables were found to have empirical relevance for efficiency. A report generator for two types of individual reports has been created. The first type gives feedback to each project manager regarding the performance of his project compared to Best Practice. This makes it possible for the project manager and his team to reflect on whether their way of managing projects is optimal. The other individual report is for line managers in companies having more than one project in the sample. Key Performance Indicators for the company are compared with those for the whole sample. This enables the line manager to evaluate the performance of the portfolio of projects – and the competitiveness of the unit/company. The intention is to stimulate experience based learning processes. Hopefully, improved productivity will follow.

Keywords: benchmarking, best practice, key performance indicators, experience-based learning, productivity, DEA.

INTRODUCTION

“Learning from Best Practice” has been an expression in almost every industrial sector in the last two-three decades. It reflects the philosophy of the ISO 9000 group of international standards of quality, where systematic, well-organized and well-facilitated processes based on facts are presented as a general recipe for success.

Increased computer capacity during the last decades, and developments in measurement theory have made formal analysis of complex systems possible. A large number of research papers about benchmarking and identification of best practice based on Data Envelopment Analysis (DEA) have been published (Tavares 2002). To the best of our knowledge, information about benchmarking between competing companies in the construction sector is not found in the literature.

In 2001, the Norwegian research council, in cooperation with the construction industry in Norway, declared ambitions to develop a “productivity measurement tools” with the purpose of Best Practice identification in construction industry.

Norwegian building research institute (now: SINTEF Byggforsk) was asked to cooperate with the DEA-skilled econometricians at the University of Oslo/Frisch

[1] thorbjorn.ingvaldsen@sintef.no

Centre in order to create the desired computer-based method for increasing the understanding of productivity in the construction industry.

THE PRODUCTIVITY RESEARCH PROJECT

The development of the method is reported elsewhere (Ingvaldsen and Edvardsen 2007). In this paper, the experience-based learning for performance improvement is in focus, based on the results from the analysis. Basic elements in the research project have been:

- Pilot study of building projects.
- Focus on on-site activities
- The project account books of the general contractors are the main sources for the information of usage of recourses.
- Blocks of flats as units in the sample.
- DEA for benchmarking of the projects’ performance.
- Multivariate regression analysis to identify Best Practice.

The research project and succeeding activities is illustrated in Figure 1. This paper addresses the main activity shown as the shaded box (no. 5), i.e. the development, content and dissemination of personal reports to each of the managers of the 122 contributing projects, as well as to the company managers behind them.

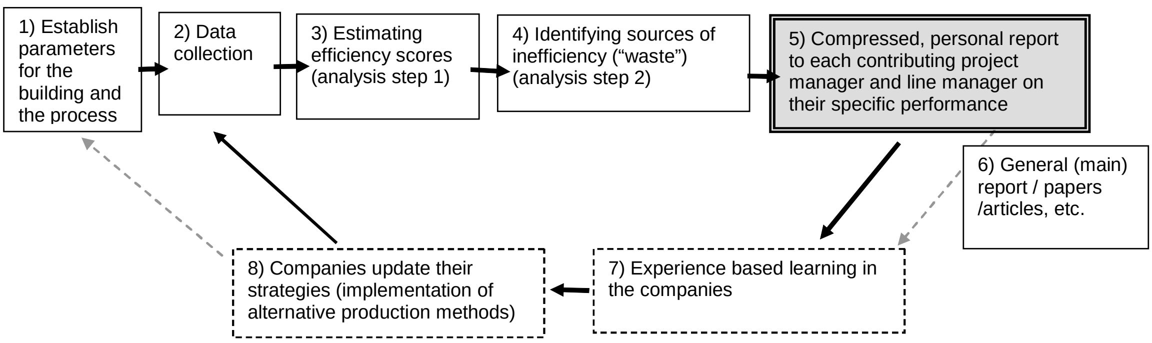

Figure 1: The main parts of the productivity research project (1–6) and expected activities in the industry (7–8)

INDIVIDUAL AND PERSONAL REPORTS

Research project reports are not what the typical construction industry representative prefers as basis for learning activities. With this in mind, the research project decided to provide each contributing project manager, as well as the line manager behind them, with substantial information on their performance compared to “best-of-breed”. The document should be compact, easily read, and include all relevant facts. A report generator was developed to create individual and personal reports of two types:

- The first type has each of the project managers as exclusive receivers. It is a document of only eight pages, containing specific information about the project benchmarked against Best Practice. The most important information is the efficiency diagram for the sample and the efficiency score (E-score) for the project in question. In addition, traditional Key Performance Indicators (partial ratios) for the project, with the sample average as benchmark, are included. The intention is to make it possible for the project manager and his team to reflect on whether their way of managing the project was optimal.

- The second type of individual reports is submitted to each line manager in the 56 profit units connected to the investigation. It includes aggregated information about all projects from his area of responsibility (company, division or sub-division) benchmarked against Best Practice. The purpose is to create a solid basis for the learning process – in order to strengthen the company's competitive edge.

The report to the line managers has the same structure as the project manager version. The content is of the same type, though with aggregated information. The idea has been to focus on performance within the receiver's area of responsibility, and to increase the awareness of improvement activities as an important part of the leadership.

The short, individual reports have three main sections:

- Traditional performance indicators
- The efficiency score
- Information on Best Practice management

Benchmarking is the core element in all three sections of the individual reports.

The remaining part of this paper is structured in the same way. In the following three main chapters the content of the individual reports are presented with particular attention to the experience based learning aspect.

TRADITIONAL PERFORMANCE INDICATORS

Despite the fact that a new and more accurate performance indicator has been introduced (the E-score, see below), the industry will still need its traditional performance indicators. The partial ratios will continue to be useful, both for the day-to-day evaluations and for the experience based learning processes. However, we expect that the new E-score indicator and the Best Practice information from now on will make valuable supplements.

The basic purpose of the data collection was the DEA modelling and the multivariate analysis for identification of Best Practice. As a bonus, the data can be used in forming traditional (partial) performance indicators. As this is where the industry's representatives "feel at home", the individual report template has been organized with one complete page (table) of traditional performance indicators in the first part of the document. The idea is to give the receivers information they easily can relate to, and by this prepare them gently for the parts with the new type of information.

The tables below with examples on performing indicators are extracted from one specific individual report. To ease the reading of this paper a certain unit from the sample has been named "P1" and will serve as our example throughout the paper.

Table 1: Main cost indicators

Indicators (Euros per gross area; equalized to January 2005 by national building cost index)	**Min/max values of 122 units**	**Average of the 122 units (Av)**	**Project P1**	**Ratio Av/P1**
General costs	14/332	151	270	1.78
Construction works	430/1295	705	795	1.13
Technical installations	30/443	178	155	0.87
TOTAL PRODUCTION COSTS	663/1961	1034	1220	1.18

The variation between the lowest and the highest value for all of the indicators is much wider than one would expect for a group of seemingly similar building projects. The total production cost ranges from 663 euros/m² to 1961 euros/m². This means that the most expensive project has a square metre cost that is three times higher than the lowest!

Some frequent comments to differences in building costs are “different standard”, “different area effectiveness”, “the topography and ground conditions”, “degree of off site production” etc. Most of these factors are present in the tables below, i.e. as traditional indicators. However, for humans it is difficult (impossible) to separate the good performance from the less good by simultaneous evaluation of these parameters (as demonstrated by the comments in connection to the tables in this chapter). However, computer software has been developed to make simultaneous evaluation of performance indicators possible – and thus made our multivariate analysis of productivity possible, as shown in the next two main chapters.

Table 1 shows that P1 is not among the best performers (18% above the average for total cost). Looking closer at the figures in Table 1, it seems that the reason is the very high general cost (78% above average). However, since all components in the total building cost affect each other through accounting practices, this understanding may be wrong. The general cost (and also the two other main costs) is decomposed into seven sub accounts (not shown in Table 1). One might expect that the more detailed information would reveal the secret of the very high general cost, but the more detailed figures for the sample shows even wider ranges.

Table 2: Some cost-related performance indicators

Indicators	**Min/max values of 122 units**	**Average of the 122 units (Av)**	**Project P1**	**Ratio Av/P1**
Average salary for main contractor’s working force (euros per hour)	25/54	36	35	0.96
Working hours per produced m² gross area	0.0/9.5	4.2	n.a.	n.a.
Cost subcontractors for construction vs. total production cost	0.0/0.84	0.39	0.27	0.69

What is Table 2 telling about the unit P1? The project pays an average salary rate. This is interesting with respect to the difference in total cost pr square metre, but the information gives us no deeper insight, especially as information in the next cells are lacking (n.a.).

P1 has a lower degree of subcontracting than the sample average. This raises the question about the effect of subcontractors on productivity. The fluctuation in the sample is from 0 (all works done by own employees) to 0.84 (most of the work done by subcontractors). P1 has a lower share of subcontracting than the average (27% vs.

39%). This might be the reason for the relatively high square metre cost of P1, but the available partial indicators do not provide a basis for further understanding.

Table 3: Some key indicators relating to floor areas

Indicators	Min/max values of 122 units	Average of the 122 units (Av)	Project P1	Ratio Av/P1
Gross area (m²)	783/79390	9455	9280	0.98
Area of flats vs. total area (“area efficiency”)	0.46/0.95	0.66	0.61	0.92
Average area of flats (m²)	25/135	78	103	1.32

Differences in floor areas, and differences in utilization of areas, are by many regarded as a main reason for differences in square metre cost. The gross area of the projects varies widely, and one may wonder if the sample deserves the denomination *homogeneous*. Tests of consistency do not define this wide range as a problem for the statistical analysis. Due to the need of as many units as possible in the sample, the research project decided to include some projects that seemed somewhat atypical.

The P1 numbers seem close to the sample average. This is significant for the gross area as well as for the “area efficiency” (0.61 vs. 0.66). On the other hand, the project contains larger flats than the average (103m² vs. 78m²). This information, and some additional information about area in the individual report (not shown here), may encourage the project manager and his team to continue the search of explanations of the relatively high square metre cost by studying traditional indicators. If they are experienced house builders, their “gut feelings” may reveal some relevant insight. But again it seems obvious that the partial approach is not ideal for understanding differences in cost.

Table 4: Examples of different performance indicators

Indicators	Min/max values of 122 units	Average of the 122 units (Av)	Project P1	Ratio Av/P1
Average standard of the building; scale 1–5	1.7/4.6	3.2	3.5	1.08
Injuries at site per 10,000m²	0.0/17.2	2.4	3,2	1.37
Experienced and estimated remedy cost of building defects during warranty period (five yrs) (% of production cost)	0.0/2.0	0.70	2.00	2.86
Amount of change orders; scale 1–4	1/4	2.61	4.0	1.53
Average ground and foundation complexity; average of six sub-indicators	0/1	0.63	1.0	1.59
Relative amount of off-site production; scale 1–9	0/9	3.6	4.0	1.11
Produced area per calendar day (“production speed”)	2.3/60.6	11.2	19.0	1.70
Sustainability; amount of waste fractioning (%)	0/100	50	60	1.2

Table 4 shows that P1 experienced relatively many injuries (37% above average) and an extremely high amount of building defects (186% above average). Together with a high amount of change orders (53% above average) and complexity in ground (59% above average) one may anticipate that these aspects explain a fair amount of the high total square metre cost of P1 (the multivariate test, see below, shows that the two parameters mentioned first have statistically significant relevance for efficiency).

Much higher “production speed” (70% above the average) and more off-site production (11% above average) may have an opposite (positive) influence on the square metre cost, but this is just a guess. Conclusion: Evaluation of the partial, performance indicators is interesting – and might be useful for people of the trade. But the original question, why does the P1 project have a square metre cost that is 18% above the average, is still not properly answered. However, the discussion itself will generate reflection and, hopefully, increase the understanding of the cost aspect of the building process. The possible gain is most likely strongest for companies with more than one project in the sample. In a well-prepared and stimulating setting, the team members can get real experience based learning, which in turn might improve the efficiency of their future projects.

Nevertheless, it is difficult to establish strict conclusions based on the traditional performance parameters alone. Fortunately, this situation can be improved with the new tool, i.e. the individual reports, the new performance parameter (E-score) and information on Best Practice.

THE EFFICIENCY SCORE

The statistical approach

The model in Figure 2 (black box) explains the principles for establishing a mathematical model for benchmarking with respect to productivity and identification of Best Practice. The initial effort was to establish a relevant set of parameters for the building and the building process, see Figure 1, box 1. Based on this, a questionnaire was produced and distributed to project managers in 56 companies (or profit units in large companies). After consistency control of the received data the research project disposed a sample consisting of 122 blocks of flats projects, with a total production cost of 1.2 billion euros, completed during the years 2001–2005.

The benchmarking of project efficiency, i.e. the ranking of the building projects in accordance with their productivity, is based on the parameters Resources (production cost) and Product (gross area, net area, average standard, numbers of lifts). Compared to the square metre cost we regard the E-score to be a more precise performance indicator due to the more detailed definition of the product.

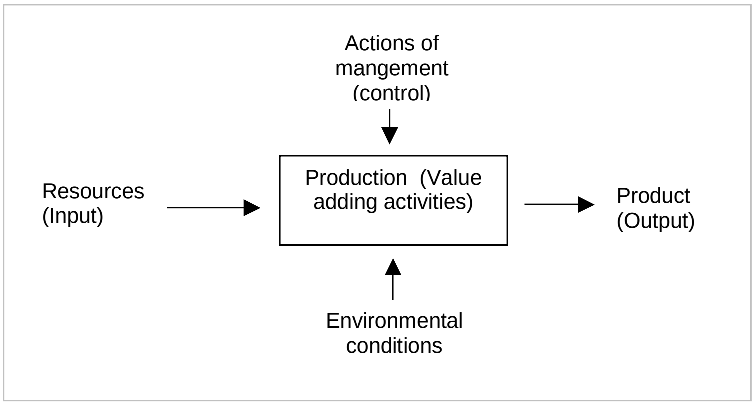

Figure 2: Efficiency analysis – the black box model with four types of variables

Based on the philosophical model in Figure 2, a mathematical model (using the DEA algorithm) was established. The results of the calculations are presented in an efficiency diagram – see further presentation in ‘Benchmarking of efficiency’ below.

The other two groups of factors in Figure 2, i.e. Environmental conditions and Actions of management, contain possible explanations of high, respectively low efficiency. In total 407 parameters (indicators, hypothesis) have been tested against the E-score in multivariate analysis. Fourteen of these were identified as elements in Best Practice, of which three examples are commented in this paper. The model is simple, due to a low amount of units in the sample. Even so, it has an "explanatory power" of approximately 60%, ($R^2 = 0.6002$). See further presentation in main chapter Best Practice – and the learning potential, below.

Benchmarking of efficiency
Based on the philosophical model (Figure 2) and statistical theory, a mathematical DEA model is adapted, through testing of the sample, into a specific model for benchmarking blocks of flats projects. The algorithm returns E-scores for each of the units in the sample and ranks them accordingly (Figure 3). Each bar represents a project and the height of a bar represents the efficiency score (E-score).

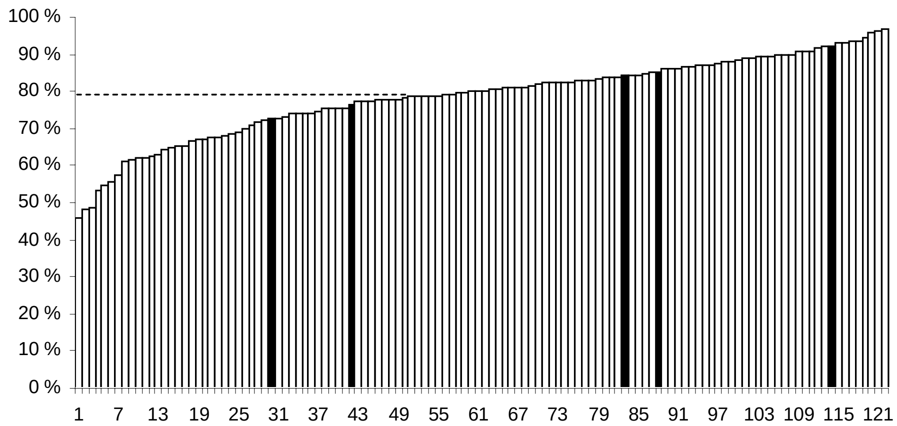

Figure 3: Efficiency diagram

The E-scores range from *c*. 50% to 100%. The Best Practice project is situated to the far right in the diagram. General interpretation: the P1 is represented by the black bar to the far left (which means that it is the least efficient of the P1-owning company's five tested projects). P1 has an E-score of 72%. The distance to full efficiency (Best Practice = 100%) is 28%, which indicates the improvement potential of the project. The *waste* of the project is another way of putting it (Lean Construction thinking, Koskela 2004).

The average E-score for the sample is 79%, indicating that the sample has an improvement potential of 21%. Since the sample represent a total production value of approximately 1.2 billion euros, the improvement potential corresponds approximately to a cost saving of 250 million euros.

Project P1 has a total production cost of *c*. 11.5 million euros. If produced as efficient as Best Practice, the total cost could have been 8.3 million euros, i.e. a cost reduction of *c*. 3.2 million Euros. – The ranking by *efficiency* seems even stricter for P1 than the signal from the *square metre cost* comparison, i.e. 28% vs. 18% improvement potential. Since the E-score is related to the sample frontier and the square metre cost is related to the average of the sample, the 2% numerical values should not be directly compared. The important thing is that the E-score for the highest performing project is approximately twice the value of the lowest (100% vs. 50%), while the worst performing project had three times as high square metre cost than the best one. Conclusion: A better benchmarking method, where a more precise product specification is one important part, reduces the spread of the performance indicator values for the sample with one third.

"The P1 company" is represented by five projects in the analysis (black bars, P1 to the far left). The average efficiency score of the company is 82%. This is above the sample average (79%), which makes it a positive message to the line manager. However, the strongest message from the efficiency diagram is that the performance of this company is rather inconsistent. The large differences in the E-scores of the five projects might depend on circumstances, of which some relate to environmental conditions, but it can also be an indication of weaknesses in the company's management system – or uneven capability/capacity of the project managers and their organizations.

Disregarding the circumstances, the cost-efficiency ranking model (DEA model) gives the P1 team a clear message: "Your performance is far from optimal. Together with your line management, representatives of the four other teams, other colleagues with knowledge on the subject - and a skilled facilitator - you should try to find improvements in the company's procedures and your own way of managing building projects. The Best Practice of the test sample may be a suitable guideline, but don't forget to compare facts about your own project with that of the four other tested ones – and information (facts) from other projects recently carried out by your company."

BEST PRACTICE – AND THE LEARNING POTENTIAL

What are the characteristics of the projects with highest E-score, i.e. the Best Practice projects? Through a multivariate regression analysis of 407 variables (hypothesis), 14 of them were found to have statistically significant relevance for efficiency (in addition, 47 parameters were "close to statistical significance" – i.e. slightly outside the 95% confidence interval. A more detailed model, made available by a new sample of blocks of flats, might deliver a more complete and precise explanation of the large variations in efficiency).

The 14 parameters correlating with the E-scores are of two main types (Figure 2):

- Six are environmental parameters, representing operational limitations for the projects. The typical Best Practice project has not experienced such limitations. Compared to this one the projects with lower E-scores might have one to six operational hindrances of this kind. Some of the hindrances are external (for instance, the weather conditions), and some are internal, meaning that the company's line management have defined the rules (for instance salary conditions).
- Eight of the findings are parameters relating to managerial aspects. This is in line with the main hypothesis of the research project: Productivity depends mainly on how the project manager acts. The findings can be divided into two groups:
    - Three are expressing *consequences* of project management (number of injuries at site, see Table 4).
    - Five are related to the project manager's prioritizing of time, attention and/or prestige.

In the individual reports, the findings are presented and commented in a structured way with the intention to feed any ongoing or upcoming, organizational learning processes in the companies. In each of the three subchapters below, one example from each type is discussed. The complete research work will be presented as a separate article.

1 Environmental conditions

The environmental conditions of a project can make hindrances for the project organization to perform in an optimal manner. The weather has been mentioned as one factor. Another is the contract, in which specific procedures concerning sustainability may be required.

The research project revealed six environmental constraints to the project organization that correlate significantly with cost-efficiency. A company can avoid or reduce the negative effect of such constraints to its projects in three ways:

- Compensate the higher cost with a higher price.
- Reduce cost by change in company policy (e.g. the purchasing policy).
- Carry out more profound changes (reorganization etc.).

Table 5: Example of report to the line manager of P1 regarding environmental constraints of the projects

The BEST PRACTICE projects in the sample are "blessed" by NOT having the limitations listed below	**YOUR COMPANY: Numbers of projects with limits like, respectively unlike the Best Practice**	
	Unlike Best Practice	**In line with Best Practice**
1) Very narrow site area	3	2

Note: The original table contains six rows, one for each of the findings

Table 5 shows that the line manger in the "P1 company" receives an individual report with information saying that three of his five projects have operated on a very narrow site (unlike the situation for the typical Best Practice project). The test revealed that these three projects had an operational handicap. Consequently, they are ranked too low in the benchmarking (too far to the left in the efficiency diagram) and a correction of the E-score is needed: A numerical correction factor is presented, which can be visualized as a short piece of bar on the top of his own bar in Figure 3. The intention is to give fair treatment to the projects that have been handicapped due to circumstances of which they have no influence. This is important with respect to the learning process where the P1 team and the four colleague teams instinctively will pay attention to the internal ranking. Hopefully, the facilitator will succeed in refocusing their attention towards the real issues:

- How can the company reduce the negative effects of very narrow sites?
- What are the *real explanations* of this finding? (Why does a *very narrow site* cause lower cost efficiency?)
- What can be done to avoid increased cost due to a very narrow site?

This rough sketch of the experience learning process may indicate a simple and easy operation. This is not the case. This type of learning processes are in general challenging for all persons involved – in the short as well as in the long term. However, we believe that individual reports based on statistically supported facts will give a far better fundament for such processes than individually interpreted, personal experiences alone can do.

The borderlines between the options in the questionnaire are defined by semantics and not by mathematics. This may cause some confusion. A process facilitator can benefit by the confusion and turn it into fruitful reflection in the working group. Better understanding of the real causes to low productivity on very narrow sites – or high productivity where the site is not very narrow, may be the contribution to the improvement process. Additional information about all the five building projects from the same firm (and possible information from other similar project carried out by the company in recent period of time) will give the participants more reliable information than what is usual in this type of discussions. During such a process, the exchange of experiences and ideas can merge into common insight. Based on this the participants might create an action plan for in situ testing of new approaches to the production of buildings on very narrow sites.

The final documentation from the research project (main report, see Figure 1, item 6) contains additional comments to each of the findings, based on follow-up tests (“nosing around” each of the findings). This type of information, even of limited statistical value, might give suitable support to the collective learning process (“is it possible that the higher cost of very narrow sites is caused by ….?”, etc.).

2a Consequences of project management

Injuries on site can be regarded as part of the product delivered by the contractor (Figure 2). We realize that the ideal efficiency benchmarking model should contain all types of deliveries of the building process, even injuries, building defects, time consume, conflicts etc. However, it has been too challenging for the research project to try this approach in the pilot. Therefore, these types of aspects are defined as *consequences of project management* and treated as a special group of explanatory parameters. Three of those have tested positively with respect to efficiency. One of these is the indicator “Number of injuries on site per Gross area”:

Table 6: Abstract from the individual report to the line manager of “the P1 company”. Topic: Consequences of project management

The BEST PRACTICE projects in the sample are (well) managed and have got results as listed below	YOUR COMPANY: Numbers of projects with limits like, respectively unlike, the Best Practice	
	Unlike Best Practice	In line with Best Practice
1) Low number of injuries per Gross area	2	3

Note: The original table contains three rows, one for each of the findings

Two of the five projects in the “P1 company” have a result regarding injuries unlike (worse than) the typical Best Practice project. The deviation is statistically significant and affects the efficiency score in a downward direction. The numeric value of the correction (%) is known, and should be used to adjust the E-score downwards for the two projects in question. Nevertheless, in the improvement perspective the discussion in the collective learning setting is even more important:

- “Why do three of our five projects succeed in keeping the injuries at a Best Practice level?”
- “How can we get all future projects to perform like Best Practice in this respect?”
- “What do the two, not successful projects with respect to injuries have in common?”
- “Do we know, from earlier block of flats production, or other types of building production, anything particular about rate of injuries?”, etc.

The process facilitator should put effort in the preparation of questions with high potential of reflection, hopefully with common understanding and specific improvement initiatives as a result.

Finally, the finding in itself should be emphasized: Avoiding injuries at the site should have the highest attention, regardless of the economic aspects. Nevertheless, the fact that the productivity is found to be higher when the number of injuries per Gross area is very low, will presumably increase the company and site management's attention to security.

2b Project manager's priorities regarding time and attention

The general hypothesis of the research project was that the productivity in building projects is strongly affected by the quality of the project managers. In the research project the quality of project managers is measured as the relative amount of time spent on 62 different specifications of managerial activities/attentions. The testing gave as result that five parameters relating to managerial aspects had empirical relevance for efficiency.

Table 7: Abstract from the individual report to the line manager in the "P1 company". Topic: Priorities of the project manager

The BEST PRACTICE projects in the sample are managed by PMs that express themselves as listed below	**YOUR COMPANY: Numbers of projects with PM priorities like, respectively unlike, the Best Practice projects**	
	Unlike Best Practice	**In line with Best Practice**
1) Compared to all other activities, I spent much of my time on following up the economy of the project	2	2

Note: The original table contains five rows, one for each of the findings

Table 7 shows how the five project managers in the "P1 company" prioritize with respect to economic aspect of the project. Two of the five project managers act according to Best Practice and two opposite to this (one gave a neutral answer to the question. To keep the table as simple as possible, this is not included).

The table reveals the potential for learning on this subject. How can this be transformed into real understanding and modified behaviour? The answer is collective learning *processes*: To succeed in having project managers to adjust their own prioritizing (behaviour), it is necessary to have them *recognize* that this can improve the productivity of the next projects they are going to manage. A well-facilitated discussion, discretely focusing the difference between the two successful projects and the other two, might lead to the wanted change. Many aspects can explain the "wrong" choices (for instance too high interest in the technical aspects of the project, inadequate delegation within the team, lack of personal competence in economic, etc). The challenge for the line manager and his subordinates is to identify what is needed to modify individual behaviour, and to plan and follow up decided, individual improvement activities. In contrast to the discussion about environmental limitations, the managerial aspect is a much more delicate issue – for all parties involved. The focus on the project manager's priorities can easily turn into a discussion of his personality, which again can affect feelings and cause conflicts. This part of the process should therefore be carefully prepared and conducted by wisdom.

The new situation is that the organizational learning processes can be based on statistical facts. If the process facilitator and line manager succeed in keeping all attention to the facts, i.e. avoiding all kinds of speculation, the benefit of the session should be substantial.

CONCLUSION

A solid foundation for experience-based learning has been established. This has been achieved through a statistical analysis of the efficiency in building projects, and individual reports to the contributing projects and companies. Each of the individual reports contains information custom made for the recipient. This provides of a new way of conducting experience based learning processes in companies.

ANALYTICAL DESCRIPTION OF THE USES OF REAL OPTIONS IN CONCESSION/BOT PROJECTS

Takayuki Minato[1] and Santi Charoenpornpattana[2]

[1]*Department of International Studies, Graduate School of Frontier Sciences, The University of Tokyo, 5-1-5 Kashiwanoha, Kashiwa, Chiba 277-8563, Japan*
[2] *Department of Civil Engineering, King Mongkut's University of Technology Thonburi, 126 Pracha-uthit road, Bangmod, Thung Kharu, Bangkok, 10140, Thailand*

The authors take value creation as an objective in concession investments, and then focus on application of real options as realistic managerial devices to respond to uncertainty. The paper offers a framework for considering concession/BOT related real options into categories, rather than reporting on actual cases of application of a real options approach. The contents consist of roughly into four parts. The introduction explains the view that expected NPV is unrealistic when used in infrastructure projects since they include contingent decisions in the future. The next three sections consist of analysis and description of the uses of real options in concessions. Here, the real options are categorized into three types: *investment*, *contractual*, and *operating options*. First, the notion of irreversibility is introduced into the public sector's valuation of concession projects. The discussion extends to using concession/BOT strategically when infrastructure construction is carried out as a series of interrelated projects. The Tokyo Bay Aqualine example is also introduced as a form of "internal purchasing investments." Next, government support schemes are analysed as forms of real contractual options. It is shown that the options change the risk profile of projects, and become particularly of value for both government and private sectors to cooperate toward their mutual interests. There is also brief reference to prepayment and rescheduling briefly as a form of operating options.

Keywords: contract strategy, government-industry partnership, private finance, real option.

INTRODUCTION

Construction requires making decisions fraught with uncertainty associated with various kinds and amount of risks associated with right-of-way acquisition, accidents, design changes, delays, cost overruns, compliances, etc. In particular, concession projects may fail due to insufficient cash flow that arises from low demand, currency fluctuations and even political risks such as termination of concession, breach of concession contract, high tax enforcement, and so on.

As a practical matter, traditional NPV method does not provide strategic vision for decision makers in concession projects. Typical problems may include optimism with which cash flow forecasts are manipulated subjectively to unlikely levels or bounded by excessive risk aversion and, therefore, discounted too heavily. Moreover, NPV method depends on an expected scenario and may not properly capture subsequent uncertain opportunities.

[1] minato@k.u-tokyo.ac.jp

Real option approach is the extension of financial options. It can be identified to options on real (non-financial) assets. It counts the value attached to management's flexibility to adapt and revise decisions in response to new information. Such opportunities are termed as "options." In general, while the value of financial options can be quantified and observed as market prices, real options perspectives give a way of aiding strategic decision making, thus providing managers with a wider set of strategic alternatives in real investment. Making decisions that contain uncertainty is hard, but a real option approach can help capture future opportunities on unfolding events.

Real options are not always needed, and traditional NPV works when there are no options or the investment includes little uncertainty. However, when investments are extremely valuable and anticipated uncertainty is enough to induce consideration of contingent decisions, option approach may be important. Large construction projects satisfy such conditions because its investment is complex and time scale is long. The features are further magnified for BOT type projects within which the project company undertakes finance, construction, operation, and maintenance.

In addition, construction projects are irreversible. That is, the investment cannot be recovered once it fails. This arises from a specific feature of construction, that is, low liquidity. Irreversible investments are often managed in a phased approach by delaying them until uncertainty is resolved in the future. Since taxes are the major source of funding for typical public construction, the use of BOT as a government option may sometimes be effective instead of direct investments. In such a circumstance, real option approach becomes of value to avoid sunk costs if used properly.

In the following, brief review of financial options is given first. This provides readers with institutional description of option structure. Then, the applications of real options will be presented in detail. The taxonomy of real options includes *investment options, contractual options*, and *operating options*, (Amram and Kutalilaka 1999). According to the classification, "investment options include decisions about scale (expansion, contraction, or disposal). Timing options that accelerate or delay investment are also categorized in this. Contractual options are specific contract terms that change the risk profile faced by asset owners. Operating options consist of when to switch inputs, when to switch outputs, and when to temporarily shut down the operation." The discussion mainly focuses on irreversible costs in investment, and government support schemes in the form of contractual options.

BRIEF REVIEW OF STOCK OPTIONS

Option trading was initially developed in the financial market. Options markets exist for a wide variety of instruments today. However, it may be still necessary to recall the definition of two types of options in finance: a call option and a put option on common stocks. In general, a *call* option is defined to be a contract giving its owner the *right to buy* a fixed number of shares of a specified common stock (underlying asset) at a fixed price (exercise price) at any time on or before given date (expiration date). On the other hand, a *put* option is a contract giving its owner the *right to sell* the shares in the same way (Cox 1985).

The determinants of option value consist of the same set of variables for both calls and puts: (1) current stock price; (2) exercise price; (3) time to expiration; (4) stock volatility; and (5) interest rates. In case of stock option, cash dividends also matter.

There are also other determinants such as expected growth rate of stock price, tax rules, transaction costs, market structure, etc.

There are reasons why investors use options. Options may offer them a wider range of alternatives available for making decisions in investments. They include, for example, a flexible pattern of returns, a favourable opportunity to borrow or lend, tax advantages, lower transaction costs, etc. In essence, options provide a means of hedging against uncertainty in stock volatility.

An option is a right, but not an obligation. It has value because there is uncertainty included in the underlying asset. In the case of stock options, the pay-off function bends at the exercise price (see the left–side diagram of Figure 4 for a call option. The pay-off of a put option is a mirror image of this.). The non-linear function shows how uncertainty creates value. With options, losses are limited to a certain level, and the option may be executed when uncertain moves toward the upside potential.

At this point, it is interesting to understand that NPV valuation is just one kind of option valuation. The decision is made to go for the investment when the sum of present value is larger than initial investment. It is simply the same as option valuation by taking the initial investment as the exercise price; the timing of a decision depends on whether there is uncertainty in the future.

The difference between investment on security and infrastructure includes the feature of risk controllability. In general, the risk of securities is not directly controllable; therefore, investors try to control the allocation of costs on the component securities. On the other hand, the scope of a project is determined according to such conditions as resource availability and necessary job sequences (Minato 1995). This indicates that engineering capacity finds more ways to apply real options in operation.

REFERENCES ON REAL OPTIONS IN CONSTRUCTION

Most of the research literature in construction management and infrastructure planning deals with the concept of investment options. Benaroch (2001) proposed a methodology for planning the creation of operating options designed to maximize the value of an investment in light of the risks underlying that investment. The paper also shows how each type of options can deal with a variety of risks in the project management context.

Jonhstones (2002) shows that government should take into account the value of options, specifically the contracting out option, in outsourcing decisions. The option to contract out provides government with opportunities to hedge against uncertainty in the cost stream. Ho and Lie (2003) proposed an analytical methodology for evaluation of the strategic value of technology investment by the real options approach. This proposed framework specifically considers the technology investment risk and embedded managerial options.

Infrastructure investment creates further investment opportunities, and changes the strategic position of the enterprise. Smit (2003) focuses on the optional and strategic features of infrastructure investment. The paper focuses on, in particular, an analysis of European airport expansion. The result indicates that airports with infrastructures that are less constrained by growth regulations capture more value, because they are in a position to exercise growth options available in the airport industry.

Zhao *et al*. (2004) developed a multistage stochastic model for decision making in highway development, operation, expansion and rehabilitation based on a real options framework. Three uncertainties are taken into account in this model, namely, traffic demand, land price, and highway deterioration and their interdependency. Real options in both development and operation phases of a highway are also incorporated in the model. A valuation model of infrastructure development and expansion is also developed by Zhao and Chung (2006), reflecting the decision maker's risk preference into analysis.

INVESTMENT OPTIONS – THE IRREVERSIBLE INVESTMENT

The notion of irreversibility is not generally considered in decision making when a new project is taken. Irreversibility refers to the loss by giving up the opportunity to change decision in the future. Once resource is committed, it cannot be recovered, reversed or radically changed without "substantial loss". Infrastructure investment is contingent on follow-on investments, and it should be taken into account as sunk cost in the case where future opportunity is sacrificed.

While opportunity cost is normally the sacrifice of equivalent alternatives at the time decision is made, "opportunity cost of irreversibility" is the cost of sacrificing the alternatives over future time and in relation to subsequent projects. By taking into account the cost, it is suggested to defer the investment until the optimal condition is achieved. The "optimal condition" is referred to the conditions that loss due to deferring exceeds opportunity cost of irreversibility (Figure 1).

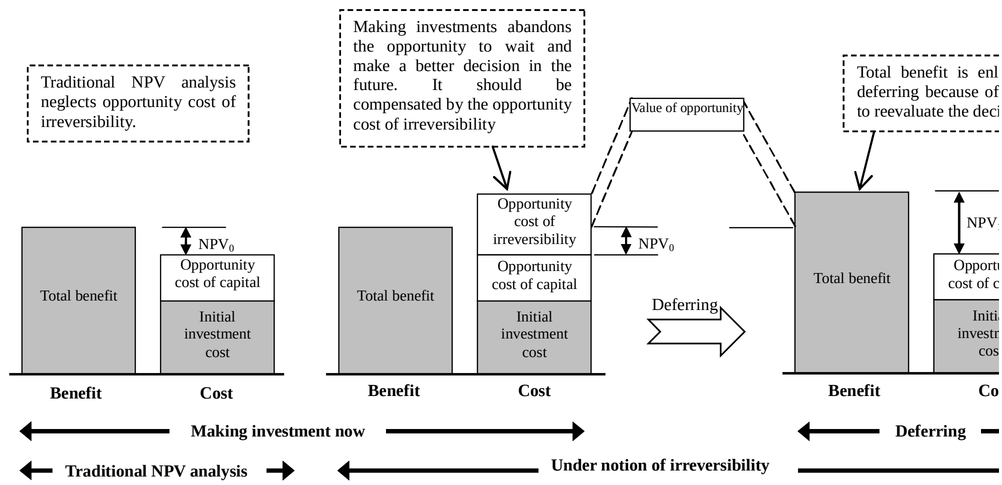

Figure 1: Concept of the "opportunity cost of irreversibility" in investment decision

In the BOT project, the government generally need not commit capital, and thus frees itself from part of the opportunity cost including opportunity cost of irreversibility by transferring this opportunity cost to the project company. This in turn means that the value for the government could be enlarged if BOT is employed instead of using traditional public investment. In effect, the government could preserve the value of opportunity associated with time otherwise sacrificed by committing irreversible cost (Charoenpornpattana 2004). This will be significant potentially if project companies are likely to differ from government in their valuations of the opportunity cost of irreversibility. Such differences may derive from the switch to user-charges as opposed to taxpayer funding and thus a different valuation of benefits, or from different attitudes to uncertainty, or from the effect of government support schemes in which case the opportunity cost is only partially transferred. With no difference in perceived opportunity cost, the project company may also choose to defer decision in all cases where government would choose to defer.

Furthermore, the effect of irreversibility is extended when infrastructure is carried out as a network of interrelated projects. Taking into account the effect of irreversibility, the government will defer public investment until the time when project A can be optimally invested. The growth opportunities to undertake projects B and C are not provided prior to the point where project A is invested (Figure 2).

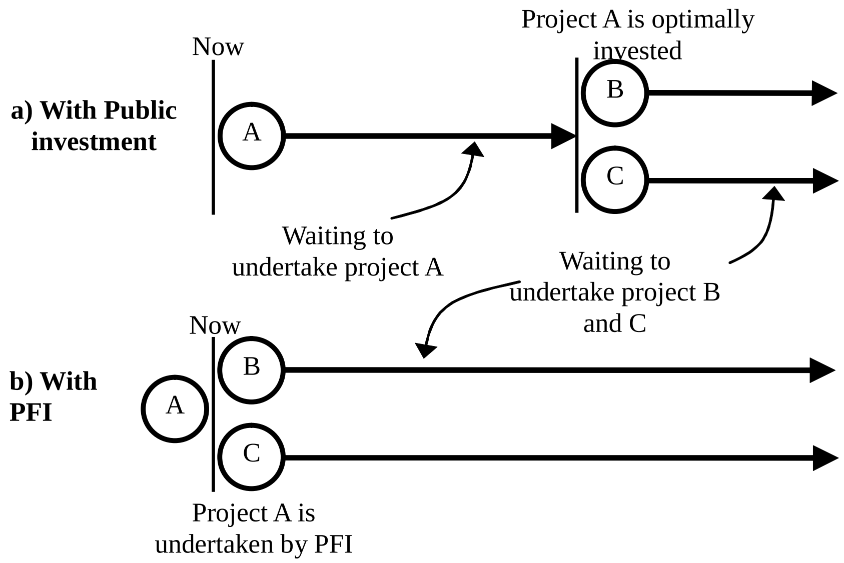

Figure 2: Growth opportunity with (a) public investment and (b) BOT

Suppose now that BOT is available to the government to undertake project A. The government does not need to consider deferring to undertake project A, because it is freed from the effects of irreversibility. In effect, the decision can be made immediately, provided that the project company is committed to invest immediately. As project A is undertaken, growth opportunity for projects B and C are activated. The implication behind this is that the dependencies between interdependent projects are resolved by using BOT, because the dependency condition is fulfilled by having project A commenced. Therefore, it allows the government to acquire growth opportunity to undertake projects B and C.

In conclusion, by public investment, the government faces an investment dilemma between (1) making the investment at the expense of value of opportunity associated with time and (2) postponing the investment at the expense of value of growth opportunity. In contrary, if BOT is employed, the government can be free from the effect of irreversibility, because it incurs no irreversible expenditure. Consequently, the government can immediately obtain the project and preserve the full value of opportunity associated with time, and the value of growth opportunity associated with related projects. Therefore, the option becomes a superior alternative over public investment by this mechanism. Then, the contributions of this research are shown to be that it sheds light on sunk cost, or irreversibility of executing the option from the government side.

INVESTMENT OPTIONS – THE INTERNAL PURCHASING INVESTMENT

An interesting application of real options is found in the Tokyo Bay Crossing Highway, also known as the Aqualine. It took ten years to be completed in 1995 as a major project to cross the Tokyo Bay, linking Kawasaki and Kisarazu. The structure contains both bridge and underground tunnel, and is made of a massive three-chamber single box girder with the web ranging from 3m to 10m in height. Although not by BOT but the “third-sector” scheme, it was initially estimated that the traffic volume for the first 20 years would be 33,000 (vehicle/day), and 64,000 (vehicle/day) thereafter. Unfortunately, however, the actual demand has been about half of the expectation.

Other than its current financial performance, it cannot be denied that the Aqualine includes a unique design option. The highway was put into utilization with four driving lanes, with an option expandable to six lanes in the future. This meant that capacity could be switched for possible traffic change in the future by flexible design, which is in fact a type of investment option. Although the option has not been executed because of the current low demand, it was planned so that internal investment on flexible design could make adjustments to capacity in accordance with actual demand magnitude. According to Marukawa (2003), suppose the structure had been constructed with six lanes then the loss would have been worsened approximately by 30%.

It is typical of planners to justify their “gut feel” in demand estimation before construction. The result is that such decision sometimes loses credibility after all if situation goes wrong. Instead, real options approach can be incorporated to strategically make decisions by incorporating “internal purchasing investments” to respond to operational uncertainty in the future.

The essence of the discussion here includes the question of how to evaluate the value of “design”. In general, design is defined in terms of such engineering criteria as shape, strength, appearance, etc., only. However, the value of infrastructure extends to not only physical functions, but also social capacity related to environment, social justice, culture, etc., over time (Minato 2007). The question is how much you are willing to pay extra costs of having valuable infrastructure for the future.

CONTRACTUAL OPTIONS – THE CONCESSION AGREEMENT

In BOT projects, government financial supports may be integrated in the contract. The private contractors are just interested in having support when they have to bear risk. As discussed in the previous section, for example, if projects are realized earlier under concession/BOT, contractual options may be effectively used together with investment options to provide private sector with “a bundle of options support” for not only the base project, but also follow-on projects.

Supports include, for example, direct investment on equity, subordinated loans, cash subsidies and other development rights such as tax benefits, land lease, extension of concession, etc. These supports sometimes play vital roles for the project company to improve income stream by reducing capital requirement and risk exposures in cash flow during the project. According to Fishbein and Babbar (1996), there are eight specific government financial supports in the case of highway projects. With the supports, the government provides a right to the project company to execute the following alternatives:

- Equity guarantees: a right to sell the project to the government with a guaranteed minimum return on equity.
- Debt guarantees: a cash-flow deficiency guarantee for repayment of debt.
- Exchange rate guarantees: a compensation for increases in local cost due to exchange rate movements.
- Grants and subordinated loans: a repayment of subordinated loan after the senior loan, or non-repaying grants. Subordinated loan will be repaid to government after the senior loan.
- Shadow tolls: a specific annual payment (per vehicle) depending on traffic demand.
- Minimum traffic guarantee (or minimum revenue guarantee): a cash compensation if traffic falls below a specified minimum. On the contrary, there is a case that cash may be reimbursed to the government if the traffic is overloaded beyond a specified ceiling, or maximum revenue ceiling.
- Revenue enhancements: a priority right with regard to limited competition, facilitated demands or development of ancillary facilities.
- Concession extensions: a right to extend the concession term in the case that the revenue falls below a specified target.

Figure 3 shows the impact on the project company's financing ability in association with government financial exposure of individual schemes. Each of the eight instruments has their own characteristics. The primary function of government support is to share some of the risks that are hard to be owned by the private company. This in turn means that government provides options to the private sector for compensating uncertainty.

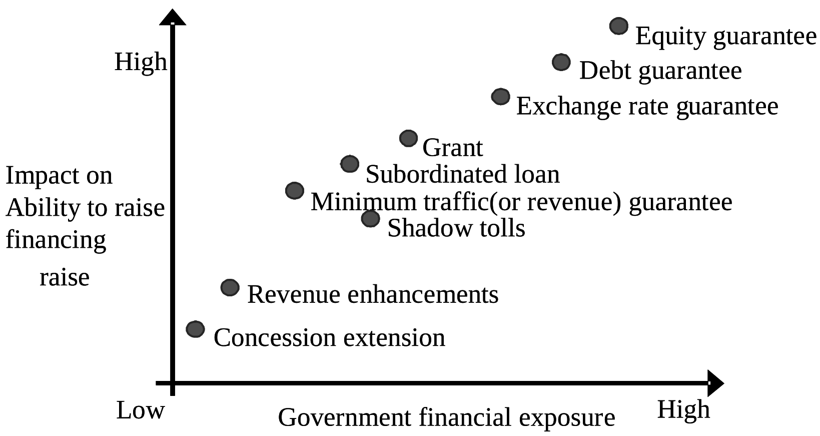

Figure 3: Range of options for government support (Fishbein and Babbar 1996)

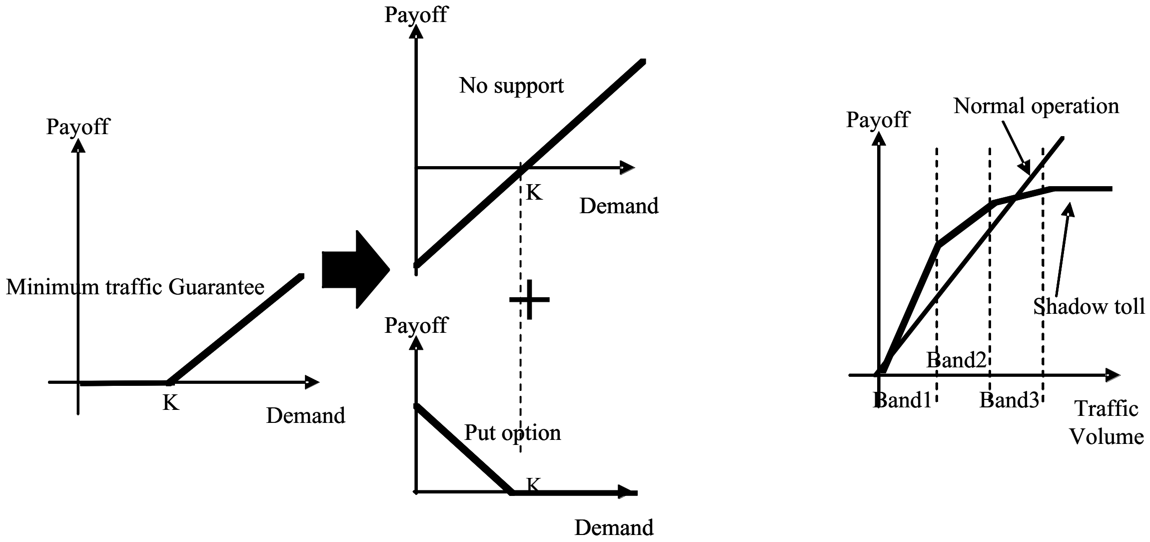
Most of these government supports consist of contingent contracts. Minimum traffic (revenue) guarantee, for example, has the feature that the project company holds a call option to hedge downside risk when actual traffic demand goes below a certain level, can be broken into two positions: one with no government support and the other with a put option. Suppose the payoff line for the position with no support is a 45" line with positive slope. If the demand is zero, the position will experience a certain loss. However, minimum revenue guarantee combines a put to cover the loss below K. In other words, minimum revenue guarantee is a type of support that has a form of put given by the government to the project company.



(a) Minimum traffic guarantee (b) Shadow tolls

Figure 4: Payoff diagram of minimum traffic guarantee and shadow tolls

In analysing the put option, the underlying asset is the project's cash flow. A set of other variables is also shown in Table 1.

Table 1: Variables of minimum traffic guarantee support

Variables	**Minimum revenue guarantee**
Underlying asset	Project's cash flow
Exercise price	Cash flow at minimum traffic guarantee
Maturity	One year
Volatility	Volatility of cash flow
Risk-free interest rate	Risk-free interest rate

Shadow tolls have the same feature as the minimum revenue guarantee and its extension. It is a government support scheme that per vehicle payment is given to the project company on the basis of actual usage. The formulation generally divides toll rates (per vehicle) into two to four bands (Figure 4b). The system is put into practice in such a way that government makes more payment per vehicle when the traffic volume is less. The rate per vehicle decreases as the traffic demand increases.

While most support schemes can be generalized in a form of ordinary calls and puts, there are some options that need complex formulation. For example, concession extension belongs to this type. As an example, the M2 toll road in Australia is a BOT project that includes concession extension on the basis of project performance. The initial concession is 36 years; however, it can be extended if internal rate of return (IRR) of the project ends below 16.5% at maturity. In the same way, the concession can be extended up to maximum 45 years depending on the IRR every three years thereafter. This scheme is different from, for example, minimum revenue guarantee, in the following; 1) the option is given at the end of project while minimum guarantee is provided yearly; therefore, 2) the option is *path-dependent*, in which the value of the option depends on the value of NPV in previous years, and 3) payoff does not simply represent increasing function in relation to IRR. It is a so-called compounded option, which is defined to be an option on an option. For detailed formulation and simulations, refer to Nakahama (2003) and Charoenpornpattana *et al*. (2003).

OPERATING OPTIONS – THE FINANCING AGREEMENT

Operating options are sometimes viable between loan providers (banks) and the project company. For example, *prepayment* and *rescheduling* are the ways that investment banks use as a device in managing credit risk. The devices are used to accelerate, stop or extend the payment of debts on the basis of future cash flow. In these schemes, the timing of re-contract becomes crucial; thus, it is important to analyse the value of project cash flow for reduced or extended timescales.

This topic includes interesting development both theoretically and practically. The above example is just one of them, and its description needs more space and careful clarification. For details, refer to Murauchi (2007)

CONCLUSIONS

The usefulness of valuation using real options is presented for concession/BOT projects. It was first argued that NPV evaluation does not give strategic consideration when investments include “attractive” contingent decisions. The traditional NPV method is just a type of real option analysis in which the decision is made to go only when the sum of present value is larger than initial investment.

By categorizing real options into *investment*, *contractual* and *operating,* it was first discussed that irreversibility is most critical in construction since the investment includes opportunity costs as sunk components. Since construction is carried out as a series of successive interrelated projects, using concession/BOT as an investment option gives government more flexibility in allocating total budget, if a project company can be found that takes a different view on the desirability of immediate investment. An example of design option was also introduced as a form of “internal purchasing investments”. The Tokyo Aqualine was shown, in which the structure was designed to “easily” increase capacity for possible up-side increase of demand. Next, it was shown that some government support schemes are formulated into contractual options for asset owners to execute “rights” to protect against liquidation of down-side risks. The contractual options particularly become of value when government and the private sector try to change risk profiles for their mutual interests. For operating options, *prepayment* and *rescheduling* are briefly referred to as a device to accelerate, stop or extend the payment of debts of projects.

RISK MANAGEMENT IN PUBLIC–PRIVATE PARTNERSIP (PPP) PROJECTS FROM THE PROJECT MANAGEMENT PERSPECTIVE

Hemanta Doloi[1] and Xiao-Hua Jin

Faculty of Architecture, Building and Planning, University of Melbourne, Victoria 3010, Australia

The research explores the project management issue and its contribution to effective management of risks in public–private partnership (PPP) projects. A framework has been established by identifying the emerging challenges and the approaches to effective risk management. While the approaches to identifying the appropriate partnership arrangement and bidding processes are reasonably established, in general, the effective management process in large-scale transactions involving two different agencies: public and private in PPP projects is quite critical. There has been increasing evidence of criticism in delivering public projects with private participation across Australia as well as many other countries. In order to evaluate the management performance of PPP projects, a thorough analysis of the nuts and bolts of the partnership arrangement is important at an early stage, considering a whole-of-life approach. The literature survey and the case study proved the importance of the management programme for the effective execution of PPPs. Appropriate understanding and quantification of critical risks in PPP projects are the keys for project managers to make the right decisions and take relevant action. A recently completed major infrastructure project in Melbourne has been studied to understand the underlying challenges in managing and delivering PPPs from the project manager's perspective. These challenges include design complexity, stakeholder integration, risk allocations and constructability issues. The framework highlights the project management approach for appropriate identification, allocation and management of risks associated in the PPP process.

Keywords: Australia, project management, public–private partnership, risk management, value management.

INTRODUCTION

Delivering public projects through private sector funding is gaining widespread popularity in many countries including Australia. Over recent years, governments around the world have redefined their role by restructuring, corporatizing or privatizing some areas of government activity that had been deemed core in the past (Arndt 1999). Government is no longer considered the sole provider of public works or services. The concept of providing concessions to financially unattractive projects has enabled governments to maintain a strategic interest in the infrastructure and finally leads to a range of public–private partnership arrangements (Miners *et al.* 1995). Public–private partnership (PPP) has been recognized as one of the major procurement strategies for governments in providing infrastructure systems.

However, the joint ownership of such a procurement strategy is quite complicated, owing to the presence of multiple stakeholders in the PPP process. While state

[1] hdoloi@unimelb.edu.au

governments in Australia have been devising their own solutions to delivering contemporary services to the public through fundamental PPP infrastructure projects, the results from a few completed projects so far have not been absorbed effectively among the end users. As anyone reading the press will have seen that there is still a strong groundswell of dissent over the effectiveness and value of PPPs as a tool to create and manage social infrastructure across the states in Australia (Millar and Moynihan 2006; Tomazin and Myer 2006). While it is becoming evident that there is a significant opportunity for private sectors in building and potentially operating the social infrastructure systems, the question whether the PPPs will be a long-term model remains unresolved. For instance, a recently completed AU$700 million redevelopment of the Southern Cross Railway Station in Melbourne with a complex roof structure resulted in a significant cost overrun. Among other things, design complexity and poor stakeholders' communications are considered to have contributed significantly to such failure. Similarly the AU$800 million Cross City Tunnel project in Sydney CBD failed in securing estimated tariff stability in the PPP arrangement which has opened up a full debate on decision makers and management competencies in the Australian context.

Today's PPPs and project delivery are seen to be a more strategic venture where multi-partner dependencies contribute to the fulfilment of strategic objectives of the entire business systems. In current PPP practices, the challenging complexities of efficient project delivery are typically due to following reasons:

1. presence of uncertainty and risks affecting virtually all aspects of project creation, delivery and operation;
2. complex project composition and associated functional integration;
3. complex network of relationships among the direct and indirect project's stakeholders;
4. multi-project operation, prioritization, investment strategy and delivery decisions in government projects;
5. increased public participation, regulatory obligations and value for end users.

Given the profound changes of project environments and the increasing evidence of the inadequacy of the current project management models, this research aims to address the following questions:

- How does the diversity and complexity of today's projects delivered through the PPP impact on establishing the next generation project management platforms?
- How can the current project management principles be used for strategic delivery of PPP projects?
- Will project management be seen as a core capability in delivering strategic advantage to the PPP projects?
- What will be the value-addition process upstream and how is project organization responsible for delivering value-for-money in PPP projects?

Over the past few years, securing value for money in PPPs have been a major area of investigation across Australia. Challenges faced in risk identification, allocation and management strategy across multifaceted stakeholders in PPPs is currently one of the major areas of research in progress at the University of Melbourne (Doloi and

Raisbeck 2007a, b; Jin and Doloi 2007). While the cynic's criticism of the process and effectiveness of delivering government projects through PPPs becomes a norm across Australian development, the project manager's role and competencies in meeting the project target (in terms of scope management, time and cost control) are easily overlooked. In this paper, the authors aimed to identify some of the project delivery risks encountered over the PPP life cycle from a project manager's perspective. A real life case study has been used to analyse and establish a benchmark of these risk issues in the Australian context. If such risks are clearly understood at the early stage, appropriate management strategy can significantly contribute towards delivering PPPs successfully.

PPP DEVELOPMENT IN AUSTRALIA

There has been considerable activity in Australia with its complex federal system. The Australian government released its private financing policy in 2001 based on three core principles, viz. value for money (VFM), accountability and transparency. Pursuant to these policies, PPPs have been implemented successfully in many jurisdictions and in many industry sectors including transport, health, education, justice, defence, energy and utilities (DFA 2005). The State of Victoria in Australia has been playing a leading role in PPPs' development. The active Partnerships Victoria (DTF 2000) and the volume and sophistication of the PPP projects, such as Southern Cross Railway Station, Melbourne Convention Centre, and EastLink projects, mark Victoria as the leading force in PPP development in Australia. Other States, such as New South Wales and Queensland, are following Victoria closely in terms of developing PPPs (Hayford 2006).

Nonetheless, the PPP model and its widespread criticisms have encompassed cost overruns, delays, design flaws, write-downs, legal disputes and anxiety over service delivery in the longer term (Coulson 2005). Consequently, the issues arising out of economic infrastructure PPPs have led some critics to argue that PPPs have become a mechanism for handing windfall profits to private investment banks while leaving taxpayers to bail out failed projects (Jay 2005). Indeed, as PPP markets have grown across the globe, there has been a corresponding rise in research focused on PPPs (Akintoye and Chinyio 2005; Dixon *et al*. 2005; Li *et al*. 2005). Studies of risk in the PPP context have tended to focus on different segments of the PPP lifecycle and for the most part they have focused on engineering and economic infrastructure rather than social infrastructure (Zhang 2005; Mattar and Cheah 2006).

This paper discusses a link between traditional project management and PPP project management for developing a framework to simulate the factors associated with the risks in PPP social infrastructure projects. The discussion is based on the case study based research in the recently completed Southern Cross Station (SCS), which is a hybrid social and economic infrastructure project in Melbourne, Australia.

SOCIAL VS. ECONOMIC INFRASTRUCTURES

In Australia, like many other countries, infrastructure is usually broken into two broad categories, which are those related to either economic or social services. Johnston *et al*. (1999), for instance, referred to infrastructures as 'the productive capital structures that underpin the economy and society and contribute over time to the achievement of its economic and social goals'. The OECD's (1991) definition of infrastructure has been frequently adopted:

> Infrastructure comprises the capital works required in urban areas for households to have access to major economic and social services. The OECD groups infrastructure into two broad categories. The first is economic infrastructure comprising networked services such as hydraulic facilities, highways and other transport facilities, and energy distribution networks. The second category, social infrastructure comprises a broad range of facilities that provide community services such as education, health and leisure and law and order.

Though conceptually a holistic view should be taken when considering infrastructure, it would be more practical to analyse social and economic infrastructures separately, owing to their inherent distinction (Duffield 2001).

An examination of the structure and related issues is timely because in Australia, PPP markets are becoming more complex as social infrastructure projects are beginning to appear in the market. These projects may include courts, hospitals, prisons and even schools and perhaps even social housing (see the National PPP Forum, at http://www.pppforum.gov.au/nationa-l_pipeline). These projects often begin with a decision within the public sector that a particular project is needed and then that the project is best financed or procured using private sector finance. Once this financing decision is made, it is naive to assume that risks are entirely allocated across from the public to the private sector. However, potential project risks and allocations between various parties depend on the financial and legal project development environments.

The emergence and presentation of risks in social infrastructure projects may not often reflect the strict partitions within the PPP environment. The risks inherent in social infrastructure PPPs are arguably more complex to manage and foresee because they require intensive architectural and urban design along with a higher degree of user consultation. Social infrastructure PPPs are often situated within a complex political context. Moreover in social infrastructure projects the PPP life cycle encompasses the entire range of building procurement and also includes the complex service agreements which are used to operate the facility after it is constructed. This situation has led to questions on the role of the project managers beyond delivery (Brady *et al*. 2005; Leiringer and Green 2005). Given that concession periods of PPP projects often extend out to 25 or 30 years, it is important for public sector promoters to understand how to foresee and manage the risks that may impact upon them, beyond delivery and into the operational period.

INVESTIGATION APPROACH

Before setting the benchmark on the risk management framework, a number of interviews and an industry workshop (total 65 participants) were conducted to seek opinions from the industry about risk management practices and allocations strategies in PPP projects. This pilot study was funded through a grant from the University of Melbourne. Most of the interviewees are senior project managers and project directors from government as well as private firms involved in PPP projects. The initial discussion was steered using a set of structured questions related to risks associated in PPP projects across the board. By adopting a detailed, project-specific questionnaire, the interviewees were then asked to identify the risks in the projects they were involved in and to specify their perceived critical success factors (CSFs) of risk management in PPP projects. The questionnaire survey was handed out to the workshop participants as well. It has been highlighted by most respondents that risk management capability and project development environment are the most important factors that would have an impact on final risk management performance of the project. It has also been admitted across the board that the success of effective risk management in PPP projects depends on the mechanism for making right parties responsible for right risk. The role of project managers and contemporary project-based management approach become pivotal in such project development environment.

SOUTHERN CROSS STATION – A CASE STUDY

Melbourne's Southern Cross Station (SCS) redevelopment project is currently the largest PPP project in Victoria worth AU$700m. This station is notable for the architectural design of a unique roof to cover the railway platforms. The roof was initially conceived as an environmentally performing element to facilitate the extraction of the diesel fumes expelled from the trains without recourse to mechanical ventilation. This roof, which has a two-way curvature and measures a massive 4.2 hectares, presented a major design and construction challenge owing to the requirement that the station had to continue full operation during construction, moving over 55 000 people per day through it. With the adoption of *Partnerships Victoria* policy in this project, it is expected that the exposure of governments adopting PPP models to risks such as cost and time overruns is minimized. The State Rail Authority of Victoria was set up to operate the station's rail function on the government's behalf. The Civic Nexus consortium, led by ABN AMRO, won the bid in July 2002. The major stakeholders involved in the project are illustrated in Table 1.

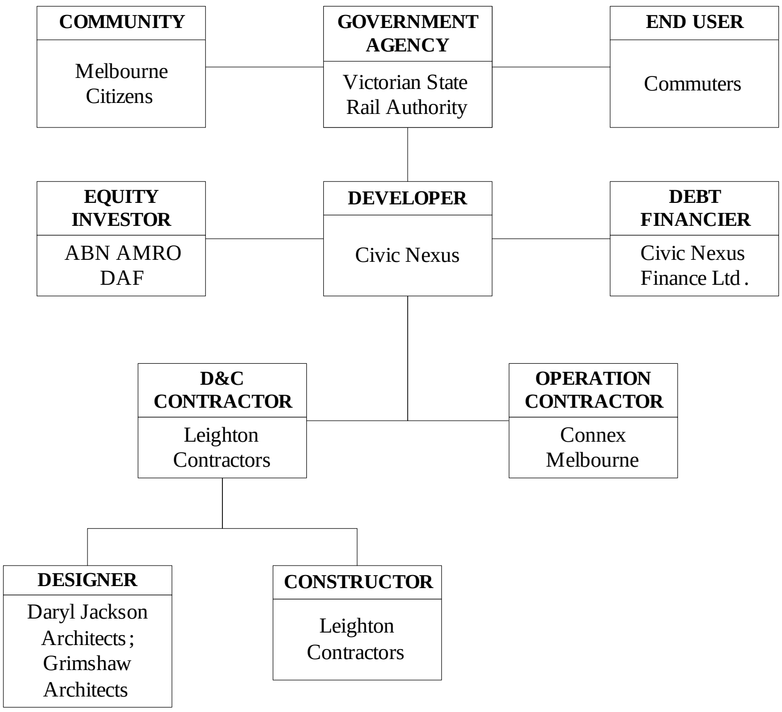

Figure 1: Major stakeholders in Southern Cross Station redevelopment project

OBSERVATIONS AND FINDINGS

The observations on the key challenges and technical difficulties in SCS project delivery presented in following section are an excerpt from the structured interviews with the key project managers in the project.

In the SCS project, the requirement of continuing station operation and the unique design of the wave-like roof limited the construction methods available. Civic Nexus (CN) and Leighton Contractor (LC) initially proposed that the work could be done at nights and weekends, which would cause minimum disruption to the ongoing operation. Though quite attractive in theory, it later became apparent that the proposal did not work in practice. The roof was much more difficult to build than CN and LC had envisaged in the design. Finally, the roof structure had to be designed as a prefabricated entity with structurally stable components. These components were cleared of tracks and associated infrastructure including overhead electrified wires during erection when the train station was not running. It was impossible to prop the roof during its construction and hence the roof columns had to be rigid enough to provide lateral stability. As a result, the size of the prefabricated structural elements had to be maximized to minimize the required number of structural lifts during construction. Besides, pre-finishing had to be maximized prior to erection to minimize the time spent in finishing the structure once it was in place.

LC's operating time was severely restricted by some work on the unique wave-roofed building, which could only be done when trains were not running. LC was thus in conflict with train operator Connex Melbourne (CM), who wanted to keep the trains running as much as possible, over the access to the construction site (Tomazin and Myer 2006). By May, 2004, LC cited the confined working environment, site access issues, the demands of the franchisee train operators, and the complex design variations as the major causes of their problems. This conflict remained unsolved, turned into dispute and LC ultimately made a claim on the resultant losses. In the SCS project, construction risks were entirely transferred by the government and then by CN to LC via a fixed term and fixed price design and construction (D&C) contract. Moreover, LC provided $60 million in case there were construction overruns or failures. Interestingly, the disputes that should have been between CN and LC become issues between the Rail Authority (RA) and LC. More surprisingly, the State government agreed to compensate LC for the cost and time overruns though the construction risks had been transferred at the cost of risk premium.

Apparently, the construction risk in the SCS project turned out to be critical and did materialize and impact on construction outcomes. As illustrated in Table 1, various parties are closely related to risks in the construction phase. A thorough analysis and quantification were necessary though it is beyond the scope of this paper.

THE PPP RISK MANAGEMENT FRAMEWORK

Once a PPP is underway, governance of its life cycle is complex and occurs across a number of processes: initial project development, briefing, calling for expressions of interest (EOI), tendering and bidding, tender selection, financing, design, design development, construction documentation, construction, operation, maintenance and finally, at some point in the future, transfer or handover. Table 1 shows the broad risk categories encountered across the PPP life cycle. It is important to understand what monetary allowance for risk should be retained by the project's public sector promoter throughout this entire process, even into the period beyond construction delivery. This allowance is defined in this paper as retained risk. In other words, this is the risk that a public sector promoter does not allocate to others but retains. In a sense this is a contingency allowance: an amount of money to be retained to allow for unforeseen circumstances across the PPP life cycle.

With regard to these risk factors during the concession period it is important first to consider how much these risk factors might affect the volatility of the facility's future cash flows. The sensitivity modelling of risk factors in social infrastructure projects is more complex than in economic infrastructure projects. This is because a greater range of factors, beyond just traffic volume, may affect the cash flows that the project delivers to its owners.

Table 1: PPP phases, broad risk categories and probable impact (Doloi and Raisbeck 2007a)

Broad risk category	**PPP phase**									
	Project development	**Briefing**	**EOI's**	**Tendering and bidding**	**Tender selection**	**Financing**	**Design development**	**Construction & documentation**	**Operation & maintenance**	**Handover**
Project risks	X			X			X	X		
Govt related	X	X	X					X	X	
Client related				X		X				
Design related							X	X	X	X
Contractor related									X	X
Consultant related									X	X
Market related							X	X	X	X
Post-construction									X	X

The types of factors that might impact on the revenue stream of the asset during the concession period include macroeconomic factors such as interest and inflation rates. But more local factors may also affect the stability of the cash flows during the concession period: e.g. the need to refit low revenue producing areas as a result of changed business conditions, the possibility of retrofitting the facility as a result of environmental issues, or the default of a long-term service contractor.

The process of delivering PPPs involves distribution of responsibility and authority to the various stakeholders involved in each PPP phase as indicated in Table 1. This process has been characterized in a way which takes into consideration a whole of PPP life approach. During the PPP process, multiple objectives such as quality performance, public satisfaction, financial return, environmental and safety performances must be reviewed for appropriate understanding of the influences on overall delivery of the project. Baldry (1998) identified a number of features embodied in committing to public sector projects, such as that the execution of the projects is rarely intended as a means to realize a pure financial reward or speculative gain; and that project function is invariably to support an operational activity or to meet a service of benefit to a large body of customers. The impact of risks extends beyond straightforward financial damage into operational disturbances, loss of service or amenity, user dissatisfaction and disruption of strategic planning processes. These features indicate that the multiple objectives in implementing a public sector project are affected by a wide range of multifaceted risks over different stages of the PPP life cycle. Thus, the risk outcomes are beyond the scope of the project itself (Shen *et al*. 2006).

A number of studies have been reported worldwide to identify risks that affect the performance of PPP projects (Li *et al*. 2005). Based on the findings of these studies, risks affecting public sector projects can be grouped into the following major categories (Shen *et al*. 2006):

- *Project-related risks*: that arise due to cost/time overruns, scope changes, poor contract management, contractual disputes and overall mismanagement of the project;
- *Government-related risks*: that arise due to inadequate project budgets, delays in obtaining permission/approvals, change of legislation, lack of coordination and bureaucrats;
- *Client-related risks*: that arise due to inadequate project budgets, ill definition of project initiation plans, oversight of project specification, inadequate cash flow and poor communication;
- *Design-related risks*: that arise due to technical project issues such as poor site access, non-standard, ambiguous and inconsistent design and change of scope/design;
- *Contractor-related risks*: that arise due to lack of experience, probity issues, loss of onsite control, poor communications, conflict between subcontractors and inadequate cashflow;
- *Consultant-related risks*: that arise due to lack of experience and expertise, oversight of the project implementation issues, performance delays, poor communication and conflicts between project owners and other project stakeholders;
- *Market-related risks*: that arise due to labour unrest, inflation, shortage of construction materials and equipments, etc.;
- *Post-construction risks*: that arise due to poor quality and service standards, customers' dissatisfaction, poor market prediction, change of ownership and consequences of conflicts and litigation between project stakeholders, etc.

As seen, though these risks spread across the project life cycle, most risks may occur during the project development and implementation phases. Figure 2 shows the consequential costs of occurrence of these risks over the project life cycle, which increase significantly as the project proceeds. The definition of consequential risk and its quantification is quite subjective. A successful project in terms of appropriate investment strategy and increased end user's satisfaction may result in significantly lower or nil consequential costs over the PPP life cycle. However, escalation of these consequential costs is a result of non-value addition activities (such as customers' dissatisfaction, tariff instability, design and functional project failures, etc.) in deemed failed projects. The remainder of the paper discusses the links between traditional construction project and PPP project management.

PPP PROJECT MANAGEMENT

Because projects are unique undertakings, they involve a degree of uncertainty. Organizations performing projects usually divide each project into several phases to improve management control. Each phase is marked by completion of one or more deliverables. Collectively, these phases are known as the project life cycle. The phase sequence defined by a project life cycle involves technology transfer or handoff such as requirements to design, or construction to operations (PMI 2001).

A PPP project life cycle has been captured in a two-dimensional chart in Figure 2. As illustrated in Figure 2, Phases III through VI describes a traditional construction project life cycle. They are as follows: (1) Initiation (and feasibility); (2) Planning (and design); (3) Execution (Construction); and (4) Closeout (Turnover and start-up). In contrast, a PPP project life cycle includes Phases I (Concept development), II (Tendering and financing), VII (Operation and maintenance), and VIII (Transfer of ownership), besides the aforementioned phases of traditional construction projects. These extra phases are rather critical to the success of PPP projects rather than peripheral. For instance, the tendering phase of PPP projects may take several years to complete, or sometimes fail, which will definitely exert far more impact on project outcome than the bidding phase of a traditional construction project does.

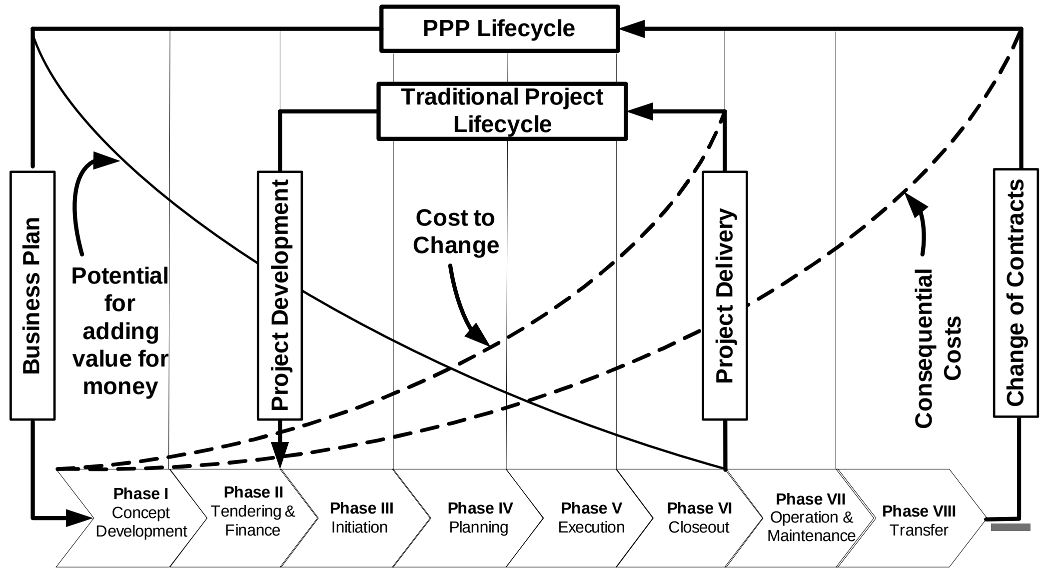

Figure 2: Consequential costs over project and PPP lifecycles

Nonetheless, the life cycle descriptions of a traditional construction project and a PPP project share a number of common characteristics:

- Cost and staffing levels are low at the start, higher towards the end, and drop rapidly as the project draws to a conclusion.
- Risk and uncertainty are highest at the start of the project and generally get progressively lower as the project continues.
- The potential of the stakeholders to influence the final characteristics of the project outcome and the final cost of the project is highest at the start and gets progressively lower as the project continues.
- The cost of changes and error correction generally increases as the project continues.

In particular, the cost of changes and error correction in a PPP project is defined in this paper as consequential cost in order to distinguish it from the similar cost in a traditional construction project. In PPP projects, such cost may include end users refusing to use the facility, and/or an adverse impact on government's reputation, which is much more substantial than the cost of changes in a traditional construction project.

CONCLUSION

The literature survey and the case study highlight the complicated and multidisciplinary management issues associated with public–private partnership (PPP) projects. The key project management issue and its contribution to large-scale transactions involving multiple stakeholders have been explored. The typical PPP life cycle phases and success–failure consequences have been illustrated over a traditional project life cycle. One of the important aspects of the PPPs is their management on two levels: government administration and private sector. Accordingly, the underlying challenges in managing and delivering PPPs from the project manager's perspective include design complexity, stakeholder integration, risk allocation and constructability issues. This research focuses on the need for management decisions on project selection and development over the whole PPP life cycle. Based on a PPP case study, risks inherent to PPP projects are categorized and the processes for appropriate identification, allocation and management of risks (both retained and transferred risks) have been discussed. It was found that the PPP projects are sensitive to good project management practices across government and private agencies. Owing to the involvement of both government and private agencies, appropriate coordination between the two parties is very important. The role of project management for the successful implementation of PPP projects helps not only to combine economic activities and resources but also facilitate successful partnerships between public and private sectors.

RISK MODELLING OF SUPPLY AND OFF-TAKE CONTRACTS IN A PETROLEUM REFINERY PROCURED THROUGH PROJECT FINANCE

Tony Merna[1] and Yan Chu

School of Mechanical, Aerospace and Civil Engineering, The University of Manchester, Manchester, UK

The procurement of refinery projects is a high-risk venture. Determining how to finance a refinery and manage typical risks in order to get sound economic returns is a major challenge. There are significant risks exposed in refinery business environment, for instance construction risk, demand risk, operation risk and especially price risk on both demand and supply sides. Availability and characteristics of types of crude oil supply and product derivatives can determine the choice of refinery types. Apart from buying crude oil in the spot market and selling its products on a similar basis, it is necessary to create significant price certainty to ensure a robust cash flow is achieved. The supply contract and off-take contract can be used to create sufficient certainty of price, quantity and availability of both crude oil and sales of refined products, and thus ensure the financial viability of a refinery project. A mechanism for assessing the risks associated with procuring a refinery is presented and an evaluation of the economic parameters modelled in Visual Basic, Crystal Ball and Excel spreadsheets is illustrated. The paper provides a case study of a refinery procurement utilizing a number of bundles of crude oil supply contracts and off-take contracts.

Keywords: cashflow, contract, modelling, risk, simulation.

INTRODUCTION

For the last three decades, the oil industry has been burdened with surplus refining capacity, often resulting in low margins. Projects procured using project finance were developed primarily for cogeneration projects, typically undertaken by independent power producers. Compared to refining projects, the technology used in cogeneration projects is known and well proven, and project profitability is reasonably predictable (Jenkins 2005). By comparison, the hydrocarbon industry is far more uncertain. Apart from typical risks in a refinery, the different types of crude oil characteristics can significantly influence refinery cash flow.

FINANCING A REFINERY PROJECT

Financing a modern refinery is a risky business. In oil and gas projects, risks can be identified in both upstream and downstream phases respectively (Merna and Al-Thani 2005). Typical risks faced by a refinery business are illustrated in Figure 1.

Project finance requires that the risks identified during the project life cycle are mitigated before sanction of a refinery and sufficient revenues can be generated to service the debt and make an acceptable profit (Merna and Njiru 2002). Typically, the

[1] anthony.merna@manchester.ac.uk

financial instruments used in a project financing are debt, mezzanine (bonds) and equity. The higher-risk projects should normally take more equity to protect the interests of lenders and bond investors and lower-risk projects can accommodate more debt (Merna and Khu 2003).

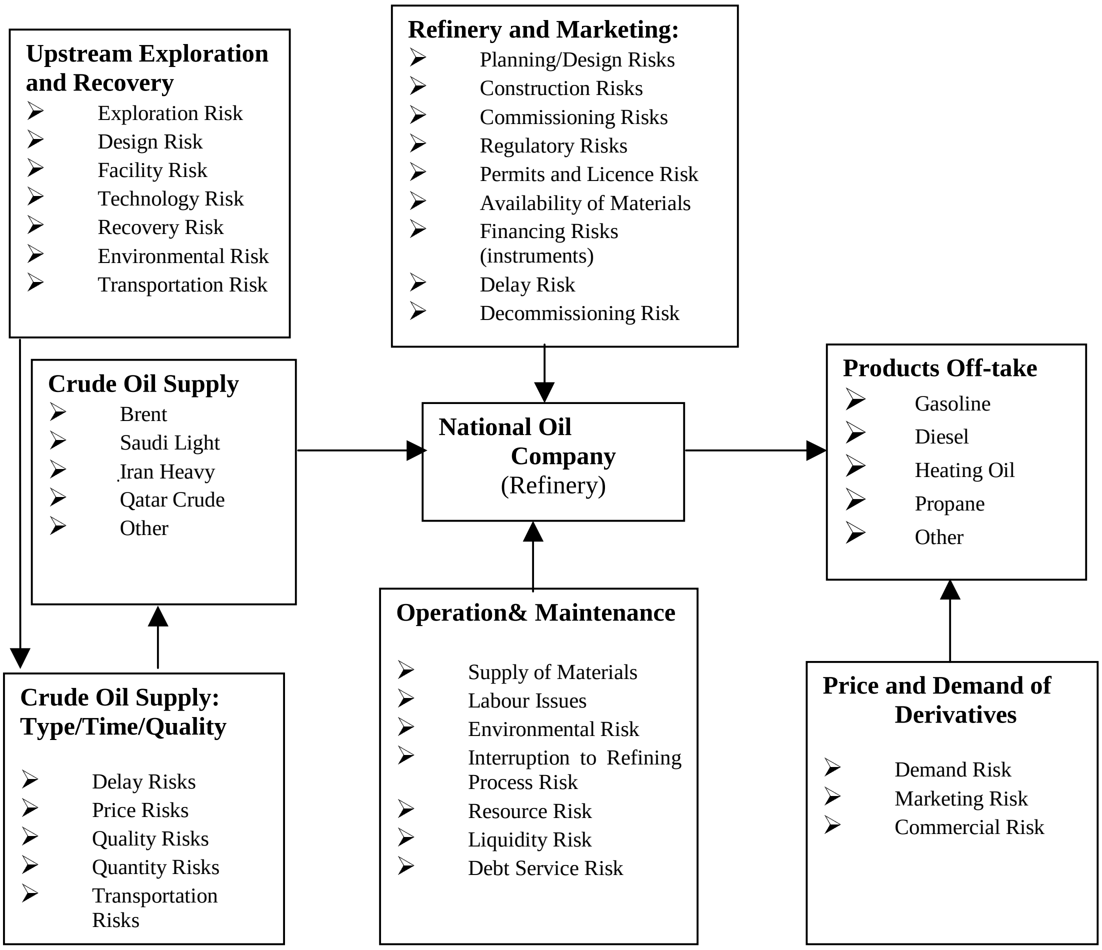

Figure 1: Typical risks in the construction and operation of a refinery

A major risk in refinery operation is associated with the characteristics and quantities of the crude oil supply, which can significantly influence refining margins. Refining low American Petroleum Institute (API) gravity crude oils requires more complex and expensive processing equipment, more processing stages and more energy; therefore, it costs more. The price difference between high-gravity and low-gravity crude oils reflects the refining cost difference. Investment in facilities to process heavier crude oils could allow refiners to improve their profits by reducing the cost of their crude oils.

Each type of crude oil will produce different percentages of refined product. Buying cheaper heavy crude oil, for example, will have a high conversation cost to light products compared to buying expensive light crude oil which is cheaper to refine. Mixing a percentage of heavy crude with light crude oil is often used to refine at a lower cost. Therefore, the price difference between light and heavy crude oils and light and heavy products are among the most important variables affecting refinery margins. These differentials are incentives for installing expensive processing facilities in a refinery, including fluid catalytic cracking, hydro-cracking, coking and other residual conversion facilities.

BUNDLING CRUDE OIL CONTRACTS

Bundling is the grouping of projects, products or services within one managed project structure in a manner that enables the group to be financed as a simple entity (Frank and Merna 2003). Similarly, bundling can be also used to bundle crude oil supply contracts to produce the optimum off-take contracts, in terms of refined products.

Modern petroleum refineries are designed to process a variety of indigenous and imported crude oils. Selecting supply contracts is crucial for companies as major costs are involved in purchasing raw materials (Bansal 2006). As the crude oil cost is about 90% of the refinery input cost, the selection of an optimum crude mix is extremely important to achieve higher margins. However, the number of options for buying crude oils under fluctuating prices and transporting them to refineries are huge, thus making evaluation of the crude oil mix extremely difficult

Refineries normally purchase crude oil and sell its products on term contracts from forward and future market and by spot purchases from the spot market. If, for example, a refinery depends on the spot market for supply, then its profit margin could be seriously affected by movements in market prices. Apart from buying crude oil in the spot market and selling its products on a similar basis, it is necessary to create significant price certainty to ensure a robust cash flow is achieved. Using a project finance strategy, the refiner would be required to enter into supply contracts to reduce spot market risk. A typical supply contract and off-take contract is arranged in a petroleum refinery project procured through project finance as Figure 2 illustrates.

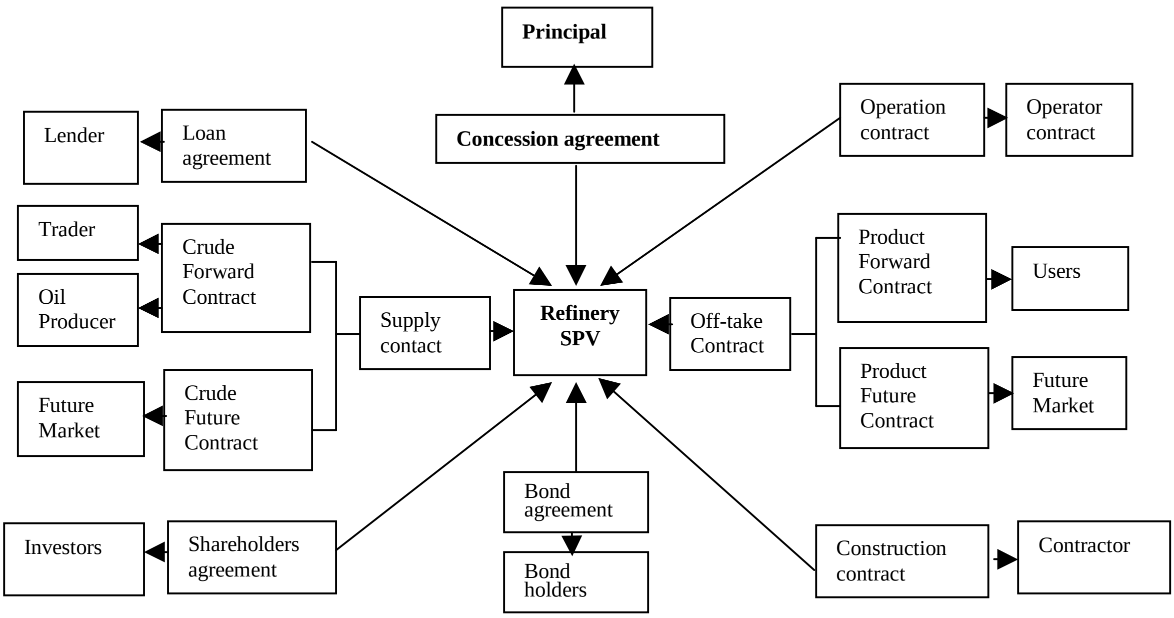

Figure 2: Contractual structure of a refinery procured through project finance

Long-term supply and off-take contracts (forward contracts) can be employed in the bundling of supply contracts to determine the cost and price structure of the off-take contracts as illustrated in Figure 3. The principal aim of the supply and off-take contract is to create sufficient certainty of price, quantity and availability of both crude oil and sales of refined products, and thus ensure the financial viability of a refinery project. It is the supply contracts and off-take contracts for refined hydrocarbons that provide the guarantee on which a “project finance” transaction is based (Elsey and Hurst 1996).

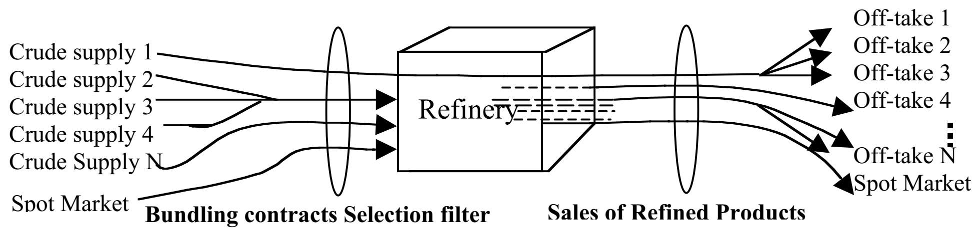

Figure 3: Typical bundling of supply contracts and their product sales

ASSESSING A CASE STUDY

The authors use a case study to assess the risks and financial viability of a refinery project procured utilizing project finance. The refinery is designed to refine both heavy crude oil and light crude oil. The characteristics of the project are show in Table 1.

Table 1: Refinery project characteristics

Location Kalamayi XinJiang Province, China
Sponsors: SINOPEC and CNPC,
Project start: 01/01/2007
Construction Completion:09/2012
Concession Period 29 years
Estimated Construction Investment: (5Years) $710 million
Estimated Operation and Maintenance Cost (24 years) $ 32500 million
Expected profits $1350 million per year
KEY Players: SINOPEC and CNPC, Kelamayi Petroleum.
Possible crude supplies:
Daqing, XinJiang, Saudi Light (Saudi L), Iran Light (Iran L), Iran Heavy (Iran H)

The refinery can refine five possible crude oils from suppliers located near to the refinery. In this mechanism, Crystal Ball is employed to assess the crude oil history data, which can be obtained from the EIA database against probability distribution by using one of several standard goodness of-fit tests. The distribution with the highest ranking fit is chosen to represent crude oil data. It is found that lognormal distribution fits Iran H crude spot market price. However, if a crude oil supply is purchased on a long-term basis and its products sold on a contract led basis, the crude oil price and refined product price are bounded. Dependencies often do exist between two variables in the system being modelled (Rodriguez 2005). When crude oil prices increase then its Gross Product Worth (GPW) increases. Clearly, they have positive correlation. Thus, the triangular distribution is assigned to this supply – off-take agreement as Figure 4 shows.

Figure 4: Iran H price triangular distribution assumption with supply contract

The risks identified have direct impact on the cost of each activity in the model: for instance, the change in construction would increase or decrease the distillation plant cost between 99.6% and 103% respectively. The deterministic cost of each activity is calculated based on those ranges. However, the economic parameters with deterministic values do not reflect uncertainties in the refinery industry. Probabilistic analysis by means of Monte Carlo simulation can deal with this problem. Thus, both range and distribution can be assigned to those variables.

The same principle can be used in other variables such as refining cost, refining margins. A triangular distribution is commonly used in the model where variable distributions are not well known but can be bounded, such as construction cost, transport costs, power and operating costs. These distributions and associated scenario input values are called assumptions.

Computing refining margin varies from refinery to refinery. To simplify the computation Gross Product Worth (GPW), crude oil prices and their GPW are imported directly from EIA database into the model.

The bundle of crude oil supply contracts and respective off-take contracts can be determined by the analyst. The decision variables – for example, the percentages of crude oil procured – are variables that can be controlled by the refinery with corresponding constraints for lower and upper bonds.

Test 1
Figure 5 shows the probability analysis for the refinery with a 100% Daqing crude oil supply (with combination of Forward Contracts, future contracts and spot market purchase) and six off-take products over a 16-year operation period. The cumulative probability diagram shows there is 85% likelihood that the IRR will not exceed 21%, with 15% probability that the IRR would be less than 4%. This result shows that there is great financial uncertainty accompanying the project.

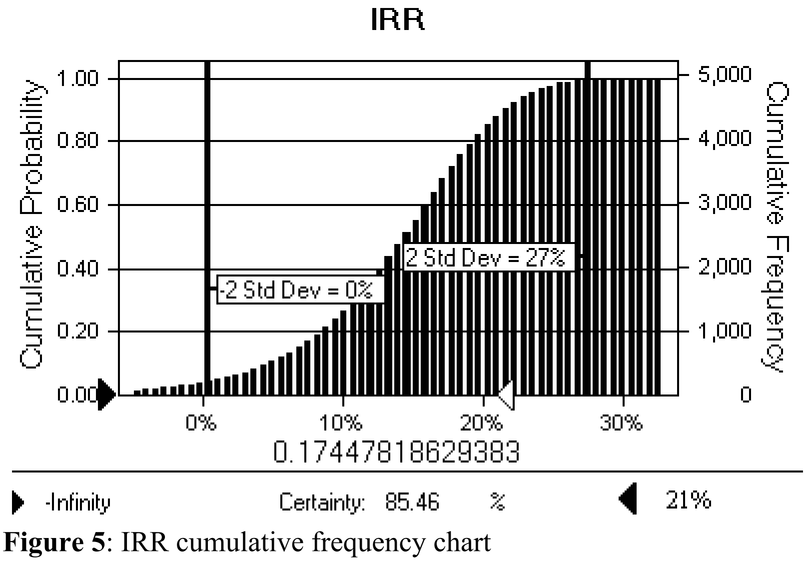

Figure 5: IRR cumulative frequency chart

Figure 6 illustrates the results of a sensitivity analysis. Curves with steep slopes, positive or negative, indicate that those variables have a large effect on the projects financial viability, whilst curves that are almost horizontal have little or no effect on the projects financial viability. Although the Daqing supply contracts and its off-take products contracts are in place, it was found that the project is still very sensitive to the crude price risk, supply default risk, supply delay risk, construction risk and GPW risk, and less sensitive to changes in refining the Daqing crude oil and design risk.

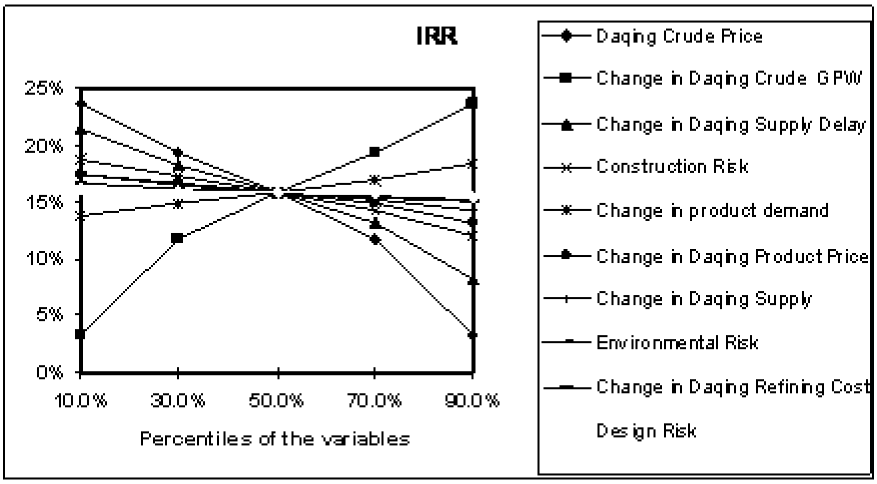

Figure 6: Sensitivity spider chart when taking Daqing crude oil supply

Table 2 and Figure 7 indicate the economic parameters and cumulative cash flow when assessed on a stochastic basis. The IRR for the base case is 16.7% and for the best case 26%; however for the worst case it is only 4%. Clearly, the project is risky with wide variation between the worst and best-case cash flow in the operation period, as illustrated in Figure 7, for a single Daqing crude oil supply.

Table 2: Economic parameters of benchmark crude supply

Economics parameter	Base Case	Best Case	Worst
NPV(Million $)	1378.49	2933.45	88.87
IRR (%)	16.7	26	4
Payback period (year)	7.92	6.71	16.22
Discounted Payback period	8.31	7.53	16.62
Cash Lock UP(m$)	-713,66	-676.21	-897.06
Discounted Cash Lock UP(m	-699.50	-659.23	-872.22
Discount Rate (%)	3	3	3

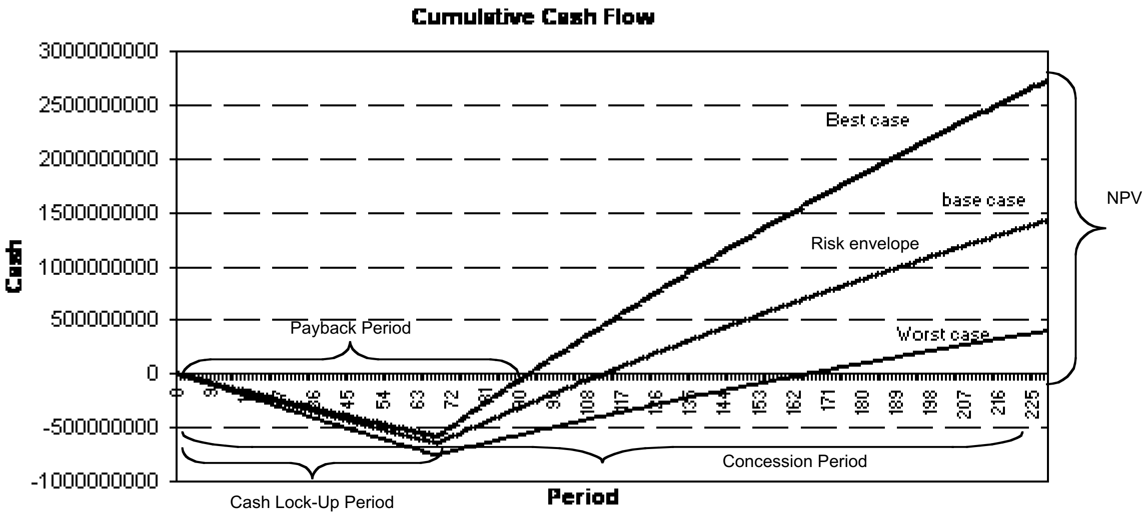

Figure 7: Cumulative cash flow of benchmark crude supply

A similar stochastic simulation process is also applied to four other possible crude oil supplies. Table 3 shows the economic parameters for each single supply. Xinjiang crude, for example, has competitive advantages such as low purchase price and low transport cost because of its location and availability to the refinery, resulting in less supply risk and price risk than other crude supply contracts.

Table 3: Summary of economic parameters of single crude supply

Crude supplies	Payback Period			IRR (%)			NPV (Million $)		
	Base	Best	Worst	Base	Best	Worst	Base	Best	Worst
Daqing	8.31	7.53	16.62	16.7	26	4	1378.49	2933.45	88.87
Iran H	9.03	8.29	13.11	15	17	13.5	1135.2	1806.44	645.5
Saudi L	12.93	7.98	Fail	9	18	1.9	507.03	1978.03	39.00
XinJiang	8.35	7.38	13.29	17	25	11.5	1387.62	2601.72	630.01
Iran L	7.42	7.13	17.2	26	29	2	1420.50	3003.05	32.01

(Note: the negative rate of return means that you cannot recover your initial investment by the end of concession period.)

Sensitivity analysis results show that most single crude oil supplies are sensitive to changes in supply, crude price, demand and GPW. The results of probability analyses of other single crude oil supplies are shown in Table 4. Clearly, there is greater financial uncertainty accompanying the project if the refinery takes a single crude oil supply. Thus, apart from the single Xinjiang supply, the other crude oil supply would be unattractive to investors when such risks were taken into account.

Table 4: Summary of probability analysis results for crude oils

Probability/Supplies	Daqing	Iran H	Saudi	Xinjiang	Iran
85% likelihood IRR not	21%	19%	15%	22%	21%
15% Likelihood IRR Less	3.5%	1.9%	1.2%	7.1%	3.2%

The same testing process is employed to test two types of crude oil supplies (Test 2), then three (Test 3), four (Test 4) and five types (Test 5). The decision in these tests is to determine the percentage of each crude oil the refinery should take to maximize the IRR and return whilst maintaining an acceptable level of risk. The constraint in those tests limit the total crude oil procured per day at no more than the refinery capacity of 220,000 b/d. Investors expect the maximum mean IRR for the minimum risk. Thus, the objective of a bundle of crude oil supplies is set to maximize the mean IRR with a standard deviation between 0.030 and 0.039.

Summary of results of Tests 2–4

It was found after a number of simulations that a combination of 75% Daqing and 25% Xinjiang crude provides the highest mean IRR in Test 2. In Test 3, if the refinery took Saudi L supply it would significantly increase risk on both supply and off-take sides in the bundle.

In Test 4, when the fourth crude supply (Iran H) was then added to the bundle and tested in the model, the bundle became more attractive than other solutions. This is because the risks associated with the fourth crude oil supply balanced the total risks on both supply and off-take sides and thus overall supply risk.

Test 5

The fifth test combines five crude oil supplies. Table 5 illustrates a bundle of 10% Daqing, 25% Iran L, 50% Xinjiang, 20% Iran H and 0% Saudi L as providing the highest return with higher risk than previous tests.

Bundle analysis

The analyses show that there is no perfect bundle solution. Some bundle solutions such as 100% Xinjiang has relatively lower return with a lower given risk, whereas some bundles have higher return with relatively higher risks. However, the best bundle of crude oil supply contracts and off-take contracts should be determined by the level of risk acceptable. Efficient frontier analysis is then employed to consider the balance between return and risk in selecting the optimal crude supply contract bundle based on the risks identified.

Table 5 illustrates Mean Return and standard deviation for combinations of crude supply contracts of a bundle of the five crude oil supplies tested. Under certain risk levels, different bundle will generate different returns.

Table 5: Solutions of mean return and standard deviation for combinations of five crude supply contracts

Solutions	Proportion Daqing %	Proportion Saudi L %	Proportion Xinjiang %	Proportion Iran H %	Proportion Iran L %	Maximize IRR Mean	Standard Deviation<=[0.03,0.06]
1	0	0	100	0	0	0.167	0.03
2	59	0	7.0	34	0	0.19	0.033
3	75	0	25	0	0	0.22	0.036
4	40	0	25	30	10	0.24	0.037
5	10	0	50	20	25	0.25	0.038

Figure 8 shows the efficient frontier for the bundle of five crude oil supplies. The efficient frontier is the intersection of the set of bundles with minimum variance (risk) and the set of bundles providing the maximum return. For example, a bundle of 59%Daqing, 0% Iran L, 0% Saudi L, 7.0 % Xinjiang and 34% Iran H crude oils is more efficient than the bundle of 61%Daqing /39%Iran H in Test 2 because it has a higher IRR and NPV although both of them are exposed to a similar risk level.

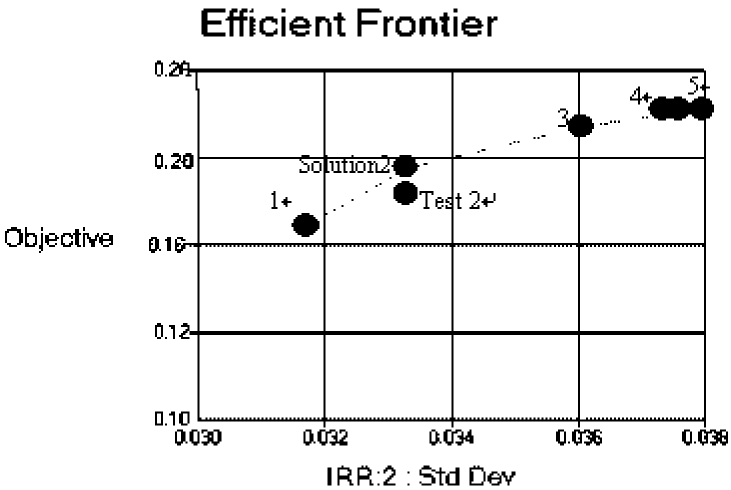

Figure 8: Efficient frontier

Bundle solutions after risk mitigation

When the bundle forming the efficient frontier was simulated new economic parameters were generated, as shown in Table 6. The risks associated with this bundle were then assessed. The risks associated with supply contracts were analysed and it was found that crude supply risks in Solution 3 (shown in Table 5) are more difficult to manage than Solution 4. Tables 7 and 8 illustrate that after risk mitigation, Solution 4 is more attractive to investors than Solution 3 because the risk level of Solution 4 can be reduced to the same risk level as Solution 3 but with high returns Therefore, Solution 3 is no longer on the efficient frontier after risk mitigation.

Table 8: Economic parameters after risk management

Crude supplies	Payback Period			IRR (%)			NPV (Million $)		
	Base	Best	Worst	Base	Best	Worst	Base	Best	Worst
XinJiang 100%	8.26	7.28	13	17	25.5	12	1367.62	2791.72	640.01
59% Daqing, 0% Iran L, 34% Iran H, 0%Saudi L, 7.0 %Xinjiang	8.2	7.7	13.9	19	29.5	12.5	1588.08	2996.76	869.0
75%Daqing 25%Xinjiang	8.3	7.2	14.0 3	22	31	12.9	1622.0	3433.7	899.0
15% Daqing, 0% Saudi L, 35% Xinjiang, 30% Iran H, 20% Iran L	7.5	7.23	15.19	24	31.5	11.1	1800.16	3528.78	765.0
10% Daqing, 25% Iran L, 50% Xinjiang, 20% Iran H, 0% Saudi L	7.5	6.9	15.21	25	34	10	2500.25	4256.0	656.9

The analyses show that the project is exposed to different levels of risks and different economic returns. After risk mitigation, Solution 5 still has highest return with highest risk; Solution 1 has lowest economic return but lowest risk. Investors choosing Solution 1 would seek a large amount of debt; whereas investors choosing Solution 5 would require more equity as risk finance.

CONCLUSIONS

The authors simulated a bundle of supply and off-take contracts and compared different economic outputs from each bundle.

The assessment clearly illustrates the bundles best, worst and base-case economic parameters with impact of both supply risk and typical refinery risks.

The assessment offers a detailed method for determining the crude oils to be purchased and their percentage within a bundle of crude oil supply contracts.

The assessment can aid stakeholders in the decision making process regarding the type and quantity of crude oil supply contracts based on identified risks.

Investors in refinery projects can assess specific risks affecting crude oil supply in relation to the overall project economic parameters.

There are numerous combinations of crude oil supply bundles. The risks associated with supply and off-take is extremely complex. From the tests shown in the analyses, the refinery economic viability is very sensitive to the crude oil supply and off-take. The choice of a bundle of crude oil supplies is paramount to the commercial viability of a refinery thus making risk management an integral part of refinery procurement and operation.

MODELLING RISK MANAGEMENT FRAMEWORK IN BOT PROJECTS: INDONESIA'S CASE STUDY

M. Agung Wibowo[1] and Andi Nusa Patria[2]

[1]*Diponegoro University, Semarang, Indonesia*
[2]*Indonesian Islamic University, Yogyakarta, Indonesia*

Build-Operate-Transfer (BOT) is perceived as a risk sensitive procurement method. In a limited concession time, the project sponsor (investor) is expected to achieve return on investment and profit by the end of the concession period. Theoretically, BOT investors have to manage greater scope of risks than the ones on traditional cost + fee projects. Various kinds of risk factors, such as public policy or economic environment of a country, are to be considered. This research aims to identify the risk management framework in BOT projects and develop a conceptual model to advance the use of a systematic approach to risk management. First, the existing approach to risk management in BOT projects on public infrastructure in Indonesia (bus stations and regional marketplaces) was observed and analysed. A survey targeted at experienced officials from public and private sector organizations involved in BOT projects was conducted to elicit industry opinions and implementations of risk management. Second, studies in BOT schemes and risk management theories are added to the existing approach. Based on these studies, a framework for implementing risk management in BOT project is proposed and refined on three rounds of focus group discussions. The research found that risk management processes in BOT projects have a cyclic form. These cyclic processes occur in the planning, construction and operation stages of the BOT projects. A systematic risk management framework is proposed to enhance the ability to take quantifiable and accountable measures in every project stage. This framework will enable the organization to strengthen accountability and encourage learning to ensure the continuous improvement of this model.

Keywords: Build-Operate-Transfer, modelling, risk management, framework, public facility.

INTRODUCTION

Uncertainty is inherent in all activities (Mawdesley 2003). It means that there are always possibilities to meet different outcomes compared to what is expected. Uncertainty could lead to a better or worse result than what is expected at the beginning. As the complexity of activity increases, there will be more uncertainty, and the variability of the results will be much greater.

Construction projects, especially large-scale ones, are activities of great complexity, regarding the various components used, quantity of resources involved and the uniqueness of every project. These characteristics usually result in a large number of unknown, unpredictable and unquantifiable problems leading to the development of various risks that could undermine the successful performance completion of a project (Wibowo 2005). Build-Operate-Transfer (BOT) is a project scheme whereby a private entity (investor) is granted concession for a right on certain period of time, along with

[1] agung_wibowo8314423@yahoo.co.uk

the responsibility to finance, build and operate a facility until the investor finally transfers it in a fully operable condition to the principal at no cost. The scheme is considered risk sensitive. The investor is expected to achieve a return on investment (RoI) and gain profit by the end of concession period. This relatively new procurement method (especially in developing countries) changed the way a public facility delivered, while also altering the culture of the parties involved in terms of how they perceive risks. Akintoye (1998) suggests that a private finance project (including BOT) should satisfy two fundamental requirements: securing value for money and allocating risks appropriately. Risks should be allocated into categories of those that are best absorbed and most efficiently managed by the private sector, and those that should remain with the government department. Therefore, adequate knowledge and good implementation of risk management in both parties are essential to bring more successful BOT project.

The decrease of investment growth and the quality of public infrastructure serviceability in Indonesia after the great recession in 1997 has sent a powerful message that this country's ability to finance and build facilities has also been in decline. A decelerated economy along with the absence of necessary knowledge and experience in the latest construction technology and management has necessitated the need to draw in private partners to form private finance initiative projects, including BOT schemes. Despite the encouragement to procure more BOT projects, there are needs to investigate their risk management process, and provide implementation and evaluation guidelines.

The aims of this paper are: (1) to identify the general processes within the risk management framework of BOT projects; and (2) to propose a conceptual model of risk management in BOT projects based on Indonesia's experiences.

REVIEW ON RISK MANAGEMENT

Risk, uncertainty and opportunity

Most business making takes place on the basis of expectations about future, while the future itself is largely unknown. Decisions that have been made based on assumptions, expectations, estimations and forecasts always involve risks. Risk is an abstract concept. It is difficult to define and, in most cases, it is hard to quantify in precision (Wibowo *et al*. 2005). The definition of risk stated in the *Oxford English Dictionary* (2000) is: "The possibility of meeting danger or suffering harm or loss". This definition proposes that risk is a form of incomplete knowledge about the future that could lead one to a danger of harm or loss. There is a strong relation between risk and uncertainty, where risk is a function of uncertainty. However, some people like to distinguish between risk and uncertainty. Raftery (1994) states that risk is taken to have quantifiable attributes, whereas uncertainty does not. Risk arose when it was possible to make a statistical assessment of the probability of occurrence of a particular event. Risks, therefore, tended to be insurable. An important question rises: why do we expose ourselves to uncertainty that could lead to a "possibility of loss"? Dawson (1997) explains that the logical answer must be that there is the possibility of gain and this can only be achieved if we place ourselves at risk. This proposes that opportunity and risk are both functions of uncertainty. Opportunity and risk are uncertain and therefore have a probability of occurrence and outcome.

Risk management

Risk management is the name given to a formalized process of balancing the risks and opportunities a decision may produce, and taking action to produce an acceptable balance between the two. The way in which this process is usually performed, when using subjective experience and gut feeling, is largely unknown or person specific, but certain procedures seem to be integral to it (Wibowo *et al*. 2005).

1. The uncertainties in the project or venture are identified.
2. The significance of each is assessed in terms of consequence and chance of occurrence.
3. The risks and opportunities are balanced to show the overall uncertainty.
4. The balance produced is judged against acceptability criteria to determine the need for actions to produce an acceptable balance.
5. The actions needed are determined with reference to the significance of each uncertainty.

Regardless of the discrepancies of the definitions of risk management provided by some experts, practitioners usually implement the process by introducing steps to fulfil specific objectives or particular requirements (Dawson and O’Reilly 1999; Thevendran 2004). General processes of risk management that have been widely understood and used are risk identification, risk analysis and risk response. Robillard (2000) suggests an integrated and more comprehensive approach to risk management. He stated that it is no longer sufficient to manage risk at the individual activity level or in functional silos. Organizations around the world are benefiting from a more comprehensive approach to dealing with all their risks. Integrated risk management is a continuous, proactive and systematic process to understand, manage and communicate risk from an organization-wide perspective. It is about making strategic decisions that contribute to the achievement of an organization's overall corporate objectives.

This approach requires an ongoing assessment of potential risks for an organization at every level then aggregating the results at the corporate level to facilitate priority setting and improved decision making. Integrated risk management should become embedded in the organization's corporate strategy and shape the organization's risk management culture. The identification, assessment and management of risk across an organization help reveal the importance of the whole, the sum of the risks and the interdependence of the parts. Integrated risk management does not focus only on the minimization or mitigation of risks, but also supports activities that foster innovation, so that the greatest returns can be achieved with acceptable results, costs and risks. Integrated risk management strives for the optimal balance at the corporate level. In this approach, the risk management framework is conceived as a comprehensive process beginning with an internal look at the ability of an organization and its risk-taking characteristics to the implementation and evaluation of risk management practices. The process is described in Figure 1 below.

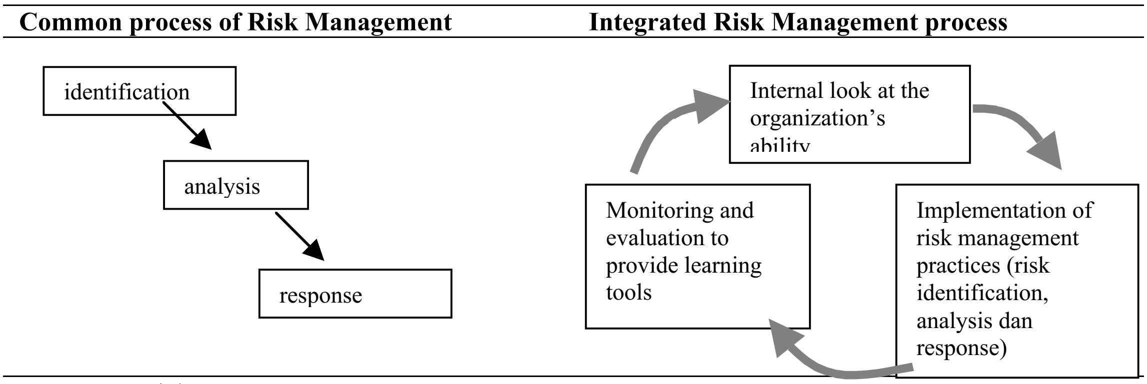

Figure 1: Risk management process

Risk management in BOT projects

BOT schemes contain large numbers of factors that may affect business uncertainty such as a long concession period, large number of parties involved and the complexity of relationships among the parties in the project itself. On the other hand, the project should run under limited resources and conditions. The factors of uncertainty combined with the limited resources and conditions have pushed managers to apply more effort in managing risks to produce more predictable results and protect the life cycle of the project itself.

Commonly, there are five stages of BOT project in which the owner and investor are involved. They are preliminary, planning and design, construction, operation and post operation. Both parties have specific roles and functions during each stage. Project stages and roles of both parties can be described as follow:

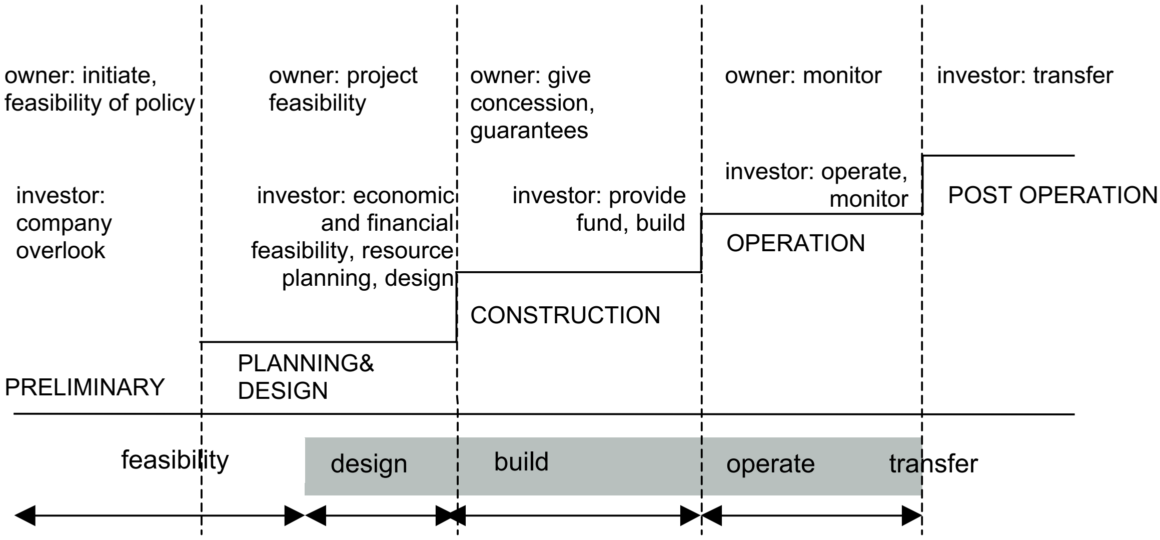

Figure 2: Build-Operate-Transfer project scheme

RISK MANAGEMENT FRAMEWORK FOR BOT PROJECTS

Studies on risk management theories show that there are common processes in risk management (as suggested in Figure 1). These common processes will be used as basic knowledge to develop a risk management framework. The common processes involved risk identification, risk analysis and risk response. This is a linear process in which identification will be succeeded by analysis, and risk response concludes these three stages.

Indonesia's BOT case

A survey was conducted on two case studies of Indonesia's BOT projects. They are Giwangan Bus Terminal and Cilacap Public Marketplace. These two projects are owned by local government and managed by a private company.

Giwangan Bus Terminal is a state-owned bus terminal in Jogjakarta City. This terminal is located on the southern side of the city, positioned to generate the area's economic growth and improve the quality of the mass transportation system. This 120 billion rupiah project will include a terminal and commercial facilities (shopping centre and hotel). The Jogjakarta City Government decided to proceed with this project through a BOT system due to the lack of investment funds needed. PT Perwita Karya, a local private company, was awarded a 30-year concession to fund, build and manage this facility.

The second case study is the Public Marketplace Project in Cilacap Region, Central Java. The project includes renovation and development of an existing marketplace. The work costs 36 billion rupiahs. As with the first case study, the Government was out budgeted. Yet, they needed to proceed with the project to promote the growth of this region's economy. Therefore, the Government invited PT Lingarjati, a public company, into a BOT arrangement to fund, build and operate the facility.

Both cases show a similar risk management framework. First, they conducted a process identified as "internal action". This is a process where owner and project sponsor prepare their organization for the project. Second, the owner hires a third party consultant to conduct a feasibility study on economic, legal and technical aspects. Meanwhile, the project sponsor assembles an internal team to conducts its own feasibility study. These studies identify risks and opportunities contained in the project. Third, risks are analysed in terms of impact and likelihood, and the ability of the organization to handle them. Fourth, the response to the risks are analysed, which includes allocating risks to one of the party considered most capable to handle them. After risks are shared, the parties involved will take mitigation measures to decrease the impact and possibility of risk occurrence. At this stage, monitoring and evaluation are consistently conducted. Results of the evaluation are used to anticipate constraints and to improve project performance. This process cycles in three phases of the project: planning, construction and operation.

The survey also shows that investors perceived the construction phase as the most risky. This may indicate their remaining mindset as contractors.

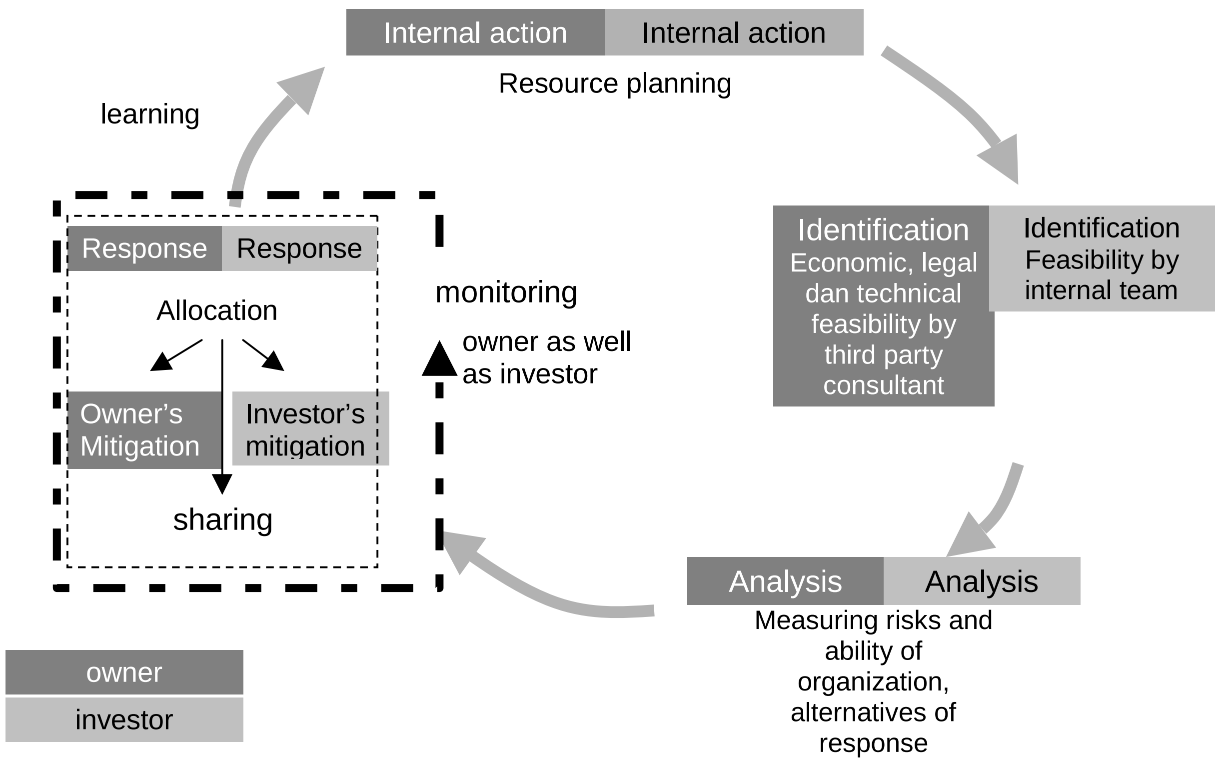

Figure 3: Risk management framework on Indonesia's BOT case

PROPOSED RISK MANAGEMENT FRAMEWORK MODEL FOR BOT PROJECTS

The proposed models are based on two areas of study: risk management theories and the case study of two public facility projects conducting BOT scheme in Indonesia. The results of these studies are compared using several parameters and combined to generate a proposed framework model. The proposed model is refined through three rounds of focus group discussions (FGDs) participated by seven Indonesian experts from government and universities. Practitioners from the public sector did not respond to the invitation of this FGD. Composition of the experts is described in Figure 4 below.

numbers of participants	**institution**	**position**
1	university	modelling adviser
3	university	private finance researchers
2	government	Head of Cooperation Department
1	government	Officer of BOT project

Figure 4: Participants of focus group discussion

Summary of the risk management frameworks in theory and case studies are compared on certain parameters as seen in Table 1. This comparison and inputs from FGDs are used to generate principles of the proposed framework model.

Table 1: Comparison of the frameworks

Concession period

Figure 5: Proposed risk management framework model

The result of the comparison above indicates common practices as well as differences in some areas. However, there are some principles to be applied to propose a model of the risk management framework on a BOT project. The model consists of a common process cycle (identification, analysis, response, evaluation) that is implemented in every phase of the project (planning, construction, operation, and post operation). All processes are started by internal action on both sides (owner and investor).

The model in Figure 5 above provides a comprehensive vision on how risks are managed in BOT projects. More detailed elements of the framework are described as follow:

Internal action on owner's side
This process begins as the owner sets strategic directing. At this stage, the owner analyses the position and capability of its organization and sets a target to achieve by implementing risk management. In both Indonesian cases, the owner formed a team to conduct a feasibility study with the assistance of external teams (professional consultants). The study reported the actual condition of the organization and the environment in which the project will be implemented. The objectives of the study are (1) to identify organization's risk profile; and (2) to set the purpose and target of risk management. Once the risk profile is identified and the target is set, the organization builds a more specified structure to conduct risk management.

Internal action on investor's side
Internal action is also implemented within the investor's organization. This is basically a similar process that is taken to develop the organization's risk profile (company's risk profile) by identifying the existing risk profile and assessing the ability of the company to manage risks. To enable the risk management function to run effectively, it has to be integrated with a decision-making system. Internal action on the investor's side does not include strategic directing.

Internal action on both sides is essential to provide a good foundation on which further process of risk management will be implemented. Next, the core process of risk management is implemented. This includes risk identification, risk analysis and risk response.

Risk identification
The purpose of the risk identification process is to identify existing risks and the capability of the organization to handle potential risks. This process is conducted by both investor and owner. There are three simultaneous elements of work required in this process: (1) to observe the environment of the project; (2) to assess resources needed to implement risk management; and (3) to analyse stakeholders.

Risk analysis
Risk analysis is one of the most critical processes of risk management. Here, existing risks in every project stage are listed and measured in terms of impact and probability. Impact and probability are factors of importance level that provide guidance for the management to assign priority to the risks that concern it most. The organization's capability is also a subject taken into consideration in determining this importance level. The process can be either qualitative or quantitative. The Jogjakarta and Cilacap case implemented qualitative techniques for risk analysis.

Risk response

Risk response is a process in which risks are delivered to the parties involved in the project (risk allocation) and minimized (risk mitigation). Parties involved in the project might negotiate in this process to make an agreement on the allocation of risks. Once risks are allocated, the parties burdened shall implement mitigation strategy to minimize the impact and likelihood of risks within their sides.

Risk evaluation

The processes of risk management need to be evaluated on their capability, handling and result to find out whether they meet the target or not. This evaluation has to be communicated throughout the work environment. Evaluation of the planning, design and construction stages may result in two conditions: satisfy the target or otherwise. The first condition leads management to re-identify risks within the same stage. The second condition leads management to the next process, which is identification of risks at the next stage. If considered successful, the next process will be preparing a learning plan for the next project.

CONCLUSION

The Indonesian Government has created opportunities for the private sector to participate in the delivery of public facilities with various kinds of investment schemes, including BOT arrangements. This scheme is perceived as risk sensitive, so a comprehensive understanding in risk and risk management process in BOT projects is needed. Furthermore, BOT requires a cultural change in which a construction contractor must act as an investor. A model of risk management in BOT project helps managers to conceive an abstract process of the risk management and translate it into a schematic concept. This process is essential to build a better understanding and implementation of risk management.

The general process identified in BOT risk management consists of internal action, identification, analysis, response and evaluation. Based on this general process, a conceptual model has been proposed. The model has a cyclic form, containing a cycle of the general processes in every project stage (planning & design, construction and operation).

One of the aims of a broad ethnographic study into how the apportionment of risk influences pricing levels of contactors was to ascertain the significant risks affecting contractors in Ghana, and their impact on prices. To do this, in the context of contractors, the difference between expected and realized return on a project is the key dependent variable examined using documentary analyses and semi-structured interviews. Most work in this has focused on identifying and prioritizing risks using relative importance indices generated from the analysis of questionnaire survey responses. However, this approach may be argued to constitute perceptions rather than direct measures of the project risk. Here, instead, project risk is investigated by examining two measures of the same quantity: one 'before' and one 'after' construction of a project has taken place. Risks events are identified by ascertaining the independent variables causing deviations between expected and actual rates of return. Risk impact is then measured by ascertaining additions or reductions to expected costs due to the occurrence of risk events. So far, data from eight substantially complete building projects indicate that consultants' inefficiency, payment delays, subcontractor-related problems and changes in macroeconomic factors are significant risks affecting contractors in Ghana.

Keywords: contractors, Ghana, risk, risk identification, risk impact.

INTRODUCTION

Project uncertainties create forces of risk that act in project environments to cause deviation of actual performance from the expected. Contractors may survive some levels of risk while others can result in losses and business failure. The identification of risks affecting contractors in specific construction environments and their impact on prices can help contractors to estimate a price for risk when building up prices. This study conceptualizes a novel experimental approach to identify and prioritize risks affecting contractors in the Ghana construction industry.

BACKGROUND

Much of the empirical work on risk can be described as measures of perceptions rather than direct measures of the risk. Methodologically, most work has resulted from questionnaire surveys where respondents rank risks to help researchers analyse what can be statistically described as relative importance indices. This can be argued to be measures of perceptions (what respondents claim to be the case) rather than direct measures of the project risk (the actual losses or gains incurred). Besides, three limitations can arise from this very common approach. First, mainly the positive risks that create losses often result. Second, besides the tendency of humans to forget,

[1] salaryea@yahoo.com

respondents may seek to portray a good image of company performance. Third, the results scarcely give an idea of the consequences of the risks in monetary terms.

Risk is a fact that we all face and act upon daily. However, its measurement is difficult and highly subjective. What poses risk to one organization may not pose risk to another. The problems of risk assessment are complex and poorly understood in practice. Contractors are often unable or unwilling to make appropriate allowances for the risk element in construction projects. While their inability may be due to nonchalance or a lack of expertise, their reluctance may be attributable also to a regard for the other factors that also affect price. This may include competition, need-for-work, perceived opportunities, and project characteristics. These factors may generally cause the price of risk to be smaller than the impact of risk as risk analysis may not equal risk accountability. Risk judgments can vary per the degree and type of uncertainty involved and the amount of information available at the time of decision making. Several definitions of risk exist in the literature, with a close link of them to formal probability theory. The commonest evaluation mechanism for one measure of project risk is to multiply its probability and its impact. The basis for evaluating the probability and the severity parameters of the concept often leads to varying risk definitions. Authors have often clashed on risk definitions. But this confusion may hinge on the common difficulty of distinguishing risk from uncertainty. For simplicity's sake, some evaluation mechanisms especially in the field of finance synonymize risk with uncertainty. But technically speaking, their meanings are different as uncertain situations involve unknowability while risky situations involve knowability (Fischer and Jordan 1996). Over the years, several questions have arisen from risk research. The key questions relate to what the natural unit of risk should be, and whether the uncertainty and severity components be multiplied directly in the sense that a small probability of a large loss is considered equivalent to a larger probability smaller loss.

Williams (1996) argues that proper consideration of project risk requires consideration of both impact and likelihood. Multiplying impact and uncertainty to 'rank' risks is misleading, since the correct treatment of the risks requires both dimensions. In dealing with a single risk, there is little danger in considering the multiplied figure. However, using the fundamental theory to combine or compare non-singular risk events can be erroneous. In trying to go round this problem, the idea of plotting such risks on probability-impact grids has gained popularity. However, rather than decreasing the dimensionality of the measure, some authors rather suggest an extension: Charette uses three-dimensional graphs with independent axes he labels severity (i.e. impact), frequency (i.e. likelihood) and 'predictability' (in technical terms, the extent to which the risk is aleatoric rather than epistemic). Wynne takes this distinction further, by distinguishing between risk (where the 'odds' are known), uncertainty (where the odds are not known, but the main parameters may be), ignorance (where we don't know what we don't know) and indeterminacy (described as 'causal chains or networks open' – so presumably implying an element of unknowability).

The variability of realized return around an expected value can be used as a quantitative description for risk (Fischer and Jordan 1996). In the finance literature, beta (β), has long been used as a statistical measure for unsystematic risk. Beta shows how the price of a security responds to market forces. As risk relates to profitability (Akintoye and MacLeod 1997), the capital asset pricing model (CAPM) provides a system for linking beta to the required return of a security or portfolio. Statistically, we can use the dispersion of realized return about an expected average as a quantitative description for risk (Fischer and Jordan 1996).

RESEARCH AIM AND OBJECTIVES

The aim is to ascertain risks affecting contractors in Ghana, and their impact on price. Specific objectives are: (1) to determine project risk levels experienced by contractors in Ghana; (2) to ascertain significant risks affecting contractors in Ghana; and (3) to ascertain impact of the risks on prices.

RESEARCH METHODOLOGY

To identify the significant risks affecting contractors in Ghana, and their impact on price, two potential strategies were identified thus:

1. Controlled experiment: where substantially complete building projects would be investigated using a before-and-after experiment and documentary analyses to directly identify project risks, and their respective impacts on prices.
2. Survey: where contractors would be asked using questionnaires to indicate risks they encountered on projects, and rank their significance.

Much of the empirical work on this has resulted from questionnaire surveys where researchers ask respondents to assign a ‘rank’ to risks listed from the literature. The significance of each risk is then made to correspond to relative importance indices calculated from the responses. Some examples in this include Liu and Ling (2005), Ghosh and Jintanapakanont (2003) and Fang *et al.* (2004). One can argue such measures of risk to constitute perceptions rather than direct measures of the risk.

To identify the significant risks in an underground rail project in Thailand, Ghosh and Jintanapakanont administered a questionnaire containing 59 variables (potential risk sub-factors) from a review of the literature in 17 previous studies. All 59 variables included in the questionnaire were set on a five-point scale – 5: extremely important, 4: very important, 3: important, 2: somewhat important, and 1: not important – and these scales were used to conduct factor analysis.

The questionnaires were sent to 150 respondents comprising project managers, managers, engineers, architects and project operation officers. In all, 122 respondents consisting of 10 project managers, 13 managers, 51 engineers, 5 architects and 43 project operation officers returned useable questionnaires. Factor analysis was the means of identifying the critical risk factors. According to importance indices, risk factors were ranked as follows: delay risk, financial and economic risk, subcontractor-related risk, contractual and legal risk, design risk, force majeure risk, safety and social risk, physical risk and operational risk. The client and project managers were also interviewed to obtain their assessment of the risk factors but it is not clear whether their assessment agreed with the ranking.

To model contractor’s mark-up estimation, it became necessary for Liu and Ling to identify the five most important factors affecting mark-up estimation, and to rate their degree of importance. The likely factors that influence mark-up were obtained from five past studies. From these studies, 52 attributes were uncovered and grouped into seven categories. The first part of the fieldwork sought to determine the most important and significant of these variables that affect mark-up estimation. A total of 142 survey packages were sent out on 1 September 2000. Responses were received between 5 September 2000 and 6 October 2000. Twenty-nine valid responses were received, giving a response rate of 20%. The primary section of the questionnaire was comprised of statements regarding the 52 attributes in seven main categories that may affect mark-up estimation, identified in the literature.

Respondents were asked to rank the main factors from 1 to 7. The 29 respondents provided different rankings and the Hungarian method was used to ascertain the overall rankings. Respondents were also asked to indicate the importance of these attributes on a five-point Likert scale, where 1 represented a response of ‘very unimportant’, 3 represented ‘moderate’, and 5 stood for ‘very important’.

The analysis helped to derive the relative importance of the seven factors. The most important attributes under the main categories were chosen to establish the model for mark-up estimation. Several other studies have used similar approaches to determine the ‘important’ risks. But this way of prioritizing risks is subject to the honest account of respondents, which may still have some distortions. Only positive risks that create losses were captured, and there is no indication of potential consequences in monetary terms.

Here, instead, we investigate direct measure of project risk by examining two measures of the same quantity, one ‘before’ and one ‘after’ construction of a project has taken place. Specifically in the context of contractors, the difference between ‘the expected return’ and ‘the realized return’ is the key measure (dependent variable) we examine through documentary analyses and interviews to identify project risks, and their respective impact on price. For the purposes of this study, we operationalize project risks as the factors (independent variables) responsible for the deviation of actual project outcome from the expected outcome. The impact of risk(s) on price will be quantified by using documentary analyses to investigate additional or reduced costs resulting from the risks.

The methodology was devised from the investigative approach used by Olken (2005) to investigate corruption levels in World Bank projects executed by local government officials in Indonesia. Using randomized controlled field experiments, he investigated missing expenditures in 608 village road projects in Indonesia. From the data on the financial reports, it was possible to calculate reported expenditures. From field surveys, it was possible for engineers to estimate the actual expenditures.

The dependent variable resulting from the difference between the two quantities on ‘what the villages claimed the road cost to build’, and ‘what the engineers estimated it to actually cost to build’, is the key measure of missing expenditure that was examined. The study controlled for some amount of normal loss during construction and measurement. Percent missing was also defined to be the difference between the log of the reported amounted and the log of the actual amount.

Most work in our field has focused on using questionnaire and interview surveys to obtain data on risks from respondents who may be clients, consultants or contractors. The annotations they assign are then resolved along the lines of relative importance indices to obtain the impact. A comparison between the proposed comprehensive experimental approach and the more common survey approach should reveal that for direct measures of risk and its impact on price, the experimental research approach is more appropriate for gaining a better understanding of risks and their impact on price.

RESEARCH DESIGN AND METHODS

To identify project risks and evaluate their impact on price, it became necessary to investigate the projects themselves and not the contractors as is commonly done by most researchers.

This work draws on a small literature to formulate an approach and measurement procedure for the investigation. In specific relation to construction, The Aqua Group (1999: 14) defines risk as the possible loss (or gain) resulting from the difference between what was anticipated and what finally happened. Shah (2001) explains that the risk concept is focused on deviation from expected outcomes. Fischer and Jordan (1996) define risk as the possibility that realized returns will be less than the returns that were expected. Based on these studies, it became logical to express the variability of return around an expected average as a quantitative description for project risk.

$$\textit{Risk} \approx \textit{realized return} - \textit{expected return} \qquad (1)$$

We can therefore quantify project risk in the context of contractors by examining two measures of the same quantity – return – one 'before' and one 'after' construction of a project has taken place. To do this, the difference between expected return (before) and actual return (after) on a project is the key measure (dependent variable) that will be examined. Project risks will be identified by investigating the forces causing deviation of actual values from the expected outcomes. The impact of each risk must show up somewhere in this difference between 'expected return' and 'actual return.' Since risk is the possibility that realized return will deviate from the expected return, we operationalize risk level as follows:

$$\textit{Risk level} \approx [(\textit{expected return} - \textit{realized return}) / \textit{expected return}] \times 100\% \qquad (2)$$

A resulting positive risk level may indicate not only the incidence of negative risks but also a greater net negative risk in some cases. The positive value may not necessarily mean the absence of some gains (positive risks) in some aspects of the project. Likewise, a resulting negative risk level may not exclusively connote the incidence of only positive risks but also a greater net positive risk in some cases. The conventions will reverse when base costs form the basis of measurement. We can thus estimate the impact of a risk event using the following relation:

$$\textit{Impact of a risk on price} \approx \frac{\textit{risk weight}}{\textit{expected price}} \times 100\% \qquad (3)$$

where: risk weight is the additional or reduced costs incurred from the occurrence of the risk event; and expected price is the price quoted by the contractor in the offer/bid.

Risk weight can be quantified by using documentary analysis to ascertain the extra or reduced costs of resources incurred from the occurrence of a risk event. This method can be supplemented by in-depth interviews to probe further. In future, we can simulate the data on each risk to ascertain whether it models a specific pattern, distribution or behaviour. Successful results can help to forecast the impact of a specific construction risk in Ghana on the price of a future project.

To control for measurement errors arising from differences in contractual capacity and varying project characteristics, only large public building projects constructed in Ghana by financial class D1 contractors were sampled. Financial class D1 contractors are the category of firms authorized by the Government of Ghana Ministry of Works and Housing to contract the largest projects because of their massive capital and resource outlay.

DATA COLLECTION

At the time of writing, data collection is still ongoing. This paper can therefore report the results obtained to date, and the plans for carrying out the rest of the work.

The data collection was done in three selected leading construction firms in Ghana, designated as sites for an ethnographic investigation into how contractors price risks.

Contractors were selected based on their suitability for the study and a willingness to allow a live study in their offices. Projects were sampled from the list of substantially complete building projects done by them in Ghana between 2000 and 2006. While obsolete data were considered undesirable, this time span was chosen to ensure a large enough sample and to help identify the impact of certain risks such as change in government and the country’s economic cycles on the performance of construction projects.

The main subjects of the study were quantity surveyors and site managers in charge of projects. Quantity surveyors usually have responsibility for cost-related issues on a project while site managers have insights into actual events encountered on the project during construction.

For each project, the inquiry started with a few general questions about the project to be investigated. This was followed with specific questions on: (1) expected return on the project (or the estimated costs to build); (2) actual return on the project (or the actual costs to build); (3) factors causing a difference between the two measures (risks); and (4) contribution of each factor to the overall deviation (risk weight).

The information may have been relatively more difficult to obtain using an ordinary research strategy. However, the ethnographic approach offered some advantage. The trust created between the researcher and subjects because of the relationships built allowed access to some classified documents and information.

It became necessary to involve the company accountants as it was realized that they possess a repertoire of cost information about projects. The accountants were helpful though not designated as original subjects for the study.

In some cases, it was difficult to obtain information relating to profitability directly. This was because of poor management practices and records keeping. It was difficult for the subjects to state the amount of return they expected from the projects. But after a project is complete, they find out the amount of profit made. They price the work, allow a safe margin for profit and overheads, and then wait until the project completes to find out the level of profit made.

The contractors rarely have a systematic mechanism for delineating a cost and profit plan against which they match actual project performance to ensure a required level of return. However, they all could tell what they expected a job to actually cost. Thus, in cases where subjects could not directly relate a required level of return, data on the ‘expected cost to build’ and the ‘actual cost to build’ were used to arrive at the same result. It became possible to approximate expected profit by applying the percentage they apportion to the base estimate for profit.

Thus, two alternative ways were used to obtain the data on profitability levels. One is a direct enquiry about expected and actual profit on a project; the second is an indirect enquiry that ascertains the expected and actual costs to build. The difference between the expected and actual return is the key measure examined to answer the research questions.

There was little control for the influence of geographic factors on performance. The nature of the study made it quite difficult to obtain a representative sample from all regions in the country. The dispersion of projects is satisfactory to permit some generalizations but the primary aim is a better understanding not representativeness.

On reflection, it was wondered whether more could realistically have been be done to control for geographic influences given the nature of the investigation. The data centre on profitability which most businesses feel quite secretive about. Besides, unlike very large countries like the USA which has four different time zones and 11 climatic regions, Ghana is a relatively small country with uniform time and weather where physical conditions do not vary much across the regions.

RESULTS

Tables 1–8 show results of risk experiments on eight building projects in Ghana.

Of the eight projects ranging between ¢850 million (Ghanaian Cedis) and ¢6.6 billion, two experienced a net negative risk while six experienced a net positive risk. In the context of this research, negative risk implies gain to a contractor while positive risk connotes a loss.

Contrary to a widespread view, there is no clear evidence that bigger projects experience higher levels of project risk. The range of impact on price is used to judge the significance of risks as follows: low significance (0–30%), medium significance (30–70%) and high significance (70–100%).

Table 1: Project no. 1 risks and their impact on price

Contract value (¢ 000)	Value of main contractor's work (¢ 000)	Expected profit – 15% of value (¢ 000)	Actual profit (¢ 000)	Risk (¢ 000)	Risk level (%)	Risk/opportunity events	Consequence (¢ 000)		Impact of risk on price (%)

DISCUSSION

Three out of eight projects experienced a net negative risk; more profit than expected was realized. These projects were observed to be of relatively medium size. The results in Tables 1–8 also show that the biggest risks contractors in Ghana face relate to inefficiency on the part of project consultants, payment problems and appointment of nominated subcontractors.

In-depth interviews accompanying the documentary analyses showed that many consultants in Ghana tend to fall short in their role as project team players. Working drawings generally carry mistakes and insufficient specification details. On projects, contractors may suffer from syndromes such as late issuance of constructional details and instructions from consultants. In addition, formal contract administration practices are not strictly the norm in most cases. Some of the shortcomings on the part of consultants may be attributable to some traditional cultural practices and norms that engulf Ghanaian society. Unfortunately, unproductive aspects of culture and mentality have filtered through into the construction process to inhibit productivity and delivery.

Poor adherence to time schedules is generally a problem in Ghana, procrastination is commonplace, suppliers and other service providers may commonly default in meeting delivery schedules. Some consultants would also expect ‘gestures of goodwill’ from contractors when they receive interim payments. The industry ought to take a serious view of this unprofessional and unethical practice in the interests of quality work and business survival. Payment delays is another risk which contractors in and entering Ghana ought to be mindful of when pricing. Clients of public projects consistently fail to honour interim payment within the contractually stipulated period of one month. Bureaucracy, insufficient project funds, a poor attitude towards work, and a need to contact almost everyone involved in the payment process (with an ‘incentive’) are the main drivers of this negative phenomenon. Sometimes, projects may stall for a while (when they are not abandoned) either because of a lack of funds or for political reasons. The appointment of nominated subcontractors usually takes a long time to happen on big projects. On site, their presence may sometimes delay the work if the chemistry with the main contractor is not appropriate.

In the years from 2001, the data show that some contractors who priced jobs before the change in government experienced windfalls on projects because of significant changes in Ghana’s macroeconomic position. Significant drops in the country’s inflation and foreign currency exchange rate meant that discerning contractors who included a price for the rising inflation and exchange rate of foreign currency in their bids started to make gains when economic policies of the new government started to lower inflation, interest rates and exchange rates significantly. We can see that in the absence of macroeconomic risks, contractors in Ghana incur an average risk of 26% in the execution of projects because of risks relating to consultants’ efficiency, delayed appointment of nominated subcontractors and payment problems.

Steps taken to deal with these risks can promote commerce and perhaps lower construction costs to clients. Problems relating to the extensive incorporation of offshore materials in designs and specifications are risks contractors also ought to consider due to import regulations. Other identified risks that relate to the management of internal resources include materials wastage, workforce strikes and poor supervision. Only three out of eight projects experienced profitability levels above what was expected. All other five projects ended up more costly than the bidders actually estimated. How then are contractors managing to cope and survive the effects of risks in the Ghanaian construction industry? Preliminary discussions with some contractors showed that they try to exploit opportunities during construction to balance losses.

CONCLUSIONS

An alternative rigorous method has been devised in this study to help identify the risks affecting contractors in Ghana, and their impact on prices. The study to date shows that consultants' inefficiency, payment problems and excessive delays in appointment of nominated subcontractors are the significant risks. Despite the heavy impact of these risks on prices, contractors are still able to cope because of their ability to exploit opportunities such as minimal enforcement of construction industry laws and regulations, stockpiling of resources, workers' due and entitlements, and inefficiency in the performance of consultants.

The investigative approach proved useful to the answering of research questions despite the belabouring amount of work involved. Poor record keeping and the sensitive nature of the data required were some of the challenges encountered. The primary concern has been for a better understanding of risks and their impact on prices, and not necessarily generalizations and representativeness. The results can help contractors in and entering Ghana to price risks into bids. Further research on the approach is recommended.

ACKNOWLDEGEMENTS

Mere thanks are inadequate to express the gratitude I owe to Professor Will Hughes of the School of Construction Management and Engineering at University of Reading for providing guidance to my PhD studies and for giving me the idea. I also need to thank Professor Edward Badu of the Department of Building Technology, KNUST, Kumasi and Dr Francis T. Oduro of the Department of Mathematics, KNUST, Kumasi.

CONSTRUCTION RISK MANAGEMENT AS A UNIVERSAL SYSTEMATIC APPLICATION

Peter J. Edwards[1] and Paul A. Bowen[2]

[1]*School of Property, Construction and Project Management, RMIT University, Melbourne, Australia*
[2]*Department of Construction Economics and Management, University of Cape Town, South Africa*

Risk is pervasive in that it is encountered in every aspect of construction projects and is experienced by every participant in the delivery process. Adopting a perspective of risk being associated with events with consequence that affect objectives, the application of risk management systematically across the management processes of construction is demonstrated. A central assumption is that a single project risk management system is neither possible nor desirable under most approaches to building procurement.

Keywords: project management, risk.

INTRODUCTION

Risk is universal. We are all exposed to it and we all have to deal with it. What differentiates risk is how each of us perceives it and responds to it (individually or organizationally). Since risk is a social construct, arising out of societies' world views and perceptions of risk events and their impacts, different people are likely to have differing views about what constitutes risk; the source of risk events; their consequences and preferred treatment. The paper explores, through the experiential learning of postgraduate students, how these differences can influence our understanding of risk management. It commences with a brief review of risk and risk management, and then follows the systematic processes of risk management as experienced in the learning activities of postgraduate project management students. The objective is to align project risk management theory with practice.

RISK AND RISK MANAGEMENT

Risk

Definitions of risk abound. Many are negatively framed as threats, defining risk in terms of the adverse consequences of risk events. Fewer definitions are positively framed, regarding risk as an opportunity giving rise to profit. A neutral perspective is provided by AS/NZS 4360 (2004) where risk is defined as: 'the chance of something happening that will have an impact on objectives'. This is appropriate in the context of construction projects, where the achievement of objectives is vigorously pursued by stakeholders. Understandably, project stakeholders still tend to hold a threat perspective of risks, since more importance is given to protecting the achievement of targeted outcomes than to windfall possibilities of exceeding them. The literature of construction risk management largely reflects this negatively skewed perspective. This is also understandable, since the techniques for managing threat and opportunity risks

[1] peter.edwards@rmit.edu.au

are not identical (Edwards and Bowen 2005). In this paper, a threat risk perspective is adopted for the sake of brevity. As Figure 1 shows, the time aspect of risk is also important, particularly in a project context.

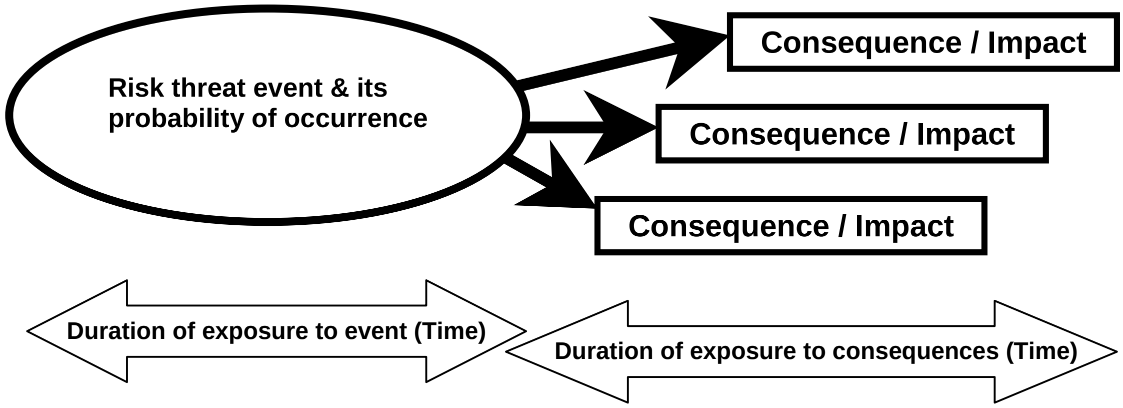

Figure 1: Components of risk

Risk management

Risk management is a systematic way of dealing with risk. While it is possible to treat risk reactively – after the risk event – it is sensible and prudent to consider risk events and their treatment *ex-ante*. The degree of risk preparedness to some extent reflects individual and organizational attitudes towards risk; i.e. risk perceptions and risk attitudes reside in people (and hence in organizations) and not in projects. Similarly, while an individual might adopt a relatively intuitive approach to dealing with risk, organizations (e.g. project stakeholders) need to be more systematic (and accountable) in their risk management.

Generic approaches to risk management are extensively offered in the literature (e.g. Flanagan and Norman 1993; Chicken 1994; Chapman and Ward 1997; AS/NZS 4360 2004; HB 436 2004; Edwards and Bowen 2005). While differing in detail, common processes of risk management emerge from these offerings. Systematic risk management should:

- establish the context;
- identify risks;
- analyse risks;
- respond to risks;
- monitor and control risks;
- capture risk knowledge.

The following section explores these processes in practice from a classroom perspective. The authors each have extensive experience of teaching risk management classes, at undergraduate and postgraduate level, at universities in Australia, South Africa and Singapore. Valuable knowledge derives from the tutorial and assignment learning experiences of postgraduate project management students when these are based upon the students' professional experiences. Many of the postgraduate students we have encountered have held quite senior positions in project management, across a variety of project types (including construction). Few have had extensive experience in systematic risk management. Fewer still have worked in organizations where formal risk management systems (RMS) are in place. The students' classroom involvement has yielded 'rich' information which is used here as comment and illustration about risk management as a universal systematic application, but with specific reference to construction projects.

ESTABLISHING THE CONTEXT FOR RISK MANAGEMENT

The obvious context for risk management is the unique construction project. However, since this is inevitably a large undertaking, it is usually found to be inadequate as a framework for risk management without careful amplification in some way. If a project is regarded from a systems perspective, it is useful as a means of distinguishing risk events occurring within the project system boundary from those occurring outside in other systems. For example, the economic risk of bottlenecks in the supply of materials or labour is extra-project in origin but intra-project in impact. On the other hand, an accident occurring on site is usually an intra-project event, with consequences likely to be both intra- and extra-project. Delineating the project system boundary was found to be a useful precursor to risk management by students.

Risks on projects arise from the decision making associated with the pursuit of project objectives (Parkin 1996). Client stakeholders may have procurement (acquiring the asset), functional (operating the asset) and strategic objectives for projects. While procurement objectives typically focus upon meeting time, cost and quality objectives, and functional objectives describe what the project is required to do, strategic objectives relate to what the client is trying to do with the project. An education department, for example, might build a new high school to improve the quality of educational facilities in a particular region; or a property investment company might develop a new shopping centre in order to change the risk profile of its asset portfolio.

Richards *et al.* (2005) have noted that, for some South African clients, mismatches may arise between desired procurement objectives and strategic objectives, but differences in inter-stakeholder procurement objectives for projects create greater problems. Project management students rapidly perceive that each stakeholder in a project could have objectives that differ from those of the client/sponsor. A contractor might accept the client's time, cost and quality procurement objectives for a project, but may have further objectives in not wanting to make a loss, in ensuring that any scope changes are reimbursed and in wanting to develop a client/contractor relationship that will positively influence the chance of obtaining future contracts. Since different stakeholders will have different objectives, and since for some stakeholders there will be conflict between objectives, the risks for each stakeholder will be different. The notion of a project risk management, as a single common system which each stakeholder can 'buy' into, is impracticable. Each stakeholder must manage its own risks, but its system for managing project risks must align with its own organizational risk system.

The nature of projects means that decisions are made, at a very early stage, which might affect the procurement of a project, its operational environment, and even its eventual disposal. Project management students with a background in construction projects sometimes find this concept difficult to follow through in terms of risk management. This is understandable, given their preoccupation with the procurement (project delivery) phase. Exposure to the needs of 'events' projects helps students to appreciate the operational and disposal phase risks of projects and a student having project management responsibility for the temporary construction work for the Australian Formula 1 Grand Prix event was able to demonstrate this. Held on a ‘street’ circuit in a public park in Melbourne, the complete event, with its supporting minor car races and official practices, takes place over one week. Twelve weeks is allowed for preparatory work on site, and the park has to be restored to its former condition within six weeks after the event. Thus all three environments – construction, operations and remediation – are experienced in just over four months. Students from the telecommunications industry found even 19 weeks a comparatively long project period. For them, projects involving new services were generally allowed no more than six weeks from inception to delivery of the product to market, in order to maintain competitive advantage.

Establishing the context for project risk management entails:

- nominating the stakeholder whose risks are to be managed;
- identifying the dominant organizational aspect of the stakeholder where project decisions are made;
- identifying the target project;
- clarifying the stakeholder’s project objectives;
- selecting the relevant project environment(s) – procurement; operation; disposal.

Knowing the context allows risk identification to proceed.

RISK IDENTIFICATION

For the most part, whether working individually or in syndicate groups, students use simple brainstorming to identify project threat risks, guided only by their understanding of the project context. This approach, however, itself poses the risk that some threats to the achievement of project objectives might go undetected. Certainly brainstorming is necessary, since no automated risk identification exists and each project is unique, but undetected risks represent real threats to projects since they cannot be managed proactively and preclude the planned exploitation of possible opportunities. For more comprehensive risk identification, students found that they needed to use brainstorming within a more structured risk identification technique.

Existing techniques of risk identification can be found in the literature, but not all are appropriate in the context of construction projects. HAZOPS (Hazard and Operability Studies) and FECMA (Failure Effects and Criticality Mode Analysis) are intended for the chemical engineering and automotive manufacturing industries respectively (AS/NZS 3931 1998) but are more suitable for application to the operational environments of those facilities rather than to their procurement (construction phase). Sutton (1992) explains event tree analysis (ETA) and fault tree analysis (FTA) as risk identification tools, but their real benefit lies more in the analytical phase of risk management. Checklists are advocated (Chong and Brown 2000) but are constrained by their reliance on the availability of information from similar historical projects.

Aids to risk identification can be regarded in terms of their primary focus, which may be verbal, numerical or graphic. Techniques with a verbal focus (qualitative relationships) include checklists, methods statements, work breakdown structures, flow charts, mind mapping, concept mapping, situation awareness (McLucas 2003) and HAZOPS. Some of these have a graphic element, but the focus is usually on the text labels that are generated. Numerically focused techniques (quantitative relationships) include scheduling, critical path analysis, FECMA, ETA and FTA. Tools with a graphic focus (visual relationships) include scenarios, rich pictures and storyboarding. The latter is a newcomer to project risk management, and largely untried but it promises to be an effective technique.

The purpose of all these techniques is to expose risks (mainly threats but also opportunities) through identifying areas of relative uncertainty in the project.

A clue to more effective risk identification lies in expanding the project context. Since establishing the context involves describing the project and its objectives, a logical question then to ask is how these are to be achieved?

The constituents of all projects are tasks (what is to be done), technologies (how it is to be done), resources (what is needed to undertake it) and organization (the framework within which decisions are made and everything is planned and managed). Devices such as method statements, work breakdown structures, activity networks and resource schedules are useful as tools to guide risk identification brainstorming, particularly when focused upon the decision making associated with them (Edwards and Bowen 2005). The risk identification questions then centre on what could threaten a successful outcome for this task, the application of this technology, the acquisition of this resource or the effective management of all of these?

Students find this decomposition approach to risk identification useful but time-consuming, and point out that the level of project decomposition is limited by the extent of project information available. To some extent, this is a circular argument, since ‘unknown’ projects are inherently more risky than ‘known’ projects (Smith 1999), but unless some attempt is made to explain the unknowns – and expose their assumptions – their risks will not be identified.

Despite encouragement to be precise, project management students tend to use only one or two words to describe the risks they have identified. ‘Cost overrun’ is a favourite term, despite the fact that it is actually the consequence of a prior risk event. More precise risk statements are necessary for effective communication among the project team, and are often useful in pointing towards appropriate risk response treatments. The importance of effective communication has been emphasized by Edwards and Bowen (2005). A precise risk statement ideally includes references to the type of risk, the risk event and its likelihood, and the consequences for the project, plus an indication of the exposure period where appropriate. An example of a contractor’s construction project risk statement might be:

> There is a chance that shortages in the supply of cement will occur over the next 12 months, causing delay and additional cost during the concrete casting phase of the project (economic risk).

This level of precision provides a clear framework for subsequent analysis and assessment of risk severity.

RISK ANALYSIS

Because of the inherent association of uncertainty with risk, some authors (e.g. Grey 1995) place a heavy emphasis on the treatment of uncertainty in risk analysis, focusing upon techniques such as Monte Carlo simulation as a modelling engine. While not eliminating uncertainty – only more and improved information can do that

– such techniques allow decision making to proceed on a more mathematically precise basis.

Few postgraduate project management students were found to have more than a superficial understanding of mathematical treatments of uncertainty. Most were unconvinced of any real need for them, and some students even suggested that, from their own project experience, detailed assessment of risks was rarely needed and that their professional judgement was enough to determine whether or not treatment was required. Many thought that a quick assessment of the relative severity of each identified risk would suffice, as this would allow them to prioritize the allocation of risk treatment resources. Students accepted that this approach would entail qualitative assessments of likelihood of occurrence (probability) and impact for each risk along the lines postulated in the guide to AS/NZS 4360 (HB 4360 2004) where five-point Likert scales are suggested. Scale intervals for probability start at *rare* for the lowest probability and proceed through *unlikely, possible,* and *likely* to *almost certain*. For threat risks, the impact scale ranges from *insignificant*, through *minor*, *moderate* and *major* to *catastrophic*. Scoring the intervals from 1 to 5 allows the product of probability and impact to represent the severity of each risk to be rated from 1 to 25. This two-dimensional assessment process can be expanded by adding a third dimension to represent duration of exposure (allowing a 1–125 severity scale, but most students thought that this would not be necessary for the types of projects they tended to undertake. Alternatively, the two-dimensional scales could each be simplified to three points: *low, medium* or *high*, giving a 1–9 severity range. Despite its greater simplicity, students did not favour this option on the grounds that it did not provide sufficient discrimination in the risk severity assessment. They suggested that very severe risks could always be subjected to more extensive mathematical analysis.

While asserting that a qualitative assessment approach to establishing relative risk severity was sufficient for their risk management needs, students were far less appreciative of the consequent need to define the scale intervals for this technique. They tended to rely on an invalid assumption that the given intervals conveyed a universal linguistic meaning that would be easily communicated and understood by everyone involved. When it was pointed out that the criteria for *unlikely* and *catastrophic*, for example, might hold different interpretations for different stakeholders, the uniquely personal/organizational perceptions of risk became much clearer to the students. They also appreciated how establishing these interpretations might be a valuable exercise in strategic risk management for their organizations, reinforcing the desirability of aligning risk assessment criteria to strategic (business) objectives.

Students found further benefits in qualitative risk analysis through the risk mapping opportunities that this presented. Two-dimensional matrices, with risk categories across the top row and work breakdown (or similar) stages down the vertical column, and with the cells populated with the identified risks, could reveal clusters of risks of particular types or for particular activities. A refinement to this approach incorporates project risk complexity mapping (Edwards *et al*. 2005) using the definitional approach to complexity suggested by Williams (1999).

RISK RESPONSE

Postgraduate project management students generally found the risk response process to be the most creative part of risk management, often coming forward with innovative ideas for avoiding, transferring or reducing risks. They were not content to simply retain risks without some attempt at mitigation, but recognized that in practice retention was sometimes the most cost-effective treatment. Students found that often their project stakeholder organizations had existing treatment procedures already in place for at least some of the identified risks. They then needed to identify and bridge any gaps. The students experienced the iterative nature of systematic risk management, since most risk reduction options require a re-analysis of residual risk severity, and risk avoidance or transfer measures may introduce new risks that must be identified and treated.

The most important learning for students in this phase of risk management was about possible targets for risk response treatments. They found that addressing the probability component of risks usually involved trying to reduce the likelihood of occurrence of a risk event by doing things better (e.g. quality management) or more safely (safety management), by enhancing or increasing the frequency of management interventions and inspections, or by raising reporting requirements for monitoring. Reducing the impact (consequences) of risk events was often a matter of providing extra resources, back-up facilities, or planning the deployment of emergency procedures, while risk exposure duration could sometimes be addressed through rescheduling or introducing more scheduling flexibility.

RISK MONITORING AND CONTROL

Since risks are usually dynamic (i.e. the probability and/or impact can change over time), it makes sense to monitor and control them once risk response decisions have been made and treatments implemented. Most students regarded this risk management activity as simply planned extensions to control measures already in place on their projects. Many thought that reporting procedures might become more onerous, but suggested that this would not be an unwelcome development, particularly in the light of modern demands for corporate responsibility and accountability. They regarded this as an important aspect of risk knowledge capture.

CAPTURING RISK KNOWLEDGE

Apart from the knowledge captured during the monitoring and control phase of project risk management, students saw value in post-project gathering of risk information. Many postgraduate project management students indicated that post-project debriefing occurred in their organizations, but nearly all suggested that this was rarely done from a risk perspective, since their organization had no formal risk management system in place. Students offered several ideas for value-adding to this activity. One reported that project risks were recorded in his organization in a ‘project risk schedule’, and that post-project risk knowledge was entered into an organization-wide ‘risk register’. Another noted that, besides risk knowledge captured from its own projects, her company gathered risk information from other sources (newspaper and magazine articles, journal papers, even television programmes). In addition to applying this knowledge on future projects, it was sometimes adapted for use as staff training material within the company. A student from the telecommunications industry stated that his organization periodically analysed information from its risk database to look for risk trends in its projects.

These ideas indicate that, not only were the organizations involved displaying a high level of risk management maturity, but also that their risk management systems were not being allowed to become simply passive repositories of risk information and knowledge.

CONCLUSIONS

Students, especially at postgraduate level, are a rich source of risk and risk management knowledge. Pooling their wisdom adds considerably to the body of practical knowledge about risk management.

In their class participation and assignments, students displayed appropriate abilities in some aspects of systematic risk management, but weaknesses in others. They were able to establish clear project contexts but, despite acknowledging the criticality of risk identification, showed an over-reliance on unstructured brainstorming to identify risks. Qualitative risk analysis was heavily preferred over quantitative techniques, unless the latter were actually required in the project design process or used for specific financial appraisal of projects. However, unwarranted assumptions were made about organizational interpretation, communication and understanding of qualitative risk assessment scale intervals. Risk mapping was thought to be a useful technique, especially for inter-project comparisons. In the risk response phase, the opportunity for creatively exploring risk treatments was appreciated. For risk monitoring and control, students generally found themselves on more familiar ground whereby existing project control procedures already flagged or monitored risks to some extent, or could be adapted to do so. The capture of project risk knowledge was seen as a somewhat neglected activity, but acknowledged as important for organizations involved in projects, not only for its applicability to future projects but also for the potential it gave for developing competitive advantage.

It was noticeable was that, in almost every project stakeholder organization where the students' stories suggested the presence of a high level of risk management maturity, a 'champion' for systematic risk management was also evident – usually a director or senior manager.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge the participatory contributions of students from Master of Project Management courses at RMIT University and the University of Cape Town.

THE APPLICATION OF INFORMATION TECHNOLOGY TO SUPPORT THE ELICITATION OF EXPERT JUDGEMENT IN PROJECT RISK MANAGEMENT

Alan D. Russell[1] and Cheryl E. Nelms

Department of Civil Engineering, University of British Columbia, 6250 Applied Science Lane, Vancouver, BC, V6T 1Z4, Canada

Of the various steps that comprise risk management, difficulties are still encountered in identifying risk events as a function of project context and project participant viewpoint, and eliciting the properties of these events. Described is an IT based approach that is especially suited for application on large infrastructure projects and which has been designed to assist with the elicitation of expert knowledge pertaining to risk drivers and associated risk events, likelihood of occurrence of the risk events identified and outcomes expressed in terms of several measures, including time, cost, quality and security. Central to the approach is the concept of profiling components of a multidimensional representation of a project in terms of attributes and their values, subsets of which in turn singly or in combination act as drivers of risk events and their properties. The approach adopted also builds on the work of others as well as the practical experience of the authors gained through the participation in risk identification and expert opinion elicitation sessions. Elaborated upon is how such an approach may be operationalized using computer-based methodologies that include knowledge management, visualization, and an integrated multi-view representation of a project which reflects its physical, process, environmental and organizational/contractual dimensions. Use is made of a case study to illustrate aspects of the approach.

Keywords: information technology, project management, risk, visualization.

INTRODUCTION

In this paper, we introduce aspects of a methodology incorporated in a project management software tool for the management and reuse of risk knowledge and related information. Emphasis is placed on a concept of profiling that is applicable to both the identification of risks and elicitation of their properties using expert opinion, and how it has been realized in an information technology (IT) environment. Motivation for the work has come in part from the increasing trend by governments worldwide to adopt alternative procurement approaches to meet infrastructure needs and achieve greater transfer to the private sector of the project scope, time, quality and cost uncertainty that is inherent in infrastructure projects. This in turn has led to more emphasis being placed on risk management in the early phases of a project to ensure government accountability and value for money. A number of commercially available software tools exist to support the project risk management process including RiskEasy® (NOWECO 2006), Risk Radar® (ICE 2006), PertMaster Project Risk

[1] adr@civil.ubc.ca

(PertMaster 2006) and RiskCom (see Hall *et al*. 2001). While very useful for the tasks for which they were designed, a number of shortcomings exist with these tools. These include the inability to connect or integrate risk issues with the project context, a disconnect between risk management and other project management processes, little if any exploitation of knowledge management concepts, limited support for different cognitive styles for both identification and elicitation tasks, and treatment of only a subset of risk event outcomes. These deficiencies combined with the need for further improvement in the state of the art of existing identification and elicitation techniques and our own experience in assisting with the development of risk profiles for infrastructure projects have provided the impetus for the work described herein.

The processes of risk identification and elicitation may be defined as identifying perceived issues or concerns and determining their characteristics or properties. Tools commonly used for risk identification include checklists, brainstorming, interviews, historical documentation reviews, cause/effect and influence diagramming techniques and expert judgement. Expert opinion elicitation is a term used to describe a process of gathering information and quantitative or qualitative estimates that can support the risk identification process. That is, and as expressed in relatively general terms, one seeks to *identify* X (the risk event) which occurs at location Y because of the presence of drivers $\{Z_1, .. Z_n\}$in the form of components and their attribute values at location Y, and *elicit* the properties including likelihood P of event X occurring (expressed quantitatively or qualitatively), the performance criteria $\{C_1, \ldots, C_m\}$ impacted and criteria outcomes $\{O_1, \ldots O_m\}$, expressed quantitatively or qualitatively or a combination of the two. Although not addressed directly in this paper, to assist with the *elicit* part of the foregoing, there is a rich literature on expert opinion elicitation techniques applicable to the field of engineering, approaches for combining expert opinions and cognitive heuristics and biases of which facilitators and participants of risk identification and expert opinion elicitation sessions must be aware (e.g. Morgan and Henrion 1990; Cooke 1991; Ayyub 2001).

Integrating the tasks associated with risk management with those associated with the overall project management process and incorporating knowledge management techniques in support of these tasks poses a significant challenge, which must be addressed if better quality risk identification and quantification is to be achieved. The importance of establishing context to assist with the risk management process is a concept adopted in the AS/NZS 4360 Risk Management Standards and highlighted in the *Enterprise risk management guidelines* (Government of British Columbia 2006), a framework for performing risk management for public sector projects in the Province of British Columbia, Canada. Also, Akintoye *et al.* 2003 summarize the results of an investigation of risk management in private finance initiative (analogous to an alternative financing mechanism) projects which highlighted that incomprehensive upfront project information, poor historic statistical risk data, and lack of risk information from previous projects in the form of a risk library adversely affected the ability to meet value for money requirements of the government sector.

The objective of this paper is to introduce features of an approach and supporting tool that concurrently improve upon current risk identification processes and expert opinion elicitation tasks. The multi-view representation of a project in terms of hierarchical structures of components, combined with the ability to profile components in terms of user and in some cases system-generated attributes and make associations among components of the various views, facilitates an integrated approach to the tasks of risk identification and elicitation. The tool provides a standardized platform in which risk terminology is made explicit. In our approach, a risk is defined as the potential variability in a project parameter from its anticipated value (e.g. higher than expected inflation rate during the construction phase which is described in terms of a density function for the inflation rate), or as a discrete risk event (e.g. contaminated soil encountered) which can be described in terms of different state values realized, likelihood of occurrence of each state, and vector of outcomes, given the realization of a specific state of occurrence. The primary focus here is on discrete risk events as opposed to assessing variability in estimates of basic variables, and within this focus, attention is directed mainly to the identification of risk events with lesser emphasis on the elicitation of risk event properties. The remainder of the paper is organized as follows. Provided first is an overview of several questions that have guided the research, and a brief description of how each question either has been or is being addressed. Next is a description of a case study scenario that reflects an amalgam of the characteristics of projects with which the authors have had some involvement. This case study is then used as a background to highlight specific aspects of our approach to risk identification and elicitation. The paper concludes with a brief discussion of ongoing work and creation of a computer-based environment to facilitate interactive risk identification and elicitation sessions.

RESEARCH QUESTIONS

A number of intellectual and practical challenges arise in developing a computer-based methodology that can be used to integrate risk information with representations of the project context. As part of the underpinnings of our current approach, De Zoysa (2006) posed several questions to guide the initial development of the tool, three of which are of direct relevance to this paper. They are:

1. How should the relationship between project context and project risks be represented and how should the project context be modelled?
2. How should representations of project risks and their relationship with project context be exploited to gain insights for decision making, and in support of this, what querying, reporting and visualization functions are of use?
3. What knowledge can be reused for future projects; how can it be archived in a project neutral format; how should it be extracted from archives; and what assistance can be given in deciding the appropriate content to reuse?

Arising from these questions, and aided by previous work (Russell and Udaipurwala 2004), a multi-view representation of a project was enhanced and extended to treat the environmental (natural and man-made) and risk views of a project (Wang 2005; De Zoysa 2006). Using the notion of risk drivers, associations can be made between view components and a grouping of like risks, called a risk issue, and individual risk events can then be defined corresponding to the existence of one or more risk drivers at a particular project location or at a particular point in time. In support of this, a knowledge management component was developed which allows for a cataloguing of lessons learned from past projects in terms of how best to represent each of the product, process, organizational/contractual, environmental and risk views. Some exploration was made of how much of the process could be automated, which led to careful consideration of the most appropriate roles of the machine versus human risk expert. Finally it was determined that much work remained to be done with respect to question (2), especially in regard to visualization in real time of any clustering of risk events in time, space and by organization, which potentially has a direct impact on values sought as part of the elicitation task.

Building on De Zoysa's work, in addition to more work being required on questions (1) and (2), further questions as follows have been posed to improve the application of the tool with respect to identification and elicitation of risks and their properties:

4. How should the groupings of risks in the temporal, spatial and project participant context and their potential interactions be treated?
5. How should the cognitive styles and value systems of the multiplicity of participants involved be accommodated in order to ensure that the full spectrum of risk events is identified and the full dimensionality of their consequences treated should they occur?
6. What features are required for the design of an interactive man–machine interface to be effective for group risk identification/elicitation sessions in support of questions (4) and (5)?
7. How should the evolution of risk information and outcomes over the project life cycle be accommodated?

As described in the following section, current work is directed at question (1) using the concept of profiling, and its relationship with question (3). Other current work is directed at the use of visualization to provide feedback on the clustering of risk events and related drivers in one or more of the spatial, temporal or organizational dimensions of a project. This is of direct assistance in terms of both identification and elicitation of risk event likelihood and outcome values. How to accommodate and calibrate different cognitive styles is of ongoing concern, with emphasis being placed on treating both quantitative and qualitative estimation approaches, including hybrid approaches. As research findings are implemented in an IT environment, careful attention is being devoted to interface design, a topic of considerable practical significance, with emphasis on improving group interaction and calibration, creating a shared understanding of project context among participants, speedy navigation of the project context and risk register, and ready feedback of available project information in a number of formats, especially visual ones.

CASE STUDY PROJECT

An elevated guideway expansion case study project, combining aspects of projects with which the authors have been involved, procured using a design–build–finance (DBF) procurement mode is used as a backdrop to illustrate our approach along with implementation details for identifying risks and eliciting their properties for purposes of risk management and other project management functions. The project consists of a 7.5km-long expansion to an existing elevated rapid transit system to connect Municipalities A and B and involves the construction of an elevated guideway structure, a bridge and four transit stations exclusive of any rail or rolling stock along a predetermined route. The construction estimate is Cdn$142.5 million (in constant dollars as of 31 March 2007) excluding costs associated with design, client oversight, client advisers, etc. The construction industry is currently at and beyond capacity in which selected trades and seasoned project management personnel shortages exist, and this situation is forecast to continue for the next two to four years.

Section 1 (3.04km) and Section 4 (1.52km) involves the construction of the new guideway built on a boulevard that runs down the middle of a main thoroughfare of

Municipalities A and B. Section 2 (0.55km) consists of the construction of three components including a transition (0.4km) from the elevated guideway to a bridge (0.065km) spanning a river and an elevated guideway commencing on the south shore of the river crossing the boundaries of a historic First Nations settlement and commercial railway track. Section 3 (2.39km) involves the construction of an elevated guideway across some light industrial and agricultural use land in the jurisdiction of Municipality B.

Risk issues in Sections 1 and 4 relate to concerns of a multiplicity of stakeholders lining the corridors (commercial, residential and business) that traffic flow and local business operations are not impeded during construction. A further concern is the substantial massing of overhead and underground utilities along the construction corridor in these Sections, the location of some of which is uncertain. Key undisclosed environmental and archaeological risks in Section 2 are the demolition of existing buildings on privately held land that may also require soil contamination abatement, environmental sensitivities and regulations where the bridge crosses a river and the existence of a historic First Nation settlement along the river shore. Stakeholder risks also exist in Section 2 where the bridge crosses a river, regulated by a multiplicity of governing authorities, used for both commercial and recreational activities and constraints imposed by a commercial rail company operating along the shore. Primary risks identified for Section 3 have been transferred to Municipality B, which has taken responsibility in securing easements for the elevated guideway across the light industrial and agricultural lands.

In summary, private sector consortia interested in the project face the challenge of identifying and quantifying potential technical, environmental, financial, participant and regulatory risks, some of which are interrelated, and determining relevant risk mitigation strategies as part of their decision as to whether or not to bid, and if yes, how to price out the risks.

APPROACH FEATURES AND IMPLEMENTATION DETAILS

Use is made of the case study to highlight features of our approach and accompanying risk management tool. Addressed, with emphasis on the second item are: (1) modelling of the project context using an integrated multi-view representation of a project; (2) profiling project view components in terms of attributes related to risk (i.e. risk drivers) and other project management functions; (3) developing a risk view (risk register and associated properties); and (4) knowledge management. These features are designed to contribute to improved decision making and risk management processes in both the project planning and execution stages relative to current standard industry best practices. Risk registers, developed by practitioners involved in infrastructure delivery and considered to conform to the current best practice approach to risk management in Canada, were used as the base reference documents to assess some of the benefits and limitations of applying the tool to model the project risks.

Integrated multi-view representation of a project
The project context is characterized through four different views: physical (what will be built and where), process (how it will be built and operated), organizational/contractual (the participants involved), and environmental (the natural and man-made environments in which it is being built). (A cost view has yet to be fully integrated with these views.) Consistency of representation has been sought for all views in the form of hierarchical modelling, with the granularity of each view

representation left to the user depending on the amount of information available and decision making required. The ability to make associations among the views is supported, including the ability to link them with the risk view by way of risk drive–risk issue associations. The physical view (not shown) treats the modelling of a project in terms of physical locations as well as physical components, with a mapping between the two. The same set of locations provides the underpinning for the process and environmental views of the project. Shown in Figures 1(a) and 1(b), respectively, are two of the hierarchical structures used to model the case study project. Each component in the hierarchy can be described in terms of a number of datasets as well as associations with entities from other views (for the latter, see the risk issues/events tabs in Figures 1(c) and 1(d)). As an example of the former for the environmental view, a geotechnical profile of the entity ‘contaminated soil’ can be described using the attributes and values tabs, with values assigned on a location-by-location basis. The integration of views allows for changes in the project context such as regulatory and scope changes to be reflected throughout the other views, including the risk view.

Profiling risk drivers

Thoughtful definition of the components and associated attributes used to represent the various views of a project can provide valuable insight to project managers and improve the overall risk management process. We have found that profiling of the different views in terms of user-specified attributes and anticipated values can be particularly useful in the elicitation of risk sessions. These sessions typically involve project participants from a range of disciplines who identify and manage risks from their own experience and knowledge domain. Few, if any, have a complete understanding of the full project context or spectrum of project risks. A multi-view representation of the project context can be used to guide or structure these sessions, help develop a common understanding among session participants, and serve as a mnemonic device to trigger the identification of potential risk events, interrelationships and mitigation strategies. Our focus on profiling here relates to defining the attributes required to characterize the constructs used for representing the various views of a project. These attributes can be described by way of a 2 × 2 matrix dealing with user vs. system-defined attributes (e.g. different attribute sets for different classes of project participant vs. schedule dates for activities), and user-specified vs. system-derived attribute values. Because of space constraints, discussion is limited to profiling for the organizational/contractual and environmental views of a project, and only touches on the use of attributes from the process view.

While implicitly the concept of profiling is not new to the construction industry literature, it could benefit from more explicit or formal treatment if management and decision-making practices are to be improved, particularly in terms of the breadth of issues that affect a project. In simple terms, profiling addresses the question: What do I really need to know about the project in order to perform the task at hand?

Profiling project stakeholders, a class of project participants, using techniques such as stakeholder mapping has been discussed in the construction literature as a means for project managers to identify stakeholders, their level of influence on the project and for improving risk and communication management. Newcombe (2003) discusses the importance of identifying project stakeholders and using stakeholder analysis or mapping techniques to analyse their power, predictability and interest to gain a better understanding of their expectations and impact on the project. Olander and Landin (2005) illustrate using stakeholder mapping on two case study projects and showed how the relevant stakeholders and the power and interest of these stakeholders changed over the course of the project and how this information may be relevant to the risk management process. Another example of profiling involves the work of Ling (2003), which deals with the selection of architects.

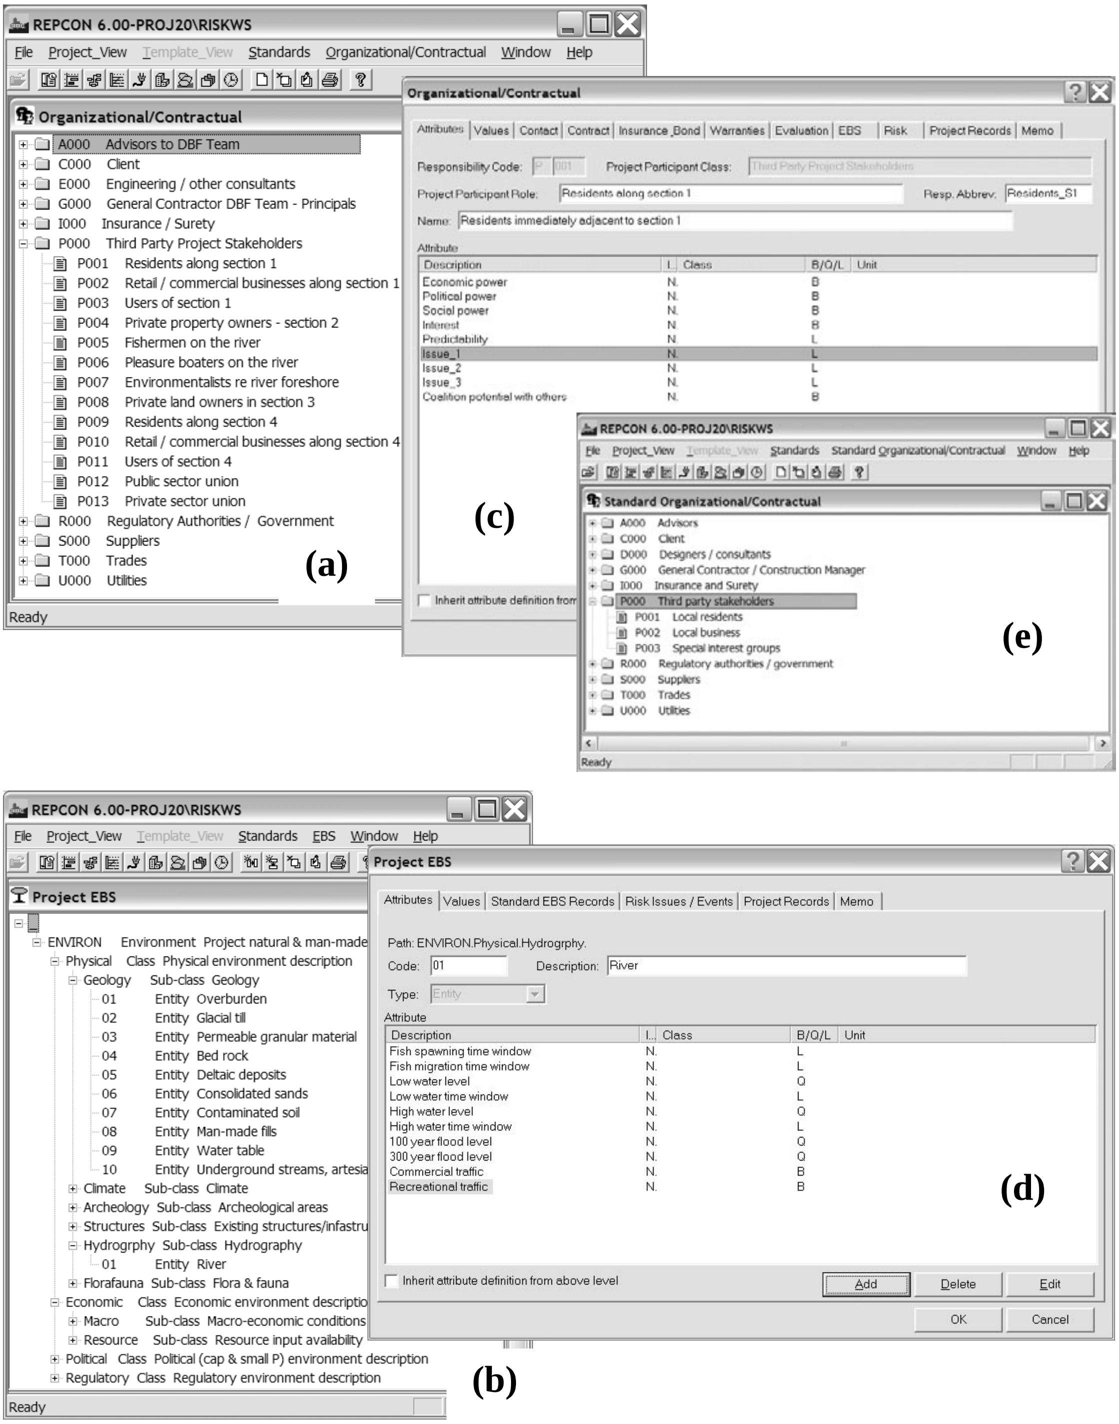

Figure 1: Representing the project context: (a) & (b) Hierarchical representation of the organizational/contractual and environmental views; (c) & (d) Profiling components of the respective views; (e) Knowledge management feature on system Standards Side

Shown in Figure 1(c) is profiling of one member of the third party project stakeholder class of project participants (Figure 1(a)), in this case residents along Section 1 of the case study project. Note the ability to define quantitative (Q), linguistic (L) and

Boolean (B) attributes, and to use inheritance to speed the definition of attributes at the individual member level of a participant class. Both expected value and actual value fields accompany the definition of attributes for the various views of a project. Profiling project stakeholders assists with the identification of risk events, drivers and even risk mitigation decisions such as the level of resources a project manager should assign to stakeholder management, as well as with other functions such as communication. Using the attributes cited and their respective values, the project manager can gain a better understanding of stakeholder dynamics or identify risk events and mitigation measures when considering such issues as anticipating how construction method decisions will affect this stakeholder group. Shown in Figure 1(d) is a profiling of the entity ‘river’ within the class-subclass-entity hierarchy of the environmental view (Figure 1(b)). Of particular interest for the case study project are attributes related to fish and water levels. These attributes may have a positive, negative or no project impact such that some are risk drivers and others are not depending on design features (the physical view), regulatory constraints (part of the environmental view) and construction methods used and timing (system derived attribute values) of related activities (the process view). The power of modelling and profiling project components and their attributes in the four views enables the user to link risk entities to the associated component and determine the temporal and spatial distribution of risks. How best to describe and structure the components of the various views and profile them in terms of attributes and values presents interesting research opportunities.

Developing the risk view

Risk events arise from the values of the attributes of the components in one or more views (organizational entities, physical aspects of the facility, schedule activities, etc.) which are risk drivers, the presence of which, either singly or in combination with other risk drivers, leads to the potential for a risk event occurring. Once the user has modelled the project context in the four project views, he is in a better position to develop a comprehensive risk register organized in the form of a hierarchy (category, sub-category, class, issue, event), which facilitates easy navigation, and then define the relevant properties of each component (e.g. at the event level, drivers, likelihoods, outcomes, mitigation measures). The term ‘risk issue’ corresponds to topics or keywords of like kind, of direct relevance to the project and around which there is a degree of uncertainty and thus associated risk events. For the current implementation, potential risk drivers are first associated with the risk issue at hand. Figure 2(a) shows an example of this for process issues under the foundation work sub-phase of the construction phase (see the left-hand side of Figure 2(b) where risk issues and corresponding events have been organized under project phase and project dimension, one possible structure of the risk register – the user is free to structure the risk register in accordance with their own preferences). From this set of issue drivers, the user can identify specific risk events as a function of risk driver attributes/values. For the example shown in Figure 2, by examining the process (schedule) view (right-hand side of Figure 2(b)), it is observed that the preliminary schedule indicates bridge foundation work is to be done in the timeframe 6 May to 30 July. For the river component of the environmental view, the value for the attribute of high water time window is mid-April to mid-June (not shown), so the timing suggests the potential for an adverse risk event, *high water/flood overtops bridge foundation work*. Not shown in the figure are performance measures likely to be affected (time, cost, safety). Thus, the ability to integrate information from various views of a project within a single system or to have ready access to similar information from multiple systems facilitates the task of risk identification, along with allowing the ready documentation of related risk drivers.

Knowledge management

Critical questions for many organizations are: (1) How does one retain their employee's project knowledge and experience to provide both added value to their customers in future projects or an edge above their competitors?; and (2) Given ever present time constraints and the level of effort required to develop a comprehensive representation of a project, what assistance is available to assist with this task? We have addressed these questions in part by designing and implementing a knowledge management feature, called the Standards Side of the system. For example, shown in Figure 1(e) is the ability to define an organizational/contractual master template or list. Although individual members of a class may not be known for a specific project, the ability exists to define classes of participants that are common to all projects, and for each class, define attributes that can be inherited down to the individual member level, either on the Standards Side if the type of member is known (but not specific identity), or on the project side when the template is copied over in whole or in part. Thus the user can draw upon an organization's experience accumulated over previous projects and documented in standardized master lists, speeding the representation process for a new project, while reducing the potential for omissions. Standards for other project views, including the risk view, are similarly supported.

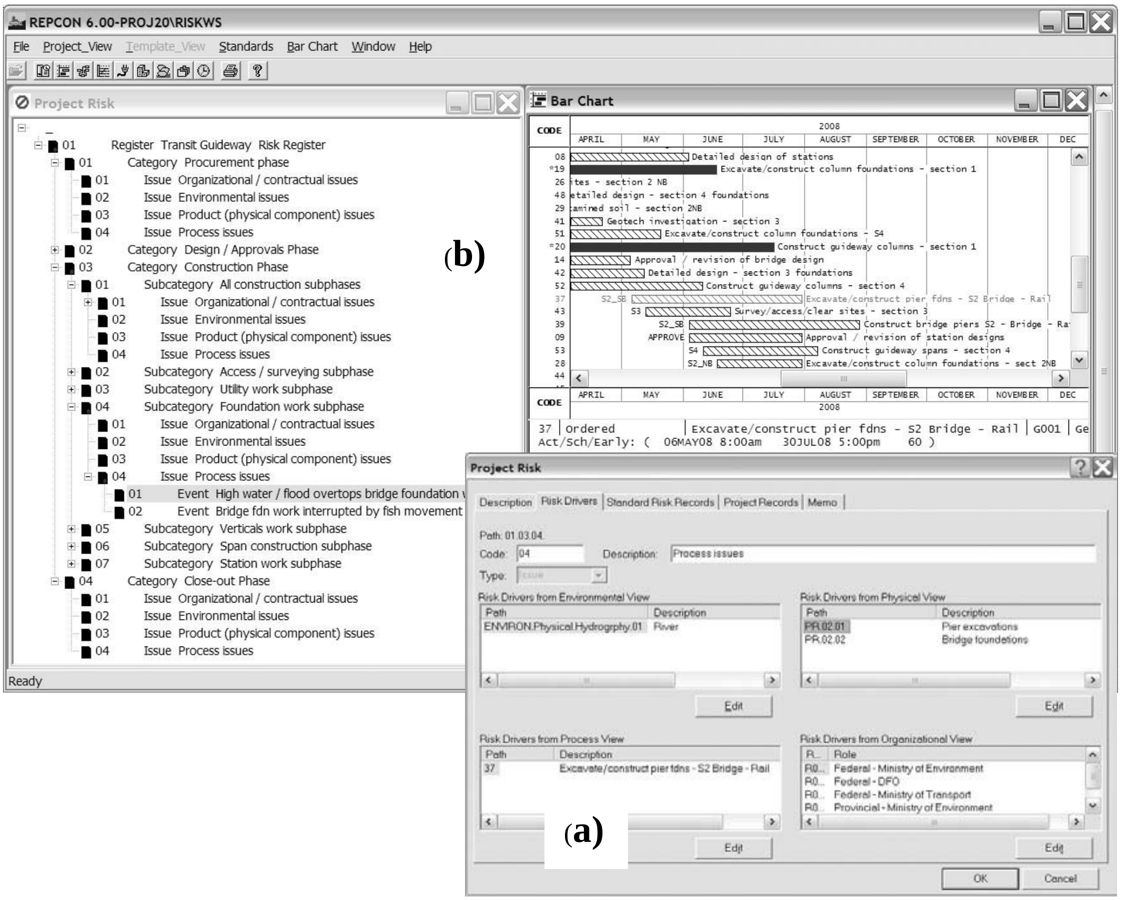

Figure 2: Identifying potential risk events based on risk drivers and their attributes

CONCLUSIONS

Described in this paper are aspects of a systematic approach using information technology to improve the risk management process. The approach offers several benefits, including development of a shared image of the project context among those charged with developing the project's risk profile, a direct linkage between project context and risk profile and the ability to document this linkage in the form of risk drivers, access to and easy use of past experience, and the ability to track the history of the project's risk profile. These benefits improve upon current risk management best practices applied on Canadian infrastructure projects; however, the limitation of the approach and accompanying tool lies with whether the project manager is willing to spend the necessary time and resources to develop a working model of the project context and integrate the approach with other project management processes. Ongoing work is directed at more comprehensive profiling of components used to represent the various views of a project in terms of attributes useful for risk management and other management functions, enhanced knowledge management capabilities, hybrid approaches to expert opinion elicitation (combined quantitative and qualitative approaches), interface issues in terms of allowing simultaneous access to data from all project views, and the use of visualization to gain insights into the risk profile of a project. Opportunities to apply the concepts to actual projects will continue to be pursued in order to refine the approach.

PRACTICAL IMPLICATIONS OF LOCATION-BASED SCHEDULING

Niclas Andersson[1] and Knud Christensen

Department of Civil Engineering, Technical University of Denmark, DK-2800, Kgs. Lyngby, Denmark

The traditional method for planning, scheduling and controlling activities and resources in construction projects is the CPM-scheduling, which has been the predominant scheduling method since its introduction in the late 1950s. Over the years, CPM has proven to be a very powerful technique for planning, scheduling and controlling projects. However, criticism has been raised on the CPM method, specifically in the case of construction projects, for deficient management of construction work and discontinuous flow of resources. Alternative scheduling techniques, often called repetitive or linear scheduling methods, have proven to be well suited for projects of a repetitive nature, such as building projects. As the repetitive or linear scheduling methods may include locations or places, they are also referred to by the comprehensive term of location-based scheduling (LBS), which is the concept that will be used in this study. LBS is a scheduling method that rests upon the theories of line-of-balance and which uses the graphic representation of a flow-line chart. As such, LBS is adapted for planning and management of workflows and, thus, may provide a solution to the identified shortcomings of CPM. Even though LBS has a long history and is well grounded theoretically, it has gained generally little attention in the construction industry. Besides the theoretical research available on LBS, some studies report on the application of LBS, but empirical data on the practical implications of LBS is limited. This study rests upon three case studies of residential projects carried out in Denmark in 2006. The purpose is to test and evaluate the practical implications of LBS when applied on site. The study concludes, with emphasis from the site management involved, that improved schedule overview, establishment of workflows and improved project control constitute the three most important implications of LBS.

Keywords: critical path method, line of balance, location-based scheduling, scheduling, workflow.

INTRODUCTION

The coordination of activities and resources in order to establish an effective work flow is central to the management of construction projects. The Critical Path Method (CPM) constitutes the predominant technique for planning and scheduling of construction projects, since it was introduced in the late 1950s. Together with Gantt charts, the universal graphical representation of schedules, which was introduced by Gantt and Taylor in the early 1900, CPM provides the common corner stone in the vast number of scheduling software tools that have been developed (Kenley 2004).

CPM has proven to be a very powerful technique for planning, scheduling and controlling projects, especially for complex and non-repetitive work (Arditi *et al*. 2002). However, despite the dominance of the CPM-method, there is criticism raised on the method for the management of construction work. The criticism of CPM refers

[1] na@byg.dtu.dk

to the inability to manage and monitor resource limitations in a way that corresponds to the reality of construction, i.e. work that to a large extent is characterized by repetition (Kenley 2006). Repetitive activities are often characterized by imbalanced production rates (Arditi *et al.* 2002), which might lead to unforeseen work stoppages and, consequently, inefficient resource usage. The activities, and their logical connections, are the principal focus of the CPM-method, whereas resources are given minor attention as the CPM-method assumes there are unlimited resources available for executing the work. Consequently, CPM-based schedules, graphically represented by Gantt charts, may result in discontinuous resource usage that in turn will lead to interruptions in the production where each trade suffers from recurrent starts and stops during the project process. It is difficult to monitor the planned resource usage from a Gantt chart, as the different amounts of work and different pace of each trade is concealed in the bars of the activities.

As construction work is generally characterized by continuous or repetitive work, where the same activities are executed at various locations of a building or construction, construction scheduling appears to be more closely aligned to repetitive scheduling methods (Russell 2004) such as “Line-of-balance”, “Time-location Matrix Model”, “Construction Planning Technique”, “Time Space Scheduling method” (Harris and Ioannou 1998), “Flow-Line” (Kenley 2004, referring to Mohr 1991) and similar methods. Arditi *et al*. (2002) refer to those alternative scheduling techniques, developed over the last 30 years, by the generic term of “linear scheduling methods” and claim that those methods have proven to be well suited for projects of a repetitive nature. Harris and Ioannou (1998) suggest the generic term of “repetitive scheduling method” as those methods involve repetitive activities. Kenley (2004) points out that the linear or repetitive scheduling methods strongly suggest locations or places and, consequently, he introduces the comprehensive term of “location-based scheduling” (LBS).

However, despite the long history and a promising potential of these repetitive, linear or location-based scheduling methods, they have gained little attention among the practitioners of the construction industry. Finland, however, constitutes an exception. As a result of two decades of research and development, a comprehensive line-of-balance-based planning, scheduling and control system, has been developed and implemented among the main contractors in Finland (Seppänen and Aalto 2005). The conception of a system does, in this case, refer to a set of planning and scheduling functions such as a risk simulation module based on the Monte Carlo technique, a bill of quantities collecting the building materials of the project that are distributed among the activities, a procurement module for the supply of building material, a national database with building productivity data etc. The various functions of this planning, scheduling and control system are integrated in a commercial software package, originally named DynaProject™ and later versions called Control™, which empowers the Finnish line-of-balance based system. It has now become the prevailing planning methodology among the large contractors in Finland (Kankainen and Seppänen 2003). The Finnish scheduling system is based on a modified line-of-balance method, in which the y-axis of the flow-line chart is represented by the locations of the project, i.e. the y-axis consists of a hierarchical structure of the physical locations of the building or construction. This line-of-balance method, in this study, will be referred to by the term of location-based scheduling, a conception originally coined by Kenley (2004).

Figure 1 presents an example of a location-based schedule developed in Control™ in which the hierarchic location structure is presented along the y-axis and four activities repeat in the different locations of the building.

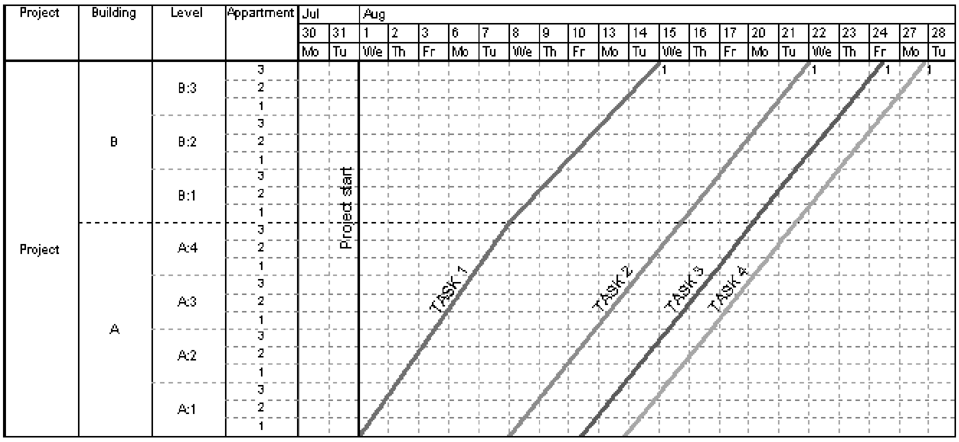

Figure 1: The graphical presentation of a location-based schedule in a flow-line chart

The flow-line chart of an LBS schedule, as seen in Figure 1, is adapted to planning and management of continuous work-flows, i.e. where resource groups can perform their work without interruptions caused by other resource groups working with other activities at the same location at the same time. Thus, LBS supports the establishment of continuous activities and a resource usage with limited waiting time and avoidance of work disturbance, and as such, LBS promotes the efficient use of resources and the delimitation of waste which corresponds to some of the principal elements of Lean construction. Kankainen and Seppänen (2003) describe the connections between LBS and lean construction, referring to the common focus on efficient resource usage and waste avoidance. Kenley (2004) explains that the application of lean construction requires a new approach to production planning and suggests LBS as a key to improve the selection of lean construction techniques. This argument rests upon the difficulties of identifying continuous workflows in a traditional CPM-based schedule, which consists of discrete activities.

Problem statement and delimitations

The argument for this study rests upon the identified shortcomings of the traditional planning and scheduling technique of CPM in the context of construction, the current attention given to the implementation of lean construction and thereby an increased focus on flow-management and, finally, the fact that there is a LBS planning and scheduling software package recently developed.

The purpose is to identify and review the main practical implications of LBS when applied on a building project in conjunction with the management on site. The research area of the study relates to the subject fields of construction management and logistics, where planning, scheduling and control are in focus. It is not within the scope of the study to develop either the scheduling method of LBS or the software tool.

Research method

The study focuses on the production phase of construction, i.e. the planning and scheduling of the activities that take place on site. Three building cases that represent typical Danish residential building projects constituted the empirical input to the study. Case 1 is a new residential building project with an 11-storied house, 144 apartments, and a total living space of 13,500m^2. Case 2 is a renovation project that includes the modernization of bathrooms, façades, windows, roofing etc. It includes 10 separate building blocks, including 385 apartments, and has a total budget of fully 40 million EUR. Case 3 is another new residential building project with 225 apartments, a living space of 20,000m^2 and a total budget of about 30 million EUR. The three largest Danish contractors were assigned as general contractors in each of the three cases. The building cases, according to the plan, will be delivered between mid 2007 and 2008.

The research in all three cases was designed as practical tests of LBS in close collaboration and dialogue with the management on the sites. The schedules that were established by the site management in each case provided the starting point for the test of LBS. Thus, the initial step was to transform the original CPM-based schedules that were developed for each case into LBS versions. For Case 1, this step is exemplified in Figure 2. In the next step, the established LBS-copies of the original schedules were worked up and were adapted to an LBS configuration. Figure 3 shows the optimized schedule for Case 1. The findings from the analysis of the three cases corresponded basically, which is why the schedules from only one of the cases are presented. All the empirical results have continuously been discussed and evaluated in dialogue with the construction managers and other relevant staff members of each case.

All schedules were developed using the scheduling software of Control™ 2005 or the later version Control™ 2007, developed by Graphisoft. An early version of the software, named DynaProject™, is referred to in the text. Graphisoft has facilitated the study with professional support regarding the application of the software.

The empirical data collection was carried out in 2006, from September to December.

ABOUT LOCATION-BASED SCHEDULING

The literature on LBS, or other repetitive scheduling methods, includes a theoretical direction, which is the greater part, and a field that reports on the application of LBS in practice. The theoretical direction typically deals with simulations or algorithms and heuristics, e.g. for optimization of resource continuity to achieve duration cuts and to model learning curves (e.g. Kang *et al.* 2001). An underlying presumption in this type of work is that LBS mainly is a tool for highly repetitive work (e.g. multi-storey buildings or road constructions) and, consequently, is not suitable for non-repetitive work. The theoretical work provides a solid foundation to the LBS-method, but it does not reveal whether LBS meets the demands of planning, scheduling and control on site and in different kinds of projects (Soini *et al.* 2004).

As indicated earlier in the text, there is a discussion going on about the argumentation that LBS has the potential to support a greater acceptance of lean construction. Kenley (2004), for example, claims that LBS allows the management of projects according to Lean concepts, including work flow, production reliability, supply chain management and just-in-time delivery. Mendez and Heineck (1998) describe a production preplanning process in which interdependent tasks are lumped together into main activities for which the number of crews that must be allocated to each task is calculated in order to achieve a balanced production pace. Kankainen and Seppänen (2003) add to the discussion about how interdependent tasks are merged together in summary activities on a master schedule level, where the activities are balanced in relation to production rate, locations and continuity, and where the summary activities are divided into delimited tasks at a detailed schedule level in order to achieve the desired level of schedule accuracy. Kankainen and Seppänen (2003) support the argument that LBS promotes the philosophy of Lean.

Kenley (2004) as well as Kankainen and Seppänen (2003) and other Finnish authors have contributed to the understanding of adopting LBS in practice and report on the experiences of using the DynaProject™ software as a practical tool to help control the project on site. However, one should be conscious about that some of the Finnish authors that report on the benefits of LBS and the advantages of using DynaProject™ (or later versions) are connected to the development of the commercial software tool.

PRACTICAL IMPLICATIONS OF LBS

The practical examination of LBS took its starting point in the existing schedules that were prepared by the site management for each of the three cases of the study. All the original schedules were prepared without any consideration of the study and it is therefore likely to believe that the schedules represent typical examples of production schedules in Danish construction projects of today. The site management in all cases used the traditional activity-based scheduling method of CPM, where the schedules typically were developed in MS Project and represented in a Gantt chart. The original schedules covered the production phase of each project, i.e. they represented the so-called production or master schedules of the respective projects. A review of the original schedules in the three cases maintained that they were generally characterized by:

- An extensive number of activities.
- Activities were organized in a WBS-structure.
- Interdependencies between activities were normally, but not always, appointed.
- Resources were delimited to labour, i.e. building materials or equipment/machinery were not considered.
- Resources were allocated solely to “own” activities, i.e. subcontracted work were not resource allocated.

As the original schedules were translated into LBS-copies, as shown in Figure 2, some common remarks were identified and reviewed together with the site managers. For example, the number of activities in the original CPM-schedules were substantially reduced in the LBS-version and consequently, made it possible to overview the whole schedule. It was also observed in the original schedules that the planned work flow of activities through the different locations of the building was frequently discontinuous, i.e. the production was typically characterized by frequent starts and stops for the various working crews.

Further, parallel activities were not always properly balanced in respect of their production pace. In some cases, this led to overlapping activities, which meant that two or more activities were planned to take place at the same location at the same time. The LBS-versions of the original schedules also revealed that there were a number of unused areas in each case, which also can be a consequence of unbalanced activities. An unused area signifies one or more locations where no work takes place during a period of time and, consequently, it indicates that the project can be scheduled in a more appropriate way.

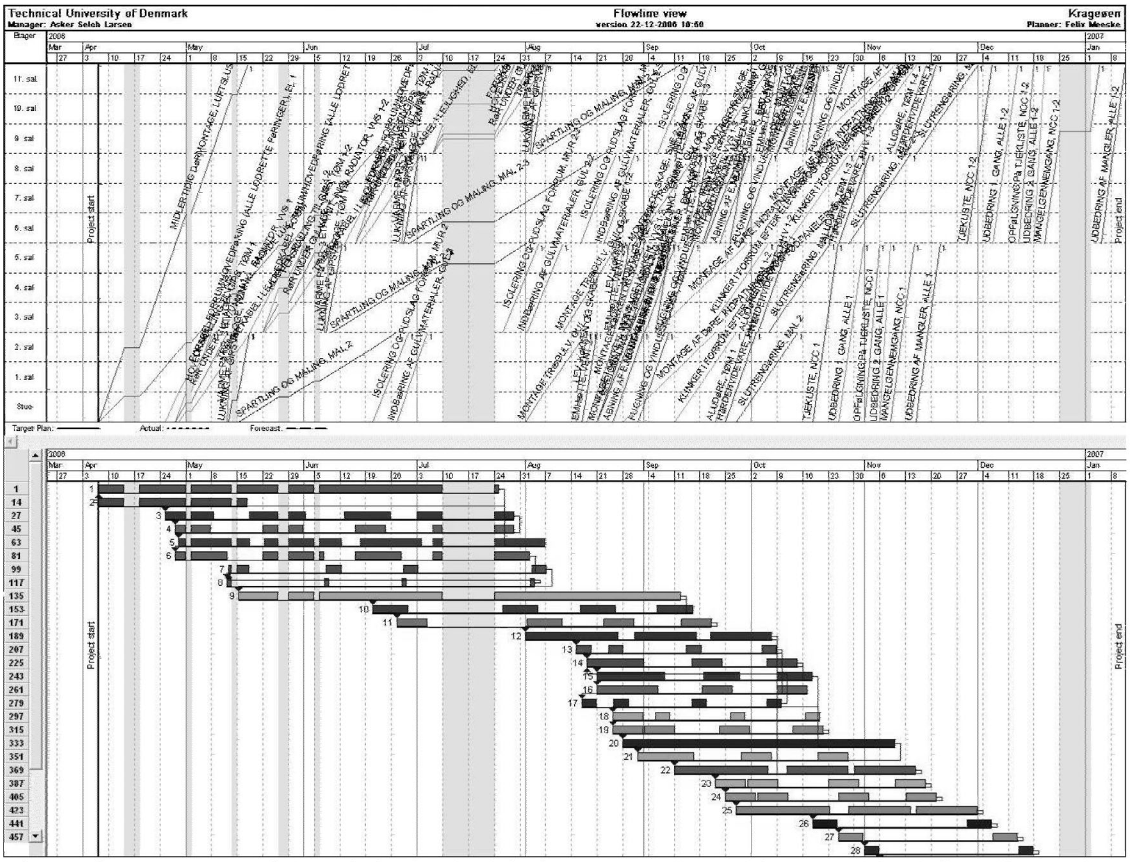

Figure 2: LBS-copy of the original schedule for Case 1 showed in a combined flow-line and Gantt-chart view. (Source: Larsen and Meeske 2007)

Based on the review of the original LBS-versions of the schedules, improvements were made in order to optimize the production planning. Figure 3 shows the optimized version of the LBS-schedule for Case 1 shown in Figure 2, which makes it possible to compare the two versions of the schedule. The analysis of the other two cases showed similar results as in Case 1, which is why the schedules from only one of the cases are displayed.

The processing of the LBS schedules revealed three major constructive implications of LBS, emphasized by the site management, namely improved schedule overview, establishment of work-flows and enhanced project control.

Improved schedule overview

The most immediate comment on the flow-line view, valued by the site managers, was the improved possibility to get an overview of the project and to actually see the activities repeating in various quantities through the multiple locations of the project. This simple implication of LBS and the flow-line view was considered a key aspect of LBS, and it constitutes a prerequisite for the establishment of work-flow and the enhanced project control.

Communication with subcontractors and other parties involved in the project is an aspect that gained from the LBS schedules as they were easier to understand and, consequently, easier to implement. This aspect of LBS is also expressed by Kenley (2004) who states that traditional project scheduling is frequently failing when it comes to communicating the management of a project from the management level down to the general site personnel.

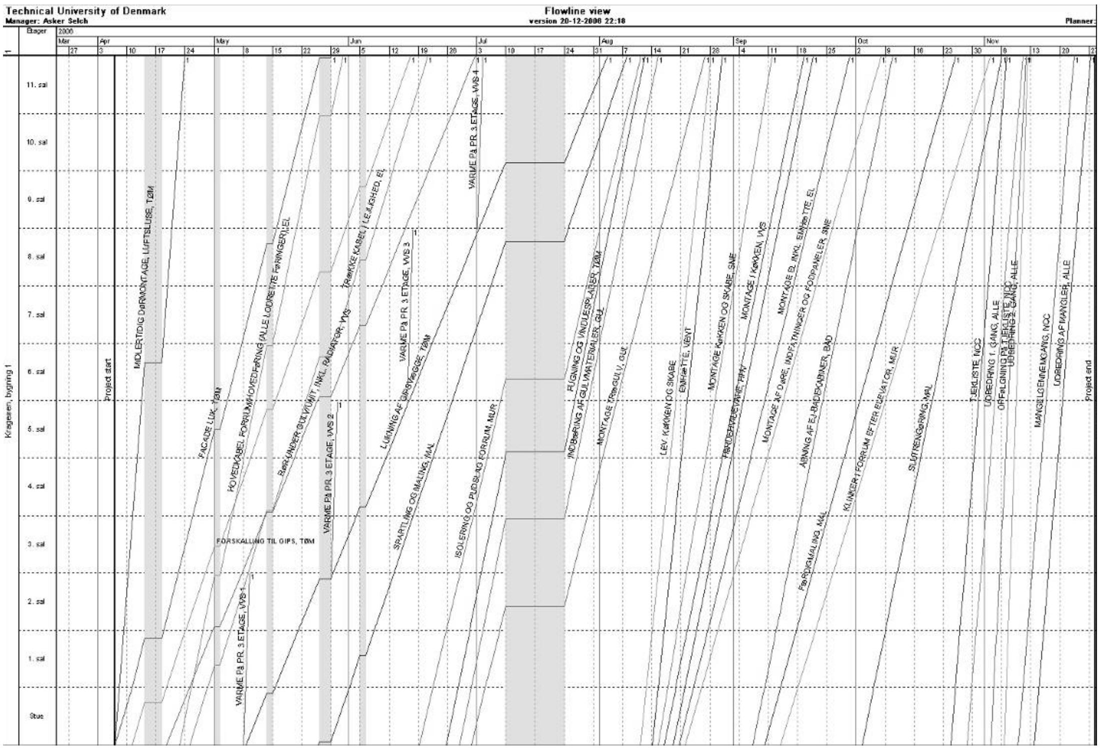

Figure 3: Improved LBS schedule for one of the three cases shown in a flow-line view (Source: Larsen and Meeske 2007)

Establishment of workflow

As indicated in the review of the original schedules developed for the three cases, it is difficult to ensure continuous workflows from a Gantt chart. The LBS schedules, however, provide information about the location of work and allocated work crews, which enables planning of continuous workflows (flow of resources through locations), avoidance of overlapping work (two or more crews working at the same location at the same time) and, possibly, avoidance of unused locations. Further, the graphical visualization of the production pace of the activities makes it possible to balance parallel activities, i.e. to adjust the resource units allocated in order to establish a sufficient production rhythm in a group of parallel activities.

LBS allows for simulations of different completion orders of the workflows following the defined locations of the project. This implication of LBS follows from an additional type of dependencies, i.e. location-dependencies, that comes with LBS. By changing the place completion order of an activity, for example from floor 1-2-3-4 to 4-3-2-1, the most sufficient completion order can be evaluated. This was of particular interest in one of the three cases where the installations originally were planned to commence at the top level of the building and continue down to the ground floor, but where a simulation in the processed LBS schedule showed that it was beneficial to commence the installations at the ground floor.

Figure 3 shows the processed LBS-version of the original schedule shown in Figure 2. It is manifested that the revised schedule includes continuous workflows that are balanced without overlaps at any time and that the empty locations are reduced.

Enhanced project control

The simple fact that an LBS schedule provides information about the planned location for each resource crew at a given time supports and simplifies project control of the work performed at each location, besides, it is generally valuable for the site management to know the precise location of a specific resource crew. In that respect, it is worth mentioning that a fundamental principle in LBS is that an activity should be fully completed in one location before the crew moves on to the next location. This principle involves a change in the current situation of planning and management of subcontracted work where the subcontractors more or less are indulged to consider their scheduled activities as a time-limit during which they are allowed to carry out the work as they whish, without respect to a specific location succession (see, for example, Conlin and Retik 1997 for more details on this subject). The insufficient consideration of the subcontractors' resources in the original schedules of the three cases, reveal that the planning and scheduling of subcontracted work can be improved. Kankainen and Seppänen (2003) suggest that agreements on payments should be connected to the work completion of locations in order to compel the subcontractor to conclude their work in the planned succession.

Seppänen and Aalto (2005) point out that improved schedule control, besides the possibility to examine how deviations from weekly plans influence the master schedule, is a significant benefit of LBS. An interesting point in this connection, presented by Kankainen and Seppänen (2003), is that the master schedule never should be updated even when the weekly schedules indicate deviations from the plan. They explain that this is because updating the master schedule will not solve the deviation problems, but rather transfer the problems towards the end of the project where they will accumulate. This is, however, an implication of LBS that is not tested or confirmed in this study.

Experienced difficulties in the application of LBS

The site management of the tree cases had none or limited experience from LBS when the study was initiated and even though the results describe LBS in generally positive terms, the study also experienced difficulties in relation to LBS. Some difficulties were directly connected to the application of LBS or the LBS-software that was used, while other problems were of a more general nature.

LBS implies a new, or preferably unfamiliar, scheduling method which requires a new approach to scheduling and it involves new conceptions. For example, LBS requires the definitions of locations and there are different more or less appropriate ways of dividing the project into locations. One aspect is about finding a sufficient level of details required for the planning, scheduling and control of the project. It is possible, but very inconvenient, to change the level of detail once the scheduling has commenced. Another difficulty experienced in one of the cases concerned the definition of different kinds of locations, e.g. how to handle ground works in relation to the locations that are connected to the actual building. The study found no guidelines for the proper approach to defining locations.

Well-known concepts of the CPM-method become irrelevant besides the introduction of new terms. For example, the concepts of critical chain and float fail as LBS principally concern the management of workflows where resource constraints become a central aspect. In connection to this, the new concepts of synchronized and paced activities become relevant. Synchronized activities imply that crews are sized in order for activities to proceed at the same pace, and paced means that crews proceed continuously through locations. Instead of the traditional total and free float, LBS includes buffers that somehow replace the conception of free float. Another difference from the traditional scheduling method is location dependencies, which caused some initial problems in the cases. Activities in LBS are location dependent on a certain hierarchy level or location independent, and it is for the manager to decide on the appropriate hierarchy level for each activity.

Besides the LBS specific difficulties, some general problems that cannot be directly connected to the specific application of LBS were identified. For instance, it became an apprehension among the site managers that the LBS software requires a significant amount of input information in the initial stage of the planning process. This is a consequence of the design of the LBS software, which uses a bill-of-quantity as the starting point for definition of activities. Thus, the LBS software calculates activity durations from a selection of the bill-of-quantity allocated to a specific activity together with the resources that are allocated and information on productivity for the specific type of work. The site management in this study experienced, which ought to be typical in a Danish context, that they did not have access to a coherent bill-of-quantity for their respective projects. Thus, activity durations were generally valued on basis of the site managements' individual experiences rather than extracted from bill-of-quantities, documented productivity data or specified numbers of resource units.

This study argues, however, that this is not a problem associated with LBS as such, but rather a consequence of the lack of a coherent and standardized information structure in the Danish context. In Finland, a productivity database with information on construction activity data has been developed by a joint effort of the construction industry, which of course facilitates the information management. Finally, it is worth mentioning that it is not a definite requirement for neither LBS scheduling in general nor the specific LBS software to use a bill-of-quantity.

CONCLUSION

The evaluation of LBS for the on-site management of building projects revealed, emphasized by the site management involved in the study, three major beneficial practical implications of location-based scheduling. First, the improved overview of the project schedule from the flow-line view of LBS supports, not only the understanding of the schedule, but also the communication with subcontractors and other involved parties and thereby it facilitates the implementation of the schedule. Second, LBS schedules support planning of continuous workflows of resources through locations, avoidance of overlapping work on the same location at the same time and avoidance of unused locations. Third, LBS supports improved project control as LBS provides information about the planned location for each resource crew at a given time, which facilitates the monitoring of work performed at each location.

Thus, it is confirmed from the three cases that LBS provides some practical implications beneficial for the on site management of building projects. This conclusion principally concurs with the findings reported in previous studies, e.g. Kenley (2004), Seppänen and Aalto (2005) and others.

The identified difficulties with the application of LBS were either LBS-specific or of a more contextual nature. The application of LBS requires basic knowledge about the LBS method and it implies the introduction of new software tools that, all together, involve new conceptions and a new approach to scheduling, which initially will challenge the site management. Another experienced difficulty was related to the general lack of a coherent and standardized information system that would facilitate the application of the LBS software. However, it is concluded in this study that a bill-of-quantities is not a definite requirement in the application of LBS or the specific

LBS software that has been used. This is rather to be considered a possibility to further develop the applicability of LBS, as a bill-of-quantity would allow for, e.g., coordinated procurement planning, material delivery schedules and on-site logistics.

TRACKING AND FORECASTING PERFORMANCE OF EARTHMOVING OPERATIONS USING GPS DATA

Adel Alshibani[1] **and Osama Moselhi**

Department of Building Engineering, Concordia University, 1190 Du Fort, Montreal, Quebec H3H 2B5, Canada

Tracking and forecasting performance of earthmoving operations during construction is a crucial task that requires close monitoring of the equipment involved. Traditionally, monitoring is based on human involvement in data collection. Such monitoring process is labour intensive, expensive, time consuming, and not necessarily accurate. This has been recognized as a challenging task for project managers. This paper presents a new method designed to overcome the previously stated limitations. The proposed method automates site data collection and forecasts time and cost of earthmoving operations at completion and/or at any intermediate time horizon based on data collected using GPS. It utilizes spatial technologies including Geographic Information System (GIS) and Global Positioning System (GPS). GIS is employed to automate data acquisition and to analyse spatial data. GPS is used to automate site data collection in near real time. The GPS data are used to estimate onsite crew productivity and to forecast time and cost. The proposed method utilizes project ratio techniques and earned value and presents a methodology that allows for more accurate forecasting of project time and cost. The developed methodology has been coded in prototype software using object-oriented programming. An example project is analysed to demonstrate the features of the developed method.

Keywords: adaptive, cost, earthworks, equipment, forecasting.

INTRODUCTION

In large-scale earthmoving operations, measuring actual performance and forecasting project time and cost during its execution are crucial management functions for the successful delivering of this class of project. Measuring actual performance enables comparison with the as-planned progress. This comparison enables the determination of project status and assists in identification of the cause(s) behind unacceptable performance so that corrective action(s) can be taken. Accurate measuring of actual performance relies on the accuracy of the data collected from construction sites, whereas accurate and efficient forecasting of project cost and time relies on the method applied and the timely collection of site data.

In this class of project, estimating actual performance requires collecting large amounts of data from construction sites. Traditionally, site data collection has been commonly based on manual methods, in which the collected data are recorded on paper by human observers. Manual methods are recognized to be costly and not necessarily accurate (John *et al*. 2005).

[1] yasienadel@hotmail.com

Problems associated with measuring actual performance have been widely recognized and are well documented (Bassioni *et al*. 2004). The industry has benefited, in recent years, from new automated field data collection tools that are able to gather large volumes of necessary data in a timely manner. Automation of site data collection leads to improvement of project tracking and control systems (Oglesby *et al*. 1989). In large-scale earthmoving operations, the most widely used automated systems for site data collection are: (1) On-board Instrumentation Systems (OBIS); and (2) Global Positioning Systems (GPS). The OBIS has been used in several earthmoving applications, including controlling scraper wheel slippage and transmission shifting, maximizing dozer production, providing increased traction to haul trucks, and preventing loader rollovers (Chironis 1987). On the other hand, the GPS in such application is relatively new. Some innovative applications, however, have been reported in recent years. This includes collusion avoidance of excavating equipment (Lothon and Akel 1996), monitoring asphalt compaction (Oloufa and Thomas 1997), and estimating duration of earthmoving operations (John *et al*. 2005). The main advantages of GPS over OBIS are: (1) it is inexpensive; and (2) it can collect data in near real time.

Literature suggests that data collected by GPS have not been used in estimating and forecasting performance of earthmoving operations. In addition to site data collection, considerable efforts have been made in developing effective methods to forecast project cost and time at completion and at target date. Each of these methods has its own assumptions (Hassanien 2002). Most of these methods are based on earned value (Moselhi *et al*. 2004; Moselhi and Hassanien 2003; and Alshibani 1999). Others employ stochastic modelling (Gabriel *et al*. 2004), or project ratios (Eldin and Hughes 1992). These methods were developed for building construction projects except for that of Moselhi and Hassanien (2003), which was designed for linear projects such those involving earthmoving operations. They all assume that either the established performance at the report date will continue until completion or the remaining work after the report date will be performed as planned, entirely blocking out certain time periods during which exceptional conditions are known to have prevailed; they estimate actual performance based on data collected manually.

This paper presents a newly developed method in an effort to circumvent the above stated limitations of current methods. The proposed method utilizes spatial technologies including GPS and GIS to automatically: (1) collect data from construction sites in near real time using GPS receivers; (2) estimate actual performance, and forecast projects' time and cost at any time horizon using GPS data. The paper focuses primarily on estimating actual productivity and on forecasting project time and cost at completion and at any projected time horizon. The developed method for forecasting is self-adapting and utilizes the earned value concept (Department of Defence 1967) and project ratios technique (Eldin and Hughes 1992).

PROPOSED METHOD

The proposed method incorporates three modules; (1) Database Module; (2) Graphical User Interfaces (GUI) Module; and (3) Geographic Information System (GIS) Module. Figure 1 represents the main component of the proposed method. The Database Module is designed to store: (1) the positioning data collected by GPS for tracking equipment on construction sites in near real time; (2) the swell and shrinkage factors for various soil types; and (3) available equipment pool. The function of the GUI Module is to acquire non-graphic data such as data pertinent to job and management conditions and actual cost data. The GIS Module performs the analysis of collected GPS data and depicts moving equipment on the map in layers.

The proposed method involves five major steps: (1) collecting site data using GPS receivers; (2) mapping moving equipment by transforming its GPS positioning data (longitude, latitude, speed, time and direction) into GIS to develop a graphical representation; (3) analysing GPS data to account for the number of cycles (trips) the tracked equipment makes within a particular period of time; (4) estimating the actual productivity rate; and (5) forecasting project time and cost. The following sections focus primarily on: (1) estimating actual productivity using GPS data as a novel method, and (2) forecasting project cost and time.

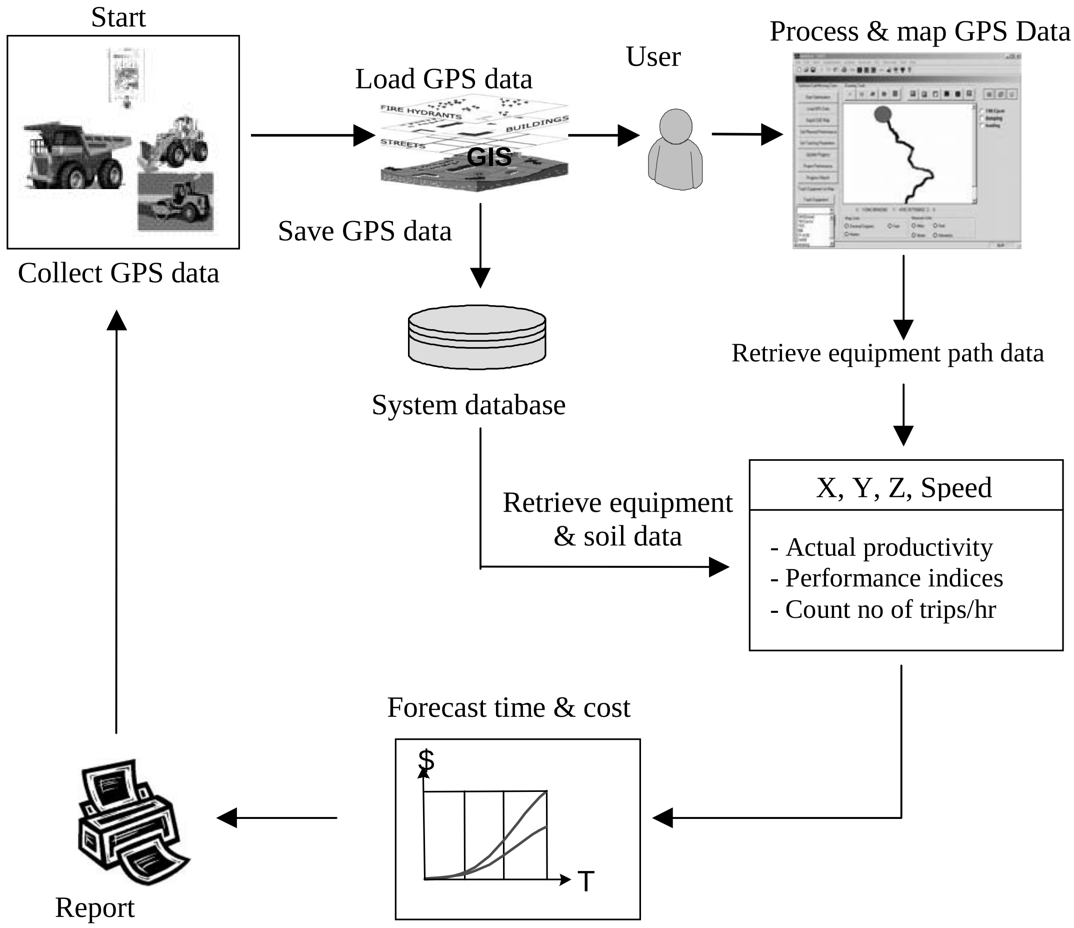

Figure 1: Main components of the proposed method

Estimating actual productivity

In order to measure project actual performance and forecast its status with respect to time and cost, the method first estimates the crew actual productivity based on the spatial data collected by the GPS receiver. The method tracks (counts) the number of cycles (trips) the equipment makes within a particular period of time. The cycle-time equals the summation of loading, travel, dumping and return time. The loading time is determined when the equipment is positioned in the loading area, the travel time is determined when the equipment moves from loading to dumping area(s), the dumping time is determined when the equipment is positioned in the dumping area, and the return time is determined as the time required for the equipment to move back from dumping to loading areas. Upon completion, the crew actual productivity is estimated considering the type of construction equipment involved. All the data needed for estimating actual productivity are stored in the system's database. In general, the actual productivity for hauling units such as trucks and scrapers can be estimated as follows:

$$(\text{P/hr})_i = (\text{No of hauling unit})_i \times \text{No of trips per hour} \times \text{Capacity} \times \text{Cf} \qquad (1)$$

in which:

$(\text{P/hr})_i$ is the estimated actual productivity per hour;

No of hauling unit is the number of hauling units in the crew;

No of trips per hour is the number of trips the hauling unit made in hour and it is accounted automatically using GPS data;

Capacity is the hauling unit capacity taking into consideration soil type, which is retrieved from the system's database;

Cf is a correction factor, entered by the user, and accounts for the efficiency factor, bucket fill factor, and job and management conditions.

It should be noted that Equation 1 can be easily adapted to suit other equipment such as compactors, graders and rollers. For example, the productivity of a compactor can be estimated in SF per hour as follows:

$$\begin{aligned}(\text{P/hr})_i = {} & (\text{No of compactors})_i \times \text{No of trips per hour} \times \text{Distance of segments} \\ & \times \text{Width of roll} \times \text{Cf}\end{aligned} \qquad (2)$$

Figure 2 represents the mapping of collected spatial data, used in estimating the crew

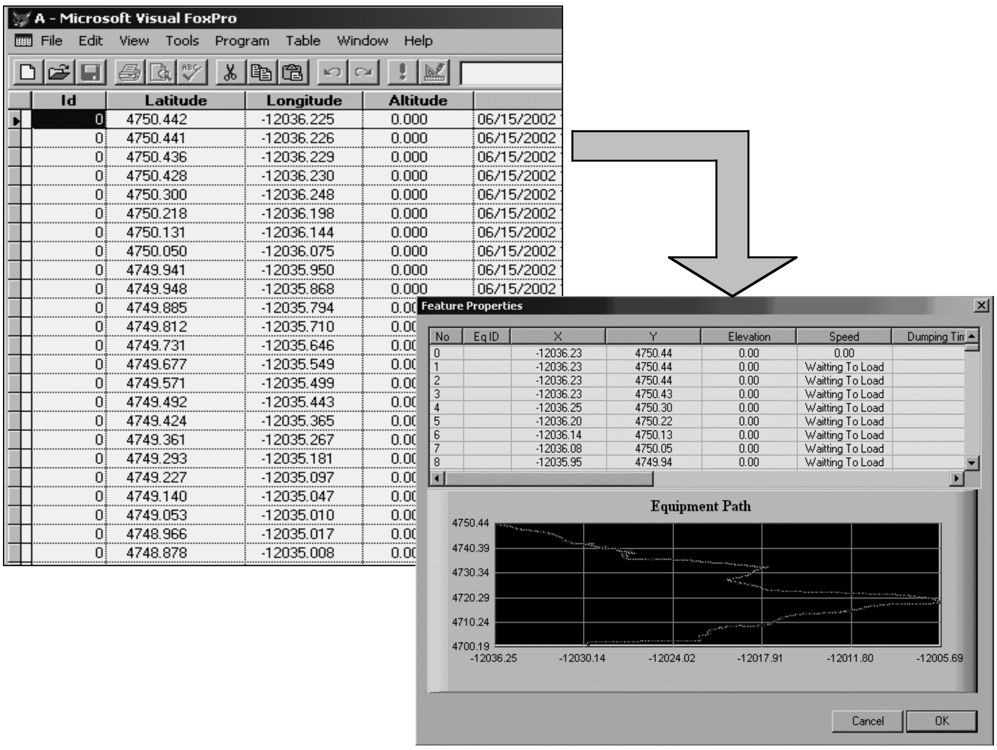

Figure 2: Mapping of spatial data

Cost and time forecasting

The proposed method utilizes the project ratios technique developed by Eldin in 1992 (Eldin and Hughes 1992) and the earned value concept developed by US Department of Defence (DoD) in 1967 (Department of Defence 1967) for forecasting project cost and time. In order to forecast time and cost, two project performance indices are calculated. These are: productivity performance index (PPI) or schedule performance index (SPI) and cost performance index (CPI). The two indices are calculated using the two methods referred to above.

Performance indices using project ratios technique

Productivity performance index

This index provides a measure of the likelihood of finishing the project within its targeted schedule and it is used here to forecast project duration. The index can be expressed as:

$$\mathrm{PPI} = \frac{(\mathrm{Whr/Q})\mathrm{b}}{(\mathrm{Whr/Q})\mathrm{a}} \tag{3}$$

in which:

PPI is the productivity performance index;

(Whr/Q)a is the actual to-date working hours per unit of work;

(Whr/Q)b is the budgeted working hours per unit of work.

Cost performance index

The cost performance index (CPI) provides a good measure as to how close a project will be completed within its targeted budget and it is used here to forecast project cost. The CPI can be expressed as:

$$\mathrm{CPI} = \frac{(\$/\mathrm{Q})\mathrm{b}}{(\$/\mathrm{Q})\mathrm{a}} \tag{4}$$

in which:

(\$/Q)b is the budgeted cost of unit rate;

(\$/Q)a is the actual cost to date of unit rate.

Forecasted cost and time at any point in time ($ti - t1$) can be calculated as follows:

$$\mathrm{C1}_{ti-t1} = \left(\mathrm{ACWP} + \left(\left(\frac{ti-t1}{\text{project time}}\right) \times (\mathrm{Q})\mathrm{b} - (\mathrm{Q})\mathrm{a}\right) \times (\$/\mathrm{Q})\mathrm{b}\right) \times \acute{a}_{\mathrm{c}} \tag{5}$$

$$\mathrm{C2}_{ti-t1} = \left(\mathrm{ACWP} + \left(\left(\frac{ti-t1}{\text{project time}}\right) \times (\mathrm{Q})\mathrm{b} - (\mathrm{Q})\mathrm{a}\right) \times (\$/\mathrm{Q})\mathrm{average}\right) \times \acute{a}_{\mathrm{c}} \tag{6}$$

$$\mathrm{T1}_{ti-t1} = \left((\mathrm{Whr})\mathrm{td} + \left(\left(\frac{ti-t1}{\text{project time}}\right) \times (\mathrm{Q})\mathrm{b} - (\mathrm{Q})\mathrm{a}\right) \times (\mathrm{Whr/Q})\mathrm{b}\right) \times \acute{a}_{\mathrm{t}} \tag{7}$$

$$T2_{ti-t1} = \left((\text{Whr})\text{td} + \left(\left(\frac{ti-t1}{\text{project time}} \right) \times (\text{Q})\text{b} - (\text{Q})\text{a} \right) \times (\text{Whr/Q})\text{average} \right) \times á_{t} \qquad (8)$$

in which:

$C1_{ti-t1}$ is the cost forecast1 @ ti – t1;

$C2_{ti-t1}$ is the cost forecast 2 @ ti – t1;

$á_{c}$ is the adaptive cost and it is calculated as follows:

$á_{c}$ = Forecasted Cost/Actual Cost

$á_{t}$ is the adaptive time and it is calculated as follows:

$á_{t}$ = Forecasted Time/Actual Time

$T1_{ti-t1}$ is the time forecast1 @ ti – t1;

$T2_{ti-t1}$ is the time forecast2 @ ti – t1;

$ti-t1$ is the time interval on horizon time;

(Q) b is the budgeted quantities;

(Q) a is the actual quantities up to report date;

($/Q)average is average actual cumulative to-date unit cost rate and it includes the normal unit cost rate achieved by the contractor in case there are exceptional conditions that are known to have prevailed in a certain period of time;

(Whr/Q) average is average actual to-date unit working hours and it includes the normal productivity rate achieved by the contractor in case there are exceptional conditions that are known to have prevailed in a certain period of time.

Performance indices using earned value concept

Schedule performance index

$$\text{SPI} = \frac{\text{BCWP}}{\text{BCWS}} \qquad (9)$$

in which:

SPI is the schedule performance index;

BCWP is the budgeted cost of work performed;

BCWS is the budgeted cost of work scheduled.

Cost performance index

$$\text{CPI} = \frac{\text{BCWP}}{\text{ACWP}} \qquad (10)$$

in which:

CPI is cost performance index;

ACWP is the actual cost of work performed.

The cost and time forecast at any point in time horizon ($ti - t1$) can be expressed as follows:

$$C1_{ti-t1} = \left(ACWP + \left(\left(\frac{ti - t1}{\text{project time}} \right) \times BCAC - BCWP \right) \right) \times á_c \tag{11}$$

$$C2_{ti-t1} = \left(ACWP + \left(\left(\frac{ti - t1}{\text{project time}} \right) \times BCAC - BCWP \right) \div (CPI)\text{average} \right) \times á_c \tag{12}$$

$$T1_{ti-t1} = \big((Whr)td + \big(ti - (\% \times (Whr)\,b\big)\big) \times á_t \tag{13}$$

$$T2_{ti-t1} = \big((Whr)td + \big(ti - (\% \times (Whr)\,b\big)/(SPI)\text{ average}\big) \times á_t \tag{14}$$

in which:

(CPI)-average is the average to-date cost performance index and it includes the normal CPI achieved by the contractor in case of exceptional conditions that are known to have prevailed at certain reporting periods;

(SPI)-average is the average to-date schedule performance index and it includes the normal SPI achieved by the contractor in case there are exceptional conditions that are known to have prevailed at certain reporting periods;

% is percentage complete to date;

(Whr)td is actual to-date working hours;

(Whr)b is budgeted working hours.

Determining two values of performance indices results in forecasting a range rather than a single crisp value. This could prove useful to project managers to examine the forecasted values and decide on which is more applicable to the case at hand and allow for reasoning about the forecasted project status. Equations 5 and 6 and Equations 11 and 12 will give different values, defining the forecasted range of project cost in this case. Similarly, Equations 7 and 8 and Equations 13 and 14 will give different values that define the forecasted project time.

Cost and time variances

In addition to forecasting project cost and time, the proposed method calculates project cost and time variances at any targeted future date. The cost variance (CV) is determined by subtracting forecasted cost from budgeted cost at that point in time. Similarly, the time variance (TV) is determined by subtracting forecasted time from that planned.

$$CV_{ti-t1} = \left(\frac{ti - t1}{\text{project time}} \right) \times (Q)b \times (\$/Q)b - \left(\frac{C1_{ti-t1} + C2_{ti-t1}}{2} \right) \tag{15}$$

$$\mathrm{TV}_{ti-t1} = \left(\frac{ti-t1}{\text{project time}}\right) \times (\mathrm{Whr})\mathrm{b} - \left(\frac{\mathrm{T1}_{ti-t1} + \mathrm{T2}_{ti-t1}}{2}\right) \tag{16}$$

in which:

CV_{ti-t1} is the cost variance at (ti – t1) in horizon time;

TV_{ti-t1} is the time variance at (ti – t1) in horizon time and measured in working hours.

The data needed to perform the analysis are retrieved directly from GPS data or entered directly by the user in the case of actual cost. Furthermore, the proposed method enables partially blocking out certain time periods during which exceptional conditions are known to have prevailed, such as a strike. Instead of blocking out the time period entirely, the performance index for this period is calculated based on the level of performance achieved by the contractor during normal conditions, just before the occurrence of such unusual conditions. For example if a strike occurred in the second period (2-1) as presented in Figure 3, instead of blocking out this period entirely, its performance index can be calculated at normal conditions just before the strike. In an effort to improve the accuracy of forecasting, the proposed method uses an adaptive, self-learning adjustment factor. The adaptive factor is generated at each reporting period and is the ratio of actual versus forecasted. This simple factor continuously adapts to the project environment and systematically reduces the gap between the forecasted and actual project status.

COMPUTER IMPLEMENTATION

As proof of concept, the proposed method has been implemented in an automated system using visual C++ V.6, object-oriented programming and Microsoft Foundation Classes (MFC) supported by GIS. The system's database is designed in a relational database using Microsoft Access Database Management System. A relational database management system is used because of its combination of power, simplicity, and ease of use (Kim 1989). The database stores the data needed for calculation. The developed software operates in Microsoft Windows's environment. The data flow and processing, in the proposed method, is represented in Figure 4.

The system accepts both graphic and non-graphic data. The system is activated through setting out of tracking parameters. It automatically progresses with the crew productivity analysis, measures the project schedule and cost status at the report date, and forecasts time and cost at completion. The analysis is essentially performed based on the user's selection of the tracking parameters and the level of detail required. The project status is represented by the cost performance index, the schedule performance index, the productivity performance index, and associated variances and forecasts. The software calculates the values of these variables using the earned-value concept, project ratios technique and developed extensions to these techniques.

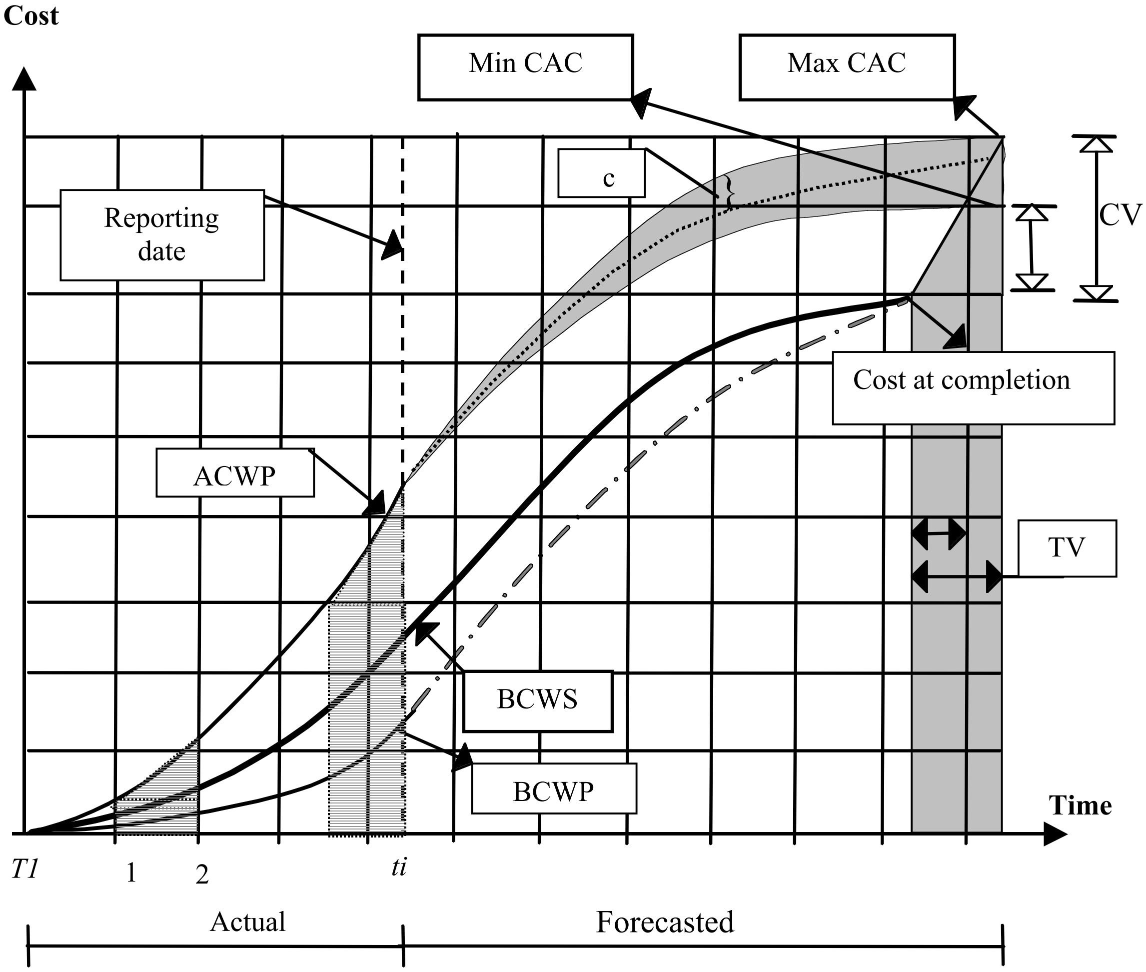

Figure 3: Cost and time forecast

Notes:

TV: time variances

CV: cost variances

ACWP: actual cost of work performed

BCWS: budgeted cost of work scheduled

BCWP: budgeted cost of work performed

CAC: cost at completion

Graphical User Interface

The Graphical User Interface (GUI) contains a series of dialog windows for the user to select from. The user interface incorporates menus, toolbars and dialog windows. The implementation of the GUI was carried out in a way that facilitates data entry and minimizes redundant data input. The GPS data are transformed to graphical presentation.

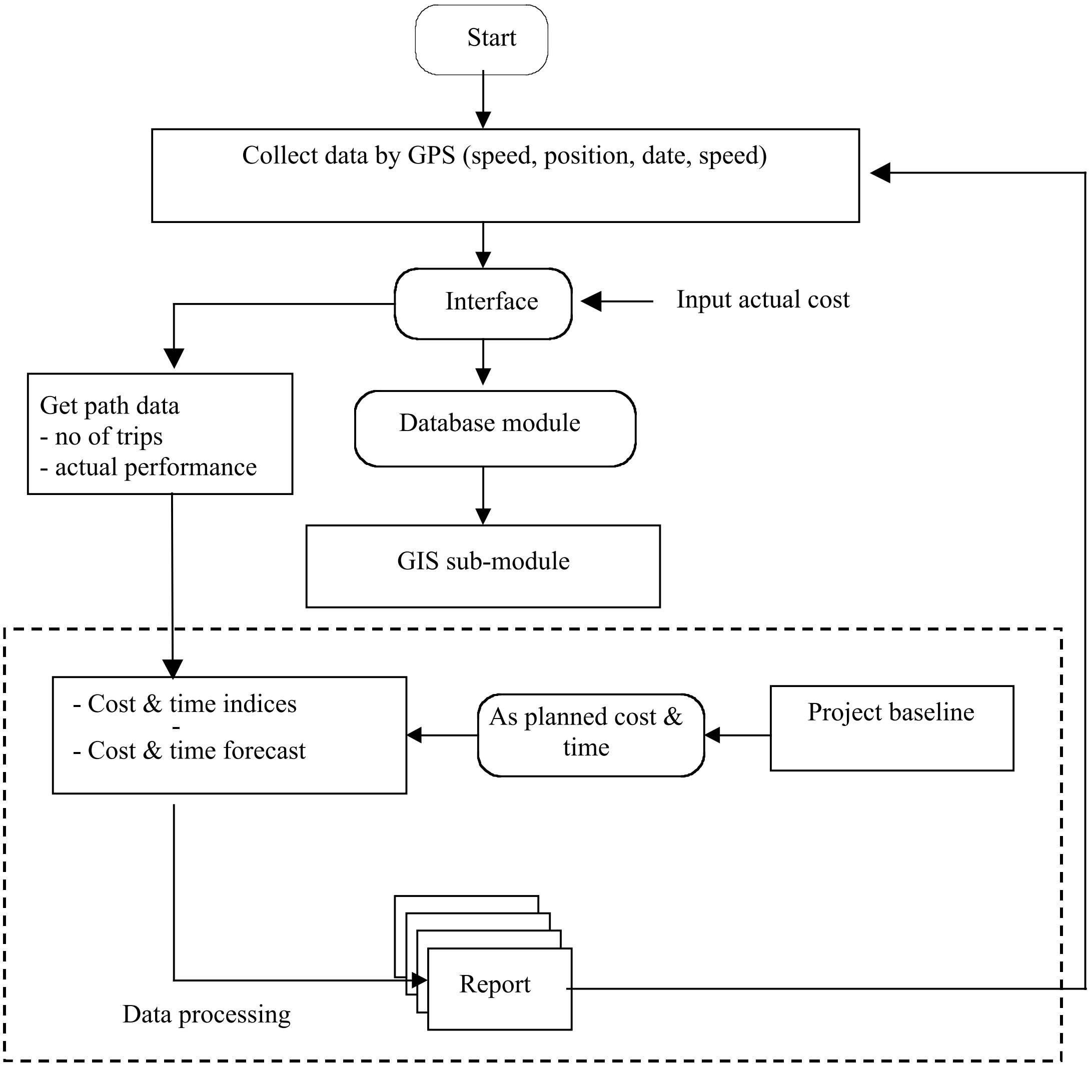

Figure 4: Data flow and processing in the proposed method

APPLICATION EXAMPLE

To illustrate the capability of the developed method in tracking and forecasting project performance, an example project is presented. The project involves moving of 100 000 cubic metres of dry clay from the pit to the site of a dam under construction. The crew formed to carry this job consist of one loader (994 CAT), 52 hauling units (740-Ejector) and one grader (24H (Global)).

Figure 5 represents a progress report taken after two days from the actual starting date (31 August 2006). The quantities of earth moved during this period are 5000 cubic metres. The actual cost incurred was $5000, $36 000 and $1500 for the loader, trucks and grader, respectively. The project is experiencing cost overrun but is ahead of schedule. The project would finish 95.8 hours earlier and at a $3994210.33 (–10280.52 – 3984067.02 + 137.21) cost overrun. It should be noted that the forecasting property page was designed to illustrate the projected range (i.e. minimum and maximum values) of cost and time, and their respective variances.

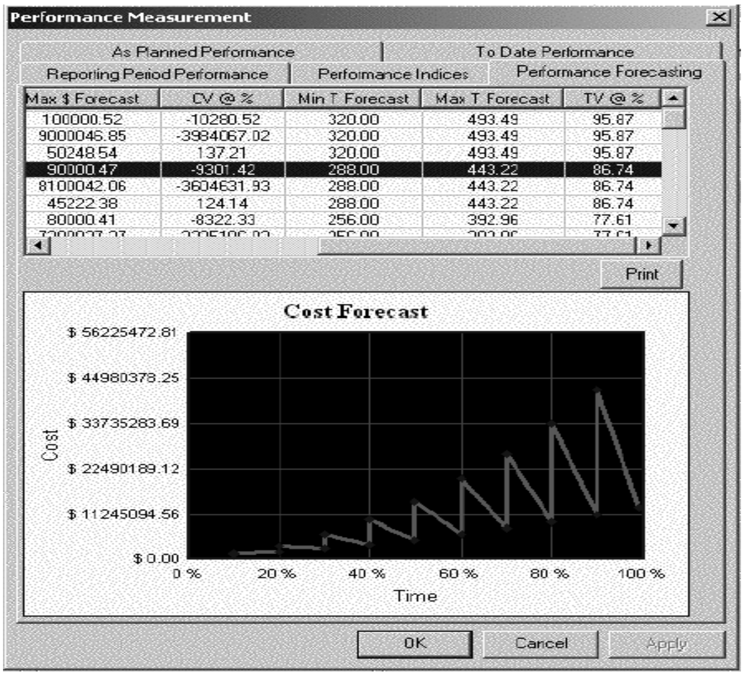

Figure 5: Forecasting dialog window

SUMMARY AND CONCLDING REMARKS

A new methodology for forecasting performance of earthmoving operations has been presented. The proposed method utilizes spatial technologies including GPS and GIS to circumvent some identified limitations in current methods. The methodology supports: (1) estimating actual productivity; (2) tracking the involved equipment in near real time to improve efficiency and productivity and to maximize contractor profit; and (3) forecasting project performance with a high level of confidence. Its basic components and the interconnectivity among them were described. The applications of GPS as a site data collection tool has been tested and proven to be accurate, effective and inexpensive. Integration of GPS and GIS makes it easy for project managers to track construction equipment on construction sites in near real time. The application of GPS and GIS for tracking earthmoving operations can solve problems associated with data quality and timing of information exchange among members of project teams. Timing of information exchange helps project management teams in taking corrective action(s) in a timely manner.

LINKING LEAN PRODUCTION AND SUSTAINABLE DESIGN ON WASTE REDUCTION

Aguinaldo dos Santos[1] and Carlo Vezzoli[2]

[1]*Rua General Carneiro, 460, EdifÃƒÂcio Dom Pedro I, sala 717, Curitiba ParanÃƒÂ¡, 80060-160, Brazil*
[2]*Politecnico di Milano Milano, Italy*

The present paper attempts to establish a connection between lean construction and sustainable design on the issue of waste reduction. Initially it presents the meaning of waste within the lean production theory and the correspondent heuristic approaches used in this area to reduce waste. It then presents the overall strategies adopted in sustainable design, focusing the review on the issue of ‘material life extension’. Finally, it presents a case study carried out in England that illustrates the implications of putting together lean principles and sustainable design. The overall conclusion is that dealing with waste using solely the lean construction theory is not enough and that better results are likely to be achieved by integrating sustainable design practices.

Keywords: design, lean construction, sustainability.

INTRODUCTION

Reduction of waste is one of the main focuses of lean construction. This is also a key issue in sustainable design where, like in the field of lean construction, there is already a considerable amount of knowledge developed both in terms of high abstract concepts and principles and in respect of heuristics and practical tools. Sustainability looks at all dimensions of the life cycle of a given product, including the production stage. However, only in the 1990s the link between production management and sustainable design began to be more clarified with a better understanding of environmental requirements for industrial products and through the concept of life cycle design (LCD).

Despite the clear link between both fields of research on the issue of waste there is little work attempting to connect their theoretical concepts and principles. In practice this lack of integration is also witnessed with companies applying sustainable design and lean production as separate managerial and technological battlegrounds. The next sections present insights on the implications of bringing these two different fields of research to work together.

PRINCIPLES FOR WASTE REDUCTION IN LEAN PRODUCTION

The lean paradigm sees the production system as a flow constituted of processing, waiting, inspecting and transporting activities. Within this model, processing activities

[1] asantos@ufpr.br

are the only ones that can add value to the customer and, therefore, waiting, inspecting and transporting are considered non-value-adding activities and should be eliminated from the main process flow.

Based on this model, a production system could be further described as a network of process flows and operations flows, lying along intersecting axes. A process flow is the designation for the flow of materials (or information) and represents the pathway in which raw material is transformed into semi-processed components and then into a finished product. An operations flow is the designation for the flow of humans or machines that carry on the work over each stage of the process flow. Operations are very diverse and dynamic in terms of content and position in time and space. The process flow should receive priority when searching for improvements in production systems. For example, and conventionally, most people simply think that improving transport efficiency refers to the adoption of forklifts or installing conveyors, etc. However, within the process/operation model, improving transport can also mean reducing or even eliminating the transport altogether. It is only after this broader analysis has been carried out in the entire 'process' that improvements should be devoted to the actual operation of 'transport' (Shingo 1989).

The aim of the flow model is to obtain 'lean production systems', with little or no waste of resources. Therefore, identifying and eliminating sources of waste is a constant preoccupation on the minds of people using this paradigm in their everyday activities. According to Imai (1997) and Shingo (1989), sources of waste (muda) are classified according to seven main categories:

1. Overproduction: this type of waste results from 'getting ahead' with respect to production schedules. Here the required number of products is disregarded in favour of efficient utilization of the production capacity.
2. Inventory: final products, semi-finished products, or parts kept in storage do not add any value. Even worse, they normally add cost to the production system by occupying space and financial resources and, also, by requiring additional equipment, facilities and manpower.
3. Repair/rejects: rejects interrupt production and, in general, require expensive rework. Moreover, they may end up discarded or damaging other equipment or generating extra paperwork when dealing with customer complaints.
4. Motion: any motion not related to adding value is unproductive.
5. Transport: although sometimes this activity seems to be an essential part of production, moving materials or products adds no value at all.
6. Processing: this waste happens when the use of inadequate technology or poor design results in inefficient processing activities. Sometimes this waste may appear as a consequence of a failure to synchronize processes, where workers achieve performance levels beyond or below the requirements of downstream processes.
7. Waiting: this waste occurs when the hands of a worker are idle such as when there are imbalances in schedule, lack of parts, machine downtime or when the worker is simply monitoring a machine performing a value-adding job.

This classification could extend further with the inclusion of vandalism, theft and other sources of waste. Koskela (1999) proposes the inclusion of a type of waste that occurs frequently in construction when production operates under 'sub-optimal conditions'. Congestion of a workstation in small places, work out-of-sequence and excessive stops in the flow are examples of these conditions that lead to production having sub-optimal performance (Ballard and Howell 1998; Koskela 1999). Formoso *et al.* (1999) add that on building sites it is possible to find waste due to 'substitution'. This waste happens when, for instance, there is a monetary loss caused by the substitution of a material by a more expensive one or when the execution of a simple task uses over-qualified workers.

There are many techniques available to analyse and improve production systems using the flow model as the conceptual base. They allow the analyst to understand actual behaviour, sequence, proportion and variability of inspecting, waiting, processing and transporting activities. Many of them were invented in the early days of Scientific Management School, such as time-lapse video recording, work sampling and flow charts. Obviously a given production process is often the direct result of the decisions taken at the design stage. The next section reviews the overall strategies of design that affected directly the reduction of waste not only at the production stage but during the entire life cycle of a given product.

PRINCIPLES FOR WASTE REDUCTION IN SUSTAINABLE DESIGN

Most authors in the field of sustainable design (Brezet and van Hemel 1997; Mont 2002; Charter and Tischner 2001; Manzini and Vezzoli 2002) agree that its leading principles include:

- the extension of the design horizon: from product design to the (systemic) design of the product life cycle stages;
- a new design reference: from product design to product function design.

Within this framework products have to be designed considering all phases of the life cycle. All activities related to the product, from the production of materials to its distribution, to its use and finally its disposal, are considered as a single unit. This leads to a shift from the design of the product to the design of the product-system, the whole of the processes characterizing its life cycle. Waste is then analysed looking at the entire flow of a material/product, far beyond the limits of production.

The second criterion is to design referring to the function delivered by the product, more than the physical product itself (Mont 2002; Vezzoli 2003). In fact it is in relation to this function (functional unit) that it is possible to assess whether the environmental impact has been reduced and how. Function, a fundamental and historic theme in the culture and practice of design, acquires in this context a new meaning and a new vitality. Waste could then be considered as any resource that does not add value to the functional unit.

When discussing LCD it is useful to bear in mind some of the criteria and guidelines that can direct product development towards smaller environmental impact:

- material consumption reduction;
- energy consumption reduction;
- toxicity and harmfulness reduction;
- bio-compatibility and resources conservation;

- product life optimization (extension and use intensification);
- material life extension;
- design for disassembly.

The last two principles of sustainable design presenting a more direct linkage with the production process are further described in the next paragraphs.

A *product with a longer lifespan* than another (having the same function) generally determines smaller environmental impact. If a product lasts a shorter time it not only generates waste prematurely, but also determines further indirect impact owing to the need to replace it. Production and distribution of a new product to replace its function involves the consumption of new resources and the further generation of emissions. In general, with regard to a product in use, the extension of its lifespan does not determine a reduction in impact; it may even happen that continuing to use an old product causes an increase in impact. If, for the same service provided, technological development offers the opportunity to have new products with better environmental effectiveness (lower consumption of energy or materials or reductions in emissions), the time will come when the need to manufacture, distribute and dispose of a new product will be compensated for, in terms of balancing environmental impact, by improved performance in use.

However, the duration of products can be planned by increasing their reliability and facilitating updating, adaptability, maintenance, repairs, reuse and re-manufacturing. Actually we can optimize the lifespan of products from the environmental point of view by intensifying their use: a number of people using the same product (or component) at different times. A product used more intensely than others leads to a reduction in the quantity of product present at a given time or in a given place in order to meet a given demand for a function; i.e. it determines a reduction in environmental impact.

In the case of *extending the lifespan of materials* it means in practice a design that valorizes material from scrapped products, which rather than ending up in landfills, can be reprocessed to obtain new secondary raw materials, or incinerated (burned) to recover their energy content. We use the term ‘recycling’ when secondary raw materials are used to manufacture new industrial products. On the other hand, when secondary raw materials are made into compost, we speak of composting. In all these cases the environmental advantage is double:

1. In the first place we avoid the environmental impact of disposing of materials in landfills.
2. In the second place resources (not virgin) are made available for the production of materials or energy which avoid the impact from the removal and production of a corresponding quantity of materials and energy from virgin natural resources. The impact of these avoided processes can be considered an indirect environmental advantage.

Design for the extension of the lifespan of materials does not mean simply choosing materials with efficient recycling or combustion technologies. We must facilitate all the stages of recycling (or composting or incineration), and design to facilitate collection and transport after use, identify materials, minimize the number of incompatible materials, facilitate separation of incompatible materials and facilitate their cleaning.

Design for disassembly: facilitating disassembly means design that aids the separation of parts (for maintenance, repairs, updating or reuse) or incompatible materials (to be recycled or from which to recover energy content). This strategy is therefore helpful for both product life extension and use intensification and material life extension.

Sustainable design has clearly a more broad perspective on waste than lean production. It starts with questioning if we really need to produce a new product/system and such questioning is not part of the lean production scope. Lean production is all about reducing waste and increasing value but when it defines value it always assumes that at a given point it will be materialized into a product/system. On sustainable design the provision of value (function) does not necessarily imply an actual production as it was described earlier in this paper. However, the theory of sustainable design is not sufficient to achieve a waste reduction at the production level since by focusing on the product it overlooks the waste on flow, both on operations (flow of people/machines) and processes (flow of material/information). Therefore, both areas have to work together in order to accomplish comprehensive reduction/elimination of waste.

RESEARCH METHOD

Case study is the main research strategy adopted in this study. It revisits data from a previous study carried out by the main author during his PhD (Santos 1999). It adopted Koskela’s (2002) theoretical framework and focused on only four of the lean construction principles proposed by that author: reduction of cycle time, reduction of variability, increase of transparency and build of continuous improvements. The analysis from a sustainable design point of view focused on the issue of material life extension, looking for evidence of practices with that objective.

The analysis uses a process called pattern matching where the researcher looked for direct replications of the theoretical propositions as described by Santos *et al*. (2001). In this process, the empirical evidence was considered to be a ‘literal replication’ when observed results matched the theoretical predictions (e.g. a visual control that contributes to facilitate measurements). In contrast, when the case study produced contrasting results but for predictable reasons, it was called a ‘theoretical replication’ (e.g. excessive measurement associated with a lack of visual controls).

Information obtained through quantitative and qualitative techniques was used to substantiate the pattern matching. Boundary searching on the typical values of key quantitative indicators contributed to the assessment of the empirical evidence and such information is available in the PhD thesis of the main author (Santos 1999).

RESULTS AND ANALYSIS

Looking at waste from a lean construction point of view

The host construction company of this case study was large (> 500 employees) and had offices all over England. The company won the contract for the site under observation after winning a bid based on the lowest price for construction. Communication with client, design management, subcontractors and supply management was the responsibility of a project manager. An experienced construction manager was also responsible for the actual daily management of all construction works.

The construction site was located in the city centre of Bradford and had an area of approximately 15 acres. At one end of the site there was a 103 000 sq. ft office development under construction that would serve as a regional office for another large company. At the other end of the site there was a retail building (105 000 sq. ft) and car parking for 600 vehicles, also under construction.

The data collection on this site concentrated on the bricklaying operating in the retail building. At the start of the data collection most of the steel structure was practically completed and painting had just been commenced. The roof fixation was around one-quarter of the total roof area. External walls, DPC and the slab had just started construction. Externally, there were many simultaneous activities being carried out such as drainage, roads and the foundations for the car park.

This case study revealed only a few 'literal replications' of lean construction heuristics and none of them had a satisfactory level of integration. The following items illustrate the status of waste observed in this case study:

- *Overproduction*: the paradigm of mass production among construction managers and workers was present in this case study. The volumes of 'transfer batches' were large and bricklayers started bricklaying operations in more workplaces than they could operate. The end result was large amounts of work-in-progress throughout the sites. Construction managers did not seem to agree that the use of resources in their full capacity, producing more sub-products than necessary was a waste of resources. In fact, for them waste due to overproduction does not appear to exist in construction since the parts of a project have to be produced anyway.
- *Inventory*: the literature shows that a good observational criterion to understand flows (and waste) on site is the amount of inventory available on site. The researcher decided to use an indicator to measure the 'flow efficiency' by linking the average storage of blocks/bricks to the rate of productivity. Ideally, the rate of deliveries of bricks/blocks should be closely linked to the production rate of bricklaying and, in this way, there should be no intermediate storage. The case study revealed five cubic metres of brick storage per bricklayer/day in the two weeks of investigation (flow efficiency = 0.05). The practice of large 'delivery batches' was worsened by the manager's decision to concentrate the blocks in a single storage area. The construction was large and the use of a single site storage area meant the need for long transportation distances. Furthermore, the large amount of blocks on site reduced transparency regarding the control of volumes and the position of machines.
- *Repair/rejects*: this company undertook no activity to find and eliminate the root cause of process problems during the period observed. The only poka-yoke device identified was a safety mechanism attached to transporting equipment. This safety mechanism produced a sound that alerted every time the equipment moved backwards. However, it had little impact on the actual reduction of variability since it had no direct effect on the main process problems and had been imposed from outside the site manager's control. This case showed very few activities relating to continuous improvement, a fundamental principle of lean production. The only clear positive practice resembling such principle was the maintenance of the same management team across different projects. This practice made the communication process easier

and led to better problem solving throughout the project, according to the interviews.

- *Motion/transport*: the lack of planning and coordination of flow among workstations resulted in an increase in transportation distances. This was because there were too many fronts of work operating at the same time, and these were spread in a large area in comparison with the number of bricklayers available.
- *Processing*: the observed process resulted in brick walls quite different from the specified result. However, the processing activities presented some lean practices that helped to reduce the problem. Visual controls, for instance, allowed bricklayers to identify vertical positions of the brickwork courses extremely quickly and, also, enabled them to accomplish their operations with more accuracy. Nevertheless, there were no visual controls to guide workers on the layout planning and workstation flow throughout the whole construction site. In addition, there was only one information area for the entire site and even that was out of the workforce's normal pathway. This lack of information for the workplace contributed to the lack of awareness among workers regarding schedule deadlines and standard procedures.
- *Waiting*: the high volume of work-in-progress added further complexity, reducing synchronization between suppliers and the workstations. This situation contributed to an increase in the amount of time spent on non-value-adding activities.

Everyday observations on the site also revealed that this company relied heavily on the intensive use of modern equipment and materials as the means of guaranteeing their objectives with respect to cost, delivery, quality and flexibility. However, the actions of managers revealed little concern with the potential gain achievable through the elimination of non-value-adding activities from production. In this respect, there was severe scepticism among the managers on this site with respect to the early involvement of subcontractors and their employees in continuous improvement activities.

The short-term basis of the relationship with subcontractors and the bonus system itself were also often pointed out as the major barrier for improving practices. Indeed, the contracting system itself did not favour the establishment of long-term relationships between subcontractor and contractor, since low price was the main winning criterion in the bidding process. Thus, as long as the subcontractor finished the job on time, under the budget and to the specified quality, there were no efforts from the contractor to push the process performance towards even higher levels.

Looking at waste from a sustainable design point of view

The analysis of the design of components with a focus on the issue of 'material life extension' revealed various weakness of the bricklaying process within this construction site. The analysis looked for literal replications of the heuristics proposed by Manzini and Vezzoli (2004). The main findings regarding what the observed process requires to improve its performance on material life extension are presented below.

A need for adopting a cascade approach for recycling

- The brick wall did not allow arranging and facilitating of the recycling of components that went into it and that presented lower/different mechanical and aesthetical requirements (wood, steel and bricks).
- The production process did not arrange and facilitate energy material recovery (for instance: contaminated cardboard packaging).

A need for selecting materials with more efficient recycling technologies

- The bricklaying process uses composite materials with inefficient recycling technology.
- It did not use ribbed and similar structures to improve rigidity of components.
- Some components for windows and doors used thermo-resistant polymers instead of flame retardant.

A need to facilitate the collection and transportation of waste

- The technology did not minimize weight.
- The technology presented poor compressibility of disposed product.
- The brick wall did not provide the end-user with information about disposal treatments.

A need for a better system for material identification

- The components did not present any code system to display their category.
- The components did not provide additional information about the age, the number of already occurred recycles and the additives used.
- No information about toxic or dangerous materials was provided in the packaging or component surfaces.

A need to minimize the number of incompatible materials and/or facilitate the separation

- There was more than one material within the bricklaying components and there were no use solutions such as homogeneous materials in sandwiching structures.
- There was a lack of connection systems made of the same, homogeneous or compatible materials with the components to be joined.

A need to facilitate cleaning

- The production process and the characteristics of components did not avoid unnecessary superficial treatments and it was difficult to remove contaminants.
- The brick wall finishings did not avoid adhesives.
- There was no code on the brick wall to direct cleaning activities.

A need to facilitate composting

- The production technology did not avoid non-degradable materials.
- This construction site lacked a system to use degradable materials for reverse logistic packaging.
- There was no system on the construction site to facilitate the separation of non-degradable materials.

- There was no system to avoid non-combustion retardant materials or avoid materials toxic in combustion or avoid additives toxic in combustion.
- There was no system to facilitate the separation of non-combustible materials.

A bridge between lean construction and sustainable design

This case study has revealed clear connections between lean construction and sustainable design with regard to waste. The major difference lay in the width of the sustainable design approach when compared to lean construction. Sustainable design looks beyond the production stage, including all phases that compose the material life cycle. On the other hand, lean production has a more consolidated set of tools and principles that one cannot find within the sustainable design literature. Rephrasing our previous argument: perhaps the most profound implications of these two different views of waste is the fact that lean production always assumes that production is necessary while sustainable design starts with the question: is there any alternative to avoid production such as sharing buildings/equipments/components and moving towards product-service systems?

A review of the construction components design and the implementation of a system that facilitates the identification, collection and transportation of waste, for instance, had a direct effect on the amount of non-value-adding time observed on the case study. A system for material identification, for instance, affects positively the 'reduction of variability' and 'increase of process transparency' within the production process, key principles of lean production, avoiding costly mistakes and waste of time with the search for information.

The implementation of a lean principle such as 'building continuous improvement into the process' provides the foundation to enable more effectiveness of sustainable design practices such as the 'cascade approach' for recycling. Without the proper involvement and commitment of workers the waste of construction process may not follow the ideal route designed by the cascade approach. Continuous improvement is also necessary to bring the knowledge of workers to support the identification of areas where it is difficult to separate one material from another or it is difficult to clean up.

CONCLUSIONS

The combined use of lean production heuristics and sustainable design expands the opportunities of reducing waste within production systems. Lean construction looks at actions that could reduce or eliminate waste out of the construction site. Sustainable design, on the other hand, when dealing with the production stage, would start by looking for alternative ways to avoid the production activity.

While lean construction would look solely into wastes such as overproduction, inventory, repair/rejects, motion, transport, processing and waiting, sustainable design will look at other sources of waste throughout the entire life cycle of a given construction component. Sustainable design can contribute to lean construction with solutions that enable material consumption reduction, energy consumption reduction, toxicity and harmfulness reduction, bio-compatibility and resources conservation, product life optimization, material life extension and design for disassembly, all of them with direct implications on the reduction of waste within the construction industry.

There are a limited number of construction professionals with knowledge and competencies to operate across both fields of knowledge and such gap presents an opportunity for construction researchers and professionals. A small but growing number of industries that used to deal with the issue of waste solely from a production management point of view are now realizing that sustainability must be integrated with the expected competencies of production managers. The authors believe that construction companies have to realize the importance of such integration since there is an increasing demand for ‘green and lean’ construction sites.

CONSTRUCTION JOB SAFETY ANALYSIS IN SUPPORT OF LEAN PROJECT MANAGEMENT

Ophir Rozenfeld[1], Rafael Sacks,[1] Yehiel Rosenfeld[1] and Hadassa Baum[2]

[2]*National Building Research Institute, Technion – Israel Institute of Technology, Haifa, 32000, Israel*

Job Safety Analysis (JSA), which is also known as Job Hazard Analysis, is an efficient proactive measure for safety risk assessment used in industrial manufacturing settings. However, unlike the manufacturing settings for which JSA was developed, in construction sites the physical environment is constantly changing, workers move through the site in the course of their work, and workers are often endangered by activities performed by other teams. To address this difficulty, a method specialized for construction has been developed, called "Construction Job Safety Analysis" (CJSA). The CJSA method was developed within the framework of research toward a lean approach to safety management in construction, which required the ability to predict fluctuating risk levels in order to support safety conscious planning and pulling of safety management efforts to the times and places in which they can be most effective. The method involves identification of potential loss of control events for detailed stages of the sub-activities commonly performed in construction, and assessment of the probability of occurrence for each event identified. The method was applied to explore 14 primary construction activities. A survey was conducted through some 100 interviews with site managers and safety experts to reveal the likelihood of loss of control events that may lead to accidents. Detailed quantitative results were obtained for 699 such events. The most frequent events are those related to exterior work at heights.

Keywords: construction planning, health and safety, lean construction, risk identification.

INTRODUCTION

In almost every country in the world, the construction industry stands out among all other industries with disproportionate numbers of severe and fatal accidents (Ahmed *et al*. 2000; Findley *et al*. 2004; Gyi *et al*. 1999; Kartam and Bouz 1998; Shepherd *et al*. 2000; Stanton and Willenbrock 1990). Construction projects are dynamic (Bobick 2004) and involve many unique factors such as frequent work team rotations, exposure to weather conditions, high rates of unskilled workers, and more, that make managing construction site safety more difficult than managing safety in manufacturing plants. A construction site, unlike other production facilities that people work in, undergoes changes in topography, topology and work conditions over time throughout the duration of the construction project and, therefore, it requires a different safety management approach in order to identify risks, increase safety and prevent accidents.

Applying lean thinking (Womack and Jones 2003) to construction in this context leads to the hypothesis that, like production control itself, activities to enhance safety should

[1] ophirr@technion.ac.il

be pulled by current system needs rather than pushed uniformly onto workers and activities. The CHASTE (Construction Hazard Assessment with Spatial and Temporal Exposure) approach (Rosenfeld *et al*. 2006) has been developed to implement and test this hypothesis. The basic idea is that although construction projects as a whole are unique and dynamic, individual construction tasks and methods are fairly well-defined and expected. For example, pouring concrete using a crane on site is a common well-understood trade activity, but the level of risk associated with it can differ from one site to another. At one site, it may be performed at the end of the day when no other tasks are being performed, while at another it might be performed at the middle of the day when many other workers are located either on or below the element being cast.

By separating the potential for loss of control from the potential for presence of victims, it becomes possible to compute a time-dependent risk level forecast, using a database of probabilities of loss of control for standard work methods, coupled with site-specific computation of workers' exposure to the possible loss of control events. The result is a more accurate assessment of actual risks than is available using current methods, such as Preliminary Hazard Analysis (PHA) (Elzarka *et al*. 1995; Hansen 1993; Saurin *et al*. 2004). The predicted risk levels can be computed for various planning windows and used either to pull safety interventions or to change production plans, both of which enhance safety. Thus, management efforts to enhance safety can be less wasteful and more effective.

For many reasons, statistical approaches based on historic accident data are unsuitable for predicting risk levels in construction in order to compile the trade method risk database. Numerous factors affect safety, directly and indirectly, producing very large combinatorial numbers of possible accident events. The number of documented accidents is many orders of magnitude smaller than the number of possible accident events. For every serious construction accident, there are multiple actual dangerous events that end with no injury (Lyachin 2004). Hence, and in addition to the fact that most accidents that result in less than ten days of absence are rarely reported, the aggregated statistics-based approach is not a suitable forecast tool for the prediction of loss-of-control events at any particular place during a particular time frame.

To overcome this problem, a different conceptual approach is required. The risk level is divided into four parameters: the probability of a loss of control event occurring, the exposure of potential victims in time and in space, and the likely severity level of an accident (which is also dependent on the use of personal safety equipment). To do this, knowledge of construction activity types is needed, including the nature and probability of loss of control events, the impact of environmental intensifying factors, the use of protective equipment, and the potential severity of accident events. Each of these must be compiled in a knowledge base in a form that can be used by the CHASTE method software to compute risk levels for specific construction projects. The following sections describe the method devised to collect this information and provide examples of the results of its application in the Israeli construction industry.

METHODOLOGY

CJSA – Construction Job Safety Analysis

Job Safety Analysis (JSA, also known as Job Hazard Analysis (JHA) is a practical method for identifying, evaluating and controlling risks in industrial procedures. The process of JSA includes three main stages (Chao and Henshaw 2002):

1. Identification – choosing a specific job or activity and breaking it down into a sequence of stages, and then, identifying all possible loss of control incident that may occur during the work.
2. Assessment – evaluating the relative level of risk for all the identified incidents.
3. Action – controlling the risk by taking sufficient measures to reduce or eliminate it.

For determining a priority order of treatment, the level of each incident risk is evaluated by assessing the incident's probability of occurrence and its most expected outcome (the level of injury). Those two measures place the risk in a standard scale from most negligible to the most severe.

The JSA method has proven to be efficient for planning the safest way to perform any task (Holt 2001). However, in its current form, it is impractical for the construction industry. Unlike other industries, construction projects are highly dynamic, the production environment changes in time and place, and work crews change frequently. Moreover, construction products are unique, and most of the time performed as a prototype; standardized procedures that may be considered safe in one project may be hazardous in the environment of a different project. Another drawback of the traditional JSA is that in construction, workers commonly endanger other workers, who may be performing a different activity at a different location. The regular JSA is not designed to reveal these dangers since it focuses on production activities in isolation, at predetermined workstations.

For these reasons, a different approach is needed for construction. This research proposes an improved technique, called Construction Job Safety Analysis (CJSA), in which the job analysis is performed independently of any specific consideration of time and place. This is achieved by separating the loss of control that precedes any accident from the potential presence of a victim in the path of harm. Loss of control events are assessed in the CJSA, which is generic across any local construction industry, while exposure of victims in time and space is assessed for specific construction projects (for details, see Sacks *et al*. 2007).

The CJSA method generates a large knowledge-base describing all possible loss of control events in construction; the database is then used by the CHASTE software system (Sacks *et al*. 2007) to compute the predicted risk levels for the activities of specific projects, using their physical layout and their planned schedule.

CJSA step 1 – identification

In the first step of the CJSA method, standard construction methods are identified and detailed. The procedure for each method consists of:

1. Breaking the activity down into sub activities and determining their expected start and finish times relative to the timeline for the whole activity as it would be represented in a construction plan. These times are expressed in percentage terms, but may extend below 0% and above 100% where preparation or clean-up actions are needed that are generally not scheduled explicitly.
2. Breaking the sub activities down into work stages and determining their location type, crew composition and the total time proportion of each stage within each sub activity. The time proportions need not represent continuous execution of the stage, nor need they be exclusive at any given time.

3. Identifying all possible loss of control events during each work stage and determining their zones of influence and type.

Unlike in fixed plants, in construction, a hazard will often endanger workers other than those performing the task. Therefore, information concerning the most likely timing and location of each worker during each activity must be collected. The logical relationship between the location in which an activity is performed to other locations where victims may be present (such as 'adjacent', 'below', 'above'), are also needed. Figure 1 illustrates the hierarchic structure of an activity analysis.

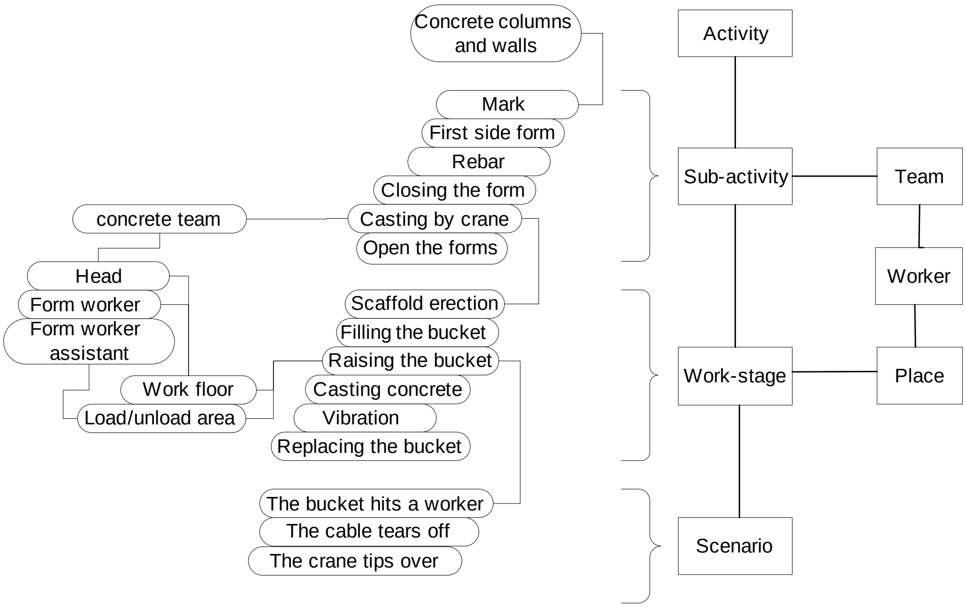

Figure 1: Information items defined in the knowledge base, relationships and examples

Step 2 – Assessment

The second step of the CJSA seeks to determine the following information about the activities that were detailed in the first step, all of which is essential for the functioning of the CHASTE model:

1. The expected rate of occurrence for each possible loss of control event as defined in the CJSA.
2. The degree of influence of the different managerial and environmental factors that affect the expected rates of occurrence.
3. The expected degree of use of personal safety equipment.

The information is collected by means of a survey, conducted through face-to-face interviews with construction superintendents. The survey instrument is a set of structured questionnaires that are produced automatically from the database of activities, sub-activities, stages, typical loss of control events, and their associated data, compiled in the previous CJSA step.

The survey is conducted among construction superintendents because they are the most appropriate source for practical information about potential loss of control events. Firstly, due to their key role in the practical execution of the work, they, more than anybody else, are aware of the overall circumstances on site: the composition of activities on site and their nature, the types of activities, the number of workers involved, equipment in use, organizational conditions, etc. Secondly, they are formally responsible for all safety issues on site and are involved in the investigations that follow any incidents, whether accidents or near misses.

Every respondent is asked to assess the frequency of all loss of control event occurrences during that single activity from the questionnaires with which they are most familiar. Each respondent is asked to provide both a numeric and a linguistic estimate of the likelihood of each of the set of loss of control events for the construction activity about which they are interviewed. The numeric response consists of two values: a number and the appropriate unit of time (for example, three times a month, once a year, twice a week, etc.). The linguistic response offers a scale from 1 to 5, where: 1 - has never occurred in my experience but is technically possible, 2 - occurs rarely, 3 - occurs seldom, 4 - occurs frequently, and 5 - occurs daily.

For each work stage, they are also asked to state the size of an average team and the influence of four intensifying factors on the occurrence rates. The team size is needed because each interviewee implicitly assesses the likelihood of occurrence for a specific team size he or she has in mind; the value assumed is essential in order to normalize the results across the survey and for later application to projects in which work teams may be of different sizes.

There are many factors that affect the safety level directly and indirectly, and they vary from one site to another. They include the record of safety training on the job-site, the company's safety culture, use of safety equipment, conditions of the work environment, weather, workers' experience, work-load pressure, the construction activity method and equipment, and more. Many researchers have tested the influence of specific factors, or groups of factors, on the rate of the accident occurrence (Hide *et al*. 2003; Hinze and Raboud 1988).

The final aspect tested for in the CJSA is the expected degree of use of personal safety equipment, including helmets, appropriate working shoes, gloves, safety harnesses and safety goggles during each particular activity.. This information is needed for the CHASTE model, because the model assumes that the degree of severity of injury resulting from any possible accident will be distributed differently depending on the victim's use of personal safety equipment. The expected severity outcome for any event is the weighted average of the two severity distributions that result when safety equipment is used and when it is not used.

TRIAL IMPLEMENTATION

Step 1 – identification

In the CJSA application for the CHASTE research project, the knowledge was elicited in a series of workshops with safety experts and senior site managers, who are legally responsible for site-safety. Each expert was asked to analyse a single construction activity according to his or her experience. For practical reasons, the research focused on just 14 common construction activities from all phases of a typical multi story building project. The activities were chosen and presented to experienced site managers and safety experts during the workshops. They were asked to analyse them as generally as possible, i.e. by trying to reflect the general construction industry rather than any single project or site.

The results of the workshop are summarized in Table 1. The electrical, plumbing and HVAC instillations are performed during all the project stages, and therefore, they were not considered as activities but scattered as sub-activities among other main activities. Finally, after sorting, filtering and dismissing repetitive data, 699 different possible loss of control events were defined for the 14 construction activities.

Sorting all the possible event events according to event type (Table 2) shows that the most common event types identified by the experts were "Fall from height", "Collision", and "Objects falling to the ground".

Table 1: Activity analysis summary (Rosenfeld *et al*. 2006)

Activity analysis summary				
Number of loss-of-control events	**Number of stages**	**Interviewee specialization**	**Activity**	
57	23	Superintendent	Piling	Foundations
85	22	Superintendent	Concrete slabs	Structural activities
74	28	Superintendent Safety inspector	Cast-in-place concrete columns and walls	
59	23	Superintendent	Erecting precast slabs	
57	23	Superintendent	Erecting precast walls	
67	24	Superintendent	Forming walls with stone cladding	
33	12	Superintendent	Brick masonry	Finishing activities
32	14	Superintendent Stone contractor	Stone cladding	
62	27	Superintendent	Exterior plastering	
25	14	Finishing foreman	Gypsum boards	
19	12	Finishing foreman	Floor tiling	
47	17	Sealing contractor	Roof sealing	
46	11	Glazing contractor	Glazing	
75	23	Electrical engineer	Electrical installation*	
57	29	Plumbing engineer	Plumbing*	
80	46	A.C. engineer	HVAC installation*	
875	**348**		**Total:**	

*Activities that are interlaced within other activities.

Table 2: Number of events according to event type

Number of appearances	**Event type**
186	Fall from height
102	Collision
52	Falling object towards ground
42	Falling object from crane
39	Collapse
35	Falling object inside work platform
31	Run over
31	Trapped
28	Crane collapse
28	Collision with transported material
25	Splashing material
22	Electrocution
20	Slipping
19	Falling object - self impact
14	Mechanical equipment collapse
13	Burn and toxic inhalation
12	Floor collapse
699	Total

Step 2 – assessment

In the CJSA implementation for the CHASTE research project, the population for the survey consisted of 91 senior superintendents from 45 construction companies. The majority were interviewed in depth about a single construction activity type. A small number of them were interviewed twice, because they were familiar with more than one activity type; a total of 101 interviews were conducted. The questionnaires collected were filtered by comparing the separate linguistic and numeric responses of each interviewee to the same questions, and by examining whether the responses were logical and complete. Of the 101 interviews, 14 were rejected, leaving 87 valid complete questionnaires.

The respondents' average period of construction experience was 21.8 years. In terms of company size, 44% were employed in small firms (up to 50 employees), 21% in medium-sized firms (51 to 100 employees), 5% in big firms (101 to 200 employees), and 30% worked for very large firms (over 201 employees). A total of 7% of the respondents were working on small projects (up to 1,500m^2), 61% on medium-sized projects (1,500 to 7,500m^2), 21% on medium-large projects (7,500 to 15,000m^2), and 11% worked on large projects (over 15,000m^2).

Likelihood of loss-of-control event occurrences

Average values for likelihood of occurrence for all loss of control events were summarized in measures of number of events per year of work per person, i.e. the expected number of times a single event might occur if a single worker performs a single task for a time period of one year. Table 3 lists five events out of the total 699 events that could arise from the 14 construction activities covered in the survey, ranging from the most frequent and to the most infrequent.

The recorded knowledge from the expert workshops included data about the proportional duration of every work stage for each sub-activity. The start and finish times of the sub- activities are available from the activity schedule of any construction project, and so the duration of each work stage can be determined. Multiplying the duration of any stage by the average event frequency and the number of workers in the work group gives the number of event occurrences expected for the stage, during any given period of activity.

Table 3: Five examples of event likelihood including the most frequent and infrequent loss-of-control events

Activity	Sub-activity	Stage	Event	Average likelihood (occurrences per worker per year)
Cast-in-place concrete walls with stone cladding	Pouring concrete using a crane bucket	Filling bucket	Concrete spatter	168.0
Cast lightweight concrete for drainage	Casting the concrete	Transporting concrete	Dropping an object	91.3
Gypsum boards	Erecting the framing	Attaching studs to exterior walls	Hit by ricochet	56.4
Exterior plastering	Manually applying an insulating layer	Curing	Hit by a tool	1.25
Concrete columns and walls	Casting concrete with a crane	Lifting a bucket full of concrete	Crane collapse	0.01

To compare the results of the survey between different activities and types of events, the likelihood of events was estimated for all loss of control events and for all of the 14 activities as if they were carried out continuously for one year. The expected number of events for each activity is shown in Figure 2. The most hazardous activity in terms of expected number of event occurrences is the application of exterior plastering, with 704 expected event occurrences for a single worker over a year (this is equivalent to a single plasterer causing an average of two loss of control events a day) which mostly result from the most commonly expected event type, that is 'dropping an object to ground level'. This event type is very common when working on an open scaffold and generated mostly during 'Exterior plastering' and 'Stone cladding' activities. As can be seen, activities with high levels of occurrence are those performed outside and at height, whilst activities performed indoors have relatively low levels of occurrence. The least frequent event type is 'floor collapse', which according to the interviewees is expected to occur once in ten years of continuous work. Although it is very rare, the expected outcome of this event is disastrous and therefore, it is a significant risk.

Intensifying factors
Implementation of the CJSA assessment step included examination of factors affecting the expected likelihood of occurrence of loss of control events. The respondents were asked to assess, based on their past experience, how the likelihood of lost of control events occurrence would be increased during each work stage of the entire activity, in the presence of the intensifying factors identified in the first step.

The influence of four intensifying factors on various activities was explored in the Israeli construction industry. The results are shown in Figure 3. The most significant intensifying factor was found to be a "worker's first day on site", followed by "crowding in work areas", "schedule delays" and "short notice before work" was to be performed. Interestingly, the management related factors were found to be more significant than the environmental factors.

CONCLUSIONS

The CHASTE approach represents a progressive way to evaluate risks in construction, which tries to confront the difficulties and uniquely hazardous nature of the construction industry. The associated CJSA method provides a mechanism for collecting the extensive knowledge of the likelihood of loss of control events in construction that is needed for implementation of the CHASTE method. The CJSA method is loosely based on the standard JSA approach to safety planning in manufacturing; it covers the first two stages of traditional JSA (identification and assessment), but does not extend to the ‘action’ stage.

The CJSA method described was implemented for the construction activities and methods typical of the Israeli construction industry, and a comprehensive analysis was conducted of its results. A number of lessons were learned from its implementation:

- The method is tractable, despite the large number of individual loss of control events that must be explored. Each interviewee was able to respond to up to 85 events within two hours.

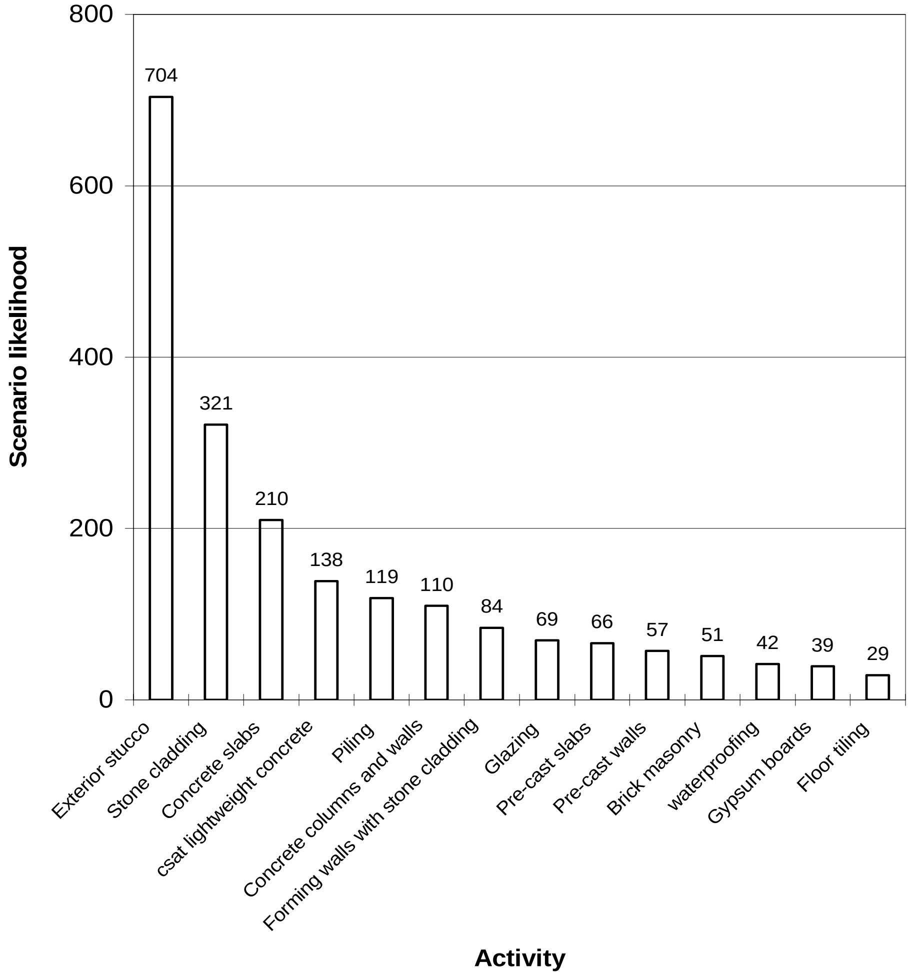

Figure 2: Number of event occurrences during a year of work according to activity type

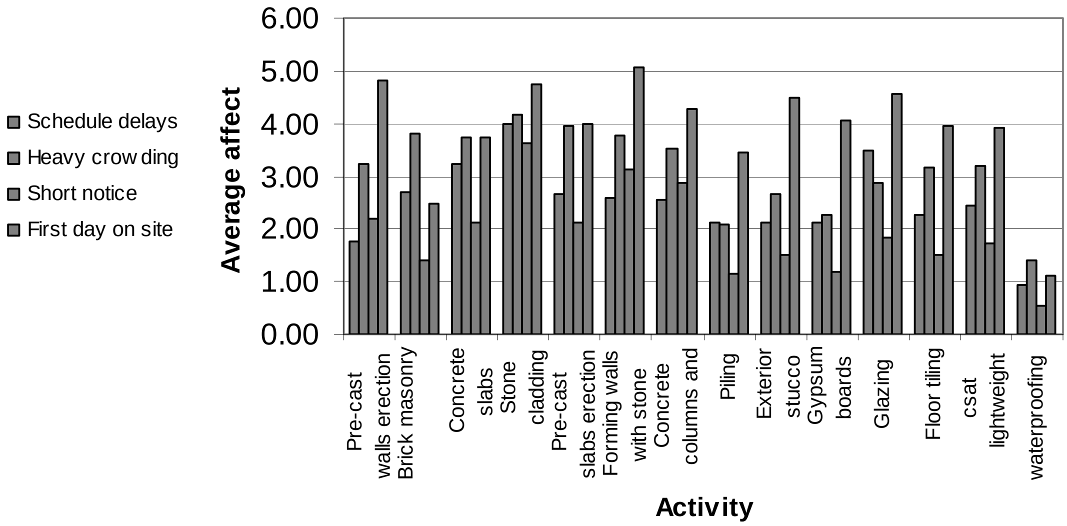

Figure 3: Average influence of intensifying factors on activity

- The need to obtain measures of likelihood of loss of control events, rather than of accident occurrence, meant that the interviewers had to explain the principle to each interviewee thoroughly in order to avoid responses based on misconceptions.

The major contribution of the CJSA method is that relative quantitative measures for each event are obtained. This information is essential to implementation of the CHASTE approach. Not surprisingly, the activities with the highest likelihoods of loss of control events were those performed outdoors and at height.

Research on the CHASTE approach is continuing with development of a computer application to predict risk levels for different work teams on sites as construction progresses. The approach as a whole will be tested on two projects. The focus will be on establishing effective ways of reporting the risk levels to site superintendents and managers, and on determining how they can use the predictions generated to pull safety management activities appropriately to where they are needed, or to change construction plans and schedules to avoid peak risk levels.

ACKNOWLEDGEMENT

This research was funded in part by the Ministry of Industry, Trade and Occupation under grant No. 2005902. The authors are also grateful to the Israeli Society for Occupational Safety and Health for their participation in the CJSA survey.

PREVAILING WAGE LAWS, PRODUCTIVITY AND CONSTRUCTION EFFICIENCY

Kevin Duncan,[1] Peter Philips[2] and Mark Prus[3]

Stochastic frontier regression is used to conduct a direct test of prevailing wage legislation on school construction efficiency. The efficiency of projects covered by the introductory stage of British Columbia's construction wage legislation, relative to the best-practice production frontier, was 9% lower than other, uncovered, projects. However, by the time of the expansion of the policy 17 months later, the efficiency of covered projects increased by 32%. These findings suggest that the introduction of prevailing wage laws disrupted construction efficiency. However, in a relatively short period of time, the construction industry adjusted to wage requirements by increasing overall efficiency.

Keywords: building regulation, productivity, econometrics.

INTRODUCTION

Prevailing wage laws require contractors of covered public projects to pay construction workers what some observers call 'super minimum wages'. This paper examines the impact of this legislation on the efficiency of construction. Others cite country-specific examples of construction industry adjustments to general increases in wages that include the increased use of industrial methods in construction, the substitution of skilled for unskilled labour and the substitution of capital for all grades of construction labour (see Risager 1993; Tan 1996; Warszawski 1990). However, these studies do not report an estimate of the total effect of these changes on the efficiency of construction, nor do they address the impact of legislated wage changes. These issues are relevant because they provide insight into the debate regarding the cost impact of prevailing wage laws. For example, Dunn *et al*. (2005) estimate that prevailing wage requirements increase the cost of covered housing projects from 9% to 38%. This finding is consistent with the view that prevailing wages are associated with less efficient, more costly construction. However, Duncan and Prus (2005) fail to find a statistically significant prevailing wage cost effect. This result implies substantial productivity changes that offset the cost implications of prevailing wages.

Elsewhere we have examined the impact of prevailing wage regulations on efficiency through an examination of construction output (see Duncan *et al*. 2006). We find that prior to the introduction of prevailing wage requirements, publicly funded school projects were from 16–19% smaller, in terms of project square feet, than comparable privately funded projects. This size differential did not change after the introduction of the wage policy. This finding suggests that wage requirements did not alter input

[1] kevin.duncan@colostate-pueblo.edu

utilization in a way that significantly affected the technical efficiency of construction, when efficiency is viewed as the ability to produce surface area. In this follow-up to our previous research, we conduct a different, more direct test of the impact of prevailing wage regulations on the efficiency of construction. Our previous analysis used stochastic frontier regression to estimate construction output, project square feet, as a function of the total input bill (bid price) and wage policy variables. In the present study, we use another variant of stochastic frontier regression to obtain project-specific measures of technical inefficiency or deviations from the best-practice production frontier. We then test if deviations from the production frontier are systematically related to the prevailing wage policy. In a sense, this is a more direct test of prevailing wages on construction efficiency since we examine the impact on measures of inefficiency instead of project size. Specifically, we use the inefficiency measures to examine the effect of British Columbia's Skills Development and Fair Wage Policy (hereinafter, SDFW) on the productive inefficiency of covered projects, relative to projects that were unaffected by the policy. Since the SDFW was introduced in two stages over time, our data allow us to examine the initial impact of the policy on technical inefficiency, as well as the impact after contractors have acquired experience with wage requirements.

THE SKILLS DEVELOPMENT AND FAIR WAGE POLICY

The Province of British Columbia introduced the first stage of the SDFW on 30 March 1992. Initially, the policy applied to building construction, with a value of at least CA$1.5 million that was funded by the Province. The second stage of the policy was introduced on 20 August 1993 with the value threshold reduced to CA$250,000 and coverage extended to other provincially funded projects (roads, dams, etc.). The skills development aspect of the policy sought to increase apprenticeship participation by requiring certified trades persons to supervise apprentices on covered projects. The policy also established the Schedule for Fair Wage Minimum Hourly Rates for construction workers employed on projects covered by either stage of the SDFW. This schedule ranged from 82% to 94%, but typically 88%, of the corresponding building trade union rate for specific construction occupations (see Globerman *et al*. 1993). Consequently, fair wage rates only applied to non-union contractors since union rates exceeded the minimums. We use the method developed by Thieblot (1995) to compare the strength of the SDFW to state-level prevailing wage legislation in the US. Based on a 2–17-point scale, the SDFW has a point total of 13. This compares to a weighted state average of 9.77. This indicates that the SDFW was above average in terms of strength, compared to legislation in the US.

DATA AND MODEL

School construction data were obtained from Canadata, an organization that collects and disseminates detailed data on the Canadian construction industry. Our sub-sample consists of 438 public K-12 school projects built between 1989 and 1995 and is used to test the impact of both stages of the SDFW on construction inefficiency.

We use stochastic frontier regression to estimate the best-practice construction frontier in our sample and to obtain the observation-specific measures of technical inefficiency. Stochastic frontier regression involves the estimation of a production function with an error term consisting of two components (see Aigner *et al*. 1977). The first component (v) is the standard, two-sided, random component with mean zero and variance σ_v^2. The second component (u) is a one-sided, non-negative, random variable with variance σ_u^2 that is assumed to be greater than zero. The value of *u*, ranging from 0 to 1.0, represents the observed level of inefficiency for a producer relative to the best-practice production frontier derived from the sample. Therefore, *u* measures the deviation of observed output from the production frontier. Like v, a value of *u* is estimated for each observation in the sample. The usual independence assumptions apply to each of the error components. Each is assumed to be independent of the other and of the independent variables in the equation. There is no theoretical rationale for the particular distribution of *u*. The results reported below are based on a truncated normal distribution. To avoid violating these error term independence assumptions, we use the FRONTIER 4.1 program described by Coelli (1996) to estimate the single-stage stochastic frontier and inefficiency models described below.

Stochastic Frontier Model:

$Ln\ Project\ Square\ Feet = \beta_0 + \beta_1\ Ln\ Real\ Bid\ Price + \beta_2\ X + (v - u)$

Inefficiency Model:

$u = \ast_0 + \ast_1\ SDFW_{92}\ Project + \ast_2\ SDFW_{93}\ Project$

where *Ln Project Square Feet* (in the Stochastic Frontier Model) is the natural log of a project's number of square feet and is our measure of construction output. *Ln Real Bid Price* is the log of a project's bid price and is our measure of inputs used in construction. We use the Non-Residential Building Cost Price Index available from Statistics Canada to adjust bid prices for inflation. *X* is a vector of project characteristics that are related to construction output. This vector includes the log of the number of stories above ground, a distinction between new construction and additions, where the project was located, and the time of year, and year, the project started. The error terms are *v* and *u*, as described above.

In the inefficiency model, *u*, the measure of construction inefficiency, is the dependent variable. As mentioned above, *u* may range from 0 to 1.0. $SDFW_{92}$ *Project* is equal to one if the public school was built during the first stage of the SDFW (between 30 March 1992 and 19 August 1993, with a value greater than CA$1.5 million), else zero. $SDFW_{93}$ *Project* is equal to one if the public school project was built during the second stage of the policy (after 19 August 1993 with a value greater than CA$250,000), else zero. The coefficients for $SDFW_{92}$ *Project* and $SDFW_{93}$ *Project* ($\ast_2$ and $\ast_3$) measure the inefficiency differential between projects covered, and not covered, by the SDFW. Negative estimates of $\ast_2$ or $\ast_3$ indicate that, after the introduction of the particular SDFW policy stage, covered public school projects were relatively less inefficient (more efficient) than projects not affected by this stage of the policy. Positive values for these coefficients indicate relatively higher inefficiency for covered projects. We have described above the possible positive and negative impacts of the SDFW on technical efficiency and construction costs. Given the bone of contention between these two possibilities, and the strong a priori expectations, two one-tailed tests are preferred to a single two-tailed test for these coefficients.

EMPIRICAL RESULTS

Summary statistics for all public school projects and those covered by each stage of the SDFW are reported in Table 1. Our sample consists of 438 public school construction projects. The nominal bid prices for these projects range from CA$58,700 to CA$31.1 million. Since this range falls below the value thresholds of either stage of the SDFW, our sample contains public projects that were not covered by the policy because they did not meet the value threshold, or because they were built prior to the fair wage regulations. The sample contains 243 projects that were not covered by the SDFW. Seventy-four of the projects were covered by the first stage of the policy (if $SDFW_{92}$ *Project* equals 1). A total of 121 were covered by the second stage (if $SDFW_{93}$ *Project* equals 1).

Source: Canadata, 1989 to 1995. Standard deviations in parentheses (deviations for dummy variables are the standard deviations of the sample proportion). Conversions for square feet, square metres, Canadian dollars and number of stories in brackets. [a]The mean for $SDFW_t$ Projects is different at the 0.05 level from the comparable mean for All Public Schools.

The averages indicate that only projects covered by the 1992 provisions of the SDFW are larger, more expensive and have more storeys when compared to the overall sample of school projects. These differences for the 1992 projects are significant at the 0.05 level. Projects covered by either stage of the policy are less likely to be built in Vancouver and to be additions. Projects covered by the 1993 provisions are less likely to be started during the high precipitation months of December through March. These differences are statistically significant at the 0.05 level.

Since our primary interest involves the effect of fair wage requirements on construction efficiency, we focus first on the results of the inefficiency model. These results are reported in Table 2 under 'Inefficiency Estimates' (columns 3 and 4). The coefficient for $SDFW_{92}$ *Project* is positive and significant at the 0.10 level (for a one-tailed test). This finding indicates that the construction of the 74 public projects covered by the first stage of the SDFW (from 30 March 1992 to 19 August 1993) was relatively less efficient, by about 9 percentage points, than other public school projects. This result indicates a disruption in technical efficiency with the introduction of the policy. The coefficient for $SDFW_{93}$ *Project* is negative suggesting that the projects covered by the second stage of the SDFW (from 20 August 1993 to the end of our data in 1995) were characterized by lower inefficiency. The difference between these projects and those that are not covered by this stage of the SDFW is statistically significant at the 0.03 level, for a one-tailed test, and at the 0.06 level, for a two-tailed test. Additionally, this coefficient is relatively large indicating a 31.8 percentage point efficiency advantage for projects covered by the second stage of the SDFW. Considered together, the results for *$SDFW_{92}$ Project* and *$SDFW_{93}$ Project* suggest that the introduction of the SDFW in March of 1992 was associated with a decrease in construction efficiency. However, by the time of the expansion of the policy 17 months later, the construction industry had adjusted to wage requirements by increasing efficiency.

We briefly discuss the results of the maximum likelihood estimate of school construction output (Stochastic Frontier Model) that are reported under columns 1 and 2 in Table 2. The coefficient for *Ln Real Bid Price* is statistically significant, but less than one indicating decreasing returns to scale in school construction. The coefficient for *Ln Stories* confirms the efficiency of multi-storied buildings that add to size, without requiring additional foundation work, holding expenditures constant. Schools built in Vancouver are approximately 10% larger, holding project expenditure constant. This statistically significant difference for projects located in the capital city may be due to greater access to input markets and more developed infrastructure. The sign of the coefficient for Wet Season suggests that projects started during high precipitation months (December through March) are smaller for a given expenditure. However, this effect is not statistically significant. Additions, which involve work around existing structures, are associated with fewer square feet, holding expenditures constant. This difference is statistically significant at the 0.01 level. The sign of the coefficient for Year suggests that projects decrease in size by approximately 3% with the passage of each year. The difference is statistically different at the 0.01 level. This finding may be an artefact of the recession in the construction industry during the early 1990s. As the industry recovered, as input prices increased, project sizes would diminish for a given expenditure.

A likelihood ratio test of the one-sided residuals indicates that the maximum likelihood model is a significant improvement (at the 0.05 level) over an OLS estimate (the critical value is 8.761). Variance parameters reported in Table 3 indicate that sigma-squared (σ^2), the sum of the variances of the two error terms (or, $\sigma^2 = \sigma^2_v + \sigma^2_u$), equals 0.097. Gamma is the proportion of the total variance in the model that is attributed to the inefficiency effects (or, (= [$\sigma^2_u /(\sigma^2)$]). This parameter indicates that 1.0% of the total variance is explained by the inefficiency effects. This implies that the random effects (v) are more important in explaining the total variance of the model than are the inefficiency effects (u). This suggests substantial variation in the production frontier across school construction projects, but relatively little variation of observed output beneath the frontier. The average level of technical efficiency for all school projects included in the sample is 94.6%.

CONCLUSION

Our examination of the impact of prevailing wage legislation on construction inefficiency reveals that the introduction of the fair wage policy in British Columbia was associated with a statistically significant decrease in the technical efficiency of covered public school projects. However, by the time of the expansion of the policy 17 months later, the technical efficiency of covered projects was substantially higher than other public school projects. The short-lived efficiency decrease, followed by a sharp increase in productivity, may explain our previous finding of an absence in the change in the relative size of private and public school projects with the introduction of the SDFW (see Duncan *et al*. 2006). During the period of reduced efficiency associated with the introduction of the policy, competitive pressures may have prevented contractors from altering project size (for a given expenditure) until adjustments were made. These adjustments may have been relatively easy given that labour costs for primary contractors in 1998 were approximately 18% of total costs, 38% of total cost if subcontract work is deleted (see CANSIM). With the subsequent increase in productivity, there were no longer any pressures to adjust the relative size of public projects. This pattern may also explain why others have failed to find a statistically significant impact of the SDFW on the cost of British Columbian school construction projects (see Bilginsoy and Philips 2000).

PERT VERSUS MONTE CARLO SIMULATION IN LOW RISK PROJECTS

K. Kirytopoulos[1], V. Leopoulos[2] and V. Diamantas[3]

Department of Financial and Management Engineering, University of the Aegean, 31 Fostini St, 82100 Chios, Greece
Sector of Industrial Management and Operational Research, Department of Mechanical Engineering National Technical University of Athens, 9 Iroon Polytexneiou St, 15780 Zografou, Greece

Project time management has been a major issue since the construction industry began. It includes activity definition, activity sequencing, activity duration estimating and schedule development. Schedule development techniques include the critical path method (CPM), Program Evaluation and Review Technique (PERT), and simulation methods such as Monte Carlo simulation (MCS). During this research the results of PERT, for 21 construction projects, were compared with those of standard MCS. The aim was to investigate whether the differences in the results produced by the two techniques are important and whether, in low risk projects, it is worth investing time and resources to perform MCS. The findings reveal that the produced differences will probably not change a project manager's decision. The construction projects under review were undertaken by small or medium size contractors. In this context, the project team usually cannot define the right distributions to model the duration of the activities involved, owing to lack of experience, time, resources and historical information. Typically, the use of MCS instead of PERT is more efficient and provides more precise results. However, small and medium size contractors that mainly deal with small and medium size projects with low risk may continue using PERT, if MCS cannot be their choice.

Keywords: construction planning, estimating, project management, risk analysis, simulation.

INTRODUCTION

Project risk has been defined as 'an uncertain event or condition that, if it occurs, has a positive or a negative effect on at least one project objective, such as time, cost, scope, or quality. A risk may have one or more causes and, if it occurs, one or more impacts' (PMI 2004). This paper focuses on the first of these four objectives, time, and provides a comparative study, in order to come up with conclusions concerning the available techniques for activity duration estimating and schedule development.

The core problem of project time management is about activity definition, activity sequencing, activity resource estimating, activity duration estimating, schedule development and schedule control. The outcome of project time management is a project schedule that includes start and finish dates of each activity. The project is unlikely to finish on schedule if either the duration of activities or the definition of dependencies is not realistic (Diamantas *et al*. 2006).

[2] vleo@central.ntua.gr
[3] vdiamant@mail.ntua.gr

The most commonly used techniques for activity duration estimating are the expert judgement, the analogous estimating and the three-point estimates. Furthermore, the most commonly used techniques for schedule development are the critical path method – CPM (Maylor 2003), the Program Evaluation and Review Technique – PERT (Malcolm *et al*. 1959) and simulation methods such as Monte Carlo simulation – MCS (van Slyke 1963).

CPM is a mathematically based algorithm for scheduling a set of project activities. It was developed in the 1950s in a joint venture between DuPont Corporation and Remington Rand Corporation for managing plant maintenance projects (Maylor 2003). Today, it is commonly used with all forms of projects, including construction, software development, research projects, engineering and plant maintenance, among others. It can be applied for the scheduling of any project with interdependent activities.

PERT is a well-known method with proven value in managing complex projects. It was developed in 1958 by the US Navy Special Projects Office as part of the Polaris mobile submarine launched ballistic missile project (Malcolm *et al*. 1959). The development of PERT was based on the assumption that the duration of any activity within a project can be adequately modelled by the beta distribution. Initially, the mean and the variance of the duration, for each activity i, were estimated as:

$$\mu_i = \frac{1}{6} \cdot \left(a_i + 4 \cdot m_i + b_i\right) \tag{1}$$

$$\sigma_i^2 = \frac{1}{36} \cdot \left(b_i - a_i\right)^2 \tag{2}$$

where a, m and b are the optimistic, most likely and pessimistic durations of activity i. Based on the central limit theorem, the distribution describing project duration is approximately normal, with the mean value of the project duration equal to the sum of the means of the critical activities. The variance of the project duration is the sum of the variances of the same critical activities.

A limitation of PERT is that since it is limited by the constraints of the central limit theorem it is obligatory to model the duration of every activity of a project with the same statistical distribution, while the statistical distributions of all the tasks are assumed to be independent. Additionally, it ignores all ‘sub-critical’ paths, taking into account a unique critical path calculated on the basis of expected activity durations (Pagnoni 1990).

Another important issue regarding PERT is the accuracy of the utilized estimators. Keefer and Verdini (1993) presented a numerical comparison of estimation methods, arguing that the use of the original PERT estimators can lead to large errors in project duration estimating, comparable in magnitude to those ones deriving from assuming a single critical path, when the longest path cannot be predetermined with certainty. They concluded that the Extended Pearson–Tukey (Pearson and Tukey 1965) estimators as well as the Extended Swanson–Megill (Megill 1977) estimators offer substantial advantages over the original PERT estimators.

Extended Pearson–Tukey:

$$\mu = 0.630x(0.50) + 0.185\left[x(0.05) + x(0.95)\right]$$
$$\sigma^2 = 0.630\left[x(0.50) - \mu\right]^2 + 0.185\left(\left[x(0.05) - \mu\right]^2 + \left[x(0.95) - \mu\right]^2\right)$$

Extended Swanson–Megill:

$$\mu = 0.400x(0.50) + 0.300\left[x(0.10) + x(0.90)\right]$$
$$\sigma^2 = 0.400\left[x(0.50) - \mu\right]^2 + 0.300\left(\left[x(0.10) - \mu\right]^2 + \left[x(0.90) - \mu\right]^2\right)$$

The *x*(0.05), *x*(0.10), *x*(0.50), *x*(0.90) and *x*(0.95) values in the Extended Pearson–Tukey and Extended Swanson–Megill formulas correspond to the durations related to 5%, 10%, 50%, 90% and 95% percentiles respectively.

According to Lau and Somarajan (1995), the original PERT estimators can be at best considered marginally defensible only after one recognizes certain implicit restrictions that are not clearly reasonable. On the other hand, Kamburowski (1997) defends the original PERT estimators.

Another approach, presented by Vose (2000), to define distributions is to ask the expert to give estimates concerning a practical minimum (a), most likely (m) and practical maximum (b) for each estimated parameter. The practical minimum and practical maximum are defined through the selection of appropriate p and q, where p is the probability that the minimum could be below a and q is the probability that the maximum could be over b.

Nevertheless, the original PERT estimators, shown in Equations 1 and 2, are still widely taught, cited and used in practice (Vose 2000; Burke 2002; Maylor 2003; Goodpasture 2004; Rad and Anantatmula 2005; Dinsmore and Cabanis-Brewin 2006).

An alternative to PERT is the MCS which seems to be able to handle more complex project scheduling problems. Van Slyke (1963) was, probably, the first to suggest the use of MCS to find the cumulative distribution function of project network completion times. He also introduced the use of non-beta duration distributions. Johnson (1997) proposed the use of the convenient, triangular distribution in order to model adequately activity duration. In MCS, the random selection process is repeated several times so as to create multiple scenarios. Each time a value is randomly selected for every variable of the objective function, a possible scenario is formed that leads to a certain outcome. This process is called iteration. The synthesis of all the iterations gives a range of possible outcomes. In its implementation, MCS can use the three-point duration estimation approach to establish a statistical distribution of the duration of each activity (Wang 2005).

It was concluded that MCS solves most of the limitations that PERT faces. Since it is not based on the central limit theorem, activity durations may be modelled by different distributions allowing the definition of the most applicable distribution for each activity instead of defining the most convenient distribution for a group of activities (Diamantas *et al.* 2006). Distributions being mainly used for the modelling of activity duration are the beta, the triangular, the uniform and the normal ones (Kirytopoulos *et al.* 2001). Likewise, no statistical independence is assumed for activity durations. MCS takes also into account potential changes in the critical path, successfully taking into consideration the effect of 'sub-critical' paths on the duration of the project. Thus, it can be concluded that a simulation tool, such as MCS, would always provide more reliable information than PERT.

However, a major methodological deduction, experienced even in MCS, is the assumption of statistical independence for individual activities which share risk factors with other activities (van Dorp and Duffey 1999), as well as the use of a single distribution, usually the beta or triangular, to model the activity duration of all the activities due to the frequent lack of sufficient data required to define a distribution with more complex parameters (Nasir *et al*. 2003). The implementation of MCS in such a context minimizes the method's advantages over PERT and creates a false assumption regarding the reliability of the results produced. In fact, in such cases, the MCS results do not differentiate significantly from the results of standard PERT.

It is argued here that this situation is frequently encountered in small and medium size contractors dealing mainly with low risk small and medium projects. An additional aspect supporting this argument is the fact that many project managers working in such contractors do not have formal project management education, relying only on past experience and tacit knowledge; skills developed through experience (Nonaka and Takeuchi 1995). Finally, in many cases there is no formal project management process in the company.

RESEARCH METHOD

A five-step method was followed in this study. The first step was the selection of the case studies that would be explored. Twenty-one construction projects undertaken by four small and medium size contractors, based in Greece, were selected. The sole common characteristic of these projects was that they were identified as low risk projects by the contractors involved.

The second step was the development of the 'project model' for every project under examination. The project model was a schedule network for each project that was created through a project scheduling software.

An activity duration estimating team (third step) was formed for each contractor, consisting of individuals (belonging to each contractor's staff) with project management experience. None of the contractors maintained a corporate knowledge repository, meaning that the project team did not have access to historical information.

The fourth step was the activity duration estimating. Since historical information was not available, the activity duration estimating team lacked sufficient data required to define the right distribution, and modelled the duration of each activity with a beta distribution, following the process of the standard PERT. Although not correct, this deduction is common practice for SMEs. The three-point estimate approach was used, requiring the estimation of an optimistic (minimum), a most likely, and a pessimistic (maximum) value for the duration of each activity. These values were estimated by the activity duration estimating team, based on its tacit knowledge acquired from similar projects. The activity duration estimation team had difficulty in answering meaningfully any question regarding a percentile of the activity duration (for example 5% and 95% or 10% and 90%) based on tacit knowledge, which was another reason for using the standard PERT estimators shown in Equations 1 and 2.

The fifth step was the conduction of PERT analysis and MCS and the comparison of the generated results. PERT was calculated through the use of the original estimators of Equations 1 and 2, while the critical path was defined based on the expected duration values. In MCS the activity duration estimating lacked the required data to define the right distribution and chose to use a beta distribution as in standard PERT. Additionally, they used the three-point estimate approach to define this Beta distribution based on the same three-point estimations (a, m, b) used in PERT.

FINDINGS AND DISCUSSION

Table 1 presents the differences (as a percentage) between the project duration for each confidence level produced by PERT and MCS for the 21 projects under investigation. These differences were calculated through the use of the formula

$$\frac{D_{MCS} - D_{PERT}}{D_{PERT}}$$

The information provided by Table 1 is that the calculated differences are quite low. However, the simulation approach provides more pessimistic results than PERT, as expected.

The confidence level is defined as the probability that a project will be completed in less or equal time than the duration corresponding to the confidence level.

The deterministic duration, calculated by CPM, and the probability that the project will be completed in less or equal duration than this value (the confidence level) in both PERT and MCS approach is given in Table 2. The results of the deterministic approach correspond to very low confidence levels, in either PERT or MCS. The maximum confidence level that the results of CPM correspond to either PERT or MCS is 35%. Planning based on such a confidence level provides a false feeling of safety and leads to decision making based on misleading information.

The mean value of the produced differences between PERT and MCS, for each confidence level and for the mean value of project duration, are presented in Table 3. The results presented in Table 3 show that the results produced from MCS, when activity duration estimating is made without the guidance of historical data, are similar and even identical in some cases with those of standard PERT. The results show that the difference of the mean values produced by MCS and PERT is approximately 0.80%, while the mean value of the difference between PERT and MCS in the 90% confidence level of project duration is approximately 1.34%. These differences might not be negligible; however, they will probably not change the decision of a project manager.

These differences, presented in Tables 1, 2 and 3 are solely generated by the effect of the sub-critical paths of each project, taken into account in MCS.

The comparison of the duration calculated by PERT and the duration simulated with the actual duration of the project is presented in Table 4. It should be noted that the duration presented as actual duration for the projects with duration greater than 270 days (refer to Table 2 – CPM duration) is the estimated project duration since these projects are still in progress and is denoted with the abbreviation ‘est’.

It is important to point out that from the 21 projects under investigation only eight of them have an actual duration, or estimated project duration, that corresponds to the confidence levels that managers usually take into account, i.e. the 70–85% range. The actual duration, or estimated project duration, of the remaining projects corresponds to a minimum confidence level of 95%, while many of them are larger than the maximum duration calculated from both PERT and MCS.

Estimated project duration is the current estimation of the project team regarding the total duration of the projects still in progress. This estimation is subject to updates due to possible changes in the conditions affecting project duration until the completion of the project.

CONCLUSIONS

The objective of this study was to present one major methodological deduction in MCS, which is frequently met in practice. This methodological deduction consists of both the modelling of the duration of activities with the same distribution, usually the beta or triangular one and the lack of historical information within the activity duration estimating phase. The authors argued that under particular circumstances the project duration estimating process will not provide significantly different results when MCS is applied instead of standard PERT. Twenty-one case studies were explored validating the initial hypothesis.

Such particular circumstances may occur when the lack of historical information does not allow the duration estimating team to define the right distribution in order to model the duration of each activity. Furthermore, the duration estimating team, based solely on tacit knowledge, is unable to meaningfully define different distributions in order to model the duration of each activity. Thus, a single distribution is used for the modelling of the duration of all project activities.

These circumstances were met in all four small and medium size contractors under investigation and are frequently met in small and medium size contractors.

In such a context the application of MCS instead of PERT during the project duration estimating process may not provide the anticipated results. Specifically, the results produced by the MCS technique under these circumstances are similar to, or even the same as, the results produced by standard PERT, providing a misleading assumption regarding the reliability of the results, and the efficiency of modelling reality. Therefore, it is concluded that small and medium size contractors, which mainly deal with small and medium size projects with low risk, may continue using PERT, if MCS cannot be their choice.

On the other hand, the results of the deterministic approach (CPM) correspond to very low confidence levels, in either PERT or MCS, indicating that the use of a stochastic approach is necessary.

However, it should be noted that the application of simulation techniques instead of deterministic or non-simulation stochastic approaches, such as CPM and PERT, during the duration estimating process, allow the more efficient modelling of the project and provide more precise and reliable results. Thus, in general, simulation techniques are greatly preferred to deterministic or non-simulation stochastic approaches. The simulation approach provides more conservative results, however closer to reality, as it takes into account several parameters that can differentiate the completion date of a project. Such parameters include the use of the right distributions (i.e. strongly positively skewed, distributions that overemphasize the tail), the better modelling of all kinds of risks and the consideration of sub-critical paths.

It is perhaps less obvious but just as important to note that during this research it was assumed that uncertainty can be adequately modelled with the three-point duration estimation.

The authors have already focused their future research on the effect of the additional parameters, which simulation approaches can take into account, on project duration estimating. Two critical issues have been recognized so far. The first issue is the effect of the definition of the right distribution for the modelling of the duration of each activity on project duration estimating. The second issue regards risk handling and whether the three-point duration estimation approach can adequately model uncertainty or not.

CONSTRUCTION SPEED INDICATORS AND THEIR ESTIMATION

Christian Stoy[1]

[1]*Institute for Construction Economics, University of Stuttgart, Keplerstr. 11, 70174 Stuttgart, Germany*

The use of a series of independent variables for an early estimation of the construction speed [m^2 gross external floor area/month] of Swiss building construction projects is proposed. Based on 200 properties, these variables serve as the speed drivers of a project, and the regression model, tested against the 200 properties, has a mean absolute percentage error of 16%. When applied to predict the speed of 25 more properties that were excluded from the 200 in the regression model, the percentage error ranges between –39% and 25%. The identified speed drivers are: project size, number of winters and type of use.

Keywords: construction duration, construction speed, regression model, Switzerland.

INTRODUCTION

Construction duration is a critical success factor of each construction project. Therefore the speed with which building proceeds (construction speed) plays an important role in the commercial success of a construction project. A construction duration that is too long, as well as one that is too short, can have a negative impact on the project's success. For this reason, planning the construction duration and/or speed must be included along with cost and quality planning as one of the major tasks of construction project management.

Only a few resources to support planning the construction speed, similar to those used for cost planning for example, have previously been available in Switzerland. The lack of indicators and models supporting an early estimate of the construction speed is particularly serious. The present study deals with this deficit. Using the analysed data as a basis, the relevant drivers, as well as indicators based on them, are clearly articulated and a regression model for estimating the construction speed is derived.

These analyses are based on primary data from 225 properties. On this basis, indicators and their drivers can be designated. Thus the remarks of this paper are based on concrete construction projects whose data are available on a uniform basis. In addition to the data pool, however, this study also builds on studies which hitherto have not delivered a uniform and thus a conclusive picture of important drivers. Prominent emphasis must be given to the work by Bromilow *et al*. (1980), which considers the connection between construction duration and building construction costs. In addition, however, the advanced studies by Chan and Kumaraswamy (2002) and Love *et al.* (2005) must be mentioned, which primarily examine project-specific characteristics, such as project size and type of façade construction, and their

[1] info@bauoekonomie.uni-stuttgart.de

influence on construction duration. But what is still lacking in spite of this work, above all for Switzerland, are indicators and models that build on a wide data pool.

The described study proposes an initial approach for attaining the objective set forth above. In the first section of this paper, the author presents the results of his study of the secondary literature. He primarily addresses the question of the different relevant drivers influencing construction speed. The second section is devoted to the data pool, which is introduced briefly. Additionally the characteristics of the proposed model and their drivers are presented in detail. In the concluding section the results of the data analysis are summarized.

LITERATURE REVIEW

Construction speed

A construction project passes through several phases. It begins with a concept and continues though the preliminary studies, planning, the construction process, and on to the new facility's start of operations. This study deals exclusively with the project's construction process, which is defined as the construction duration from the start of work at the construction site until the entire work is completed.

The construction speed defines the average progress of construction over the construction duration. Normal units of measure are revenue [€ revenue/month], area completed [m^2 gross external floor area/month], or volume completed [m^3 building volume/month]. This study defines construction speed using floor area, i.e. the study's functional unit parameter [m^2 gross external floor area/month].

State of the art

There are already studies available that evaluate drivers of construction duration and, in part, of the construction speed of new construction projects. Table 1 summarizes these studies. For reasons of scope, no consideration has been given here to studies that are concerned, for example, with civil engineering projects or the reasons for construction delays (for example Al-Khalil and Al-Ghafly 1999).

Based on the secondary literature, it is possible to identify relevant drivers. There are 11 studies in this connection, which are presented briefly below.

Table 1: Related studies and their relevant drivers

Study	**Data pool (country)**	**Relevant drivers**
Bromilow *et al*. (1980)	395 (Australia)	Building construction costs Building age Client (government/private)
Chan and Kumaraswamy (1995)	111 (Hong Kong)	Client (government/private) Project type (building/civil engineering works) Building construction costs Gross floor area Number of levels
Walker (1995)	33 (Australia)	Building construction costs Work type (fit-out, etc.) Client objectives Management style Communication (between architect/engineer and contractor) Use of information technology

Study	Data pool (country)	Relevant drivers
Chan (1999)	110 (Hong Kong)	Building construction costs Client (government/private)

Boussabaine (2001)	230	Building construction costs Type of call for tenders Tender type Contract type
Chan (2001)	51 (Malaysia)	Building construction costs
Chan and Kumaraswamy (2002)	71 (Hong Kong)	Building construction costs Frame type (presence/absence of precast façades) Building volume Average floor size Type of scheme (rental/purchase)
Ng *et al*. (2001); Skitmore and Ng (2003)	93 (Australia)	Building construction costs Type of use (education/residential, etc.) Type of call for tenders Tender type Client (government/private) Building age
Love *et al*. (2005)	161 (Australia)	Gross floor area Number of levels

EMPIRICAL STUDY

Available data

The data pool is formed by 225 Swiss construction projects. These are properties from different construction companies, for which not all of the relevant drivers can be recorded owing to limits on the data provided (cf. Table 1). Especially so-called ‘soft’ drivers, such as client objectives, management style, communication (between architect/engineer and contractor), and use of information technology are not available. The detailed description of the data pool can be found in the Annex to this paper (cf. Table 5, Table 6 and Table 7).

The data pool encompasses 225 real properties that are assigned the following types of use:

- office (R = 55);
- residential (R = 83);
- other types of use, e.g. cultural, sport, education, health (R = 87).

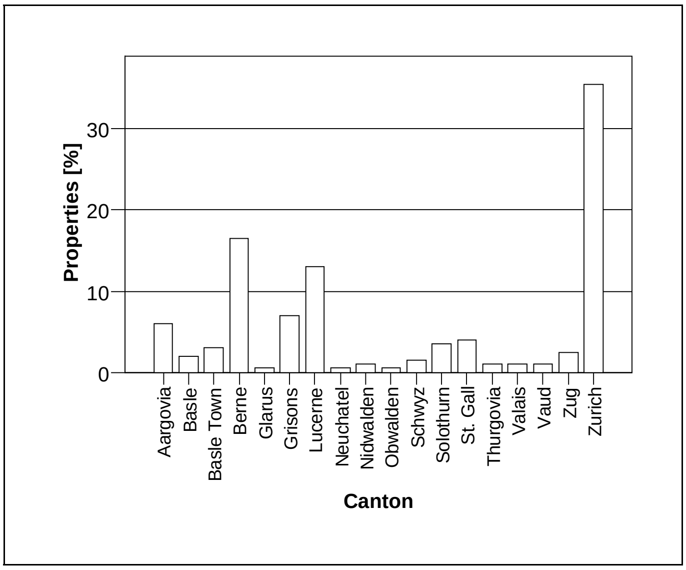

Figure 1: Geographic distribution of properties (%) (R = 225)

The geographic distribution of the survey sample is shown in Figure 1. It becomes apparent that the large Canton of Zurich is prominently represented. The absolute size of the properties can be specified in m^2 of gross external floor area, with the sample showing a median size of 7545 m^2 (mean of 11 408 m^2, lower and upper quartiles respectively of 2276 m^2 and 14 723 m^2).

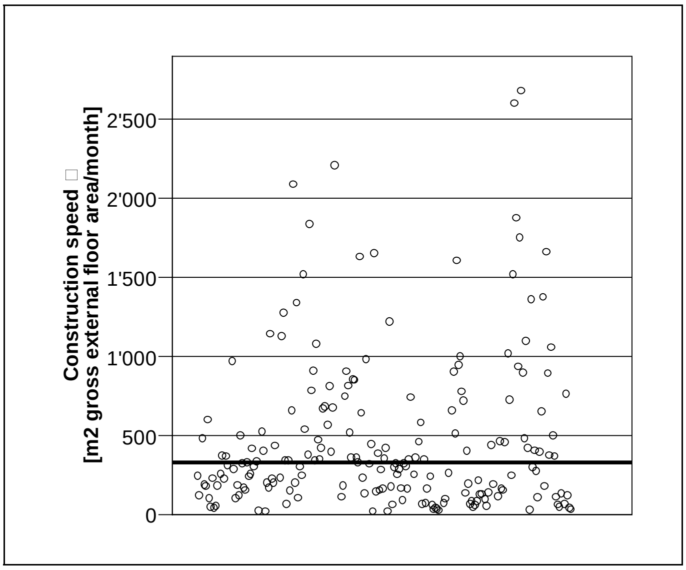

Figure 2: Construction speed indicators (R = 225) (median is shown)

On the basis of the sample survey, the construction speed indicators are illustrated in Figure 2 (median value of 325 m^2 gross external floor area/month, mean of 493 m^2 gross external floor area/month) (R = 225). On the basis of this figure it becomes apparent that substantial differences can be found among the duration speeds of the individual properties. Thus the question arises of which are the relevant drivers that cause these differences. To answer this question, the drivers listed in Table 1 are confronted with the database.

Proposed regression model

There are several options that may be used in creating a regression model (cf. Cropper and McConnell 1988). Log-log, semi-log and linear models were examined. In past studies, log-log and linear models have produced the best results (Table 1). However, there is debate as to whether the best results are obtained using absolute construction duration [months] or construction speed [m^2 gross external floor area/month] as the dependent variable. The former produces better fits, but the latter tends to have more normally distributed errors. Each of the different methods was tested, and in this analysis the model that produced the best statistical results in terms of parameter significance was a log-log regression of m^2 of gross external floor area per month (Table 2).

Table 2: Summaries of models (dependent variable: construction speed [m^2 gross external floor area/month], R = 200)

Model	Transformation	R^2	R^2 adjusted	F-Value	Significance	MAPE [%]
1	linear (non)	0.825	0.821	229.599	0.000	83.1
2	log-log	0.966	0.966	1395.246	0.000	15.8

The 25 test properties show differences between observed and predicted construction speeds between –39% and 25% (Table 3). Additionally the proposed model shows:

- R^2 of 0.966 (R^2 adjusted of 0.966);
- mean absolute percentage error (MAPE) of 16% (Love *et al*. (2005): MAPE of 50%);
- root mean squared error (RMSE) of 123 (Love *et al*. (2005): RMSE of 221);
- mean absolute deviation (MAD) of 70.5.

Thus the quality of the developed log-log regression model can be classified as comparatively good.

Table 3: Observed and predicted construction speed of 25 test properties for Model 1 (dependent variable: construction speed [m^2 gross external floor area/month])

No. of property	Observed construction speed [m^2 gross external floor area/month]	Predicted construction speed [m^2 gross external floor area/month]	Difference [%]
3	473	439	8
20	1306	1186	10
21	353	374	–6
36	436	348	25
39	162	221	–26
49	69	104	–33
50	1531	1574	–3
67	632	570	11
79	612	580	5
85	1463	1403	4
86	607	789	–23
87	1645	1521	8
104	285	324	–12
131	128	170	–25
134	378	484	–22
141	171	233	–27
148	42	45	–6
149	34	57	–39
152	373	388	–4
154	556	495	12

No. of property	Observed construction speed [m^2 gross external floor area/month]	Predicted construction speed [m^2 gross external floor area/month]	Difference [%]
174	82	97	–15
178	313	350	–11
182	3249	2739	19
188	144	142	1
222	89	105	–15

The regression model as developed (Model 1 from Table 2) can ultimately incorporate three independent variables (Table 4):

- project size (1000 m^2 gross external floor area);
- number of winters;
- type of use (office, residential, other) (dummy).

Table 4: Coefficients table for Model 1 (dependent variable: construction speed [m^2 gross external floor area/month], R = 200)

	B	Std. error	T-Value	Significance
Project size [1000 m^2 gross external floor area]	0.881	0.013	69.325	0.000
Number of winters	–0.361	0.017	–21.411	0.000
Type of use – office	–0.054	0.038	–1.427	0.155
Type of use – other	–0.160	0.034	–4.780	0.000
(constant)	4.923	0.034	145.171	0.000
