18 MEETING TITLE: Causes and Predictions of Extremes in the East Asian Water Cycle

19 WHAT: Thirty selected participants, representing the active early-career researchers in

20 China and the UK, met to plan future science initiatives and establish long-term sustainable  
21 collaborations in understanding and predicting East Asia water cycle extremes.

22 WHEN: 17-19th September 2019

23 WHERE: Reading, UK

24

25

## 26 Introduction

27 Water security is a major threat to economic development and social welfare in East  
28 Asia (EA), particularly for countries with rapidly increasing water demand, such as  
29 China and other EA countries, due to population growth and water consumption  
30 pattern change. Climate change may increase the risk of hydro-meteorological  
31 extremes in EA, including more frequent floods and droughts (e.g. Sillmann et al.,  
32 2013; Zhou et al., 2014; Guo et al., 2016). Likewise, climate variability alters the risk  
33 of hydro-meteorological extremes, including those from tropical cyclones and  
34 monsoons (e.g. Wang et al., 2000, 2008; Camargo and Sobel, 2005). Numerical  
35 models, such as the Numerical Weather Prediction (NWP) models and the climate  
36 models in the Coupled Model Intercomparison Project Phase 5 (CMIP5), have  
37 become central in understanding the causes of variability and change in the EA  
38 water cycle and accurately predicting extremes. Recently, Chinese universities and  
39 research institutes have made considerable efforts to understand and predict EA  
40 water cycle extremes, which is highlighted by the rapid development of high-  
41 resolution earth system models that run on China's most powerful supercomputers.  
42 In the UK, intensive research has focused on identifying the causes of EA water  
43 cycle extremes and developing numerical models to predict these high-impact  
44 events, in part to develop UK capability to deliver global weather and climate  
45 services. These significant research achievements are mainly made through the  
46 efforts of early-career researchers (ECRs).

47

48 The workshop 'Causes and Predictions of Extremes in the East Asian Water Cycle'  
49 gathered early-career researchers (ECRs; less than 10 years since PhD award)  
50 working in China and the UK with a wide range of research interests in the EA water

51 cycle. The workshop organisers also invited senior scientists to speak about the  
52 current challenges and opportunities in understanding and predicting EA water cycle  
53 extremes, to motivate ECR discussions of future collaborations. The workshop  
54 provided a venue to share recent research achievements in understanding and  
55 predicting EA water cycle extremes, and more importantly also a platform to develop  
56 future science initiatives and long-term sustainable partnerships between Chinese  
57 and UK ECRs. The workshop was held at the University of Reading, and organized  
58 by the National Centre for Atmospheric Science (NCAS), and the National  
59 Laboratory for Marine Science and Technology (QNLN) at the Ocean University of  
60 China. Thirty participants were selected covering universities (China: Ocean  
61 University of China, Sun Yat-sen University, Hohai University; UK: Universities of  
62 Edinburgh, Oxford and Reading), and national service centres for weather and  
63 climate science and forecast (China: the China Meteorological Administration,  
64 Institute of Atmospheric Physics (Chinese Academy of Sciences); UK: the Met  
65 Office, the Centre for Ecology & Hydrology, the National Centre for Earth  
66 Observation, and NCAS).

67

68 Held over two and a half days, the workshop included 23 ECR and four senior  
69 scientist talks, related to phenomena that drive EA water cycle extremes on  
70 timescales from synoptic to climate. Keywords from these 27 talks are presented in a  
71 word cloud (Figure 1). On each day, the workshop had 3 sections. First, ECRs  
72 presented their research, with talks organised by timescale (synoptic, subseasonal-  
73 to-seasonal and climate); secondly, one or two senior scientists discussed  
74 challenges and future opportunities in numerical modeling; finally, there were small-

75 group discussions led by ECRs, with a task for each group to develop one or several  
76 topics for future UK-China collaborations for water-cycle research.

77

## 78 ECR talk highlights

79 In the workshop, ECRs presented research to distinguish the contributions of  
80 individual weather phenomena to EA water cycle extremes, based on observations  
81 and reanalyses. These approaches associate extreme rainfall to tropical cyclones  
82 (TCs), Tibetan Plateau Vortices (TPVs), *Meiyu* frontal rainbands, cold surges and  
83 persistent circulations such as quasi-stationary Rossby waves. A method for tracing  
84 moisture sources of rainfall was also presented, including applications to sources of  
85 TC-related rainfall and to separating the contributions to rainfall from mean and eddy  
86 moisture transports. ECRs have applied these useful tools to output from forecast  
87 models and high-resolution CMIP6 models. By continuing this analysis in the coming  
88 years, these evaluations will help to identify the sources of error in predictions and  
89 projections of the EA water cycle, including errors in the large-scale circulation or in  
90 the representations of local mesoscale and synoptic features (e.g. TCs and TPVs),  
91 and how these errors grow with lead time or depend on the state of large-scale  
92 phenomena such as ENSO.

93

94 ECRs also presented research on subseasonal-to-seasonal (S2S) phenomena  
95 relevant to the EA water cycle, including rapid-onset “flash” droughts and the  
96 northward progression of the summer monsoon, and their connections to large-scale  
97 climate variability such as the Pacific-Japan pattern, the Silk Road pattern and the  
98 Boreal Summer IntraSeasonal Oscillation (BSISO). ECRs showed that existing S2S  
99 models, including China’s FGOALS-f2 model, are able to predict summer drought

100 and TC genesis. Evaluations of S2S predictions for other extreme phenomena, such  
101 as TPVs, are an active area of ECR research and UK-China collaboration, as is  
102 analysis of the teleconnections between S2S phenomena and synoptic extremes  
103 (e.g., how the BSISO modulates TC genesis in FGOALS-f2).

104

105 Interannual and decadal variability in the EA water cycle from the perspective of  
106 extremes is studied mainly by associating it with atmospheric and oceanic large-  
107 scale climate variability. In this research topic, one challenge is how to effectively  
108 isolate the impacts of each phenomena on EA water cycle. In the workshop, ERCs  
109 showed the potential addressing this challenge with sensitivity experiments in  
110 coupled general circulation models (GCMs), in which for example ocean temperature  
111 anomalies are imposed only in a certain ocean basin, to eliminate interactions  
112 between climate modes. Sensitivity experiments reproduce the observed  
113 teleconnections from the Atlantic Multidecadal Variability to climate over China, while  
114 it remains challenging for models to reproduce the observed effects of Pacific  
115 variability (i.e. ENSO and Interdecadal Pacific Oscillation) on the 'North dry–South  
116 wet' pattern in China. An active area of research and collaboration is identifying the  
117 dominant modes of variability for the EA water cycle, as well as whether these  
118 modes are independent. The sensitivity experiments performed so far highlight a  
119 novel approach to address these challenges in long-term EA water cycle variability,  
120 including extremes, through ECR-led collaborative model development and  
121 evaluation.

122

123 To address future projections of the EA water cycle under global warming and  
124 anthropogenic forcing, ECRs have analysed changes in both mean and extreme

125 rainfall in CMIP5 models under different RCP scenarios. Across EA, the mean  
126 strength of the water cycle (including precipitation, evaporation and runoff) is likely to  
127 increase; the seasonal cycle is likely to intensify; and the frequency of drought and  
128 heavy rain events is likely to increase. These changes will present an increased risk  
129 of hydro-meteorological extremes for EA society. ECRs will continue to evaluate  
130 projections of other phenomena relevant for EA water cycle extremes, e.g. TCs,  
131 TPVs, the *Meiyu* front and flash drought. Workshop presentations demonstrated that  
132 uncertainty in EA water cycle projections, especially for extremes, remains  
133 substantial. ECRs plan to collaborate to understand whether this uncertainty is  
134 reduced in CMIP6 models, which typically have a higher horizontal resolution and  
135 updated model physics.

136

## 137 Outputs

138 The aim of the workshop was for ECRs to develop future science initiatives and long-  
139 term sustainable partnerships for water-cycle research in the next 5-10 years. To  
140 motivate ECR discussions of future research and collaboration, four senior scientists  
141 were invited to discuss the current challenges and opportunities for simulating EA  
142 water cycle extremes. After the senior scientist talks on each day, ECRs led small-  
143 group discussions, with each group appointing an ECR to report discussion  
144 outcomes to, and record feedback from, the wider workshop. Each group was tasked  
145 to develop one or several potential topics for future collaborations. ECRs benefited  
146 from in-depth discussions with other ECRs and senior scientists on research  
147 objectives and career-development opportunities, and also gained experience in  
148 planning international collaborations. The following summarises these collaboration  
149 topics, which ECRs are now developing into outline research proposals.

150

151 There is rapidly growing interest in developing high-resolution prediction systems for  
152 the EA water cycle. Chinese participants presented the newly developed high-  
153 resolution global and regional earth modeling systems in China, which are run on  
154 China's most powerful supercomputers. Several other weather and climate  
155 prediction systems in China were also introduced and mentioned in the workshop,  
156 e.g., FGOALS-f2, which features with a finite-volume dynamical core and includes a  
157 convection-resolving precipitation parameterization. UK participants presented the  
158 UK high-resolution model contributions to CMIP6. So far, evaluations of EA water  
159 cycle extremes in these models have been limited, presenting an opportunity for  
160 ECR-led research. The objective tools for diagnosing water cycle characteristics,  
161 developed by ECRs as mentioned above, will be extremely valuable for advanced  
162 process-level evaluation of these systems. ECRs believe these new systems will  
163 provide a good platform for collaborative research, which will in turn help to identify  
164 priority areas for further model development. Topics agreed between ECRs include  
165 extreme rainfall related to TCs and TPVs (including path and related moisture flux  
166 transport), EASM and droughts, and their teleconnections with climate variability.

167

168 Contemporary weather and climate forecast models share biases in simulating the  
169 Asian water cycle, e.g. dry biases in South Asia and wet biases in East Asia during  
170 the monsoon season. Many efforts have been made to reduce these biases, such as  
171 including ocean coupling, increasing model resolution and adjusting convection  
172 parameterisations. However, these efforts have had limited success, indicating the  
173 complexity and intractability of errors in water cycle simulation, at least when model  
174 development is performed in isolation. ECRs planned UK-China collaborative

175 research in model development and evaluation, including running common sensitivity  
176 tests in UK and Chinese models, to help to understand the source of model error.

177

178 In the meantime, improved observations of the East Asian water cycle, across  
179 timescales, is urgently needed for model improvement. In recent years, remote  
180 sensing has provided essential observations of water cycle processes. For example,  
181 an ECR mentioned the High resOlution Land Atmosphere surface Parameters from  
182 Space (HOLAPS) framework, which ensures consistent estimation of surface water  
183 and energy fluxes between different satellite-based products. ECRs plan to use  
184 these products to verify models for EA water cycle extreme prediction in multi-  
185 dimensional domain.

186

187 Additionally, model parameterizations usually require years of development,  
188 particularly at global scales for lengthy coupled integrations. Parameterization  
189 typically happens to the parameters whose values are consistently poorly  
190 represented in models with respect to observations, due to the complexity of the  
191 climate system and the approximate descriptions on unresolved processes.

192 Parameterizing a model to improve its performance on one phenomenon may  
193 degrade performance on others. Therefore, a number of parameterizations across  
194 different media (atmosphere, ocean and land) are normally tuned together. For  
195 example, over the ocean atmospheric convection needs to be parameterized  
196 together with parameterizations in sea surface temperature and salinity, while over  
197 the land it needs to be performed together with parameters tuning for soil moisture.

198 'Parameterization scientists', who well know the process-oriented error metrics both in  
199 models and in observations, have become an opportunity of new career for ECRs.

200

201 Modern forecast systems can predict well slowly-evolving modes of climate  
202 variability, but have less skill in predicting EA water cycle extremes (e.g. TC-related  
203 rainfall and drought) at user-relevant scales (e.g. local and regional average scales).  
204 For example, the MJO can be well predicted 3-4 weeks ahead in many models, and  
205 ENSO is predictable 6 months in advance. This suggests models may struggle to  
206 simulate the teleconnections from climate modes to the water cycle extremes. In the  
207 next 5-10 years, evaluation of teleconnections on timescales from intra-seasonal to  
208 decadal will be a key topic for UK-China ECR collaborations.

209

210 ECRs also planned to strengthen multidisciplinary collaborations on the impact of EA  
211 water cycle extremes. For example, with preliminary analysis based on observations,  
212 ECRs confirmed a close hydrological relationship between inter-annual variability in  
213 the water level of the Pearl River networks and southern China rainfall during the  
214 flood season. In the coming years, ECRs will work together on the predictability of  
215 the Pearl River networks, in terms of extreme events for river flow, water level and  
216 saltwater intrusions, on varying timescales, by leveraging predictions of the EA water  
217 cycle and its variability.

218

## 219 Acknowledgments

220 This workshop was supported by the Newton Fund Researcher Links grant, under  
221 the UK–China Research and Innovation Partnership. The grant was funded by the  
222 UK Department for Business, Energy and Industrial Strategy and National Natural  
223 Science Foundation of China (NSFC) and delivered by the British Council. We thank  
224 the two delegates from NSFC for attending this workshop. We also thank the

225 organizing committee in the University of Reading and the Ocean University of China  
226 for their valuable contributions.
